CHAPTER 1

Product Overview 1-1

Layer 2 Software Features 1-1

Cisco Discovery Protocol 1-2

Cisco Group Management Protocol (CGMP) server 1-2

EtherChannel Bundles 1-2

Flexible NetFlow 1-2

Internet Group Management Protocol (IGMP) Snooping 1-3

IPv6 Multicast Listen Discovery (MLD) and Multicast Listen Discovery snooping 1-3

Jumbo Frames 1-3

Link Aggregation Control Protocol 1-4

Cisco IOS XE IP Application Services Features in Cisco IOS XE 3.1.0SG 1-4

Link Layer Discovery Protocol 1-4

Multiple Spanning Tree 1-5

Per-VLAN Rapid Spanning Tree 1-5

Quality of Service 1-5

Spanning Tree Protocol 1-6

Stateful Switchover 1-6

SVI Autostate 1-6

Unidirectional Ethernet 1-7

UniDirectional Link Detection 1-7
Contents

User Based Rate Limiting  1-7
Virtual Switch System Client  1-7
VLANs  1-7

Layer 3 Software Features  1-8
   Cisco Express Forwarding  1-9
   Enhanced Object Tracking  1-9
   GLBP  1-9
   Cisco IOS XE IP Application Services Features in Cisco IOS XE 3.1.0SG  1-9
   HSRP  1-10
      Cisco IOS XE IP Application Services: HSRP Features in Cisco IOS XE 3.1.0SG  1-10
   SSO Aware HSRP  1-11

IP Routing Protocols  1-11
   BGP  1-11
   EIGRP  1-12
   OSPF  1-13
   RIP  1-13

In Service Software Upgrade  1-14
Multicast Services  1-14
   NSF with SSO  1-14
Policy-Based Routing  1-14
   Unidirectional Link Routing  1-15
   Unicast Reverse Path Forwarding  1-15
   VRF-lite  1-15
   Virtual Router Redundancy Protocol  1-15

Management Features  1-15
   Cisco Call Home  1-16
   Cisco Energy Wise  1-16
   Cisco IOS IP Service Level Agreement  1-16
   Dynamic Host Control Protocol  1-17
   Embedded CiscoView  1-17
   Embedded Event Manager  1-17
   File System Management on Supervisor Engine 7-E  1-17
   Forced 10/100 Autonegotiation  1-18
   Intelligent Power Management  1-18
   MAC Address Notification  1-18
   MAC Notify MIB  1-18
   Secure Shell  1-18
   Simple Network Management Protocol  1-19
   SPAN and RSPAN  1-19
   XML LPI  1-19
Security Features  1-20
  802.1X Identity-Based Network Security  1-20
  Dynamic ARP Inspection  1-21
  Dynamic Host Configuration Protocol Snooping  1-21
  Flood Blocking  1-22
  Hardware-Based Control Plane Policing  1-22
  IP Source Guard  1-22
  Local Authentication, RADIUS, and TACACS+ Authentication  1-22
  Network Admission Control  1-23
  Network Security with ACLs  1-23
  Port Security  1-23
  Storm Control  1-24
  uRPF Strict Mode  1-24
Utilities  1-24
  Layer 2 Traceroute  1-24
  Time Domain Reflectometry  1-24
  Debugging Features  1-25
Web-based Authentication  1-25

CHAPTER 2
  Command-Line Interfaces  2-1
    File Management Commands  2-1
    Accessing the Switch CLI  2-2
      Accessing the CLI Using the EIA/TIA-232 Console Interface  2-2
      Accessing the CLI Through Telnet  2-2
    Performing Command-Line Processing  2-3
    Performing History Substitution  2-4
    About Cisco IOS Command Modes  2-4
    Getting a List of Commands and Syntax  2-5
      Virtual Console for Standby Supervisor Engine  2-6
    ROM MON Command-Line Interface  2-7

CHAPTER 3
  Configuring the Switch for the First Time  3-1
    Default Switch Configuration  3-1
    Configuring DHCP-Based Autoconfiguration  3-2
      DHCP-Based Autoconfiguration  3-2
      DHCP Client Request Process  3-3
      Configuring the DHCP Server  3-4
Contents

Configuring the TFTP Server 3-4
Configuring the DNS Server 3-5
Configuring the Relay Device 3-5
Obtaining Configuration Files 3-6
Example Configuration 3-7
Configuring the Switch 3-8
  Using Configuration Mode to Configure Your Switch 3-9
  Verifying the Running Configuration Settings 3-9
  Saving the Running Configuration Settings to Your Start-Up File 3-10
  Reviewing the Configuration in NVRAM 3-10
  Configuring a Default Gateway 3-11
  Configuring a Static Route 3-11
Controlling Access to Privileged EXEC Commands 3-13
  Setting or Changing a Static enable Password 3-13
  Using the enable password and enable secret Commands 3-14
  Setting or Changing a Privileged Password 3-14
  Controlling Switch Access with TACACS+ 3-15
    Understanding TACACS+ 3-15
    TACACS+ Operation 3-17
    Configuring TACACS+ 3-17
    Displaying the TACACS+ Configuration 3-22
Encrypting Passwords 3-22
Configuring Multiple Privilege Levels 3-23
  Setting the Privilege Level for a Command 3-23
  Changing the Default Privilege Level for Lines 3-23
  Logging In to a Privilege Level 3-24
  Exiting a Privilege Level 3-24
  Displaying the Password, Access Level, and Privilege Level Configuration 3-24
Recovering a Lost Enable Password 3-25
Modifying the Supervisor Engine Startup Configuration 3-25
  Understanding the Supervisor Engine Boot Configuration 3-25
    Understanding the ROM Monitor 3-26
  Configuring the Software Configuration Register 3-26
    Modifying the Boot Field and Using the boot Command 3-27
    Modifying the Boot Field 3-28
    Verifying the Configuration Register Setting 3-29
Specifying the Startup System Image 3-30
  Flash Memory Features 3-30
  Security Precautions 3-31
Contents

Configuring Flash Memory 3-31
Controlling Environment Variables 3-31
Resetting a Switch to Factory Default Settings 3-32
Configuring Crashinfo 3-32
  About Crashinfo 3-33
    Process Crashinfo File 3-33
    Process Core Dump File 3-34
    Kernel Crashinfo File 3-34
Configuring Crashinfo 3-35
  Default Configuration 3-35
  Configuring commands 3-35
  show Commands 3-36
  Enabling the Generation of the Process Core Dump File 3-38
  Saving Crash Files to a Secondary Devices 3-39
  Determining the Process that Crashed 3-39

CHAPTER 4
Administering the Switch 4-1
  Managing the System Time and Date 4-1
    System Clock 4-2
    Understanding Network Time Protocol 4-2
    Configuring NTP 4-3
      Default NTP Configuration 4-4
      Configuring NTP Authentication 4-4
      Configuring NTP Associations 4-6
      Configuring NTP Broadcast Service 4-7
      Configuring NTP Access Restrictions 4-8
      Configuring the Source IP Address for NTP Packets 4-10
      Displaying the NTP Configuration 4-11
    Configuring Time and Date Manually 4-11
      Setting the System Clock 4-11
      Displaying the Time and Date Configuration 4-12
      Configuring the Time Zone 4-12
      Configuring Summer Time (Daylight Saving Time) 4-13
  Configuring a System Name and Prompt 4-14
    Configuring a System Name 4-15
    Understanding DNS 4-15
      Default DNS Configuration 4-16
      Setting Up DNS 4-16
      Displaying the DNS Configuration 4-17
Creating a Banner 4-17
- Default Banner Configuration 4-18
- Configuring a Message-of-the-Day Login Banner 4-18
- Configuring a Login Banner 4-19

Managing the MAC Address Table 4-19
- Building the Address Table 4-20
- MAC Addresses and VLANs 4-20
- Default MAC Address Table Configuration 4-21
- Changing the Address Aging Time 4-21
- Removing Dynamic Address Entries 4-22
- Configuring MAC Change Notification Traps 4-22
- Configuring MAC Move Notification Traps 4-24
- Configuring MAC Threshold Notification Traps 4-26
- Adding and Removing Static Address Entries 4-27
- Configuring Unicast MAC Address Filtering 4-28
- Displaying Address Table Entries 4-30

Managing the ARP Table 4-30
- Configuring Embedded CiscoView Support 4-30
- Understanding Embedded CiscoView 4-31
- Installing and Configuring Embedded CiscoView 4-31
- Displaying Embedded CiscoView Information 4-33

Configuring Supervisor Engine Redundancy Using RPR and SSO 5-1

- About Supervisor Engine Redundancy 5-2
  - Overview 5-2
  - RPR Operation 5-3
  - SSO Operation 5-3

- About Supervisor Engine Redundancy Synchronization 5-5
  - RPR Supervisor Engine Configuration Synchronization 5-5
  - SSO Supervisor Engine Configuration Synchronization 5-6

- Supervisor Engine Redundancy Guidelines and Restrictions 5-6

- Configuring Supervisor Engine Redundancy 5-7
  - Configuring Redundancy 5-8
  - Virtual Console for Standby Supervisor Engine 5-9
  - Synchronizing the Supervisor Engine Configurations 5-11

- Performing a Manual Switchover 5-12
- Performing a Software Upgrade 5-13
- Manipulating Bootflash on the Standby Supervisor Engine 5-14
CHAPTER 6

Configuring the Cisco IOS XE In Service Software Upgrade Process  6-1

- Related Documents  6-2
- Prerequisites to Performing ISSU  6-2
- About Performing ISSU  6-3
  - Stateful Switchover  6-3
  - NSF  6-5
- ISSU Process  6-6
  - Performing an ISSU Upgrade: 2 Methods  6-11
  - Changeversion Process  6-12
    - Changeversion: Quick Option (LV to INIT)  6-12
    - Scheduled Changeversion: “in” and “at” Options  6-12
    - Changeversion Deployment Scenario  6-13
    - Aborting an In-Progress Changeversion Procedure  6-13
- Guidelines for Performing ISSU  6-13
  - Compatibility Matrix  6-13
  - SNMP Support for ISSU  6-14
  - Compatibility Verification Using Cisco Feature Navigator  6-14
- How to Perform the ISSU Process  6-15
  - Verifying the ISSU Software Installation  6-15
  - Verifying Redundancy Mode Before Beginning the ISSU Process  6-16
  - Verifying the ISSU State Before Beginning the ISSU Process  6-17
  - Loading New Cisco IOS XE Software on the Standby Supervisor Engine  6-18
  - Switching to the Standby Supervisor Engine  6-21
  - Stopping the ISSU Rollback Timer (Optional)  6-23
  - Loading New Cisco IOS XE Software on the New Standby Supervisor Engine  6-24
  - Using changeversion to Automate an ISSU Upgrade  6-25
  - Aborting a Software Upgrade During ISSU  6-31
  - Configuring the Rollback Timer to Safeguard Against Upgrade Issues  6-32
  - Displaying ISSU Compatibility Matrix Information  6-34
- Cisco High Availability Features in Cisco IOS XE 3.1.0 SG  6-35

CHAPTER 7

Configuring Interfaces  7-1

- About Interface Configuration  7-2
- Using the interface Command  7-2
- Configuring a Range of Interfaces  7-4
- Defining and Using Interface-Range Macros  7-6
- Deploying SFP+ in X2 Ports  7-7
- Deploying 10-Gigabit Ethernet or Gigabit Ethernet Ports on WS-X4606-10GE-E  7-7
## Contents

**Overview** 8-4  
- **Running the TDR Test** 8-4  
- **TDR Guidelines** 8-5  

**Using Telnet** 8-5  
- **Changing the Logout Timer** 8-6  
- **Monitoring User Sessions** 8-6  

**Using Ping** 8-7  
- **Understanding How Ping Works** 8-7  
- **Running Ping** 8-8  

**Using IP Traceroute** 8-8  
- **Understanding How IP Traceroute Works** 8-9  
- **Running IP Traceroute** 8-9  

**Using Layer 2 Traceroute** 8-10  
- **Layer 2 Traceroute Usage Guidelines** 8-10  
- **Running Layer 2 Traceroute** 8-11  

**Configuring ICMP** 8-12  
- **Enabling ICMP Protocol Unreachable Messages** 8-12  
- **Enabling ICMP Redirect Messages** 8-13  
- **Enabling ICMP Mask Reply Messages** 8-13  

**Chapter 9**  
**Configuring Cisco NSF with SSO Supervisor Engine Redundancy** 9-1  
- **About NSF with SSO Supervisor Engine Redundancy** 9-1  
- **About Cisco IOS NSF-Aware and NSF-Capable Support** 9-2  
- **NSF with SSO Supervisor Engine Redundancy Overview** 9-3  
- **SSO Operation** 9-4  
- **NSF Operation** 9-4  
- **Cisco Express Forwarding** 9-4  
- **Routing Protocols** 9-5  
  - **BGP Operation** 9-5  
  - **OSPF Operation** 9-6  
  - **EIGRP Operation** 9-6  
- **NSF Guidelines and Restrictions** 9-7  

**Configuring NSF with SSO Supervisor Engine Redundancy** 9-7  
- **Configuring SSO** 9-8  
- **Configuring CEF NSF** 9-8  
- **Verifying CEF NSF** 9-9  
- **Configuring BGP NSF** 9-9  
- **Verifying BGP NSF** 9-10  
- **Configuring OSPF NSF** 9-11
CHAPTER 10

Environmental Monitoring and Power Management 10-1

About Environmental Monitoring 10-1
Using CLI Commands to Monitor your Environment 10-2
Displaying Environment Conditions 10-2
Emergency Actions 10-3
System Alarms 10-4

Power Management 10-5
Power Management for the Catalyst 4500 Series Switches 10-5
Supported Power Supplies 10-5
Power Management Modes for the Catalyst 4500 Switch 10-7
Selecting a Power Management Mode 10-7
Power Management Limitations in Catalyst 4500 Series Switches 10-8
Available Power for Catalyst 4500 Series Switches Power Supplies 10-12
Special Considerations for the 4200 W AC and 6000 W AC Power Supplies 10-13
Combined Mode Power Resiliency 10-15
Special Considerations for the 1400 W DC Power Supply 10-16
Special Considerations for the 1400 W DC SP Triple Input Power Supply 10-17

Powering Down a Module 10-18

CHAPTER 11

Configuring Power over Ethernet 11-1

About Power over Ethernet 11-1
Hardware Requirements 11-2
Power Management Modes 11-3
Intelligent Power Management 11-4
Configuring Power Consumption for Powered Devices on an Interface 11-5
Displaying the Operational Status for an Interface 11-6
Displaying the PoE Consumed by a Module 11-7
PoE Policing and Monitoring 11-11
PoE Policing Modes 11-12
Configuring Power Policing on an Interface 11-12
Displaying Power Policing on an Interface 11-13
Configuring Errdisable Recovery 11-14
CHAPTER 12

Configuring VLANs, VTP, and VMPS

VLANs

About VLANs 12-1
VLAN Configuration Guidelines and Restrictions 12-3
VLAN Ranges 12-3
Configurable Normal-Range VLAN Parameters 12-4
VLAN Default Configuration 12-4
Configuring VLANs 12-5
Configuring VLANs in Global Configuration Mode 12-5
Assigning a Layer 2 LAN Interface to a VLAN 12-7

VLAN Trunking Protocol 12-7
About VTP 12-7
Understanding the VTP Domain 12-8
Understanding VTP Modes 12-8
Understanding VTP Advertisements 12-9
Understanding VTP Versions 12-9
Understanding VTP Pruning 12-11
VTP Configuration Guidelines and Restrictions 12-12
VTP Default Configuration 12-13
Configuring VTP 12-14
Configuring VTP Global Parameters 12-14
Configuring the VTP Mode 12-16
Starting a Takeover 12-19
Displaying VTP Statistics 12-19
Displaying VTP Devices in a Domain 12-20

VLAN Membership Policy Server 12-20
About VMPS 12-21
VMPS Server 12-21
Security Modes for VMPS Server 12-22
Fallback VLAN 12-23
Illegal VMPS Client Requests 12-23
Overview of VMPS Clients 12-23
Understanding Dynamic VLAN Membership 12-23
Default VMPS Client Configuration 12-24
Configuring a Switch as a VMPS Client 12-24
Administering and Monitoring the VMPS 12-28
Troubleshooting Dynamic Port VLAN Membership 12-29
CHAPTER 13
Configuring IP Unnumbered Interface 13-1
Related Documents 13-2
About IP Unnumbered Support 13-2
IP Unnumbered Interface Support with DHCP Server and Relay Agent 13-2
DHCP Option 82 13-3
IP Unnumbered with Connected Host Polling 13-4
Limitations and Restrictions 13-4
Configuring IP Unnumbered Interface Support with DHCP Server 13-5
Configuring IP Unnumbered Interface Support on LAN and VLAN Interfaces 13-5
Configuring IP Unnumbered Interface Support on a Range of Ethernet VLANs 13-6
Configuring IP Unnumbered Interface Support with Connected Host Polling 13-7
Displaying IP Unnumbered Interface Settings 13-8
Troubleshooting IP Unnumbered 13-9

CHAPTER 14
Configuring Layer 2 Ethernet Interfaces 14-1
About Layer 2 Ethernet Switching 14-1
Layer 2 Ethernet Switching 14-2
switching Frames Between Segments 14-2
Building the MAC Address Table 14-2
VLAN Trunks 14-3
Encapsulation Types 14-3
Layer 2 Interface Modes 14-4
Default Layer 2 Ethernet Interface Configuration 14-4
Layer 2 Interface Configuration Guidelines and Restrictions 14-5
Configuring Ethernet Interfaces for Layer 2 Switching 14-5
Configuring an Ethernet Interface as a Layer 2 Trunk 14-6
Configuring an Interface as a Layer 2 Access Port 14-8
Clearing Layer 2 Configuration 14-9

CHAPTER 15
Configuring SmartPort Macros 15-1
About SmartPort Macros 15-1
Configuring SmartPort Macros 15-2
Passing Parameters Through the Macro 15-2
Macro Parameter Help 15-3
Default SmartPort Macro Configuration 15-3
  cisco-global 15-4
  cisco-desktop 15-4
  cisco-phone 15-4
  cisco-router 15-5
  cisco-switch 15-5

SmartPort Macro Configuration Guidelines 15-6

Creating SmartPorts Macros 15-7
Applying SmartPorts Macros 15-8
  cisco-global 15-9
  cisco-desktop 15-9
  cisco-phone 15-10
  cisco-switch 15-11
  cisco-router 15-11

Displaying SmartPort Macros 15-12

Chapter 16
Configuring STP and MST 16-1

Overview of STP 16-1
  Understanding the Bridge ID 16-2
    Bridge Priority Value 16-2
    Extended System ID 16-2
    STP MAC Address Allocation 16-3
  Bridge Protocol Data Units 16-3
  Election of the Root Bridge 16-4
  STP Timers 16-4
  Creating the STP Topology 16-4
  STP Port States 16-5
    MAC Address Allocation 16-5
    STP and IEEE 802.1Q Trunks 16-6
    Per-VLAN Rapid Spanning Tree 16-6

Default STP Configuration 16-6

Configuring STP 16-7
  Enabling STP 16-7
  Enabling the Extended System ID 16-8
  Configuring the Root Bridge 16-9
  Configuring a Secondary Root Switch 16-12
  Configuring STP Port Priority 16-13
  Configuring STP Port Cost 16-15
  Configuring the Bridge Priority of a VLAN 16-16
Configuring the Hello Time 16-17
Configuring the Maximum Aging Time for a VLAN 16-18
Configuring the Forward-Delay Time for a VLAN 16-18
Disabling Spanning Tree Protocol 16-19
Enabling Per-VLAN Rapid Spanning Tree 16-20
Specifying the Link Type 16-21
Restarting Protocol Migration 16-21

Overview of MST 16-21
IEEE 802.1s MST 16-22
IEEE 802.1w RSTP 16-23
RSTP Port Roles 16-23
RSTP Port States 16-24
MST-to-SST Interoperability 16-24
Common Spanning Tree 16-25
MST Instances 16-26
MST Configuration Parameters 16-26
MST Regions 16-26
MST Region Overview 16-26
Boundary Ports 16-27
IST Master 16-27
Edge Ports 16-27
Link Type 16-28
Message Age and Hop Count 16-28
MST-to-PVST+ Interoperability 16-28

MST Configuration Restrictions and Guidelines 16-29
Configuring MST 16-29
Enabling MST 16-29
Configuring MST Instance Parameters 16-31
Configuring MST Instance Port Parameters 16-32
Restarting Protocol Migration 16-33
Displaying MST Configurations 16-33

Configuring Optional STP Features 18-1
About Root Guard 18-2
Enabling Root Guard 18-2
About Loop Guard 18-3
Enabling Loop Guard 18-5
About EtherChannel Guard 18-6
Enabling EtherChannel Guard (Optional) 18-6
About PortFast 18-7
Enabling PortFast 18-7
About BPDU Guard 18-8
Enabling BPDU Guard 18-9
About PortFast BPDU Filtering 18-9
Enabling PortFast BPDU Filtering 18-10
About UplinkFast 18-11
Enabling UplinkFast 18-12
About BackboneFast 18-14
Enabling BackboneFast 18-16

CHAPTER 19
Configuring EtherChannel 19-1
EtherChannel Overview 19-1
Port-Channel Interfaces 19-2
How EtherChannels Are Configured 19-2
EtherChannel Configuration Overview 19-3
Manual EtherChannel Configuration 19-3
PAgP EtherChannel Configuration 19-3
IEEE 802.3ad LACP EtherChannel Configuration 19-4
Load Balancing 19-5
EtherChannel Configuration Guidelines and Restrictions 19-5
Configuring EtherChannel 19-6
Configuring Layer 3 EtherChannels 19-6
Creating Port-Channel Logical Interfaces 19-7
Configuring Physical Interfaces as Layer 3 EtherChannels 19-7
Configuring Layer 2 EtherChannels 19-9
Configuring the LACP System Priority and System ID 19-11
Configuring EtherChannel Load Balancing 19-12
Removing an Interface from an EtherChannel 19-13
Removing an EtherChannel 19-14
Displaying EtherChannel to a Virtual Switch System 19-14
Understanding VSS Client 19-15
Virtual Switch System 19-15
Dual-Active Scenarios 19-15
Dual-Active Detection Using Enhance PAgP 19-15
Displaying EtherChannel Links to VSS 19-17
CHAPTER 20
Configuring CDP

About CDP

Configuring CDP

Enabling CDP Globally
Displaying the CDP Global Configuration
Enabling CDP on an Interface
Displaying the CDP Interface Configuration
Monitoring and Maintaining CDP

CHAPTER 21
Configuring IGMP Snooping and Filtering

Overview of IGMP Snooping
Immediate-Leave Processing
IGMP Configurable-Leave Timer
IGMP Snooping Querier
Explicit Host Tracking

Configuring IGMP Snooping

Default IGMP Snooping Configuration
Enabling IGMP Snooping Globally
Enabling IGMP Snooping on a VLAN
Configuring Learning Methods
Configuring PIM/DVMRP Learning
Configuring CGMP Learning
Configuring a Static Connection to a Multicast Router
Enabling IGMP Immediate-Leave Processing
Configuring the IGMP Leave Timer
Configuring IGMP Snooping Querier
Configuring Explicit Host Tracking
Configuring a Host Statically
Suppressing Multicast Flooding
IGMP Snooping Interface Configuration
IGMP Snooping Switch Configuration

Displaying IGMP Snooping Information

Displaying Querier Information
Displaying IGMP Host Membership Information
Displaying Group Information
Displaying Multicast Router Interfaces
Displaying MAC Address Multicast Entries
Displaying IGMP Snooping Information on a VLAN Interface
Displaying IGMP Snooping Querier Information
### Configuring IGMP Filtering

- Default IGMP Filtering Configuration 21-20
- Configuring IGMP Profiles 21-21
- Applying IGMP Profiles 21-22
- Setting the Maximum Number of IGMP Groups 21-23
- Displaying IGMP Filtering Configuration 21-24

### Configuring IPv6 MLD Snooping

- About MLD Snooping 22-1
  - MLD Messages 22-2
  - MLD Queries 22-3
  - Multicast Client Aging Robustness 22-3
  - Multicast Router Discovery 22-3
  - MLD Reports 22-4
  - MLD Done Messages and Immediate-Leave 22-4
- Topology Change Notification Processing 22-4
- Configuring IPv6 MLD Snooping 22-5
  - Default MLD Snooping Configuration 22-5
  - MLD Snooping Configuration Guidelines 22-6
  - Enabling or Disabling MLD Snooping 22-6
  - Configuring a Static Multicast Group 22-7
  - Configuring a Multicast Router Port 22-7
  - Enabling MLD Immediate Leave 22-8
  - Configuring MLD Snooping Queries 22-9
  - Disabling MLD Listener Message Suppression 22-10
- Displaying MLD Snooping Information 22-11

### Configuring LLDP, and LLDP-MED

- About LLDP and LLDP-MED 23-1
  - Understanding LLDP 23-1
  - Understanding LLDP-MED 23-2
- Configuring LLDP and LLDP-MED 23-3
  - Default LLDP Configuration 23-3
  - Configuring LLDP Characteristics 23-4
  - Disabling and Enabling LLDP Globally 23-5
  - Disabling and Enabling LLDP on an Interface 23-6
  - Configuring LLDP-MED TLVs 23-7
  - Configuring LLDP Power Negotiation 23-8
  - Configuring LLDP and Location TLV 23-9
CHAPTER 24
Configuring UDLD 24-1
About UDLD 24-1
Modes of Operation 24-1
Default UDLD Configuration 24-2
Configuring UDLD on the Switch 24-3
Enabling UDLD Globally 24-4
Enabling UDLD on Individual Interfaces 24-4
Disabling UDLD on Non-Fiber-Optic Interfaces 24-5
Configuring the UDLD Probe Message Interval 24-5
Resetting Disabled LAN Interfaces 24-5

CHAPTER 25
Configuring Unidirectional Ethernet 25-1
About Unidirectional Ethernet 25-1
Configuring Unidirectional Ethernet 25-2

CHAPTER 26
Configuring Layer 3 Interfaces 26-1
Overview of Layer 3 Interfaces 26-1
Logical Layer 3 VLAN Interfaces 26-2
Physical Layer 3 Interfaces 26-2
Understanding SVI Autostate Exclude 26-3
Understanding Layer 3 Interface Counters 26-3

CHAPTER 29 Configuring IP Multicast

Overview of IP Multicast

IP Multicast Protocols
- Internet Group Management Protocol
- Protocol-Independent Multicast
- Rendezvous Point (RP)
- IGMP Snooping

IP Multicast on the Catalyst 4500 Series Switch
- CEF, M FIB, and Layer 2 Forwarding
- IP Multicast Tables
- Hardware and Software Forwarding
- Non-Reverse Path Forwarding Traffic
- Multicast Fast Drop
- Multicast Forwarding Information Base
- S/M, 224/4

Restrictions on using Bidirectional PIM

Unsupported Feature

Configuring IP Multicast Routing
- Default Configuration in IP Multicast Routing
- Enabling IP Multicast Routing
- Enabling PIM on an Interface
  - Enabling Dense Mode
  - Enabling Sparse Mode
  - Enabling Sparse-Dense Mode
- Enabling Bidirectional Mode
- Enabling PIM -SSM M apping
- Configuring a Rendezvous Point
- Configuring Auto-RP
Configuring a Single Static RP 29-19
Monitoring and Maintaining IP Multicast Routing 29-21
Displaying System and Network Statistics 29-21

### CHAPTER 32

**Configuring Flexible NetFlow** 32-1

### CHAPTER 33

**Configuring Quality of Service** 33-1

Overview of QoS on the Catalyst 4500 Series Switch 33-1
- Prioritization 33-2
- QoS Terminology 33-3
- Basic QoS Model 33-5
- Classification 33-6
- Classification Based on QoS ACLs 33-6
- Classification Based on Class Maps and Policy Maps 33-7
- Policing and Marking 33-8
- Queueing and Scheduling 33-8
- Active Queue Management 33-9
- Sharing Link Bandwidth Among Transmit Queues 33-9
- Strict Priority / Low Latency Queueing 33-9
- Traffic Shaping 33-9
- Packet Modification 33-9
- Per Port Per VLAN QoS 33-10
- Flow-based QoS 33-10
- Configuring QoS 33-11
- MQC-based QoS Configuration 33-11
- Platform-supported Classification Criteria and QoS Features 33-11
Platform Hardware Capabilities       33-12
Prerequisites for Applying a QoS Service Policy       33-13
Restrictions for Applying a QoS Service Policy       33-13
Classification       33-13
  Classification Statistics       33-13
  Configuring a Policy Map       33-14
  Attaching a Policy Map to an Interface       33-14
Policing       33-14
  How to Implement Policing       33-15
Platform Restrictions       33-16
Marking Network Traffic       33-16
  Contents       33-16
  Information About Marking Network Traffic       33-16
  Marking Action Drivers       33-19
  Traffic Marking Procedure Flowchart       33-19
  Restrictions for Marking Network Traffic       33-20
  Multi-attribute Marking Support       33-20
  Hardware Capabilities for Marking       33-21
  Configuring the Policy Map Marking Action       33-21
  Marking Statistics       33-22
Shaping, Sharing (Bandwidth), Priority Queuing, Queue-limiting and DBL       33-23
  Shaping       33-23
  Sharing(bandwidth)       33-25
  Priority queuing       33-28
  Queue-limiting       33-29
  Active Queue Management (AQM) via Dynamic Buffer Limiting (DBL)       33-32
  Transmit Queue Statistics       33-33
Enabling Per-Port Per-VLAN QoS       33-33
  Policy Associations       33-37
  Software QoS       33-38
Applying Flow-based QoS Policy       33-39
  Examples       33-39
  Configuration Guidelines       33-42
Configuring Auto-QoS       33-43

CHAPTER  34

Configuring Voice Interfaces       34-1
  About Voice Interfaces       34-1
    Cisco IP Phone Voice Traffic       34-2
    Cisco IP Phone Data Traffic       34-2
Configuring Private VLANs 35-1
Command List 35-1
Private VLANs 35-2
Definition Table 35-4
Private VLANs across Multiple Switches 35-5
Standard Trunk Ports 35-5
Isolated Private VLAN Trunk Ports 35-6
Promiscuous Private VLAN Trunk Ports 35-8
Private-VLAN Interaction with Other Features 35-8
PVLANs and VLAN ACL/QoS 35-9
Private VLANs and Unicast, Broadcast, and Multicast Traffic 35-9
Private VLANs and SVIs 35-10
Per-Virtual-Port Error Disable on Private VLANs 35-10
Configuring PVLANs 35-10
Tasks for Configuring Private VLANs 35-11
Default Private-VLAN Configuration 35-11
PVLAN Configuration Guidelines and Restrictions 35-11
Configuring a VLAN as a PVLAN 35-13
Associating a Secondary VLAN with a Primary VLAN 35-14
Configuring a Layer 2 Interface as a PVLAN Promiscuous Port 35-16
Configuring a Layer 2 Interface as a PVLAN Host Port 35-17
Configuring a Layer 2 Interface as an Isolated PVLAN Trunk Port 35-18
Configuring a Layer 2 Interface as a Promiscuous PVLAN Trunk Port 35-19
Permitting Routing of Secondary VLAN Ingress Traffic 35-21

Configuring 802.1X Port-Based Authentication 36-1
About 802.1X Port-Based Authentication 36-1
Device Roles 36-2
802.1X and Network Access Control 36-3
Authentication Initiation and Message Exchange 36-3
Ports in Authorized and Unauthorized States 36-4
802.1X Host Mode 36-6
Single-Host Mode 36-7
Multiple-Hosts Mode 36-7
Configuring 802.1X with Guest VLANs 36-46
Configuring 802.1X with MAC Authentication Bypass 36-48
Configuring 802.1X with Inaccessible Authentication Bypass 36-50
Configuring 802.1X with Unidirectional Controlled Port 36-52
Configuring 802.1X with Authentication Failed 36-53
Configuring 802.1X with Voice VLAN 36-54
Configuring 802.1X with VLAN Assignment 36-55
Cisco ACS Configuration for VLAN Assignment 36-56
Enabling Fallback Authentication 36-57
Enabling Periodic Reauthentication 36-61
Enabling Multiple Hosts 36-62
Changing the Quiet Period 36-63
Changing the Switch-to-Client Retransmission Time 36-63
Setting the Switch-to-Client Frame-Retransmission Number 36-64
Manually Reauthenticate a Client Connected to a Port 36-66
Initializing the 802.1X Authentication State 36-66
Removing 802.1X Client Information 36-66
Resetting the 802.1X Configuration to the Default Values 36-66
Displaying 802.1X Statistics and Status 36-67
Displaying Authentication Details 36-67
Determining the Authentication Methods Registered with the Auth Manager 36-67
Displaying the Auth Manager Summary for an Interface 36-67
Displaying the Summary of All Auth Manager Sessions on the Switch 36-68
Displaying a Summary of All Auth Manager Sessions on the Switch Authorized for a Specified Authentication Method 36-68
Verifying the Auth Manager Session for an Interface 36-68
Displaying MAB Details 36-70
EPM Logging 36-70
Cisco IOS Security Features in Cisco IOS XE 3.1.0 SG Release 36-71

CHAPTER 37
Configuring Web-Based Authentication 37-1
About Web-Based Authentication 37-1
Device Roles 37-2
Host Detection 37-2
Session Creation 37-3
Authentication Process 37-3
Customization of the Authentication Proxy Web Pages 37-4
Web-based Authentication Interactions with Other Features 37-4
Port Security 37-4
LAN Port IP 37-4
ACLs 37-5
Context-Based Access Control 37-5
802.1X Authentication 37-5
EtherChannel 37-5
Switchover 37-5

Configuring Web-Based Authentication 37-5
Default Web-Based Authentication Configuration 37-6
Web-Based Authentication Configuration Guidelines and Restrictions 37-6
Web-Based Authentication Configuration Task List 37-7
Configuring the Authentication Rule and Interfaces 37-7
Configuring AAA Authentication 37-8
Configuring Switch-to-RADIUS-Server Communication 37-8
Configuring the HTTP Server 37-10
  Customizing the Authentication Proxy Web Pages 37-11
  Specifying a Redirection URL for Successful Login 37-12
  Configuring the Web-Based Authentication Parameters 37-13
  Removing Web-Based Authentication Cache Entries 37-13
Displaying Web-Based Authentication Status 37-13

CHAPTER 38 Configuring Port Security 38-1

Command List 38-1
Port Security 38-3
  Secure MAC Addresses 38-3
  Maximum Number of Secure MAC Addresses 38-4
  Aging Secure MAC Addresses 38-5
  Sticky Addresses on a Port 38-5
  Violation Actions 38-6
  Invalid Packet Handling 38-6

Configuring Port Security on Access Ports 38-7
Configuring Port Security on Access Ports 38-7
Examples 38-10
  Example 1: Setting Maximum Number of Secure Addresses 38-11
  Example 2: Setting a Violation Mode 38-11
  Example 3: Setting the Aging Timer 38-11
  Example 4: Setting the Aging Timer Type 38-12
  Example 5: Configuring a Secure MAC Address 38-12
  Example 6: Configuring Sticky Port Security 38-13
  Example 7: Setting a Rate Limit for Bad Packets 38-13
Example 8: Clearing Dynamic Secure MAC Addresses 38-14

Configuring Port Security on PVLAN Ports 38-14
Configuring Port Security on an Isolated Private VLAN Host Port 38-14
Example of Port Security on an Isolated Private VLAN Host Port 38-16
Configuring Port Security on a Private VLAN Promiscous Port 38-16
Example of Port Security on a Private VLAN Promiscous Port 38-17

Configuring Port Security on Trunk Ports 38-17
Configuring Trunk Port Security 38-17
Examples of Trunk Port Security 38-19
  Example 1: Configuring a Maximum Limit of Secure MAC Addresses for all VLANs 38-19
  Example 2: Configuring a Maximum Limit of Secure MAC Addresses for Specific VLANs 38-20
  Example 3: Configuring Secure MAC Addresses in a VLAN Range 38-20

Trunk Port Security Guidelines and Restrictions 38-21
Port Mode Changes 38-22

Configuring Port Security on Voice Ports 38-22
Configuring Port Security on Voice Ports 38-23
Examples of Voice Port Security 38-25
  Example 1: Configuring Maximum MAC Addresses for Voice and Data VLANs 38-25
  Example 2: Configuring Sticky MAC Addresses for Voice and Data VLANs 38-26

Voice Port Security Guidelines and Restrictions 38-27

Displaying Port Security Settings 38-27
Examples 38-28
  Example 1: Displaying Security Settings for the Entire Switch 38-28
  Example 2: Displaying Security Settings for an Interface 38-29
  Example 3: Displaying all Secure Addresses for the Entire Switch 38-29
  Example 4: Displaying a Maximum Number of MAC Addresses on an Interface 38-30
  Example 5: Displaying Security Settings on an Interface for a VLAN Range 38-30
  Example 6: Displaying Secured MAC Addresses and Aging Information on an Interface 38-30
  Example 7: Displaying Secured MAC Addresses for a VLAN Range on an Interface 38-30

Configuring Port Security with Other Features/Environments 38-31
  DHCP and IP Source Guard 38-31
  802.1X Authentication 38-32
  Configuring Port Security in a Wireless Environment 38-32

Guidelines and Restrictions 38-33

CHAPTER 39

Configuring Control Plane Policing 39-1

About Control Plane Policing 39-2
CoPP Default Configuration 39-3
Configuring CoPP 39-3
CHAPTER 39
Configure CoPP for Control Plane Traffic 39-3
Configure CoPP for Data Plane and Management Plane Traffic 39-5
CoPP Configuration Guidelines and Restrictions 39-7
Monitoring CoPP 39-7

CHAPTER 40
Configuring DHCP Snooping, IP Source Guard, and IPSG for Static Hosts 40-1
About DHCP Snooping 40-1
Trusted and Untrusted Sources 40-2
Overview of the DHCP Snooping Database Agent 40-2
Option-82 Data Insertion 40-4
Configuring DHCP Snooping 40-6
Default Configuration for DHCP Snooping 40-7
Enabling DHCP Snooping 40-7
Enabling DHCP Snooping on the Aggregation Switch 40-9
Enabling DHCP Snooping and Option 82 40-10
Enabling DHCP Snooping on Private VLAN 40-11
Configuring DHCP Snooping on Private VLAN 40-12
Configuring DHCP Snooping with an Ethernet Channel Group 40-12
Enabling the DHCP Snooping Database Agent 40-12
Limiting the Rate of Incoming DHCP Packets 40-13
Configuration Examples for the Database Agent 40-15
Example 1: Enabling the Database Agent 40-15
Example 2: Reading Binding Entries from a TFTP File 40-16
Example 3: Adding Information to the DHCP Snooping Database 40-18
Displaying DHCP Snooping Information 40-18
Displaying a Binding Table 40-18
Displaying the DHCP Snooping Configuration 40-19
About IP Source Guard 40-19
Configuring IP Source Guard 40-20
Configuring IP Source Guard on Private VLANs 40-22
Displaying IP Source Guard Information 40-22
Displaying IP Source Binding Information 40-23

CHAPTER 41
Configuring Dynamic ARP Inspection 41-1
About Dynamic ARP Inspection 41-1
ARP Cache Poisoning 41-2
Purpose of Dynamic ARP Inspection 41-2
Interface Trust State, Security Coverage and Network Configuration 41-3
Relative Priority of Static Bindings and DHCP Snooping Entries 41-4
Logging of Dropped Packets 41-4
Rate Limiting of ARP Packets 41-4
Port Channels and Their Behavior 41-5
Configuring Dynamic ARP Inspection 41-5
  Configuring Dynamic ARP Inspection in DHCP Environments 41-5
    On Switch A 41-7
    On Switch B 41-9
  Configuring ARP ACLs for Non-DHCP Environments 41-11
Configuring the Log Buffer 41-14
Limiting the Rate of Incoming ARP Packets 41-16
Performing Validation Checks 41-19

CHAPTER 42
Configuring Network Security with ACLs 42-1
About ACLs 42-2
  ACL Overview 42-2
Supported Features That Use ACLs 42-3
Router ACLs 42-3
Port ACLs 42-4
VLAN Maps 42-5
Hardware and Software ACL Support 42-5
TCAM Programming and ACLs 42-6
  Troubleshooting High CPU Due to ACLs 42-6
  Selecting Mode of Capturing Control Packets 42-7
    Caveats and Restriction 42-7
    Configuration 42-8
  Layer 4 Operators in ACLs 42-9
    Restrictions for Layer 4 Operations 42-9
    Configuration Guidelines for Layer 4 Operations 42-10
    How ACL Processing Impacts CPU 42-11
Configuring Unicast MAC Address Filtering 42-12
Configuring Named MAC Extended ACLs 42-12
Configuring EtherType Matching 42-14
Configuring Named IPv6 ACLs 42-15
Applying IPv6 ACLs to a Layer 2 Interface 42-16
Applying IPv6 ACLs to a Layer 3 Interface 42-16
Configuring VLAN Maps 42-17
  VLAN Map Configuration Guidelines 42-18
Creating and Deleting VLAN Maps 42-19
Examples of ACLs and VLAN Maps 42-19
Applying a VLAN Map to a VLAN 42-21
Using VLAN Maps in Your Network 42-22
Denying Access to a Server on Another VLAN 42-23
Displaying VLAN Access Map Information 42-24
Using VLAN Maps with Router ACLs 42-25
Guidelines for Using Router ACLs and VLAN Maps on the Same VLAN 42-25
Examples of Router ACLs and VLAN Maps Applied to VLANs 42-25
ACLs and Switched Packets 42-25
ACLs and Routed Packets 42-26
Configuring PACLs 42-27
Creating a PACL 42-27
PACL Configuration Guidelines 42-28
Configuring IPv6, IP, and MAC ACLs on a Layer 2 Interface 42-28
Using PACL with Access-Group Mode 42-29
Configuring Access-group Mode on Layer 2 Interface 42-30
Applying ACLs to a Layer 2 Interface 42-30
Displaying an ACL Configuration on a Layer 2 Interface 42-31
Using PACL with VLAN Maps and Router ACLs 42-31

CHAPTER 43
Support for IPv6 43-1
Finding Feature Information 43-1
About IPv6 43-1
IPv6 Addressing and Basic Connectivity 43-2
DHCP 43-3
Security 43-3
QoS 43-3
Management 43-4
Multicast 43-4
Static Routes 43-4
First-Hop Redundancy Protocols 43-5
Unicast Routing 43-5
RIP 43-5
OSPF 43-5
EIGRP 43-6
Multicast BGP 43-6
Tunneling 43-6
IPv6 Default States 43-7
## Port Unicast and Multicast Flood Blocking

### About Flood Blocking
### Configuring Port Blocking
- Blocking Flooded Traffic on an Interface
- Resuming Normal Forwarding on a Port

## Configuring Storm Control

### About Storm Control
- Hardware-based Storm Control Implementation
- Software-based Storm Control Implementation
- Enabling Broadcast Storm Control
- Enabling Multicast Storm Control
- Disabling Broadcast Storm Control
- Disabling Multicast Storm Control
- Displaying Storm Control

## Configuring SPAN and RSPAN

### About SPAN and RSPAN
- SPAN and RSPAN Concepts and Terminology
- SPAN Session
- Traffic Types
- Source Port
- Destination Port
- VLAN-Based SPAN
- SPAN Traffic
- SPAN and RSPAN Session Limits
- Default SPAN and RSPAN Configuration
- Configuring SPAN
- SPAN Configuration Guidelines and Restrictions
- Configuring SPAN Sources
- Configuring SPAN Destinations
- Monitoring Source VLANs on a Trunk Interface
- Configuration Scenario
- Verifying a SPAN Configuration
- CPU Port Sniffing
- Encapsulation Configuration
- Ingress Packets
- Access List Filtering
Contents

ACL Configuration Guidelines 46-13  
Configuring Access List Filtering 46-14  
Packet Type Filtering 46-14  
Configuration Example 46-15  
Configuring RSPAN 46-16  
  RSPAN Configuration Guidelines 46-16  
  Creating an RSPAN Session 46-17  
  Creating an RSPAN Destination Session 46-18  
  Creating an RSPAN Destination Session and Enabling Ingress Traffic 46-19  
  Removing Ports from an RSPAN Session 46-21  
  Specifying VLANs to Monitor 46-22  
  Specifying VLANs to Filter 46-23  
  Displaying SPAN and RSPAN Status 46-24  

 CHAPTER 47  
Configuring System Message Logging 47-1  
  About System Message Logging 47-1  
  Configuring System Message Logging 47-2  
    System Log Message Format 47-2  
    Default System Message Logging Configuration 47-3  
    Disabling Message Logging 47-4  
    Setting the Message Display Destination Device 47-5  
    Synchronizing Log Messages 47-6  
    Enabling and Disabling Timestamps on Log Messages 47-7  
    Enabling and Disabling Sequence Numbers in Log Messages (Optional) 47-7  
    Defining the Message Severity Level (Optional) 47-8  
    Limiting Syslog Messages Sent to the History Table and to SNMP (Optional) 47-9  
    Configuring UNIX Syslog Servers 47-10  
      Logging Messages to a UNIX Syslog Daemon 47-10  
      Configuring the UNIX System Logging Facility 47-11  
  Displaying the Logging Configuration 47-12  

 CHAPTER 48  
Configuring Onboard Failure Logging (OBFL) 48-1  
  Prerequisites for OBFL 48-1  
  Restrictions for OBFL 48-2  
  Information About OBFL 48-2  
    Overview of OBFL 48-2  
    Information about Data Collected by OBFL 48-2  
      OBFL Data Overview 48-2
Temperature 48-3
Operational Uptime 48-4
Interrupts 48-7

CHAPTER 49
Configuring SNMP 49-1
About SNMP 49-1
   SNMP Versions 49-2
   SNMP Manager Functions 49-3
   SNMP Agent Functions 49-4
   SNMP Community Strings 49-4
   Using SNMP to Access MIB Variables 49-4
   SNMP Notifications 49-5
Configuring SNMP 49-5
   Default SNMP Configuration 49-5
   SNMP Configuration Guidelines 49-6
   Disabling the SNMP Agent 49-7
   Configuring Community Strings 49-7
   Configuring SNMP Groups and Users 49-9
   Configuring SNMP Notifications 49-11
   Setting the Agent Contact and Location Information 49-15
   Limiting TFTP Servers Used Through SNMP 49-15
   SNMP Examples 49-16
Displaying SNMP Status 49-17

CHAPTER 50
Configuring Cisco IOS IP SLAs Operations 50-1
Command Table 50-2
About Cisco IOS IP SLAs 50-2
   Using Cisco IOS IP SLAs to Measure Network Performance 50-3
   IP SLAs Responder and IP SLAs Control Protocol 50-4
   Response Time Computation for IP SLAs 50-5
   IP SLAs Operation Scheduling 50-6
Contents

Software Configuration Guide—Release IOS-XE 3.1.0 SG

IP SLAs Operation Threshold Monitoring

Configuring IP SLAs Operations
    Default Configuration
    Configuration Guidelines
    Configuring the IP SLAs Responder
    Analyzing IP Service Levels by Using the UDP Jitter Operation
    Analyzing IP Service Levels by Using the ICMP Echo Operation

Monitoring IP SLAs Operations

Preface

This preface describes who should read this document, how it is organized, and its conventions. The preface also tells you how to obtain Cisco documents, as well as how to obtain technical assistance.

Audience

This guide is for experienced network administrators who are responsible for configuring and maintaining Catalyst 4500 series switches.

Organization

This guide is organized into the following chapters:

<table>
<thead>
<tr>
<th>Chapter</th>
<th>Title</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chapter 1</td>
<td>Product Overview</td>
<td>Presents an overview of the Cisco IOS software for the Catalyst 4500 series switches.</td>
</tr>
<tr>
<td>Chapter 2</td>
<td>Command-Line Interfaces</td>
<td>Describes how to use the CLI.</td>
</tr>
<tr>
<td>Chapter 3</td>
<td>Configuring the Switch for the First Time</td>
<td>Describes how to perform a baseline configuration of the switch.</td>
</tr>
<tr>
<td>Chapter 4</td>
<td>Administering the Switch</td>
<td>Describes how to administer the switch.</td>
</tr>
<tr>
<td>Chapter 6</td>
<td>Configuring the Cisco IOS XE In Service Software Upgrade Process</td>
<td>Describes how to configure ISSU on the switch.</td>
</tr>
<tr>
<td>Chapter 7</td>
<td>Configuring Interfaces</td>
<td>Describes how to configure non-layer-specific features on Fast Ethernet, Gigabit Ethernet, and 10-Gigabit Ethernet interfaces.</td>
</tr>
<tr>
<td>Chapter 8</td>
<td>Checking Port Status and Connectivity</td>
<td>Describes how to check module and interface status.</td>
</tr>
<tr>
<td>Chapter 5</td>
<td>Configuring Supervisor Engine Redundancy Using RPR and SSO</td>
<td>Describes how to configure RPR and SSO on the Catalyst 4507R and 4510R switches.</td>
</tr>
<tr>
<td>Chapter 9</td>
<td>Configuring Cisco NSF with SSO Supervisor Engine Redundancy</td>
<td>Describes how to configure supervisor engine redundancy using Cisco nonstop forwarding (NSF) with stateful switchover (SSO).</td>
</tr>
<tr>
<td>Chapter</td>
<td>Title</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>--------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>10</td>
<td>Environmental Monitoring and Power Management</td>
<td>Describes how to configure power management and environmental monitoring features.</td>
</tr>
<tr>
<td>11</td>
<td>Configuring Power over Ethernet</td>
<td>Describes how to configure Power over Ethernet (PoE).</td>
</tr>
<tr>
<td>12</td>
<td>Configuring VLANs, VTP, and VMPS</td>
<td>Describes how to configure VLANs, VTP, and VMPS.</td>
</tr>
<tr>
<td>13</td>
<td>Configuring IP Unnumbered Interface</td>
<td>Describes how to configure IP Unnumbered support.</td>
</tr>
<tr>
<td>14</td>
<td>Configuring Layer 2 Ethernet Interfaces</td>
<td>Describes how to configure interfaces to support Layer 2 features, including VLAN trunks.</td>
</tr>
<tr>
<td>15</td>
<td>Configuring SmartPort Macros</td>
<td>Describes how to configure SmartPort macros.</td>
</tr>
<tr>
<td>16</td>
<td>Configuring STP and MST</td>
<td>Describes how to configure the Spanning Tree Protocol (STP) and the Multiple Spanning Tree (MST) protocol and explains how they work.</td>
</tr>
<tr>
<td>18</td>
<td>Configuring Optional STP Features</td>
<td>Describes how to configure the spanning-tree PortFast, UplinkFast, BackboneFast, and other STP features.</td>
</tr>
<tr>
<td>19</td>
<td>Configuring EtherChannel</td>
<td>Describes how to configure Layer 2 and Layer 3 EtherChannel port bundles.</td>
</tr>
<tr>
<td>20</td>
<td>Configuring CDP</td>
<td>Describes how to configure the Cisco Discovery Protocol (CDP).</td>
</tr>
<tr>
<td>21</td>
<td>Configuring IGMP Snooping and Filtering</td>
<td>Describes how to configure Internet Group Management Protocol (IGMP) snooping.</td>
</tr>
<tr>
<td>22</td>
<td>Configuring IPv6 MLD Snooping</td>
<td>Describes how to configure IPv6 MLD Snooping.</td>
</tr>
<tr>
<td>23</td>
<td>Configuring LLDP, and LLDP-MED</td>
<td>Describes how to configure Link Layer Discovery Protocol (LLDP).</td>
</tr>
<tr>
<td>24</td>
<td>Configuring UDLD</td>
<td>Describes how to configure the UniDirectional Link Detection (UDLD) protocol.</td>
</tr>
<tr>
<td>25</td>
<td>Configuring Unidirectional Ethernet</td>
<td>Describes how to configure Unidirectional Ethernet.</td>
</tr>
<tr>
<td>26</td>
<td>Configuring Layer 3 Interfaces</td>
<td>Describes how to configure interfaces to support Layer 3 features.</td>
</tr>
<tr>
<td>27</td>
<td>Configuring Cisco Express Forwarding</td>
<td>Describes how to configure Cisco Express Forwarding (CEF) for IP unicast traffic.</td>
</tr>
<tr>
<td>28</td>
<td>Configuring Unicast Reverse Path Forwarding</td>
<td>Describes how to configure Unicast Reverse Path Forwarding.</td>
</tr>
<tr>
<td>29</td>
<td>Configuring IP Multicast</td>
<td>Describes how to configure IP Multicast Multilayer Switching (MMLS).</td>
</tr>
<tr>
<td>30</td>
<td>Configuring Policy-Based Routing</td>
<td>Describes how to configure policy-based routing.</td>
</tr>
<tr>
<td>31</td>
<td>Configuring VRF-lite</td>
<td>Describes how to configure multiple VPN routing/forwarding (multi-VRF) instances in customer edge (CE) devices.</td>
</tr>
<tr>
<td>Chapter</td>
<td>Title</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>--------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Chapter 32</td>
<td>Configuring Flexible NetFlow</td>
<td>Describes how to configure Flexible NetFlow.</td>
</tr>
<tr>
<td>Chapter 33</td>
<td>Configuring Quality of Service</td>
<td>Describes how to configure quality of service (QoS).</td>
</tr>
<tr>
<td>Chapter 34</td>
<td>Configuring Voice Interfaces</td>
<td>Describes how to configure voice interfaces.</td>
</tr>
<tr>
<td>Chapter 35</td>
<td>Configuring Private VLANs</td>
<td>Describes how to set up and modify private VLANs.</td>
</tr>
<tr>
<td>Chapter 36</td>
<td>Configuring 802.1X Port-Based Authentication</td>
<td>Describes how to configure 802.1X port-based authentication</td>
</tr>
<tr>
<td>Chapter 37</td>
<td>Configuring Web-Based Authentication</td>
<td>Describes how to configure web-based authentication.</td>
</tr>
<tr>
<td>Chapter 38</td>
<td>Configuring Port Security</td>
<td>Describes how to configure port security and trunk port security.</td>
</tr>
<tr>
<td>Chapter 39</td>
<td>Configuring Control Plane Policing</td>
<td>Describes how to protect your Catalyst 4500 series switch using control plane policing (CoPP).</td>
</tr>
<tr>
<td>Chapter 40</td>
<td>Configuring DHCP Snooping, IP Source Guard, and IPSG for Static Hosts</td>
<td>Describes how to configure DHCP snooping and IP Source Guard.</td>
</tr>
<tr>
<td>Chapter 41</td>
<td>Configuring Dynamic ARP Inspection</td>
<td>Describes how to configure Dynamic ARP Inspection.</td>
</tr>
<tr>
<td>Chapter 42</td>
<td>Configuring Network Security with ACLs</td>
<td>Describes how to configure ACLS, VACLs, and MACLS.</td>
</tr>
<tr>
<td>Chapter 43</td>
<td>Support for IPv6</td>
<td>Describes the IPv6 support on the switch.</td>
</tr>
<tr>
<td>Chapter 44</td>
<td>Port Unicast and Multicast Flood Blocking</td>
<td>Describes how to configure unicast flood blocking.</td>
</tr>
<tr>
<td>Chapter 45</td>
<td>Configuring Storm Control</td>
<td>Describes how to configure storm control suppression.</td>
</tr>
<tr>
<td>Chapter 46</td>
<td>Configuring SPAN and RSPAN</td>
<td>Describes how to configure the Switched Port Analyzer (SPAN).</td>
</tr>
<tr>
<td>Chapter 47</td>
<td>Configuring System Message Logging</td>
<td>Describes how to configure system message logging.</td>
</tr>
<tr>
<td>Chapter 48</td>
<td>Configuring Onboard Failure Logging (OBFL)</td>
<td>Describes how to configure OBFL.</td>
</tr>
<tr>
<td>Chapter 49</td>
<td>Configuring SNMP</td>
<td>Describes how to configure the Simple Network Management Protocol (SNMP).</td>
</tr>
<tr>
<td>Chapter 50</td>
<td>Configuring Cisco IOS IP SLA Operations</td>
<td>Describes how to configure Cisco IOS IP SLA operations.</td>
</tr>
<tr>
<td>Chapter 51</td>
<td>Configuring RMON</td>
<td>Describes how to configure Remote Network Monitoring (RMON).</td>
</tr>
<tr>
<td>Chapter 52</td>
<td>Configuring Call Home</td>
<td>Describes how to configure Call Home.</td>
</tr>
<tr>
<td>Chapter 53</td>
<td>Performing Diagnostics</td>
<td>Describes various types of diagnostics on the Catalyst 4500 series switch.</td>
</tr>
<tr>
<td>Chapter 54</td>
<td>ROM Monitor</td>
<td>Describes the ROM Monitor.</td>
</tr>

Notes use the following conventions:

**Note**

Means reader take note. Notes contain helpful suggestions or references to material not covered in the publication.

Cautions use the following conventions:

**Caution**

Means reader be careful. In this situation, you might do something that could result in equipment damage or loss of data.
Commands in Task Tables

Commands listed in task tables show only the relevant information for completing the task and not all available options for the command. For a complete description of a command, refer to the command in the Catalyst 4500 Series Switch Cisco IOS Command Reference.

Related Documentation

Refer to the following documents for additional Catalyst 4500 series information:

Obtaining Documentation and Submitting a Service Request

For information on obtaining documentation, submitting a service request, and gathering additional information, see the monthly What’s New in Cisco Product Documentation, which also lists all new and revised Cisco technical documentation, at:

Subscribe to the What’s New in Cisco Product Documentation as a Really Simple Syndication (RSS) feed and set content to be delivered directly to your desktop using a reader application. The RSS feeds are a free service and Cisco currently supports RSS Version 2.0.
Product Overview

This chapter provides an overview of Catalyst 4500 series switches and includes the following major sections:

- Layer 2 Software Features, page 1-1
- Layer 3 Software Features, page 1-8
- Management Features, page 1-15
- Security Features, page 1-20

For complete syntax and usage information for the switch commands used in this chapter, first look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Series Switch Command Reference, it will be found in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

Layer 2 Software Features

The following subsections describe the key Layer 2 switching software features on the Catalyst 4500 series switch:

- Cisco Discovery Protocol, page 1-2
- Cisco Group Management Protocol (CGMP) server, page 1-2
- EtherChannel Bundles, page 1-2
- Flexible NetFlow, page 1-2
- Internet Group Management Protocol (IGMP) Snooping, page 1-3
- IPv6 Multicast Listen Discovery (MLD) and Multicast Listen Discovery snooping, page 1-3
- Jumbo Frames, page 1-3
- Link Aggregation Control Protocol, page 1-4
- Link Layer Discovery Protocol, page 1-4
Cisco Discovery Protocol

The Cisco Discovery Protocol (CDP) is a device-discovery protocol that is both media- and protocol-independent. CDP is available on all Cisco products, including routers, switches, bridges, and access servers. Using CDP, a device can advertise its existence to other devices and receive information about other devices on the same LAN. CDP enables Cisco switches and routers to exchange information, such as their MAC addresses, IP addresses, and outgoing interfaces. CDP runs over the data-link layer only, allowing two systems that support different network-layer protocols to learn about each other. Each device configured for CDP sends periodic messages to a multicast address. Each device advertises at least one address at which it can receive Simple Network Management Protocol (SNMP) messages.

For information on configuring CDP, see Chapter 20, “Configuring CDP.”

Cisco Group Management Protocol (CGMP) server

CGMP server manages multicast traffic. Multicast traffic is forwarded only to ports with attached hosts that request the multicast traffic.

EtherChannel Bundles

EtherChannel port bundles allow you to create high-bandwidth connections between two switches by grouping multiple ports into a single logical transmission path.

For information on configuring EtherChannel, see Chapter 19, “Configuring EtherChannel.”

Flexible NetFlow

Flow is defined as unique set of key fields attributes, which might include fields of packet, packet routing attributes, and input and output interface information. A NetFlow feature defines a flow as a sequence of packets that have the same values for the feature key fields. Flexible Netflow (FNF) allows a flow record that specifies various flow attributes to be collected and optionally exported. Netflow collection supports IP, IPv6 and Layer 2 traffic.

For information on configuring Flexible NetFlow, see Chapter 32, “Configuring Flexible NetFlow.”
Internet Group Management Protocol (IGMP) Snooping

IGMP snooping manages multicast traffic. The switch software examines IP multicast packets and forwards packets based on their content. Multicast traffic is forwarded only to ports with attached hosts that request multicast traffic.

Support for IGMPv3 provides constrained flooding of multicast traffic in the presence of IGMPv3 hosts or routers. IGMPv3 snooping listens to IGMPv3 query and membership report messages to maintain host-to-multicast group associations. It enables a switch to propagate multicast data only to ports that need it. IGMPv3 snooping is fully interoperable with IGMPv1 and IGMPv2.

Explicit Host Tracking (EHT) is an extension to IGMPv3 snooping. EHT enables immediate leave operations on a per-port basis. EHT can be used to track per host membership information or to gather statistics about all IGMPv3 group members.

The IGMP Snooping Querier is a Layer 2 feature required to support IGMP snooping in a VLAN where PIM and IGMP are not configured because the multicast traffic does not require routing.

With SSO support, Stateful IGMP Snooping propagates the IGMP data learned by the active supervisor engine to the redundant supervisor engine so that when a switchover occurs, the newly active supervisor engine is aware of the multicast group membership, which alleviates a disruption to multicast traffic during a switchover.

For information on configuring IGMP snooping, see Chapter 21, “Configuring IGMP Snooping and Filtering.”

IPv6 Multicast Listen Discovery (MLD) and Multicast Listen Discovery snooping

MLD is a protocol used by IPv6 multicast devices to discover the presence of multicast listeners (nodes that want to receive IPv6 multicast packets) on its directly attached links and to discover which multicast packets are of interest to neighboring nodes. MLD snooping is supported in two different versions: MLD v1 and MLD v2. Network switches use MLD snooping to limit the flood of multicast traffic, causing IPv6 multicast data to be selectively forwarded to a list of ports that want to receive the data, instead of being flooded to all ports in a VLAN. This lessens the load on devices in the network, minimizing unnecessary bandwidth on links, enabling efficient distribution of IPv6 multicast data.

For information on configuring multicast services, see Chapter 22, “Configuring IPv6 MLD Snooping.”

Jumbo Frames

The jumbo frames feature allows the switch to forward packets as large as 9216 bytes (larger than the IEEE Ethernet MTU), rather than declare those frames “oversize” and discard them. This feature is typically used for large data transfers. The jumbo frames feature can be configured on a per-port basis on Layer 2 and Layer 3 interfaces.

The feature is supported only on the following hardware:

- WS-X4306-GB: All ports
- WS-X4232-GB-RJ: Ports 1-2
- WS-X4418-GB: Ports 1-2
- WS-X4412-2GB-TX: Ports 13-14
Layer 2 Software Features

- WS-4648-RJ45V-E
- WS-X4648+RJ45V+E
- WS-X4706-10GE linecards
- supervisor engine uplink ports

For information on Jumbo Frames, see Chapter 7, “Configuring Interfaces.”

Link Aggregation Control Protocol

LACP supports the automatic creation of EtherChannels by exchanging LACP packets between LAN ports. LACP packets are exchanged only between ports in passive and active modes. The protocol "learns" the capabilities of LAN port groups dynamically and informs the other LAN ports. After LACP identifies correctly matched Ethernet links, it facilitates grouping the links into an EtherChannel. Then the EtherChannel is added to the spanning tree as a single bridge port.

Cisco IOS XE IP Application Services Features in Cisco IOS XE 3.1.0SG

This section lists the IP Application Services software features that are supported in Cisco IOS XE 3.1.0SG. Links to the feature documentation are included.

Feature guides may contain information about more than one feature. To find information about a specific feature within a feature guide, see the Feature Information table at the end of the guide.

Feature guides document features that are supported on many different software releases and platforms. Your Cisco software release or platform may not support all the features documented in a feature guide. See the Feature Information table at the end of the feature guide for information about which features in that guide are supported in your software release. Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

IEEE 802.3ad Link Aggregation (LACP)

Link Aggregation Control Protocol (LACP) (802.3ad) for Gigabit Interfaces

Link Layer Discovery Protocol

To support non-Cisco devices and to allow for interoperability between other devices, the switch supports the IEEE 802.1AB LLDP. Link Layer Discovery Protocol (LLDP) is a neighbor discovery protocol that is used for network devices to advertise information about themselves to other devices on the network. This protocol runs over the data-link layer, which allows two systems running different network layer protocols to learn about each other.

LLDP supports a set of attributes that it uses to discover neighbor devices. These attributes contain type, length, and value descriptions and are referred to as TLVs. LLDP supported devices can use TLVs to receive and send information to their neighbors. Details such as configuration information, device capabilities, and device identity can be advertised using this protocol.

For information on configuring LLDP, see Chapter 23, “Configuring LLDP, and LLDP-MED.”
Multiple Spanning Tree

IEEE 802.1s Multiple Spanning Tree (MST) allows for multiple spanning tree instances within a single 802.1Q or Inter-Switch Link (ISL) VLAN trunk. MST extends the IEEE 802.1w Rapid Spanning Tree (RST) algorithm to multiple spanning trees. This extension provides both rapid convergence and load balancing within a VLAN environment.

MST allows you to build multiple spanning trees over trunks. You can group and associate VLANs to spanning tree instances. Each instance can have a topology independent of other spanning tree instances. This new architecture provides multiple forwarding paths for data traffic and enables load balancing. Network fault tolerance is improved because a failure in one instance (forwarding path) does not affect other instances (forwarding paths).

For information on configuring MST, see Chapter 16, “Configuring STP and MST.”

Per-VLAN Rapid Spanning Tree

Per-VLAN Rapid Spanning Tree (PVRST+) is the implementation of 802.1w on a per-VLAN basis. It is the same as PVST+ with respect to STP mode and runs RSTP protocol based on 802.1w.

For information on configuring PVRST+, see Chapter 16, “Configuring STP and MST.”

Quality of Service

The quality of service (QoS) feature prevents congestion by selecting network traffic and prioritizing it according to its relative importance. Implementing QoS in your network makes network performance more predictable and bandwidth use more effective.

The Catalyst 4500 series switch supports the following QoS features:

- Classification and marking
- Ingress and egress policing, including per-port per-VLAN policing
- Sharing and shaping

Catalyst 4500 series switch supports trusted boundary, which uses the Cisco Discovery Protocol (CDP) to detect the presence of a Cisco IP phone (such as the Cisco IP Phone 7910, 7935, 7940, and 7960) on a switch port. If the telephone is not detected, the trusted boundary feature disables the trusted setting on the switch port and prevents misuse of a high-priority queue.

The Catalyst 4500 series switch also supports QoS Automation (Auto QoS), which simplifies the deployment of existing QoS features through automatic configuration.

Cisco Modular QoS command-line-interface

Cisco Modular QoS CLI (MQC) is the framework that implements Cisco IOS software QoS. MQC allows the user to define a traffic class, create a traffic policy (containing the QoS feature to be applied to the traffic class), and attach the traffic policy to an interface. MQC is a cross-Cisco baseline that provides a consistent syntax and behavior of QoS features across multiple product families. MQC enables rapid deployment of new features and technology innovations and facilitates the management of network performance with respect to bandwidth, delay, jitter, and packet loss, enhancing the performance of mission-critical business applications. The rich and advanced QoS features that are supported as part of the Supervisor Engine 7-E are enabled using Cisco MQC.
The Two-Rate Three-Color Policing feature (also termed Hierarchical QoS) limits the input or output transmission rate of a class of traffic based on user-defined criteria and marks or colors packets by setting the applicable differentiated services code point (DSCP) values. This feature is often configured on the interfaces at the edge of a network to limit the rate of traffic entering or leaving the network. Using this feature, traffic that conforms to user-defined criteria can be sent through the interfaces, while traffic that exceeds or violates these criteria is sent out with a decreased priority setting or even dropped.

For information on QoS and Auto QoS, see Chapter 33, “Configuring Quality of Service.”

Spanning Tree Protocol

The Spanning Tree Protocol (STP) allows you to create fault-tolerant internetworks that ensure an active, loop-free data path between all nodes in the network. STP uses an algorithm to calculate the best loop-free path throughout a switched network.

For information on configuring STP, see Chapter 16, “Configuring STP and MST.”

The Catalyst 4500 series switch supports the following STP enhancements:

- Spanning tree PortFast—PortFast allows a port with a directly attached host to transition to the forwarding state directly, bypassing the listening and learning states.
- Spanning tree UplinkFast—UplinkFast provides fast convergence after a spanning-tree topology change and achieves load balancing between redundant links using uplink groups. Uplink groups provide an alternate path in case the currently forwarding link fails. UplinkFast is designed to decrease spanning-tree convergence time for switches that experience a direct link failure.
- Spanning tree BackboneFast—BackboneFast reduces the time needed for the spanning tree to converge after a topology change caused by an indirect link failure. BackboneFast decreases spanning-tree convergence time for any switch that experiences an indirect link failure.
- Spanning tree root guard—Root guard forces a port to become a designated port so that no switch on the other end of the link can become a root switch.

For information on the STP enhancements, see Chapter 18, “Configuring Optional STP Features.”

Stateful Switchover

Stateful switchover (SSO) enables you to propagate configuration and state information from the active to the redundant supervisor engine so that sub-second interruptions in Layer 2 traffic occur when the active supervisor engine switches over to the redundant supervisor engine.

For information about SSO, see Chapter 9, “Configuring Cisco NSF with SSO Supervisor Engine Redundancy.”

SVI Autostate

When an SVI has multiple ports on a VLAN, normally the SVI will go down when all the ports in the VLAN go down. You can design your network so that some ports are not counted in the calculation of SVI “going up or down.” SVI Autostate provides a knob to mark a port so that it is not counted in the SVI “going up and down” calculation and applies to all VLANs that are enabled on that port.
Unidirectional Ethernet

**Note**

Unidirectional Ethernet is *not* supported on either Supervisor Engine 6-E or a Catalyst 4900M chassis.

Unidirectional Ethernet uses only one strand of fiber for either transmitting or receiving one-way traffic for the Gigaport, instead of two strands of fiber for a full-duplex Gigaport Ethernet.

For information about Unidirectional Ethernet, see Chapter 25, “Configuring Unidirectional Ethernet.”

UniDirectional Link Detection

The UniDirectional Link Detection (UDLD) protocol allows devices connected through fiber-optic or copper Ethernet cables to monitor the physical configuration of the cables and detect a unidirectional link.

For information about UDLD, see Chapter 24, “Configuring UDLD.”

User Based Rate Limiting

User Based Rate Limiting (UBRL) enables you to adopt microflow policing to dynamically learn traffic flows and rate limit each unique flow to an individual rate. UBRL is available only on the Supervisor Engine V-10GE with the built-in NetFlow support.

For information about UBRL, see the “Flow-based QoS” section on page 33-10.

Virtual Switch System Client

Catalyst 4500 series switches support enhanced PAgP. If a Catalyst 4500 series switch is connected to a Catalyst 6500 series Virtual Switch System (VSS) via a PAgP EtherChannel, the Catalyst 4500 series switch will automatically serve as a VSS client, using enhanced PAgP on this EtherChannel for dual-active detection. This VSS client feature has no impact on the performance of Catalyst 4500 series switches and does not require any user configuration.

For information on VSS, see Chapter 19, “Configuring EtherChannel.”

VLANs

A VLAN configures switches and routers according to logical, rather than physical, topologies. Using VLANs, you can combine any collection of LAN segments within an internetwork into an autonomous user group, such that the segments appear as a single LAN in the network. VLANs logically segment the network into different broadcast domains so that packets are switched only between ports within the VLAN. Typically, a VLAN corresponds to a particular subnet, although not necessarily.

For more information about VLANs, VTP, and Dynamic VLAN Membership, see Chapter 12, “Configuring VLANs, VTP, and VMPS.”

The following VLAN-related features also are supported:
Layer 3 Software Features

A Layer 3 switch is a high-performance switch that has been optimized for a campus LAN or an intranet, and it provides both wirespeed Ethernet routing and switching services. Layer 3 switching improves network performance with two software functions: route processing and intelligent network services. Compared to conventional software-based switches, Layer 3 switches process more packets faster by using application-specific integrated circuit (ASIC) hardware instead of microprocessor-based engines.

The following sections describe the key Layer 3 switching software features on the Catalyst 4500 series switch:

- **Cisco Express Forwarding**, page 1-9
- **Enhanced Object Tracking**, page 1-9
- **GLBP**, page 1-9
- **HSRP**, page 1-10
- **IP Routing Protocols**, page 1-11
- **In Service Software Upgrade**, page 1-14
- **Multicast Services**, page 1-14
- **NSF with SSO**, page 1-14
- **Policy-Based Routing**, page 1-14
- **Unidirectional Link Routing**, page 1-15
- **Unicast Reverse Path Forwarding**, page 1-15
- **VRF-lite**, page 1-15

• VLAN Trunking Protocol (VTP)—VTP maintains VLAN naming consistency and connectivity between all devices in the VTP management domain. You can have redundancy in a domain by using multiple VTP servers, through which you can maintain and modify the global VLAN information. Only a few VTP servers are required in a large network.

• Private VLANs—Private VLANs are sets of ports that have the features of normal VLANs and also provide some Layer 2 isolation from other ports on the switch.

For information about private VLANs, see Chapter 35, “Configuring Private VLANs.”

• Private VLAN Trunk Ports—Private VLAN trunk ports allow a secondary port on a private VLAN to carry multiple secondary VLANs.

• Private VLAN Promiscuous Trunk Ports—Private VLAN promiscuous trunk extends the promiscuous port to a 802.1Q trunk port, carrying multiple primary VLANs (hence multiple subnets). Private VLAN promiscuous trunk is typically used to offer different services or content on different primary VLANs to isolated subscribers. Secondary VLANs can not be carried over the private VLAN promiscuous trunk.

• Dynamic VLAN Membership—Dynamic VLAN Membership allows you to assign switch ports to VLANs dynamically, based on the source Media Access Control (MAC) address of the device connected to the port. When you move a host from a port on one switch in the network to a port on another switch in the network, that switch dynamically assigns the new port to the proper VLAN for that host. With the VMPS Client feature, you can convert a dynamic access port to a VMPS client. VMPS clients can use VQP queries to communicate with the VMPS server to obtain a VLAN assignment for the port based on the MAC address of the host attached to that port.
Cisco Express Forwarding

Cisco Express Forwarding (CEF) is an advanced Layer 3 IP-switching technology. CEF optimizes network performance and scalability in networks with large and dynamic traffic patterns, such as the Internet, and on networks that use intensive web-based applications or interactive sessions. Although you can use CEF in any part of a network, it is designed for high-performance, highly resilient Layer 3 IP-backbone switching.

For information on configuring CEF, see Chapter 27, “Configuring Cisco Express Forwarding.”

Enhanced Object Tracking

Before the introduction of the Enhanced Object Tracking feature, the Hot Standby Router Protocol (HSRP) had a simple tracking mechanism that allowed you to track the interface line-protocol state only. If the line-protocol state of the interface went down, the HSRP priority of the router was reduced, allowing another HSRP router with a higher priority to become active.

The Enhanced Object Tracking (EOT) feature separates the tracking mechanism from HSRP and creates a separate standalone tracking process that can be used by other Cisco IOS processes as well as HSRP. This feature allows tracking of other objects in addition to the interface line-protocol state.

A client process, such as HSRP, Virtual Router Redundancy Protocol (VRRP), or Gateway Load Balancing Protocol (GLBP), can now register its interest in tracking objects and then be notified when the tracked object changes state.

For details on EOT, refer to this URL:

GLBP

The Gateway Load Balancing Protocol (GLBP) feature provides automatic router backup for IP hosts configured with a single default gateway on a LAN. Multiple first hop routers on the LAN combine to offer a single virtual first hop IP router while sharing the IP packet forwarding load. GLBP devices share packet-forwarding responsibilities, optimizing resource usage, thereby reducing costs. Other routers on the LAN may act as redundant GLBP routers that will become active if any of the existing forwarding routers fail. This improves the resiliency of the network and reduces administrative burden.

For details on GLBP, refer to this URL:

Cisco IOS XE IP Application Services Features in Cisco IOS XE 3.1.0SG

This section list the IP Application Services software features that are supported in Cisco IOS XE 3.1.0SG. Links to the feature documentation are included.

Feature guides may contain information about more than one feature. To find information about a specific feature within a feature guide, see the Feature Information table at the end of the guide.
Feature guides document features that are supported on many different software releases and platforms. Your Cisco software release or platform may not support all the features documented in a feature guide. See the Feature Information table at the end of the feature guide for information about which features in that guide are supported in your software release. Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

**Gateway Load Balancing Protocol (GLBP), GLBP MD5 Authentication**

**HSRP**

The Hot Standby Router Protocol (HSRP) provides high network availability by routing IP traffic from hosts on Ethernet networks without relying on the availability of any single Layer 3 switch. This feature is particularly useful for hosts that do not support a router discovery protocol and do not have the functionality to switch to a new router when their selected router reloads or loses power.

For information on configuring HSRP, refer to the following URL:

**Cisco IOS XE IP Application Services: HSRP Features in Cisco IOS XE 3.1.0SG**

This section lists the IP Application Services: HSRP software features that are supported in Cisco IOS XE 3.1.0SG. Links to the feature documentation are included.

Feature guides may contain information about more than one feature. To find information about a specific feature within a feature guide, see the Feature Information table at the end of the guide.

Feature guides document features that are supported on many different software releases and platforms. Your Cisco software release or platform may not support all the features documented in a feature guide. See the Feature Information table at the end of the feature guide for information about which features in that guide are supported in your software release. Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

**HSRP—Hot Standby Router Protocol**

**HSRP MD5 Authentication**

**HSRP Support for ICMP Redirects**

**IP Precedence Accounting**

**ISSU—HSRP**
SSO—HSRP

SSO Aware HSRP

SSO Aware HSRP offers continuous data packet forwarding during a supervisor engine switchover without a path change to the standby HSRP router. During supervisor engine switchover, NSF with SSO continues forwarding data packets along known routes using the HSRP virtual IP address. When both supervisor engines fail on the active HSRP router, the standby HSRP router takes over as the active HSRP router. SSO Aware HSRP extends the reliability and availability offered by NSF with SSO to Layer 3 aggregation with redundant chassis.

IP Routing Protocols

The following routing protocols are supported on the Catalyst 4500 series switch:

- BGP, page 1-11
- EIGRP, page 1-12
- OSPF, page 1-13
- RIP, page 1-13

BGP

The Border Gateway Protocol (BGP) is an exterior gateway protocol that allows you to set up an interdomain routing system to automatically guarantee the loop-free exchange of routing information between autonomous systems. In BGP, each route consists of a network number, a list of autonomous systems that information has passed through (called the autonomous system path), and a list of other path attributes.

The Catalyst 4500 series switch supports BGP version 4, including classless interdomain routing (CIDR). CIDR lets you reduce the size of your routing tables by creating aggregate routes, resulting in supernets. CIDR eliminates the concept of network classes within BGP and supports the advertising of IP prefixes. CIDR routes can be carried by OSPF, EIGRP, and RIP.

BGP Route-Map Continue

The BGP Route-Map Continue feature introduces the continue clause to the BGP route-map configuration. The continue clause provides more programmable policy configuration and route filtering. It introduces the capability to execute additional entries in a route map after an entry is executed with successful match and set clauses. Continue clauses allow configuring and organizing more modular policy definitions to reduce the number of policy configurations that are repeated within the same route map.

For details on BGP, refer to this URL:
EIGRP

The Enhanced Interior Gateway Routing Protocol (EIGRP) is a version of IGRP that combines the advantages of link-state protocols with distance-vector protocols. EIGRP incorporates the Diffusing Update Algorithm (DUAL). EIGRP includes fast convergence, variable-length subnet masks, partially bounded updates, and multiple network-layer support. When a network topology change occurs, EIGRP checks its topology table for a suitable new route to the destination. If such a route exists in the table, EIGRP updates the routing table instantly. You can use the fast convergence and partial updates that EIGRP provides to route Internetwork Packet Exchange (IPX) packets.

EIGRP saves bandwidth by sending routing updates only when routing information changes. The updates contain information only about the link that changed, not the entire routing table. EIGRP also takes into consideration the available bandwidth when determining the rate at which it transmits updates.

---

**Note**

Layer 3 switching does not support the Next Hop Resolution Protocol (NHRP).

---

**Note**

Customers can configure Enhanced Interior Gateway Routing Protocol (EIGRP) to route IPv6 prefixes. EIGRP configuration and protocol behavior for both IPv4 and IPv6 prefixes are similar, providing operational familiarity and continuity. EIGRP support for IPv6 will enable customers to use their existing EIGRP knowledge and processes, allowing them to deploy an IPv6 network at a low cost.

For details on EIGRP, refer to this URL:

---

Cisco IOS XE IP Routing: EIGRP Features in Cisco IOS XE 3.1.0SG

This section lists the IP Routing: EIGRP software features that are supported in Cisco IOS XE 3.1.0SG. Links to the feature documentation are included.

Feature guides may contain information about more than one feature. To find information about a specific feature within a feature guide, see the Feature Information table at the end of the guide.

Feature guides document features that are supported on many different software releases and platforms. Your Cisco software release or platform may not support all the features documented in a feature guide. See the Feature Information table at the end of the feature guide for information about which features in that guide are supported in your software release. Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

**Enhanced IGRP (EIGRP)**

**EIGRP Stub Routing**

**EIGRP Support for Route Map Filtering**

**IP Enhanced IGRP Route Authentication**

OSPF

The Open Shortest Path First (OSPF) protocol is a standards-based IP routing protocol designed to overcome the limitations of RIP. Because OSPF is a link-state routing protocol, it sends link-state advertisements (LSAs) to all other routers within the same hierarchical area. Information on the attached interfaces and their metrics is used in OSPF LSAs. As routers accumulate link-state information, they use the shortest path first (SPF) algorithm to calculate the shortest path to each node. Additional OSPF features include equal-cost multipath routing and routing based on the upper-layer type of service (ToS) requests.

OSPF employs the concept of an area, which is a group of contiguous OSPF networks and hosts. OSPF areas are logical subdivisions of OSPF autonomous systems in which the internal topology is hidden from routers outside the area. Areas allow an additional level of hierarchy different from that provided by IP network classes, and they can be used to aggregate routing information and mask the details of a network. These features make OSPF particularly scalable for large networks.

For details on OSPF, refer to this URL:

Cisco IOS XE IP Routing: OSPF Features in Cisco IOS XE 3.1.0SG

This section lists the IP Routing: OSPF software features that are supported in Cisco IOS XE 3.1.0SG. Links to the feature documentation are included.

Feature guides may contain information about more than one feature. To find information about a specific feature within a feature guide, see the Feature Information table at the end of the guide.

Feature guides document features that are supported on many different software releases and platforms. Your Cisco software release or platform may not support all the features documented in a feature guide. See the Feature Information table at the end of the feature guide for information about which features in that guide are supported in your software release. Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

RIP

The Routing Information Protocol (RIP) is a distance-vector, intradomain routing protocol. RIP works well in small, homogeneous networks. In large, complex internetworks it has many limitations, such as a maximum hop count of 15, lack of support for variable-length subnet masks (VLSMs), inefficient use of bandwidth, and slow convergence. RIP II does support VLSMs.

For details on RIP, refer to this URL:
Layer 3 Software Features

Chapter 1      Product Overview

In Service Software Upgrade

SSO requires the same version of IOS on both the active and standby supervisor engines. Because of version mismatch during an upgrade or downgrade of the Cisco IOS software, a Catalyst 4500 series switch is forced into operating in RPR mode. In this mode, after the switchover, you can observe link-flaps and a disruption in service. This issue is solved by the In Service Software Upgrade (ISSU) feature that enables you to operate in SSO/NSF mode while performing software upgrade or downgrade.

In Service Software Upgrade (ISSU) allows an upgrade or downgrade of the Catalyst IOS XE images at different release levels on both the active and standby supervisor engines by utilizing the Version Transformation Framework between the stateful components running on each supervisor engine.

For details, refer to Chapter 6, “Configuring the Cisco IOS XE In Service Software Upgrade Process.”

Multicast Services

Multicast services save bandwidth by forcing the network to replicate packets only when necessary and by allowing hosts to join and leave groups dynamically. The Catalyst 4500 series switch supports Protocol Independent Multicast (PIM), which is a protocol-independent because it can leverage whichever unicast routing protocol is used to populate the unicast routing table, including EIGRP, OSPF, BGP, or static route. PIM also uses a unicast routing table to perform the Reverse Path Forwarding (RPF) check function instead of building a completely independent multicast routing table.

For information on configuring multicast services, see Chapter 29, “Configuring IP Multicast.”

For information on PIM-SSM mapping, see the URL:

NSF with SSO

Non-Stop Forwarding with Stateful Switchover (NSF/SSO) offers continuous data packet forwarding in a Layer 3 routing environment during supervisor engine switchover. NSF extends the reliability and availability offered by the SSO feature to Layer 3 networks. During supervisor engine switchover, NSF/SSO continues forwarding data packets along known routes while the routing protocol information is recovered and validated, avoiding unnecessary route flaps and network instability. With NSF/SSO, IP phone calls do not drop. NSF/SSO is supported for OSPF, BGP, EIGRP, and Cisco Express Forwarding (CEF). NSF/SSO is typically deployed in the most critical parts of an enterprise or service provider network, such as Layer 3 aggregation/core or a resilient Layer 3 wiring closet design. It is an essential component of single chassis deployment for critical applications. NSF/SSO is available for all shipping supervisor engines on redundant chassis.

For information on NSF with SSO, see Chapter 9, “Configuring Cisco NSF with SSO Supervisor Engine Redundancy.”

Policy-Based Routing

Traditional IP forwarding decisions are based purely on the destination IP address of the packet being forwarded. Policy Based Routing (PBR) enables forwarding based upon other information associated with a packet, such as the source interface, IP source address, Layer 4 ports, and so on. This feature allows network managers more flexibility in how they configure and design their networks.

For more information on policy-based routing, see Chapter 30, “Configuring Policy-Based Routing.”
Unidirectional Link Routing

Unidirectional link routing (UDLR) provides a way to forward multicast packets over a physical unidirectional interface (such as a satellite link of high bandwidth) to stub networks that have a back channel.

For information on configuring unidirectional link routing, refer to the chapter “Configuring Unidirectional Link Routing” in the *Cisco IP and IP Routing Configuration Guide*.

Unicast Reverse Path Forwarding

The Unicast Reverse Path Forwarding (Unicast RPF) feature helps to mitigate problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network by discarding IP packets that lack a verifiable IP source address.

For information on URPF, see Chapter 28, “Configuring Unicast Reverse Path Forwarding.”

VRF-lite

VPN routing and forwarding (VRF-lite) is an extension of IP routing that provides multiple routing instances. Along with BGP, it enables the creation of a Layer 3 VPN service by keeping separate IP routing and forwarding tables for each VPN customer. VRF-lite uses input interfaces to distinguish routes for different VPNs. It forms virtual packet-forwarding tables by associating one or more Layer 3 interfaces with each VRF, allowing the creation of multiple Layer 3 VPNs on a single switch. Interfaces in a VRF could be either physical, such as an Ethernet port, or logical, such as a VLAN switch virtual interface (SVI). However, interfaces cannot belong to more than one VRF at any time.

For information on VRF-lite, see Chapter 31, “Configuring VRF-lite.”

Virtual Router Redundancy Protocol

Virtual Router Redundancy Protocol (VRRP) is a standard based first-hop redundancy protocol. With VRRP, a group of routers function as one virtual router by sharing one virtual IP address and one virtual MAC address. The master router performs packet forwarding, while the backup routers stay idle. VRRP is typically used in the multivendor first-hop gateway redundancy deployment.

For details on VRRP, refer to this URL:

The following link is to the VRRP features supported in Cisco IOS XE 3.1.0SG:

Management Features

The Catalyst 4500 series switch offers network management and control through the CLI or through alternative access methods, such as SNMP. The switch software supports these network management features:

- Cisco Call Home, page 1-16
Cisco Call Home

Call Home provides e-mail-based and web-based notification of critical system events. A versatile range of message formats are available for optimal compatibility with pager services, standard e-mail, or XML-based automated parsing applications. Common uses of this feature may include direct paging of a network support engineer, e-mail notification to a Network Operations Center, XML delivery to a support website, and utilization of Cisco Smart Call Home services for direct case generation with the Cisco Systems Technical Assistance Center (TAC).

The Call Home feature can deliver alert messages containing information on configuration, diagnostics, environmental conditions, inventory, and syslog events.

For more information on Call Home, see Chapter 52, “Configuring Call Home.”

Cisco Energy Wise

Cisco EnergyWise is an energy-management technology added onto Cisco switching solutions to help you measure, report, and reduce energy consumption across your entire infrastructure. With EnergyWise’s management interface, network management applications can communicate with endpoints and each other, using the network as the unifying fabric.

Refer to the following link for more details:

Cisco IOS IP Service Level Agreement

Cisco IOS IP Service Level Agreements (SLAs) allows Cisco customers to analyze IP service levels for IP applications and services by using active traffic monitoring—the generation of traffic in a continuous, reliable, and predictable manner—for measuring network performance. With Cisco IOS IP SLAs, service provider customers can measure and provide service level agreements, and enterprise customers
Management Features

can verify service levels, verify outsourced service level agreements, and understand network performance. Cisco IOS IP SLAs can perform network assessments, verify quality of service (QoS), ease the deployment of new services, and assist with network troubleshooting.

For more information on IP SLA, see Chapter 50, “Configuring Cisco IOS IP SLAs Operations.”

Dynamic Host Control Protocol

The Catalyst 4500 series switch uses DHCP in the following ways:

- **Dynamic Host Control Protocol server**—The Cisco IOS DHCP server feature is a full DHCP server implementation that assigns and manages IP addresses from specified address pools within the router to DHCP clients. If the Cisco IOS DHCP server cannot satisfy a DHCP request from its own database, it can forward the request to one or more secondary DHCP servers defined by the network administrator.

- **Dynamic Host Control Protocol autoconfiguration**—With this feature your switch (the DHCP client) is automatically configured at startup with IP address information and a configuration file.

For DHCP server configuration information, refer to the chapter, “Configuring DHCP,” in the Cisco IOS IP and IP Routing Configuration Guide at the following URL:

Embedded CiscoView

A web-based tool to configure the Catalyst 4500 series switch. Embedded CiscoView is a device management application that can be embedded on the switch flash and provides dynamic status, monitoring, and configuration information for your switch.

For more information on Embedded CiscoView, see Chapter 4, “Administering the Switch.”

Embedded Event Manager

Embedded Event Manager (EEM) is a distributed and customized approach to event detection and recovery offered directly in a Cisco IOS device. EEM offers the ability to monitor events and take informational, corrective, or any desired EEM action when the monitored events occur or when a threshold is reached. An EEM policy is an entity that defines an event and the actions to be taken when that event occurs.

For information on EEM, see the URL:

File System Management on Supervisor Engine 7-E

The format command for IOS XE 3.1.0 SG has changed slightly compared to the classic IOS format because the later does not support ext2 format.

For USB flash under IOS XE 3.1.0 SG, there are 3 optional formats, i.e. FAT16, FAT32 and EXT2:

```
Switch# format usb0: ?
FAT16  FAT16 filesystem type
```
For SD card under IOS XE 3.1.0 SG, the default format is FAT16:

```
Switch# format slaveusb0: ?
  FAT16  FAT16 filesystem type
  FAT32  FAT32 filesystem type
  ext2   ext2 filesystem type
```

**Forced 10/100 Autonegotiation**

This feature allows you to configure a port to limit the speed at which it will autonegotiate to a speed lower than the physically maximum speed. This method of reducing the throughput incurs much less overhead than using an ACL.

**Intelligent Power Management**

Working with powered devices (PDs) from Cisco, this feature uses power negotiation to refine the power consumption of an 802.3af-compliant PD beyond the granularity of power consumption provided by the 802.3af class. Power negotiation also enables the backward compatibility of newer PDs with older modules that do not support either 802.3af or high-power levels as required by IEEE standard.

For more information on Intelligent Power Management, see the “Intelligent Power Management” section in Chapter 11, “Configuring Power over Ethernet.”

**MAC Address Notification**

MAC address notification monitors the MAC addresses that are learned by, aged out or removed from the Catalyst 4500 series switch. Notifications are sent out or retrieved via the CISCO-MAC-NOTIFICATION MIB. It is typically used by a central network management application to collect such MAC address notification events for host moves. User configurable MAC table utilization thresholds can be defined to notify any potential DoS or man-in-the-middle attack.

For information on MAC Address Notification, see Chapter 4, “Administering the Switch.”

**MAC Notify MIB**

The MAC Notify MIB feature monitors network performance, utilization, and security conditions enabling a network administrator to track the MAC addresses that are learned or removed on the switch forwarding the Ethernet frames.

**Secure Shell**

Secure Shell (SSH) is a program that enables you to log into another computer over a network, to execute commands remotely, and to move files from one machine to another. The switch may not initiate SSH connections: SSH will be limited to providing a remote login session to the switch and will only function as a server.
Simple Network Management Protocol

Simple Network Management Protocol (SNMP) facilitates the exchange of management information between network devices. The Catalyst 4500 series switch supports these SNMP types and enhancements:

- SNMP—A full Internet standard
- SNMP v2—Community-based administrative framework for version 2 of SNMP
- SNMP v3—Security framework with three levels: noAuthNoPriv, authNoPriv, and authPriv (available only on a crypto image, like cat4000-i5k91s-mz)
- SNMP trap message enhancements—Additional information with certain SNMP trap messages, including spanning-tree topology change notifications and configuration change notifications

For more information on SNMP, see Chapter 49, “Configuring SNMP.”

SPAN and RSPAN

Switched Port Analyzer (SPAN) allows you to monitor traffic on any port for analysis by a network analyzer or Remote Monitoring (RMON) probe. You also can do the following:

- Configure ACLs on SPAN sessions.
- Allow incoming traffic on SPAN destination ports to be switched normally.
- Explicitly configure the encapsulation type of packets that are spanned out of a destination port.
- Restrict ingress sniffing depending on whether the packet is unicast, multicast, or broadcast, and depending on whether the packet is valid.
- Mirror packets sent to or from the CPU out of a SPAN destination port for troubleshooting purposes.

For information on SPAN, see Chapter 46, “Configuring SPAN and RSPAN.”

Remote SPAN (RSPAN) is an extension of SPAN, where source ports and destination ports are distributed across multiple switches, allowing remote monitoring of multiple switches across the network. The traffic for each RSPAN session is carried over a user-specified RSPAN VLAN that is dedicated for that RSPAN session on all participating switches.

For information on RSPAN, see Chapter 46, “Configuring SPAN and RSPAN.”

XML-PI

eXtensible Markup Language Programmatic Interface (XML-PI) Release 1.0 leverages the Network Configuration Protocol (NETCONF). It provides new data models that collect running configurations and show command output down to the keyword level without requiring the technologies or external XML-to-command line interface (CLI) gateways. XML-PI allows you to develop XML-based network management applications to control any number of network devices simultaneously.

Refer to the following link for more details:

Security Features

The Catalyst 4500 series switch offers network management and control through the CLI or through alternative access methods, such as SNMP. The switch software supports these security features:

- **802.1X Identity-Based Network Security**, page 1-20
- **Dynamic ARP Inspection**, page 1-21
- **Dynamic Host Configuration Protocol Snooping**, page 1-21
- **Flood Blocking**, page 1-22
- **Hardware-Based Control Plane Policing**, page 1-22
- **IP Source Guard**, page 1-22
- **Local Authentication, RADIUS, and TACACS+ Authentication**, page 1-22
- **Network Admission Control**, page 1-23
- **Network Security with ACLs**, page 1-23
- **Port Security**, page 1-23
- **Storm Control**, page 1-24
- **uRPF Strict Mode**, page 1-24
- **Utilities**, page 1-24
- **Web-based Authentication**, page 1-25

### 802.1X Identity-Based Network Security

This security feature consists of the following:

- **802.1X protocol**—Provides a means for a host that is connected to a switch port to be authenticated before it is given access to the switch services.
- **802.1X with VLAN assignment**—Enables you to enable non-802.1X-capable hosts to access networks that use 802.1X authentication.
- **802.1X RADIUS accounting**—Enables you to track the usage of network devices.
- **802.1X authentication for Guest VLANs**—Enables you to use VLAN assignment to limit network access for certain users.
- **802.1X with MAC Authentication Bypass**—Provides network access to agentless devices without 802.1X supplicant capabilities, such as printers. Upon detecting a new MAC address on a switch port, the Catalyst 4500 series switch will proxy an 802.1X authentication request based on the device’s MAC address.
- **802.1X with Inaccessible Authentication Bypass**—Applies when the AAA servers are unreachable or nonresponsive. In this situation, 802.1X user authentication typically fails with the port closed, and the user is denied access. Inaccessible Authentication Bypass provides a configurable alternative on the Catalyst 4500 series switch to grant a critical port network access in a locally specified VLAN.
- **802.1X with Unidirectional Controlled Port**—Allows the Wake-on-LAN (WoL) magic packets to reach a workstation attached to an unauthorized 802.1X switch port. Unidirectional Controlled Port is typically used to send operating systems or software updates from a central server to workstations at night.
• 802.1X Authentication Failed Open Assignment—Enables you to configure a switch to handle the case when a device fails to authenticate itself correctly through 802.1X (for example, not providing the correct password).

• 802.1X with Port Security—Enables port security on an 802.1X port in either single- or multiple-host mode. When you enable port security and 802.1X on a port, 802.1X authenticates the port, and port security manages the number of MAC addresses allowed on that port, including that of the client.

• 802.1X Authentication with ACL Assignment—Downloads per-host policies such as ACLs and redirect URLs to the switch from the RADIUS server during 802.1X or MAB authentication of the host.

• 802.1X Authentication with Per-User ACL and Filter-ID ACL—Allows ACL policy enforcement using a third-party AAA server.

• 802.1X with RADIUS-Provided Session Timeouts—Enables you to specify whether a switch uses a locally configured or a RADIUS-provided reauthentication timeout.

• 802.1X with Voice VLAN—Enables you to use 802.1X security on a port while enabling it to be used by both Cisco IP phones and devices with 802.1X supplicant support.

• 802.1X Convergence—Provides consistency between the switching business units in 802.1X configuration and implementation.

• Multi-Domain Authentication—Allows both a data device and a voice device, such as an IP phone (Cisco or non-Cisco), to authenticate on the same switch port, which is divided into a data domain and a voice domain.

For more information on 802.1X identity-based network security, see Chapter 36, “Configuring 802.1X Port-Based Authentication.”

Dynamic ARP Inspection

Dynamic ARP Inspection (DAI) intercepts all ARP requests, replies on untrusted ports, and verifies each intercepted packet for valid IP to MAC bindings. Dynamic ARP Inspection helps to prevent attacks on a network by not relaying invalid ARP replies out to other ports in the same VLAN. Denied ARP packets are logged by the switch for auditing.

For more information on dynamic ARP inspection, see Chapter 41, “Configuring Dynamic ARP Inspection.”

Dynamic Host Configuration Protocol Snooping

Dynamic Host Configuration Protocol (DHCP) Snooping is a security feature that is a component of a DHCP server. DHCP snooping provides security by intercepting untrusted DHCP messages and by building and maintaining a DHCP snooping binding table. An untrusted message is a message that is received from outside the network or firewall that can cause traffic attacks within your network.

DHCP snooping acts like a firewall between untrusted hosts and DHCP servers. It also provides a way to differentiate between untrusted interfaces connected to the end-user and trusted interfaces connected to the DHCP server or another switch.

With SSO support, DHCP Snooping propagates the DHCP-snooped data from the active supervisor engine to the redundant supervisor engine so that when a switchover occurs, the newly active supervisor engine is aware of the DHCP data that was already snooped, and the security benefits continue uninterrupted.
For DHCP server configuration information, refer to the chapter, “Configuring DHCP,” in the Cisco IOS IP and IP Routing Configuration Guide at the following URL:

For information on configuring DHCP snooping, see Chapter 40, “Configuring DHCP Snooping, IP Source Guard, and IPSG for Static Hosts.”

**Flood Blocking**

Flood blocking enables users to disable the flooding of unicast and multicast packets on a per-port basis. Occasionally, unknown unicast or multicast traffic from an unprotected port is flooded to a protected port because a MAC address has timed out or has not been learned by the switch.

For information on flood blocking, see Chapter 44, “Port Unicast and Multicast Flood Blocking.”

**Hardware-Based Control Plane Policing**

Control Plane Policing provides a unified solution to limit the rate of CPU bound control plane traffic in hardware. It enables users to install system wide control plane ACLs to protect the CPU by limiting rates or filtering out malicious DoS attacks. Control plane policing ensures the network stability, availability and packet forwarding, and prevents network outages such as loss of protocol updates despite an attack or heavy load on the switch. Hardware-based control plane policing is available on Supervisor Engine 7-E, supporting various Layer 2 and Layer 3 control protocols, such as CDP, EAPOL, STP, DTP, VTP, ICMP, CGMP, IGMP, DHCP, RIPv2, OSPF, PIM, TELNET, SNMP, HTTP, and packets destined to 224.0.0.* multicast link local addresses. Predefined system policies or user-configurable policies can be applied to those control protocols.

For information on control plane policing, see Chapter 39, “Configuring Control Plane Policing.”

**IP Source Guard**

Similar to DHCP snooping, this feature is enabled on an untrusted 12 port that is configured for DHCP snooping. Initially all IP traffic on the port is blocked except for the DHCP packets, which are captured by the DHCP snooping process. When a client receives a valid IP address from the DHCP server, a PVACL is installed on the port, which restricts the client IP traffic only to clients with assigned IP addresses, so any IP traffic with source IP addresses other than those assigned by the DHCP server will be filtered out. This filtering prevents a malicious host from attacking a network by hijacking neighbor host's IP address.

For information on configuring IP Source Guard, see Chapter 40, “Configuring DHCP Snooping, IP Source Guard, and IPSG for Static Hosts.”

**Local Authentication, RADIUS, and TACACS+ Authentication**

Local Authentication, Remote Authentication Dial-In User Service (RADIUS), and Terminal Access Controller Access Control System Plus (TACACS+) authentication methods control access to the switch. For additional information, refer to the following URL:
Network Admission Control

Network Admission Control consists of two features:

- **NAC Layer 2 IP validation**
  
  NAC Layer 2 IP is an integral part of Cisco Network Admission Control. It offers the first line of defense for infected hosts (PCs and other devices attached to a LAN port) attempting to connect to the corporate network. NAC Layer 2 IP on the Cisco Catalyst 4500 series switch performs posture validation at the Layer 2 edge of the network for non-802.1x-enabled host devices. Host device posture validation includes antivirus state and OS patch levels. Depending on the corporate access policy and host device posture, a host may be unconditionally admitted, admitted with restricted access, or quarantined to prevent the spread of viruses across the network.

  For more information on Layer 2 IP validation, see the URL:

- **NAC Layer 2 802.1X authentication**
  
  The Cisco Catalyst 4500 series switch extends NAC support to 802.1x-enabled devices. Like NAC Layer 2 IP, the NAC Layer 2 802.1x feature determines the level of network access based on endpoint information.

  For more information on 802.1X identity-based network security, see Chapter 36, “Configuring 802.1X Port-Based Authentication.”

Network Security with ACLs

An access control list (ACL) filters network traffic by controlling whether routed packets are forwarded or blocked at the router interfaces. The Catalyst 4500 series switch examines each packet to determine whether to forward or drop the packet based on the criteria you specified within the access lists.

MAC access control lists (MACLs) and VLAN access control lists (VACLs) are supported. VACLs are also known as VLAN maps in Cisco IOS.

The following security features are supported:

- MAC address filtering, which enables you to block unicast traffic for a MAC address on a VLAN interface.

- Port ACLs, which enable you to apply ACLs to Layer 2 interfaces on a switch for inbound traffic.

For information on ACLs, MACLs, VLAN maps, MAC address filtering, and Port ACLs, see Chapter 42, “Configuring Network Security with ACLs.”

Port Security

Port security restricts traffic on a port based upon the MAC address of the workstation that accesses the port. Trunk port security extends this feature to trunks, including private VLAN isolated trunks, on a per-VLAN basis.
Sticky port security extends port security by saving the dynamically learned MAC addresses in the running configuration to survive port link down and switch reset. It enables a network administrator to restrict the MAC addresses allowed or the maximum number of MAC addresses on each port.

Voice VLAN sticky port security further extends the sticky port security to the Voice-over-IP deployment. Voice VLAN sticky port security locks a port and blocks access from a station with a MAC address different from the IP phone and the workstation behind the IP phone.

For information on port security, see Chapter 38, “Configuring Port Security.”

### Storm Control

Broadcast suppression is used to prevent LANs from being disrupted by a broadcast storm on one or more switch ports. A LAN broadcast storm occurs when broadcast packets flood the LAN, creating excessive traffic and degrading network performance. Errors in the protocol-stack implementation or in the network configuration can cause a broadcast storm. Multicast and broadcast suppression measures how much broadcast traffic is passing through a port and compares the broadcast traffic with some configurable threshold value within a specific time interval. If the amount of broadcast traffic reaches the threshold during this interval, broadcast frames are dropped, and optionally the port is shut down.

For information on configuring broadcast suppression, see Chapter 45, “Configuring Storm Control.”

### uRPF Strict Mode

The uRPF feature mitigates problems caused by the introduction of malformed or forged (spoofed) IP source addresses into a network by discarding IP packets that lack a verifiable IP source address. uRPF deflects denial-of-service (DoS) and distributed denial-of-service (DDoS) attacks by forwarding only packets that have source addresses that are valid and consistent with the IP routing table. This helps to protect the network of the customer, the ISP, and the rest of the Internet. When using uRPF in strict mode, the packet must be received on the interface that the router would use to forward the return packet. uRPF strict mode is supported for both IPv4 and IPv6 prefixes.

For information on configuring broadcast suppression, see Chapter 28, “Configuring Unicast Reverse Path Forwarding.”

### Utilities

The following utilities are supported on the Catalyst 4500 series switch.

#### Layer 2 Traceroute

Layer 2 traceroute allows the switch to identify the physical path that a packet takes from a source device to a destination device. Layer 2 traceroute supports only unicast source and destination MAC addresses.

For information about Layer 2 Traceroute, see Chapter 8, “Checking Port Status and Connectivity.”

#### Time Domain Reflectometry

Time Domain Reflectometry (TDR) is a technology used for diagnosing the state and reliability of cables. TDR can detect open, shorted, or terminated cable states. The calculation of the distance to the failure point is also supported.
For information about TDR, see Chapter 8, “Checking Port Status and Connectivity.”

**Debugging Features**

The Catalyst 4500 series switch has several commands to help you debug your initial setup. These commands are included in the following command groups:

- platform
- debug platform

For more information, refer to the *Catalyst 4500 Series Switch Cisco IOS Command Reference.*

**Web-based Authentication**

The web-based authentication feature, known as Web Authentication Proxy, enables you to authenticate end users on host systems that do not run the IEEE 802.1X supplicant. When you initiate an HTTP session, this feature intercepts ingress HTTP packets from the host and sends an HTML login page to your. You key in the credentials, which the web-based authentication feature sends to the AAA server for authentication. If authentication succeeds, web-based authentication sends a Login-Successful HTML page to the host and applies the access policies returned by the AAA server.

For information on configuring web-based authentication, see Chapter 37, “Configuring Web-Based Authentication.”
CHAPTER 2

Command-Line Interfaces

This chapter describes the CLIs you use to configure the Catalyst 4500 series switch. This chapter includes the following major sections:

- File Management Commands, page 2-1
- Accessing the Switch CLI, page 2-2
- Performing Command-Line Processing, page 2-3
- Performing History Substitution, page 2-4
- About Cisco IOS Command Modes, page 2-4
- Getting a List of Commands and Syntax, page 2-5
- ROMMON Command-Line Interface, page 2-7

Note
For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

File Management Commands

The following file management commands are supported on Supervisor Engine 7-E:

- **verify <filename>**
- **rename <old_name> <new_name>**
- **delete <filename>**
- **copy <source_filename> ,target_filename>**
Accessing the Switch CLI

The following sections describe how to access the switch CLI:

- Accessing the CLI Using the EIA/TIA-232 Console Interface, page 2-2
- Accessing the CLI Through Telnet, page 2-2

Accessing the CLI Using the EIA/TIA-232 Console Interface

Note

EIA/TIA-232 was known as recommended standard 232 (RS-232) before its acceptance as a standard by the Electronic Industries Alliance (EIA) and Telecommunications Industry Association (TIA).

Perform the initial switch configuration over a connection to the EIA/TIA-232 console interface. Refer to the Catalyst 4500 Series Switch Module Installation Guide for console interface cable connection procedures.

To access the switch through the console interface, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch&gt; enable</td>
</tr>
</tbody>
</table>
| Step 2  | Password: password
Switch# | At the password prompt, enter the system password. The prompt (#) appears, indicating that you have accessed the CLI in enabled mode. |
| Step 3  | Switch# quit | When you are finished executing the task command, exit the session. |

After accessing the switch through the EIA/TIA-232 interface, you see this display:

Press Return for Console prompt

Switch> enable
Password:< >
Switch#

Accessing the CLI Through Telnet

Note

Before you make a Telnet connection to the switch, you must set the IP address for the switch. See the “Configuring Physical Layer 3 Interfaces” section on page 26-10.

The switch supports up to eight simultaneous Telnet sessions. Telnet sessions disconnect automatically after remaining idle for the period specified by the exec-timeout command.
To make a Telnet connection to the switch, perform this task:

**Command** | **Purpose**  
--- | ---  
Step 1 telnet (hostname | ip_addr) | From the remote host, enter the telnet command and the name or IP address of the switch you want to access.  
Step 2 Password: password | At the prompt, enter the password for the CLI. If no password has been configured, press Return.  
Step 3 | Enter the necessary commands to complete your desired tasks.  
Step 4 Switch# quit | When finished, exit the Telnet session.  

This example shows how to open a Telnet session to the switch:

```
unix_host% telnet Switch_1  
Trying 172.20.52.40...  
Connected to 172.20.52.40.  
Escape character is '^]'.  
User Access Verification  
Password:< >  
Switch_1> enable  
Password:  
Switch_1#  
```

### Performing Command-Line Processing

Switch commands are not case sensitive. You can abbreviate commands and parameters if the abbreviations contain enough letters to be different from any other currently available commands or parameters.

You can scroll through the last 20 commands stored in the history buffer and enter or edit a command at the prompt. Table 2-1 lists the keyboard shortcuts for entering and editing switch commands.

**Table 2-1  Keyboard Shortcuts**

<table>
<thead>
<tr>
<th>Keystrokes</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Press Ctrl-B or press the Left Arrow key¹</td>
<td>Moves the cursor back one character.</td>
</tr>
<tr>
<td>Press Ctrl-F or press the Right Arrow key¹</td>
<td>Moves the cursor forward one character.</td>
</tr>
<tr>
<td>Press Ctrl-A</td>
<td>Moves the cursor to the beginning of the command line.</td>
</tr>
<tr>
<td>Press Ctrl-E</td>
<td>Moves the cursor to the end of the command line.</td>
</tr>
<tr>
<td>Press Esc-B</td>
<td>Moves the cursor back one word.</td>
</tr>
<tr>
<td>Press Esc-F</td>
<td>Moves the cursor forward one word.</td>
</tr>
</tbody>
</table>

¹. The Arrow keys function only on ANSI-compatible terminals, such as VT100s.
Performing History Substitution

The history buffer stores the last 20 command lines you entered. History substitution enables you to access these command lines without retyping them. Table 2-2 lists the history substitution commands.

Table 2-2 History Substitution Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ctrl-P or the Up Arrow key</td>
<td>Recalls commands in the history buffer, beginning with the most recent command. Repeat the key sequence to recall older commands successively.</td>
</tr>
<tr>
<td>Ctrl-N or the Down Arrow key</td>
<td>Returns to more recent commands in the history buffer after commands have been recalled with Ctrl-P or the Up Arrow key. Repeat the key sequence to recall more recent commands.</td>
</tr>
<tr>
<td>Switch# show history</td>
<td>Lists the last several commands you have entered in EXEC mode.</td>
</tr>
</tbody>
</table>

1. The Arrow keys function only on ANSI-compatible terminals such as VT100s.

About Cisco IOS Command Modes

For complete information about Cisco IOS command modes, refer to the Cisco IOS Configuration Fundamentals Configuration Guide and the Cisco IOS Configuration Fundamentals Command Reference at the following URLs:

The Cisco IOS user interface has many different modes: user EXEC, privileged EXEC (enable), global configuration, interface, subinterface, and protocol-specific. The commands available to you depend on which mode you are in. To get a list of the commands in a given mode, enter a question mark (?) at the system prompt. See the “Getting a List of Commands and Syntax” section on page 2-5 for more information.

When you start a session on the switch, you begin in user mode, also called user EXEC mode. Only a small subset of commands are available in EXEC mode. To have access to all commands, you must enter privileged EXEC mode, also called enable mode. To access the privileged EXEC mode, you must enter a password. When you are in the privileged EXEC mode, you can enter any EXEC command or access global configuration mode. Most EXEC commands are one-time commands, such as show commands, which display the current configuration status, and clear commands, which reset counters or interfaces. The EXEC commands are not saved when the switch is rebooted.

The configuration modes allow you to make changes to the running configuration. If you save the configuration, these commands are stored when you reboot the switch. You must start in global configuration mode. From global configuration mode, you can enter interface configuration mode, subinterface configuration mode, and a variety of protocol-specific modes.
You would use a separate mode called ROMMON when the switch cannot boot up properly. For example, the switch might enter ROMMON mode if it does not find a valid system image when it is booting, or if its configuration file is corrupted. For more information, see the “ROMMON Command-Line Interface” section on page 2-7.

Table 2-3 lists and describes frequently used Cisco IOS modes.

<table>
<thead>
<tr>
<th>Mode</th>
<th>What You Use It For</th>
<th>How to Access</th>
<th>Prompt</th>
</tr>
</thead>
<tbody>
<tr>
<td>User EXEC</td>
<td>To connect to remote devices, change terminal settings on a temporary basis, perform basic tests, and display system information.</td>
<td>Log in.</td>
<td>Switch&gt;</td>
</tr>
<tr>
<td>Privileged EXEC (enable)</td>
<td>To set operating parameters. The privileged command set includes the commands in user EXEC mode, as well as the configure command. Use the configure command to access the other command modes.</td>
<td>From user EXEC mode, enter the enable command and the enable password (if a password has been configured).</td>
<td>Switch#</td>
</tr>
<tr>
<td>Global configuration</td>
<td>To configure features that affect the system as a whole, such as the system time or switch name.</td>
<td>From privileged EXEC mode, enter the configure terminal command.</td>
<td>Switch(config)#</td>
</tr>
<tr>
<td>Interface configuration</td>
<td>To enable or modify the operation of a 10-Gigabit Ethernet, Gigabit Ethernet, or Fast Ethernet interface with interface commands.</td>
<td>From global configuration mode, enter the interface type location command.</td>
<td>Switch(config-if)#</td>
</tr>
<tr>
<td>Console configuration</td>
<td>To configure the console interface; from the directly connected console or the virtual terminal; used with Telnet.</td>
<td>From global configuration mode, enter the line console 0 command.</td>
<td>Switch(config-line)#</td>
</tr>
</tbody>
</table>

The Cisco IOS command interpreter, called the EXEC, interprets and runs the commands you enter. You can abbreviate commands and keywords by entering just enough characters to make the command unique from other commands. For example, you can abbreviate the show command to sh and the configure terminal command to config t.

When you type exit, the switch backs out one level. To exit configuration mode completely and return to privileged EXEC mode, press Ctrl-Z.

**Getting a List of Commands and Syntax**

In any command mode, you can get a list of available commands by entering a question mark (?).

```
Switch> ?
```

To obtain a list of commands that begin with a particular character sequence, enter those characters followed by the question mark (?). Do not include a space before the question mark. This form of help is called word help, because it completes a word for you.
To list keywords or arguments, enter a question mark in place of a keyword or argument. Include a space before the question mark. This form of help is called command syntax help, because it reminds you which keywords or arguments are applicable based on the command, keywords, and arguments you have already entered.

Switch# configure ?
memory Configure from NV memory
network Configure from a TFTP network host
overwrite-network Overwrite NV memory from TFTP network host
terminal Configure from the terminal
<cr>

To redisplay a command you previously entered, press the Up Arrow key or Ctrl-P. You can continue to press the Up Arrow key to see the last 20 commands you entered.

Tip
If you are having trouble entering a command, check the system prompt and enter the question mark (?) for a list of available commands. You might be in the wrong command mode or using incorrect syntax.

Type exit to return to the previous mode. Press Ctrl-Z or enter the end command in any mode to immediately return to privileged EXEC mode.

Virtual Console for Standby Supervisor Engine

Catalyst 4500 series switches can be configured with 2 supervisor engines to provide redundancy. When the switch is powered, one of the supervisor engines becomes active and remains active until a switchover occurs. The other supervisor engine remains in standby mode.

Each supervisor engine has its own console port. Access to the standby supervisor engine is possible only through the console port of the standby supervisor engine. Therefore, you must connect to the standby console to access, monitor or debug the standby supervisor.

Virtual Console for Standby Supervisor Engine enables you to access the standby console from the active supervisor engine without requiring a physical connection to the standby console. It uses IPC over EOBC to communicate with the standby supervisor engine and thus emulate the standby console on the active supervisor engine. Only one active standby console session is active at any time.

The virtual console for standby supervisor engine enables users who are logged onto the active supervisor engine to remotely execute show commands on the standby supervisor engine and view the results on the active supervisor engine. Virtual console is available only from the active supervisor engine.

You can access the standby virtual console from the active supervisor engine with the attach module, session module, or remote login commands on the active supervisor engine. You must be in privilege EXEC mode (level 15) to run these commands to access the standby console.

Once you enter the standby virtual console, the terminal prompt automatically changes to "<hostname>-standby-console#", where hostname is the configured name of the switch. The prompt is restored back to the original prompt when you exit the virtual console.

You exit the virtual console with the exit or quit commands. When the inactivity period of the terminal on the active supervisor engine where you logged in exceeds the configured idle time, you are automatically logged out of the terminal on the active supervisor engine. In such a case, the virtual console session is also terminated. Virtual console session is also automatically terminated when the standby is rebooted. After the standby boots up, you need to create another virtual console session.
To log in to the standby supervisor engine using a virtual console, do the following:

```
Switch# session module 2
Connecting to standby virtual console
Type 'exit' or 'quit' to end this session
Switch-standby-console# exit
```

If the standby console is not enabled, the following message appears:

```
Switch-standby-console#
Standby console disabled.
Valid commands are: exit, logout
```

Virtual session into the standby console is N/A with RPR:

```
Switch# session module 2
IPC server port name IFConsoleServer:2 not registered on standby.
Secondary cannot be accessed by virtual console
```

Note

The standby virtual console provides the standard features that are available from the supervisor console such as command history, command completion, command help and partial command keywords.

The following limitations apply to the standby virtual console:

- All commands on the virtual console run to completion. It does not provide the auto-more feature; it behaves as if the `terminal length 0` command has been executed. It is also noninteractive. Therefore, a running command cannot be interrupted or aborted by any key sequence on the active supervisor engine. If a command produces considerable output, the virtual console displays it on the supervisor screen.

- The virtual console is noninteractive. Because the virtual console does not detect the interactive nature of a command, any command that requires user interaction causes the virtual console to wait until the RPC timer aborts the command. The virtual console timer is set to 60 seconds. The virtual console returns to its prompt after 60 seconds. During this time, you cannot abort the command from the keyboard. You must wait for the timer to expire before you continue.

- You cannot use virtual console to view debug and syslog messages that are being displayed on the standby supervisor engine. The virtual console only displays the output of commands that are executed from the virtual console. Other information that is displayed on the real standby console does not appear on the virtual console.

### ROMMON Command-Line Interface

ROMMON is a ROM-based program that is involved at power-up or reset, or when a fatal exception error occurs. The switch enters ROMMON mode if the switch does not find a valid software image, if the NVRAM configuration is corrupted, or if the configuration register is set to enter ROMMON mode. From the ROMMON mode, you can load a software image manually from flash memory, from a network server file, or from bootflash.

You can also enter ROMMON mode by restarting the switch and pressing `Ctrl-C` during the first five seconds of startup.

Note

`Ctrl-C` is always enabled for 60 seconds after you reboot the switch, even if `Ctrl-C` is configured to be off in the configuration register settings.
When you enter ROMMON mode, the prompt changes to `rommon 1>`.

Use the `?` command to see the available ROMMON commands.

For more information about the ROMMON commands, refer to the *Catalyst 4500 Series Switch Cisco IOS Command Reference*. 
CHAPTER 3

Configuring the Switch for the First Time

This chapter describes how to initially configure a Catalyst 4500 series switch.

The information presented here supplements the administration information and procedures in this publication: Cisco IOS Configuration Fundamentals Command Reference, Release 12.2SR, at this URL:

This chapter includes the following major sections:

- Default Switch Configuration, page 3-1
- Configuring DHCP-Based Autoconfiguration, page 3-2
- Configuring the Switch, page 3-8
- Controlling Access to Privileged EXEC Commands, page 3-13
- Recovering a Lost Enable Password, page 3-25
- Modifying the Supervisor Engine Startup Configuration, page 3-25
- Resetting a Switch to Factory Default Settings, page 3-32
- Configuring Crashinfo, page 3-32

Note
For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

Default Switch Configuration

This section describes the default configurations for the Catalyst 4500 series switch. Table 3-1 shows the default configuration settings for each feature.
Table 3-1  Default Switch Configuration

<table>
<thead>
<tr>
<th>Feature</th>

Configuring DHCP-Based Autoconfiguration

These sections describe how to configure DHCP-based autoconfiguration:

- DHCP-Based Autoconfiguration, page 3-2
- DHCP Client Request Process, page 3-3
- Configuring the DHCP Server, page 3-4
- Configuring the TFTP Server, page 3-4
- Configuring the DNS Server, page 3-5
- Configuring the Relay Device, page 3-5
- Obtaining Configuration Files, page 3-6
- Example Configuration, page 3-7

If your DHCP server is a Cisco device, or if you are configuring the switch as a DHCP server, refer to the “IP Addressing and Services” section in the Cisco IOS IP and IP Routing Configuration Guide for Cisco IOS Release 12.1 for additional information about configuring DHCP.

DHCP-Based Autoconfiguration

Note

Starting with Release 12.2(20)EW, you can enable DHCP AutoConfiguration by entering the write erase command. This command clears the startup-config in NVRAM. In images prior to Release 12.2(20)EW, this command will not enable autoconfiguration.

DHCP provides configuration information to Internet hosts and internetworking devices. This protocol consists of two components: one component for delivering configuration parameters from a DHCP server to a device and another component that is a mechanism for allocating network addresses to devices. DHCP is built on a client-server model, in which designated DHCP servers allocate network addresses and deliver configuration parameters to dynamically configured devices. The switch can act as both a DHCP client and a DHCP server.
With DHCP-based autoconfiguration, no DHCP client-side configuration is needed on your switch because your switch (the DHCP client) is automatically configured at startup with IP address information and a configuration file. However, you need to configure the DHCP server or the DHCP server feature on your switch for various lease options associated with IP addresses. If you are using DHCP to relay the configuration file location on the network, you might also need to configure a Trivial File Transfer Protocol (TFTP) server and a Domain Name System (DNS) server.

DHCP-based autoconfiguration replaces the BOOTP client functionality on your switch.

**DHCP Client Request Process**

At startup the switch automatically requests configuration information from a DHCP server if a configuration file is not present on the switch. Figure 3-1 shows the sequence of messages that are exchanged between the DHCP client and the DHCP server.

![Figure 3-1 DHCP Client and Server Message Exchange](image)

The client, Switch A, broadcasts a DHCPDISCOVER message to locate a DHCP server. The DHCP server offers configuration parameters (such as an IP address, subnet mask, gateway IP address, DNS IP address, lease for the IP address, and so forth) to the client in a DHCPOFFER unicast message.

In a DHCPREQUEST broadcast message, the client returns a formal request for the offered configuration information to the DHCP server. The formal request is broadcast so that all other DHCP servers that received the DHCPDISCOVER broadcast message from the client can reclaim the IP addresses that they offered to the client.

The DHCP server confirms that the IP address has been allocated to the client by returning a DHCPACK unicast message to the client. With this message, the client and server are bound, and the client uses the configuration information that it received from the server. The amount of information the switch receives depends on how you configure the DHCP server. For more information, see the “Configuring the DHCP Server” section on page 3-4.

If the configuration parameters sent to the client in the DHCPOFFER unicast message are invalid (if configuration error exists), the client returns a DHCPDECLINE broadcast message to the DHCP server. The DHCP server sends the client a DHCPNAK denial broadcast message, which means that the offered configuration parameters have not been assigned, that an error has occurred during the negotiation of the parameters, or that the client has been slow in responding to the DHCPOFFER message. (The DHCP server might have assigned the parameters to another client.)

A DHCP client might receive offers from multiple DHCP servers and can accept any of them; however, the client usually accepts the first offer it receives. The offer from the DHCP server is not a guarantee that the IP address will be allocated to the client; however, the server usually reserves the address until the client has had a chance to formally request the address.
Configuring the DHCP Server

A switch can act as both the DHCP client and the DHCP server. By default, the Cisco IOS DHCP server and relay agent features are enabled on your switch.

You should configure the DHCP server, or the DHCP server feature running on your switch, with reserved leases that are bound to each switch by the switch hardware address.

If you want the switch to receive IP address information, you must configure the DHCP server with these lease options:

- IP address of the client (required)
- Subnet mask of the client (required)
- DNS server IP address (optional)
- Router IP address (required)

**Note**

The router IP address is the default gateway address for the switch.

If you want the switch to receive the configuration file from a TFTP server, you must configure the DHCP server with these lease options:

- TFTP server name or IP address (required)
- Boot filename (the name of the configuration file that the client needs) (recommended)
- Host name (optional)

Depending on the settings of the DHCP server or the DHCP server feature running on your switch, the switch can receive IP address information, the configuration file, or both.

If you do not configure the DHCP server, or the DHCP server feature running on your switch, with the lease options described earlier, the switch replies to client requests with only those parameters that are configured. If the IP address and subnet mask are not in the reply, the switch is not configured. If the router IP address or TFTP server name (or IP address) are not found, the switch might send broadcast, instead of unicast, TFTP requests. Unavailability of other lease options does not impact autoconfiguration.

The DHCP server, or the DHCP server feature running on your switch, can be on the same LAN or on a different LAN than the switch. If the DHCP server is running on a different LAN, you should configure a DHCP relay, which forwards broadcast traffic between two directly connected LANs. A router does not forward broadcast packets, but it forwards packets based on the destination IP address in the received packet. For more information on relay devices, see the “Configuring the Relay Device” section on page 3-5.

Configuring the TFTP Server

Based on the DHCP server configuration, the switch attempts to download one or more configuration files from the TFTP server. If you configured the DHCP server to respond to the switch with all the options required for IP connectivity to the TFTP server, and if you configured the DHCP server with a TFTP server name, address, and configuration filename, the switch attempts to download the specified configuration file from the specified TFTP server.

If you did not specify the configuration filename or the TFTP server name, or if the configuration file could not be downloaded, the switch attempts to download a configuration file using various combinations of filenames and TFTP server addresses. The files include the specified configuration
filename (if any) and the following files: network-config, cisconet.cfg, hostname.config, or hostname.cfg, where hostname is the current hostname of the switch and router-config and ciscorrr.cfg. The TFTP server addresses used include the specified TFTP server address (if any) and the broadcast address (255.255.255.255).

For the switch to successfully download a configuration file, the TFTP server must contain one or more configuration files in its base directory. The files can include the following:

- The configuration file named in the DHCP reply (the actual switch configuration file).
- The network-config or the cisconet.cfg file (known as the default configuration files).
- The router-config or the ciscorrr.cfg file. (These files contain commands common to all switches. Normally, if the DHCP and TFTP servers are properly configured, these files are not accessed.)

If you specify the TFTP server name in the DHCP server-lease database, you must also configure the TFTP server name-to-IP-address mapping in the DNS-server database.

If the TFTP server you plan to use is on a different LAN from the switch, or if you plan to access it with the switch through the broadcast address (which occurs if the DHCP server response does not contain all the required information described earlier), you must configure a relay to forward the TFTP packets to the TFTP server. For more information, see the “Configuring the Relay Device” section on page 3-5. The preferred solution is to configure either the DHCP server or the DHCP server feature running on your switch with all the required information.

### Configuring the DNS Server

The DHCP server, or the DHCP server feature running on your switch, uses the DNS server to resolve the TFTP server name to an IP address. You must configure the TFTP server name-to-IP address map on the DNS server. The TFTP server contains the configuration files for the switch.

You can configure the IP addresses of the DNS servers in the lease database of the DHCP server where the DHCP replies will retrieve them. You can enter up to two DNS server IP addresses in the lease database.

The DNS server can be on the same or on a different LAN as the switch. If it is on a different LAN, the switch must be able to access it through a router.

### Configuring the Relay Device

You must configure a relay device to forward received broadcast packets to the destination host whenever a switch sends broadcast packets to which a host on a different LAN must respond. Examples of such broadcast packets are DHCP, DNS, and in some cases, TFTP packets.

If the relay device is a Cisco router, enable IP routing (ip routing global configuration command), and configure helper addresses (ip helper-address interface configuration command). For example, in Figure 3-2, configure the router interfaces as follows:

On interface 10.0.0.2:

```
router(config-if)# ip helper-address 20.0.0.2
router(config-if)# ip helper-address 20.0.0.3
router(config-if)# ip helper-address 20.0.0.4
```

On interface 20.0.0.1:

```
router(config-if)# ip helper-address 10.0.0.1
```
Obtaining Configuration Files

Depending on the availability of the IP address and the configuration filename in the DHCP reserved lease, the switch obtains its configuration information in these ways:

- The IP address and the configuration filename are reserved for the switch and provided in the DHCP reply (one-file read method).

  The switch receives its IP address, subnet mask, TFTP server address, and the configuration filename from either the DHCP server or the DHCP server feature running on your switch. The switch sends a unicast message to the TFTP server to retrieve the named configuration file from the base directory of the server, and upon receipt, completes its boot-up process.

- The IP address and the configuration filename is reserved for the switch, but the TFTP server address is not provided in the DHCP reply (one-file read method).

  The switch receives its IP address, subnet mask, and the configuration filename from either the DHCP server or the DHCP server feature running on your switch. The switch sends a broadcast message to a TFTP server to retrieve the named configuration file from the base directory of the server, and upon receipt, completes its boot-up process.

- Only the IP address is reserved for the switch and provided in the DHCP reply. The configuration filename is not provided (two-file read method).

  The switch receives its IP address, subnet mask, and the TFTP server address from either the DHCP server or the DHCP server feature running on your switch. The switch sends a unicast message to the TFTP server to retrieve the network-config or cisconet.cfg default configuration file. (If the network-config file cannot be read, the switch reads the cisconet.cfg file.)

  The default configuration file contains the host names-to-IP-address mapping for the switch. The switch fills its host table with the information in the file and obtains its host name. If the host name is not found in the file, the switch uses the host name in the DHCP reply. If the host name is not specified in the DHCP reply, the switch uses the default Switch as its host name.

  After obtaining its host name from the default configuration file or the DHCP reply, the switch reads the configuration file that has the same name as its host name (hostname-config or hostname.cfg, depending on whether or not the network-config file or the cisconet.cfg file was read earlier) from the TFTP server. If the cisconet.cfg file is read, the filename of the host is truncated to eight characters.
If the switch cannot read the network-config, cisconet.cfg, or the hostname file, it reads the router-config file. If the switch cannot read the router-config file, it reads the ciscortr.cfg file.

**Note**
The switch broadcasts TFTP server requests provided that one of these conditions is met: the TFTP server is not obtained from the DHCP replies; all attempts to read the configuration file through unicast transmissions fail; or the TFTP server name cannot be resolved to an IP address.

**Example Configuration**

*Figure 3-3* shows a network example for retrieving IP information using DHCP-based autoconfiguration.

*Figure 3-3 DHCP-Based Autoconfiguration Network Example*

![DHCP-Based Autoconfiguration Network Example](image)

*Table 3-2 shows the configuration of the reserved leases on either the DHCP server or the DHCP server feature running on your switch.*

<td><em>switch1</em></td>
<td><em>switch2</em></td>
<td><em>switch3</em></td>
<td><em>switch4</em></td>
</tr>
</tbody>
</table>
**DNS Server Configuration**

The DNS server maps the TFTP server name *maritsu* to IP address 10.0.0.3.

**TFTP Server Configuration (on UNIX)**

The TFTP server base directory is set to /tftpserver/work/. This directory contains the network-confg file used in the two-file read method. This file contains the host name that you plan to assign to the switch based on its IP address. The base directory also contains a configuration file for each switch (*switch1-confg*, *switch2-confg*, and so forth) as shown in the following display:

```
prompt> cd /tftpserver/work/
prompt> ls
network-confg
switch1-confg
switch2-confg
switch3-confg
switch4-confg
prompt> cat network-confg
ip host switch1 10.0.0.21
ip host switch2 10.0.0.22
ip host switch3 10.0.0.23
ip host switch4 10.0.0.24
```

**DHCP Client Configuration**

No configuration file is present on Switch 1 through Switch 4.

**Configuration Explanation**

In Figure 3-3, Switch 1 reads its configuration file as follows:

- Switch 1 obtains its IP address 10.0.0.21 from the DHCP server.
- If no configuration filename is given in the DHCP server reply, Switch 1 reads the network-confg file from the base directory of the TFTP server.
- Switch 1 adds the contents of the network-confg file to its host table.
- Switch 1 reads its host table by indexing its IP address 10.0.0.21 to its host name (switch1).
- Switch 1 reads the configuration file that corresponds to its host name; for example, it reads *switch1-confg* from the TFTP server.

Switches 2 through 4 retrieve their configuration files and IP addresses in the same way.

---

**Configuring the Switch**

The following sections describe how to configure your switch:

- Using Configuration Mode to Configure Your Switch, page 3-9
- Verifying the Running Configuration Settings, page 3-9
- Saving the Running Configuration Settings to Your Start-Up File, page 3-10
- Reviewing the Configuration in NVRAM, page 3-10
- Configuring a Default Gateway, page 3-11
- Configuring a Static Route, page 3-11
Using Configuration Mode to Configure Your Switch

To configure your switch from configuration mode, perform this procedure:

**Step 1** Connect a console terminal to the console interface of your supervisor engine.

**Step 2** After a few seconds, you will see the user EXEC prompt (Switch>). Now, you may want to enter privileged EXEC mode, also known as enable mode. Type `enable` to enter enable mode:

```
Switch> enable
```

**Note** You must be in enable mode to make configuration changes.

The prompt will change to the enable prompt (#):

```
Switch#
```

**Step 3** At the enable prompt (#), enter the `configure terminal` command to enter global configuration mode:

```
Switch# configure terminal
```

Enter configuration commands, one per line. End with CNTL/Z.

```
Switch(config)#
```

**Step 4** At the global configuration mode prompt, enter the `interface` `type` `slot/interface` command to enter interface configuration mode:

```
Switch(config)# interface fastethernet 5/1
Switch(config-if)#
```

**Step 5** In either of these configuration modes, enter changes to the switch configuration.

**Step 6** Enter the `end` command to exit configuration mode.

**Step 7** Save your settings. (See the “Saving the Running Configuration Settings to Your Start-Up File” section on page 3-10.)

Your switch is now minimally configured and can boot with the configuration you entered. To see a list of the configuration commands, enter ? at the prompt or press the `help` key in configuration mode.

Verifying the Running Configuration Settings

To verify the configuration settings you entered or the changes you made, enter the `show running-config` command at the enable prompt (#), as shown in this example:

```
Switch# show running-config
```

Building configuration...

```
Current configuration:
!
version 12.0
service timestamps debug uptime
service timestamps log uptime
no service password-encryption
!
hostname Switch
```
Chapter 3  Configuring the Switch for the First Time

Configuring the Switch

<...output truncated...>

! line con 0
  transport input none
line vty 0 4
  exec-timeout 0 0
  password lab
  login
  transport input lat pad dsipcon mop telnet rlogin udptn nasi
! end
Switch#

Saving the Running Configuration Settings to Your Start-Up File

Caution
This command saves the configuration settings that you created in configuration mode. If you fail to do this step, your configuration will be lost the next time you reload the system.

To store the configuration, changes to the configuration, or changes to the startup configuration in NVRAM, enter the `copy running-config startup-config` command at the enable prompt (#), as follows:

Switch# copy running-config startup-config

Reviewing the Configuration in NVRAM

To display information stored in NVRAM, enter the `show startup-config` EXEC command.

The following example shows a typical system configuration:

Switch# show startup-config
Using 1579 out of 491500 bytes, uncompressed size = 7372 bytes
Uncompressed configuration from 1579 bytes to 7372 bytes
!
version 12.1
no service pad
service timestamps debug uptime
service timestamps log uptime
no service password-encryption
service compress-config

!
!
interface GigabitEthernet1/1
  no snmp trap link-status
!
interface GigabitEthernet1/2
  no snmp trap link-status
!--More--
<...output truncated...>
 Configuring the Switch

Chapter 3  Configuring the Switch for the First Time

Configuring a Default Gateway

The switch uses the default gateway only when it is not configured with a routing protocol.

Configure a default gateway to send data to subnets other than its own when the switch is not configured with a routing protocol. The default gateway must be the IP address of an interface on a router that is directly connected to the switch.

To configure a default gateway, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# ip default-gateway IP-address</td>
<td>Configures a default gateway.</td>
</tr>
<tr>
<td>Step 2</td>
<td></td>
</tr>
<tr>
<td>Switch# show ip route</td>
<td>Verifies that the default gateway is correctly displayed in the IP routing table.</td>
</tr>
</tbody>
</table>

This example shows how to configure a default gateway and how to verify the configuration:

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# ip default-gateway 172.20.52.35
Switch(config)# end
3d17h: %SYS-5-CONFIG_I: Configured from console by console
Switch# show ip route
Default gateway is 172.20.52.35

Host  Gateway       Last Use  Total Uses Interface
ICMP redirect cache is empty
Switch#

Configuring a Static Route

If your Telnet station or SNMP network management workstation is on a different network from your switch and a routing protocol has not been configured, you might need to add a static routing table entry for the network where your end station is located.
To configure a static route, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>Step 2</strong></td>
</tr>
<tr>
<td>Switch(config)# `ip route dest_IP_address mask (forwarding_IP</td>
<td>vlan vlan_ID)`</td>
</tr>
</tbody>
</table>

This example shows how to use the `ip route` command to configure a static route to a workstation at IP address 171.10.5.10 on the switch with a subnet mask and IP address 172.20.3.35 of the forwarding router:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# ip route 171.10.5.10 255.255.255.255 172.20.3.35
Switch(config)# end
```

This example shows how to use the `show running-config` command to confirm the configuration of the static route:

```
Switch# show running-config
Building configuration...
...output truncated...
ip default-gateway 172.20.52.35
ip classless
ip route 171.10.5.10 255.255.255.255 172.20.3.35
no ip http server
!
line con 0
transport input none
line vty 0 4
exec-timeout 0 0
password lab
login
transport input lat pad dsipcon mop telnet rlogin udptn nasi
!
end
```

This example shows how to use the `ip route` command to configure the static route IP address 171.20.5.3 with subnet mask and connected over VLAN 1 to a workstation on the switch:

```
Switch# configure terminal
Switch(config)# ip route 171.20.5.3 255.255.255.255 vlan 1
Switch(config)# end
Switch#
```

This example shows how to use the `show running-config` command to confirm the configuration of the static route:

```
Switch# show running-config
Building configuration...
...output truncated...
```

ip default-gateway 172.20.52.35  
ip classless  
ip route 171.20.5.3 255.255.255.255 Vlan1  
no ip http server  
!
!  
x25 host z  
!  
line con 0  
 transport input none  
line vty 0 4  
 exec-timeout 0 0  
 password lab  
 login  
 transport input lat pad dsipcon mop telnet rlogin udptn nasi  
!
end
Switch#

Controlling Access to Privileged EXEC Commands

The procedures in these sections let you control access to the system configuration file and privileged EXEC commands:

- Setting or Changing a Static enable Password, page 3-13
- Using the enable password and enable secret Commands, page 3-14
- Setting or Changing a Privileged Password, page 3-14
- Encrypting Passwords, page 3-22
- Encrypting Passwords, page 3-22
- Configuring Multiple Privilege Levels, page 3-23

Setting or Changing a Static enable Password

To set or change a static password that controls access to the enable mode, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# enable password password</td>
<td>Sets a new password or changes an existing password for the privileged EXEC mode.</td>
</tr>
</tbody>
</table>

This example shows how to configure an enable password as “lab” at the privileged EXEC mode:

Switch# configure terminal
Switch(config)# enable password lab
Switch(config)#

For instructions on how to display the password or access level configuration, see the “Displaying the Password, Access Level, and Privilege Level Configuration” section on page 3-24.
Using the enable password and enable secret Commands

To provide an additional layer of security, particularly for passwords that cross the network or that are stored on a TFTP server, you can use either the `enable password` or `enable secret` command. Both commands configure an encrypted password that you must enter to access the enable mode (the default) or any other privilege level that you specify.

We recommend that you use the `enable secret` command.

If you configure the `enable secret` command, it takes precedence over the `enable password` command; the two commands cannot be in effect simultaneously.

To configure the switch to require an enable password, perform either one of these tasks:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`Switch(config)# enable password [level level] [password</td>
<td>encryption-type encrypted-password]`</td>
</tr>
<tr>
<td>`Switch(config)# enable secret [level level] [password</td>
<td>encryption-type encrypted-password]`</td>
</tr>
</tbody>
</table>

When you enter either of these password commands with the `level` option, you define a password for a specific privilege level. After you specify the level and set a password, give the password only to users who need to have access at this level. Use the `privilege level` configuration command to specify commands accessible at various levels.

If you enable the `service password-encryption` command, the password you enter is encrypted. When you display the password with the `more system:running-config` command, the password displays the password in encrypted form.

If you specify an encryption type, you must provide an encrypted password—an encrypted password you copy from another Catalyst 4500 series switch configuration.

Note

You cannot recover a lost encrypted password. You must clear NVRAM and set a new password. See the “Recovering a Lost Enable Password” section on page 3-25 for more information.

For information on how to display the password or access level configuration, see the “Displaying the Password, Access Level, and Privilege Level Configuration” section on page 3-24.

Setting or Changing a Privileged Password

To set or change a privileged password, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Switch(config-line)# password password</code></td>
<td>Sets a new password or changes an existing password for the privileged level.</td>
</tr>
</tbody>
</table>
Controlling Access to Privileged EXEC Commands

For information on how to display the password or access level configuration, see the “Displaying the Password, Access Level, and Privilege Level Configuration” section on page 3-24.

Controlling Switch Access with TACACS+

This section describes how to enable and configure TACACS+, which provides detailed accounting information and flexible administrative control over authentication and authorization processes. TACACS+ is facilitated through authentication, authorization, accounting (AAA) and can be enabled only through AAA commands.

For complete syntax and usage information for the commands used in this section, see the Cisco IOS Security Command Reference, Release 12.2.

This section contains this configuration information:

- Understanding TACACS+, page 3-15
- TACACS+ Operation, page 3-17
- Configuring TACACS+, page 3-17
- Displaying the TACACS+ Configuration, page 3-22

Understanding TACACS+

TACACS+ is a security application that provides centralized validation of users attempting to gain access to your switch. TACACS+ services are maintained in a database on a TACACS+ daemon typically running on a UNIX or Windows NT workstation. You should have access to and should configure a TACACS+ server before configuring TACACS+ features on your switch.

TACACS+ provides for separate and modular AAA facilities. TACACS+ allows for a single access control server (the TACACS+ daemon) to provide each service—authentication, authorization, and accounting—independently. Each service can be locked into its own database to take advantage of other services available on that server or on the network, depending on the capabilities of the daemon.

The goal of TACACS+ is to provide a method for managing multiple network access points from a single management service. Your switch can be a network access server along with other Cisco routers and access servers. A network access server provides connections to a single user, to a network or subnetwork, and to interconnected networks as shown in Figure 3-4.
Controlling Access to Privileged EXEC Commands

Chapter 3  Configuring the Switch for the First Time

Figure 3-4  Typical TACACS+ Network Configuration

TACACS+ administered through the AAA security services can provide these services:

- Authentication—Provides complete control of authentication through login and password dialog, challenge and response, and messaging support.

  The authentication facility can conduct a dialog with the user (such as, after a username and password are provided, to challenge a user with several questions such as home address, mother’s maiden name, service type, and social security number). The TACACS+ authentication service can also send messages to user screens. For example, a message could notify users that their passwords must be changed because of the company’s password aging policy.

- Authorization—Provides strict control over user capabilities for the duration of the user’s session, including but not limited to setting autocommands, access control, session duration, or protocol support. You can also enforce restrictions on the commands a user can execute with the TACACS+ authorization feature.

- Accounting—Collects and sends information used for billing, auditing, and reporting to the TACACS+ daemon. Network managers can use the accounting facility to track user activity for a security audit or to provide information for user billing. Accounting records include user identities, start and stop times, executed commands (such as PPP), number of packets, and number of bytes.

The TACACS+ protocol provides authentication between the switch and the TACACS+ daemon, and it ensures confidentiality because all protocol exchanges between the switch and the TACACS+ daemon are encrypted.

You need a system running the TACACS+ daemon software to use TACACS+ on your switch.

Configure the switches with the TACACS+ server addresses.
Set an authentication key (also configure the same key on the TACACS+ servers).
Enable AAA.
Create a login authentication method list.
Apply the list to the terminal lines.
Create an authorization and accounting method list as required.
TACACS+ Operation

When a user attempts a simple ASCII login by authenticating to a switch using TACACS+, this process occurs:

1. When the connection is established, the switch contacts the TACACS+ daemon to obtain a username prompt, which is then displayed to the user. The user enters a username, and the switch then contacts the TACACS+ daemon to obtain a password prompt. The switch displays the password prompt to the user, the user enters a password, and the password is then sent to the TACACS+ daemon.

TACACS+ allows a conversation between the daemon and the user until the daemon receives enough information to authenticate the user. The daemon prompts for a username and password combination, but can include other items such as the user’s mother’s maiden name.

2. The switch eventually receives one of these responses from the TACACS+ daemon:
   - ACCEPT—The user is authenticated and service can begin. If the switch is configured to require authorization, authorization begins at this time.
   - REJECT—The user is not authenticated. The user can be denied access or is prompted to retry the login sequence, depending on the TACACS+ daemon.
   - ERROR—An error occurred at some time during authentication with the daemon or in the network connection between the daemon and the switch. If an ERROR response is received, the switch typically tries to use an alternative method for authenticating the user.
   - CONTINUE—The user is prompted for additional authentication information.

After authentication, the user undergoes an additional authorization phase if authorization has been enabled on the switch. Users must first successfully complete TACACS+ authentication before proceeding to TACACS+ authorization.

3. If TACACS+ authorization is required, the TACACS+ daemon is again contacted, and it returns an ACCEPT or REJECT authorization response. If an ACCEPT response is returned, the response contains data in the form of attributes that direct the EXEC or NETWORK session for that user and the services that the user can access:
   - Telnet, Secure Shell (SSH), rlogin, or privileged EXEC services
   - Connection parameters, including the host or client IP address, access list, and user timeouts

Configuring TACACS+

This section describes how to configure your switch to support TACACS+. At a minimum, you must identify the host or hosts maintaining the TACACS+ daemon and define the method lists for TACACS+ authentication. You can optionally define method lists for TACACS+ authorization and accounting. A method list defines the sequence and methods used to authenticate, to authorize, or to keep accounts on a user. You can use method lists to designate one or more security protocols, ensuring a backup system if the initial method fails. The software uses the first method listed to authenticate, to authorize, or to keep accounts on users; if that method does not respond, the software selects the next method in the list. This process continues until there is successful communication with a listed method or the method list is exhausted.
This section contains this configuration information:

- Default TACACS+ Configuration, page 3-18
- Identifying the TACACS+ Server Host and Setting the Authentication Key, page 3-18
- Configuring TACACS+ Login Authentication, page 3-19
- Configuring TACACS+ Authorization for Privileged EXEC Access and Network Services, page 3-21
- Starting TACACS+ Accounting, page 3-21

Default TACACS+ Configuration

TACACS+ and AAA are disabled by default.

To prevent a lapse in security, you cannot configure TACACS+ through a network management application. When enabled, TACACS+ can authenticate users accessing the switch through the CLI.

**Note**

Although TACACS+ configuration is performed through the CLI, the TACACS+ server authenticates HTTP connections that have been configured with a privilege level of 15.

Identifying the TACACS+ Server Host and Setting the Authentication Key

You can configure the switch to use a single server or AAA server groups in order to group existing server hosts for authentication. You can group servers to select a subset of the configured server hosts and use them for a particular service. The server group is used with a global server-host list and contains the list of IP addresses of the selected server hosts.

Beginning in privileged EXEC mode, follow these steps to identify the IP host or host maintaining TACACS+ server and optionally set the encryption key:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong> tacacs-server host hostname [port integer] [timeout integer] [key string]</td>
<td>Identifies the IP host or hosts maintaining a TACACS+ server. Enter this command multiple times to create a list of preferred hosts. The software searches for hosts in the order in which you specify them.</td>
</tr>
<tr>
<td>Step 3 aaa new-model</td>
<td>Enables AAA.</td>
</tr>
<tr>
<td><strong>Step 4</strong> aaa group server tacacs+ group-name</td>
<td>(Optional) Defines the AAA server-group with a group name. This command puts the switch in a server group subconfiguration mode.</td>
</tr>
</tbody>
</table>

- For **hostname**, specify the name or IP address of the host.
- (Optional) For **port integer**, specify a server port number. The default is port 49. The range is 1 to 65535.
- (Optional) For **timeout integer**, specify a time in seconds the switch waits for a response from the daemon before it times out and declares an error. The default is 5 seconds. The range is 1 to 1000 seconds.
- (Optional) For **key string**, specify the encryption key for encrypting and decrypting all traffic between the switch and the TACACS+ daemon. You must configure the same key on the TACACS+ daemon for encryption to succeed.
### Configuring TACACS+ Login Authentication

To configure AAA authentication, define a named list of authentication methods and then apply that list to various ports. The method list defines the types of authentication you intend to perform and the sequence in which you intend to perform them; you must apply the list to a specific port before you can perform any of the defined authentication methods. The only exception is the default method list (which, by coincidence, is named `default`). The default method list is automatically applied to all ports except those that have a named method list explicitly defined. A defined method list overrides the default method list.

A method list describes the sequence and authentication methods that must be queried to authenticate a user. You can designate one or more security protocols for authentication, ensuring a backup system for authentication in case the initial method fails. The software uses the first method listed to authenticate users; if that method fails to respond, the software selects the next authentication method in the method list. This process continues until there is successful communication with a listed authentication method or until all defined methods are exhausted. If authentication fails at any point in this cycle—meaning that the security server or local username database responds by denying the user access—the authentication process stops, and no other authentication methods are attempted.

Beginning in privileged EXEC mode, follow these steps to configure login authentication:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td></td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td></td>
</tr>
<tr>
<td><code>aaa new-model</code></td>
<td>Enables AAA.</td>
</tr>
</tbody>
</table>

To remove the specified TACACS+ server name or address, use the `no tacacs-server host hostname` global configuration command. To remove a server group from the configuration list, use the `no aaa group server tacacs+ group-name` global configuration command. To remove the IP address of a TACACS+ server, use the `no server ip-address` server group subconfiguration command.

### Command Table

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 5</td>
<td>(Optional) Associates a particular TACACS+ server with the defined server group. Repeat this step for each TACACS+ server in the AAA server group. Each server in the group must be previously defined in Step 2.</td>
</tr>
<tr>
<td>Step 6</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Step 7</td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td>Step 8</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

To remove the specified TACACS+ server name or address, use the `no tacacs-server host hostname` global configuration command. To remove a server group from the configuration list, use the `no aaa group server tacacs+ group-name` global configuration command. To remove the IP address of a TACACS+ server, use the `no server ip-address` server group subconfiguration command.
### Step 3

**Command**

```plaintext
aaa authentication login [default | list-name] method1 [method2...]
```

**Purpose**

Creates a login authentication method list.

- To create a default list that is used when a named list is not specified in the `login authentication` command, use the `default` keyword followed by the methods that you plan to use in default situations. The default method list is automatically applied to all ports.
- For `list-name`, specify a character string to name the list you are creating.
- For `method1...`, specify the actual method the authentication algorithm tries. The additional methods of authentication are used only if the previous method returns an error, not if it fails.

Select one of these methods:

- **enable**—Use the enable password for authentication. Before you can use this authentication method, you must define an enable password by using the `enable password` global configuration command.
- **group tacacs+**—Uses TACACS+ authentication. Before you can use this authentication method, you must configure the TACACS+ server. For more information, see the “Identifying the TACACS+ Server Host and Setting the Authentication Key” section on page 3-18.
- **line**—Use the line password for authentication. Before you can use this authentication method, you must define a line password. Use the `password password` line configuration command.
- **local**—Use the local username database for authentication. You must enter username information in the database. Use the `username password` global configuration command.
- **local-case**—Use a case-sensitive local username database for authentication. You must enter username information in the database by using the `username name password` global configuration command.
- **none**—Do not use any authentication for login.

### Step 4

**Command**

```plaintext
line [console | tty | vty] line-number [ending-line-number]
```

**Purpose**

Enters line configuration mode, and configure the lines to which you want to apply the authentication list.

### Step 5

**Command**

```plaintext
login authentication [default | list-name]
```

**Purpose**

Applies the authentication list to a line or set of lines.

- If you specify `default`, use the default list created with the `aaa authentication login` command.
- For `list-name`, specify the list created with the `aaa authentication login` command.

### Step 6

**Command**

`end`

**Purpose**

Returns to privileged EXEC mode.

### Step 7

**Command**

`show running-config`

**Purpose**

Verifies your entries.

### Step 8

**Command**

```plaintext
copy running-config startup-config
```

**Purpose**

(Optional) Saves your entries in the configuration file.
To disable AAA, use the `no aaa new-model` global configuration command. To disable AAA authentication, use the `no aaa authentication login {default | list-name} method1 [method2...]` global configuration command. To either disable TACACS+ authentication for logins or to return to the default value, use the `no login authentication {default | list-name}` line configuration command.

**Configuring TACACS+ Authorization for Privileged EXEC Access and Network Services**

AAA authorization limits the services available to a user. When AAA authorization is enabled, the switch uses information retrieved from the user’s profile, which is located either in the local user database or on the security server, to configure the user’s session. The user is granted access to a requested service only if the information in the user profile allows it.

You can use the `aaa authorization` global configuration command with the `tacacs+` keyword to set parameters that restrict a user’s network access to privileged EXEC mode.

The `aaa authorization exec tacacs+ local` command sets these authorization parameters:

- Use TACACS+ for privileged EXEC access authorization if authentication was performed by using TACACS+.
- Use the local database if authentication was not performed by using TACACS+.

**Note** Authorization is bypassed for authenticated users who log in through the CLI even if authorization has been configured.

Beginning in privileged EXEC mode, follow these steps to specify TACACS+ authorization for privileged EXEC access and network services:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>enter</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>enter</td>
</tr>
<tr>
<td>aaa authorization network tacacs+</td>
<td>Configures the switch for user TACACS+ authorization for all network-related service requests.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>enter</td>
</tr>
<tr>
<td>aaa authorization exec tacacs+</td>
<td>Configures the switch for user TACACS+ authorization if the user has privileged EXEC access. The <code>exec</code> keyword might return user profile information (such as <code>autocommand</code> information).</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>enter</td>
</tr>
<tr>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>enter</td>
</tr>
<tr>
<td>show running-config</td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>enter</td>
</tr>
<tr>
<td>copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

To disable authorization, use the `no aaa authorization {network | exec} method1 global configuration command.`

**Starting TACACS+ Accounting**

The AAA accounting feature tracks the services that users are accessing and the amount of network resources that they are consuming. When AAA accounting is enabled, the switch reports user activity to the TACACS+ security server in the form of accounting records. Each accounting record contains accounting attribute-value (AV) pairs and is stored on the security server. This data can then be analyzed for network management, client billing, or auditing.
Beginning in privileged EXEC mode, follow these steps to enable TACACS+ accounting for each Cisco IOS privilege level and for network services:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>aaa accounting network start-stop tacacs+</td>
<td>Enables TACACS+ accounting for all network-related service requests.</td>
</tr>
<tr>
<td>aaa accounting exec start-stop tacacs+</td>
<td>Enables TACACS+ accounting to send a start-record accounting notice at the beginning of a privileged EXEC process and a stop-record at the end.</td>
</tr>
<tr>
<td>end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>show running-config</td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td>copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

To disable accounting, use the **no aaa accounting** {network | exec} {start-stop} method1... global configuration command.

**Displaying the TACACS+ Configuration**

To display TACACS+ server statistics, use the **show tacacs** privileged EXEC command.

**Encrypting Passwords**

Because protocol analyzers can examine packets (and read passwords), you can increase access security by configuring the Cisco IOS software to encrypt passwords. Encryption prevents the password from being readable in the configuration file.

To configure the Cisco IOS software to encrypt passwords, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# service password-encryption</td>
<td>Encrypts a password.</td>
</tr>
</tbody>
</table>

Encryption occurs when the current configuration is written or when a password is configured. Password encryption is applied to all passwords, including authentication key passwords, the privileged command password, console and virtual terminal line access passwords, and Border Gateway Protocol (BGP) neighbor passwords. The **service password-encryption** command keeps unauthorized individuals from viewing your password in your configuration file.

**Caution**

The **service password-encryption** command does not provide a high level of network security. If you use this command, you should also take additional network security measures.

Although you cannot recover a lost encrypted password (that is, you cannot get the original password back), you can regain control of the switch after having lost or forgotten the encrypted password. See the “Recovering a Lost Enable Password” section on page 3-25 for more information.
For information on how to display the password or access level configuration, see the “Displaying the Password, Access Level, and Privilege Level Configuration” section on page 3-24.

**Configuring Multiple Privilege Levels**

By default, Cisco IOS software has two modes of password security: user EXEC mode and privileged EXEC mode. You can configure up to 16 hierarchical levels of commands for each mode. By configuring multiple passwords, you can allow different sets of users to have access to specified commands.

For example, if you want many users to have access to the `clear line` command, you can assign it level 2 security and distribute the level 2 password fairly widely. If you want more restricted access to the `configure` command, you can assign it level 3 security and distribute that password to fewer users.

The procedures in the following sections describe how to configure additional levels of security:

- Setting the Privilege Level for a Command, page 3-23
- Changing the Default Privilege Level for Lines, page 3-23
- Logging In to a Privilege Level, page 3-24
- Exiting a Privilege Level, page 3-24
- Displaying the Password, Access Level, and Privilege Level Configuration, page 3-24

### Setting the Privilege Level for a Command

To set the privilege level for a command, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Switch(config)# privilege mode level level command</code></td>
<td>Sets the privilege level for a command.</td>
</tr>
<tr>
<td><code>Switch(config)# enable password level level [encryption-type] password</code></td>
<td>Specifies the enable password for a privilege level.</td>
</tr>
</tbody>
</table>

For information on how to display the password or access level configuration, see the “Displaying the Password, Access Level, and Privilege Level Configuration” section on page 3-24.

### Changing the Default Privilege Level for Lines

To change the default privilege level for a given line or a group of lines, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Switch(config-line)# privilege level level</code></td>
<td>Changes the default privilege level for the line.</td>
</tr>
</tbody>
</table>

For information on how to display the password or access level configuration, see the “Displaying the Password, Access Level, and Privilege Level Configuration” section on page 3-24.
Logging In to a Privilege Level

To log in at a specified privilege level, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# enable level</td>
<td>Logs in to a specified privilege level.</td>
</tr>
</tbody>
</table>

Exiting a Privilege Level

To exit to a specified privilege level, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# disable level</td>
<td>Exits to a specified privilege level.</td>
</tr>
</tbody>
</table>

Displaying the Password, Access Level, and Privilege Level Configuration

To display detailed password information, perform this task:

<table>
<thead>
<tr>
<th>Step</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Switch# show running-config</td>
<td>Displays the password and access level config.</td>
</tr>
<tr>
<td>2</td>
<td>Switch# show privilege</td>
<td>Shows the privilege level configuration.</td>
</tr>
</tbody>
</table>

This example shows how to display the password and access level configuration:

Switch# show running-config
Building configuration...

Current configuration:
!
version 12.0
service timestamps debug datetime localtime
service timestamps log datetime localtime
no service password-encryption
!
hostname Switch
!
boot system flash sup-bootflash
enable password lab
!
<...output truncated...>

This example shows how to display the privilege level configuration:

Switch# show privilege
Current privilege level is 15
Switch#
Recovering a Lost Enable Password

Note
For more information on the configuration register which is preconfigured in NVRAM, see “Configuring the Software Configuration Register” section on page 3-26.

To recover a lost enable password, follow these steps:

Step 1  Connect to the console interface.
Step 2  Stop the boot sequence and enter ROM monitor by pressing Ctrl-C during the first 5 seconds of bootup.
Step 3  Configure the switch to boot-up without reading the configuration memory (NVRAM).
Step 4  Reboot the system.
Step 5  Access enable mode (this can be done without a password if a password has not been configured).
Step 6  View or change the password, or erase the configuration.
Step 7  Reconfigure the switch to boot-up and read the NVRAM as it normally does.
Step 8  Reboot the system.

Modifying the Supervisor Engine Startup Configuration

These sections describe how the startup configuration on the supervisor engine works and how to modify the BOOT variable and the configuration register:

- Understanding the Supervisor Engine Boot Configuration, page 3-25
- Configuring the Software Configuration Register, page 3-26
- Specifying the Startup System Image, page 3-30
- Controlling Environment Variables, page 3-31

Understanding the Supervisor Engine Boot Configuration

The supervisor engine boot process involves two software images: ROM monitor and supervisor engine software. When the switch is booted or reset, the ROMMON code is executed. Depending on the NVRAM configuration, the supervisor engine either stays in ROMMON mode or loads the supervisor engine software.

Two user-configurable parameters determine how the switch boots: the configuration register and the BOOT environment variable. The configuration register is described in the “Modifying the Boot Field and Using the boot Command” section on page 3-27. The BOOT environment variable is described in the “Specifying the Startup System Image” section on page 3-30.
Understanding the ROM Monitor

The ROM monitor (ROMMON) is invoked at switch bootup, reset, or when a fatal exception occurs. The switch enters ROMMON mode if the switch does not find a valid software image, if the NVRAM configuration is corrupted, or if the configuration register is set to enter ROMMON mode. From ROMMON mode, you can manually load a software image from bootflash or a flash disk, or you can boot up from the management interface. ROMMON mode loads a primary image from which you can configure a secondary image to boot up from a specified source either locally or through the network using the BOOTLDR environment variable. This variable is described in the “Switch#” section on page 3-32.

You can also enter ROMMON mode by restarting the switch and then pressing Ctrl-C during the first five seconds of startup.

Note

Ctrl-C is always enabled for five seconds after you reboot the switch, regardless of whether the configuration-register setting has Ctrl-C disabled.

The ROM monitor has these features:

- Power-on confidence test
- Hardware initialization
- Boot capability (manual bootup and autoboot)
- File system (read-only while in ROMMON)

Configuring the Software Configuration Register

The switch uses a 16-bit software configuration register, which allows you to set specific system parameters. Settings for the software configuration register are preconfigured in NVRAM.

Here are some reasons why you might want to change the software configuration register settings:

- To select a boot source and default boot filename
- To control broadcast addresses
- To set the console terminal baud rate
- To load operating software from flash memory
- To recover a lost password
- To manually boot the system using the boot command at the bootstrap program prompt
- To force an automatic bootup from the system bootstrap software (boot image) or from a default system image in onboard flash memory, and read any boot system commands that are stored in the configuration file in NVRAM

Caution

To avoid possibly halting the Catalyst 4500 series switch switch, remember that valid configuration register settings might be combinations of settings and not just the individual settings listed in Table 3-3. For example, the factory default value of 0x2101 is a combination of settings.

Table 3-3 lists the meaning of each of the software configuration memory bits. Table 3-4 defines the boot field.
Chapter 3  Configuring the Switch for the First Time

Modifying the Supervisor Engine Startup Configuration

Table 3-3  Software Configuration Register Bits

<table>
<thead>
<tr>
<th>Bit Number</th>
<th>Hexadecimal</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>00 to 03</td>
<td>0x0000 to 0x000F</td>
<td>Boot field (see Table 3-4)</td>
</tr>
<tr>
<td>04</td>
<td>0x0010</td>
<td>Unused</td>
</tr>
<tr>
<td>05</td>
<td>0x0020</td>
<td>Bit two of console line speed</td>
</tr>
<tr>
<td>06</td>
<td>0x0040</td>
<td>Causes system software to ignore NVRAM contents</td>
</tr>
<tr>
<td>07</td>
<td>0x0080</td>
<td>OEM² bit enabled</td>
</tr>
<tr>
<td>08</td>
<td>0x0100</td>
<td>Unused</td>
</tr>
<tr>
<td>09</td>
<td>0x0200</td>
<td>Unused</td>
</tr>
<tr>
<td>10</td>
<td>0x0400</td>
<td>IP broadcast with all zeros</td>
</tr>
<tr>
<td>11 to 12</td>
<td>0x0800 to 0x1000</td>
<td>Bits one and zero of Console line speed (default is 9600 baud)</td>
</tr>
<tr>
<td>13</td>
<td>0x2000</td>
<td>Loads ROM monitor after netboot fails</td>
</tr>
<tr>
<td>14</td>
<td>0x4000</td>
<td>IP broadcasts do not have network numbers</td>
</tr>
</tbody>
</table>

1. The factory default value for the configuration register is 0x2101. This value is a combination of the following: binary bit 13, bit 8 = 0x0100 and binary bits 00 through 03 = 0x0001. (See Table 3-4.)

2. OEM = original equipment manufacturer.

Table 3-4  Explanation of Boot Field (Configuration Register Bits 00 to 03)

<table>
<thead>
<tr>
<th>Boot Field</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Stays at the system bootstrap prompt (does not autoboot).</td>
</tr>
<tr>
<td>01</td>
<td>Boots the first file in onboard flash memory.</td>
</tr>
<tr>
<td>02 to 0F</td>
<td>Autoboots using image(s) specified by the BOOT environment variable. If more than one image is specified, the switch attempts to boot the first image specified in the BOOT variable. As long as the switch can successfully boot from this image, the same image will be used on a reboot. If the switch fails to boot from the image specified in the BOOT variable, the switch will try to boot from the next image listed in the BOOT variable. If the end of the BOOT variable is reached without the switch booting successfully, the switch attempts the boot from the beginning of the BOOT variable. The autoboot continues until the switch successfully boots from one of the images specified in the BOOT variable.</td>
</tr>
</tbody>
</table>

Modifying the Boot Field and Using the boot Command

The configuration register boot field determines whether the switch loads an operating system image and, if so, where it obtains this system image. The following sections describe how to use and set the configuration register boot field and the procedures you must perform to modify the configuration register boot field. In ROMMON, you can use the confreg command to modify the configuration register and change boot settings.

Bits 0 through 3 of the software configuration register contain the boot field.

Note

The factory default configuration register setting for systems and spares is 0x2101. However, the recommended value is 0x0102.
When the boot field is set to either 00 or 01 (0-0-0-0 or 0-0-0-1), the system ignores any boot instructions in the system configuration file and the following occurs:

- When the boot field is set to 00, you must boot up the operating system manually by issuing the `boot` command at the system bootstrap or ROMMON prompt.
- When the boot field is set to 01, the system boots the first image in the bootflash single in-line memory module (SIMM).
- When the entire boot field equals a value between 0-0-1-0 and 1-1-1-1, the switch loads the system image specified by `boot system` commands in the startup configuration file.

**Caution**

If you set bootfield to a value between 0-0-1-0 and 1-1-1-1, you must specify a value in the `boot system` command, else the switch cannot boot up and will remain in ROMMON.

You can enter the `boot` command only or enter the command and include additional boot instructions, such as the name of a file stored in flash memory, or a file that you specify for booting from a network server. If you use the `boot` command without specifying a file or any other boot instructions, the system boots from the default flash image (the first image in onboard flash memory). Otherwise, you can instruct the system to boot up from a specific flash image (using the `boot system flash filename` command).

You can also use the `boot` command to boot up images stored in the compact flash cards located in slot 0 on the supervisor engine.

## Modifying the Boot Field

Modify the boot field from the software configuration register.

To modify the software configuration register boot field, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# <code>show version</code></td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch# <code>configure terminal</code></td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config)# <code>config-register value</code></td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config)# <code>end</code></td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch# <code>reload</code></td>
</tr>
</tbody>
</table>

To modify the configuration register while the switch is running Cisco IOS software, follow these steps:

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Enter the <code>enable</code> command and your password to enter privileged level, as follows:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Switch&gt; <code>enable</code></td>
</tr>
<tr>
<td></td>
<td>Password:</td>
</tr>
<tr>
<td></td>
<td>Switch#</td>
</tr>
</tbody>
</table>
**Step 2** Enter the `configure terminal` command at the EXEC mode prompt (#), as follows:

```
Switch# configure terminal
```

Enter configuration commands, one per line. End with CTRL/Z.

```
Switch(config)#
```

**Step 3** Configure the configuration register to 0x102 as follows:

```
Switch(config)# config-register 0x102
```

Set the contents of the configuration register by specifying the `value` command variable, where `value` is a hexadecimal number preceded by 0x (see Table 3-3 on page 3-27).

**Step 4** Enter the `end` command to exit configuration mode. The new value settings are saved to memory; however, the new settings do not take effect until the system is rebooted.

**Step 5** Enter the `show version` EXEC command to display the configuration register value currently in effect; it will be used at the next reload. The value is displayed on the last line of the screen display, as shown in this sample output:

```
Configuration register is 0x141 (will be 0x102 at next reload)
```

**Step 6** Save your settings.

See the “Saving the Running Configuration Settings to Your Start-Up File” section on page 3-10. Note that configuration register changes take effect only after the system reloads, such as when you enter a `reload` command from the console.

**Step 7** Reboot the system. The new configuration register value takes effect with the next system boot up.

---

**Verifying the Configuration Register Setting**

Enter the `show version` EXEC command to verify the current configuration register setting. In ROMMON mode, enter the `show version` command to verify the configuration register setting.

To verify the configuration register setting for the switch, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# show version</td>
<td>Displays the configuration register setting.</td>
</tr>
</tbody>
</table>

In this example, the `show version` command indicates that the current configuration register is set so that the switch does not automatically load an operating system image. Instead, it enters ROMMON mode and waits for you to enter ROM monitor commands.

```
Switch# show version
Cisco IOS Software, IOS-XE Software, Catalyst 4500 L3 Switch Software (cat4500e-UNIVERSAL-M), Version 03.01.00.SG RELEASE SOFTWARE (fc4)

cisco WS-C4503-E (MPC8572) processor (revision 8) with 786516K/16384K bytes of memory.
Processor board ID SPE134600QA
MPC8572 CPU at 1.5GHz, Supervisor 7
Last reset from Reload
  1 Virtual Ethernet interface
  96 Gigabit Ethernet interfaces
  4 Ten Gigabit Ethernet interfaces
  511K bytes of non-volatile configuration memory.

Configuration register is 0x40

/specifying the Startup System Image

You can enter multiple boot commands in the startup configuration file or in the BOOT environment
variable to provide backup methods for loading a system image.

The BOOT environment variable is also described in the “Specify the Startup System Image in the
Configuration File” section in the “Loading and Maintaining System Images and Microcode” chapter of
the Cisco IOS Configuration Fundamentals Configuration Guide.

Use the following sections to configure your switch to boot from flash memory. flash memory can be
either single in-line memory modules (SIMMs) or flash disks. Check the appropriate hardware
installation and maintenance guide for information about types of flash memory.

Flash Memory Features

Flash memory allows you to do the following:

• Remotely load multiple system software images through TFTP or RCP transfers (one transfer for
each file loaded)
• Boot a switch manually or automatically from a system software image stored in flash memory (you
can also boot directly from ROM)
• Copy the system image to flash memory using TFTP
• Boot the system from flash memory either automatically or manually
• Copy the flash memory image to a network server using TFTP or RCP

For more information on Flash Memory, see this URL:

1.
Security Precautions

Note the following security precaution when loading from flash memory:

⚠️ **Caution**

You can only change the system image stored in flash memory from privileged EXEC level on the console terminal.

Configuring Flash Memory

To configure your switch to boot from flash memory, perform the following procedure. (Refer to the appropriate hardware installation and maintenance publication for complete instructions on installing the hardware.)

**Step 1**  
Copy a system image to flash memory using TFTP or other protocols. Refer to the “Cisco IOS File Management” and “Loading and Maintaining System Images” chapters in the *Cisco IOS Configuration Fundamentals Configuration Guide*, Release 12.2, at the following URL:

**Step 2**  
Configure the system to boot automatically from the desired file in flash memory.

You might need to change the configuration register value. See the “Modifying the Boot Field and Using the boot Command” section on page 3-27, for more information on modifying the configuration register.

**Step 3**  
Save your configurations.

**Step 4**  
Power cycle and reboot your system to verify that all is working as expected.

Controlling Environment Variables

Although the ROM monitor controls environment variables, you can create, modify, or view them with certain commands. To create or modify the BOOT and BOOTLDR variables, use the `boot system` and `boot bootldr` global configuration commands, respectively. Refer to the “Specify the Startup System Image in the Configuration File” section in the “Loading and Maintaining System Images and Microcode” chapter of the *Configuration Fundamentals Configuration Guide* for details on setting the BOOT environment variable.

**Note**

When you use the `boot system` and `boot bootldr` global configuration commands, you affect only the running configuration. To save the configuration for future use, you must save the environment variable settings to your startup configuration, which places the information under ROM monitor control. Enter the `copy system:running-config nvram:startup-config` command to save the environment variables from your running configuration to your startup configuration.

You can view the contents of the BOOT and BOOTLDR variables using the `show bootvar` command. This command displays the settings for these variables as they exist in the startup configuration and in the running configuration if a running configuration setting differs from a startup configuration setting. This example shows how to check the BOOT and BOOTLDR variables on the switch:

```
Switch# show bootvar  
BOOTLDR variable = bootflash:cat4000-is-mz,1;
```
Resetting a Switch to Factory Default Settings

Manufacturing and repair centers can use the `erase /all non-default` command to do the following:

- Clear the non-volatile configurations and states of the local supervisor engine (NVRAM and flashes).
- Set the factory default parameters on the Catalyst 4500 series switch before it is ready to ship to a customer.

For example, entering this command can generate the following output:

```plaintext
Switch# erase /all non-default
Erase and format operation will destroy all data in non-volatile storage. Continue? [confirm]
Formatting bootflash: ...
Format of bootflash complete
Erasing nvram:
Erasing cat4000_flash:
Clearing crashinfo:data
Clearing the last power failure timestamp
Clearing all ROMMON variables
Setting default ROMMON variables:
  ConfigReg=0x2101
  PS1=rommon ! >
  EnableAutoConfig=1
Setting vtp mode to transparent
%WARNING! Please reboot the system for the changes to take effect
Switch#
00:01:48: %SYS-7-NV_BLOCK_INIT: Initialized the geometry of nvram
Switch#
```

If the Catalyst 4500 series switch is accessible to a TFTP server, you can copy an image to the bootflash memory with the TFTP command:

```plaintext
Switch# copy tftp://192.20.3.123/tftpboot/abc/cat4500-entservices-mz.bin bootflash:
```

When the copying is completed, you can reboot the just-copied Catalyst 4500 series switch image to the image stored in the bootflash memory with the `reload` command:

```plaintext
Switch# reload
System configuration has been modified. Save? [yes/no]: no
Proceed with reload? [confirm]
00:06:17: %SYS-5-RELOAD: Reload requested by console. Reload Reason: Reload Command.
```

To see details about the default parameters set by the `erase /all non-default` command, see the usage guidelines for the `erase` command in the `Catalyst 4500 Series Switch Cisco IOS Command Reference`.

Configuring Crashinfo

The crashinfo file is a collection of useful debugging information related to a process that has crashed. A system might have numerous processes running, and occasionally, one or more of them may crash.
because of a software defect. The crashinfo file not only contain a snapshot of the process’s state information of the process state at crash time, but it also contains a snapshot of the system’s state information (such as the state of system resources). The information in the crashinfo file helps to identify a crash’s possible root cause.

This section contains the following subsections:
- About Crashinfo, page 3-33
- Configuring Crashinfo, page 3-35

About Crashinfo

This subsection describes the three types of crashinfo files (process crashinfo, process core dump, and kernel crashinfo).

The following topics are discussed:
- Process Crashinfo File, page 3-33
- Process Core Dump File, page 3-34
- Kernel Crashinfo File, page 3-34

Process Crashinfo File

The naming convention of the crashinfo filename is

```
crashinfo_<process_name>_YYYYMMDD-HHMMSS-UTC
```

By default, this process crashinfo file is always generated for a process crash. Although the file’s contents are in readable text format, some parts of the file can only be decoded by a specific Cisco debugging tool. For nearly all process crashes, this file is required for root cause analysis.

This file contains the following information:
- Software exception that cause the crash
- Identity summary of the process
- Register values at the time of crash
- Stack dump of each of the threads of the process
- Files that are opened and used at the time of crash
- Command line as the process was launched
- Environment variables and resource limits
- Memory addresses where executable code are loaded
- Status of memory usage and CPU usage for each of the threads
- Application specific debugging information
- System boot log message
- System up time and CPU usage
- List of kernel loadable modules in the system
- System devices and their status
- List of mounted filesystems
• System memory total, free, and usage information
• Information on memory zones and slabs, and their status
• Virtual memory usage
• Resources maintained by the kernel
• List of program identifiers, called TRACEKEYs

**Process Core Dump File**

The naming convention for the core dump file name is

`fullcore_<process_name>_YYYYMMDD-HHMMSS-UTC`

By default, this file is not generated for a process crash. It can be enabled with the `exception` CLI command.

The file is of compressed binary type and can only be decoded by a specific Cisco debugging tool. The uncompressed file of this type is basically a coredump, which is a copy of memory pages that are used by the process that crashed. You should provide the coredump file, if available, as part of debugging information for root cause analysis.

By default, compression is enabled. We do not recommend that you enable coredump to obtain an uncompressed coredump because it requires a considerable storage space and time to save to the storage device. Enabling the uncompressed crash data generation is better suited for those systems with faster and larger storage capacity.

**Kernel Crashinfo File**

The filename of the kernel crashinfo file is `koops.dat`.

By default, the kernel crashinfo dump is enabled and cannot be disabled. The kernel crashinfo, also known Kernel OOPS (KOOPS), represents a defect in the kernel software code (a detected undesirable hardware condition). The term OOPS is an interjection made after a mistake.

Although the file’s contents are in readable text format, some parts of this file can only be decoded by a trained engineer. For nearly all kernel crashes, this file is required for root cause analysis.

This file contains the following information:

• Exception summary
• CPU information
• List of kernel loadable modules
• Register values at the time of kernel oops event taken place
• Task that was running at the time of oops event
• List of code blocks executed leading up to the oops event
• A number of code instructions
• Time the oops event taken place
Configuring Crashinfo

The crashinfo is configured with default values. It is not necessary to configure the crashinfo because the default values are designed to be optimal. The configuration may require customization to account for system configuration, storage availability, and capacity.

Topics include:
- Default Configuration, page 3-35
- Configuring commands, page 3-35
- show Commands, page 3-36
- Enabling the Generation of the Process Core Dump File, page 3-38
- Saving Crash Files to a Secondary Devices, page 3-39
- Determining the Process that Crashed, page 3-39

Default Configuration

By default, the crash files are saved in crashinfo: partition, which cannot be changed. Two additional storage devices can be configured to save the crash files.

Using the **crashinfo** configuration commands, you can set the maximum number of files stored in each of the storage devices. This allows you to use the storage device wisely, saving the crash files, and increasing their manageability. By default, you can save up to 10 crashinfo files and up to 10 coredump files. Recall that the generation of the process core dump file is disabled by default. When the maximum number of files has been achieved and a new crash file is created, one or more of the oldest files, among the process crashinfo and core dump files, are deleted to create space for the new crash file.

The file named **last_crashinfo** possesses the file name of the latest crash file. View this file when it is hard to locate the latest crash file because multiple crash files exist on multiple storage devices.

Configuring commands

The following commands define the number of crashinfo files or coredump files respectively to be retained on each of the storage partition such as crashinfo:. Depending on the size of the storage partition, you might not be able to retain the configured number of files. Also, when a new crash file is created, and if there is insufficient space to store the new crash file, the oldest crash files are deleted until enough storage space is available for the new crash file.

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# exception crashinfo maximum-files ? &lt;1-20&gt; A value between 1-20</td>
<td>Sets the maximum number of process crashinfo files to be retained. The initial default values is 10.</td>
</tr>
<tr>
<td>Switch# exception coredump maximum-files ? &lt;1-20&gt; A value between 1-20</td>
<td>Sets the maximum number of process core dump files to be retained. The initial default values are 10.</td>
</tr>
</tbody>
</table>
The following command is used to configure the list of storage devices to be searched for space defined by the system when space is required to store newly created crash files. The first device is always the crashinfo: partition and cannot be changed. For example, if a second device is configured and there is insufficient space to store the new crash files, the system attempts to save these new crash files on the second device rather than deleting files from the crashinfo: partition.

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# exception dump device ? second second search device to store crashinfo</td>
<td>Sets the second and third storage devices that are checked for available storage space for saving the new crash files. crashinfo: is the default device and cannot be changed.</td>
</tr>
<tr>
<td>Switch# exception coredump</td>
<td>Enables the generation of compressed process core dump file.</td>
</tr>
<tr>
<td>Switch# exception coredump uncompress</td>
<td>Enables the generation of the uncompressed process core dump file.</td>
</tr>
</tbody>
</table>

The following command enables the generation of coredump crash data. The coredump data is a binary data, and it is compressed by default.

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# exception coredump</td>
<td>Enables the generation of compressed process core dump file.</td>
</tr>
<tr>
<td>Switch# exception coredump uncompress</td>
<td>Enables the generation of the uncompressed process core dump file.</td>
</tr>
</tbody>
</table>

The following command directs the system to generate uncompressed coredump crash data. Typically, you should not generate uncompressed coredump data because the file can very large (on the order of 1-2 Gigabytes), and storage space for the crash file will be insufficient.

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# exception coredump uncompress</td>
<td>Enables the generation of the uncompressed process core dump file.</td>
</tr>
</tbody>
</table>

**Note** An uncompressed coredump file can be very large.

The default is to generate compressed process core dump file.

**show Commands**

Use the following command to display the current configuration of the crashinfo:

Switch# show exception information

Exception configuration information
Coredump file - disabled, compressed
Maximum number of files
  Core - 10 file(s)
  Process crashinfo - 10 file(s)
Configured storage devices
  1 - crashinfo:
  2 - not assigned
  3 - not assigned
### Configuring Crashinfo

#### Dump protocol - not configured

Use the following command to determine the file name of latest crash file:

```
Switch# more crashinfo: last_crashinfo
```

Use the following command to view the contents of a process crashinfo file:

```
Switch# more crashinfo: crashinfo_iod_20100803-073408-UTC
```

---

Use the following command to view the contents of kernel crash information:

```
Switch# more crashinfo: koops.dat
```

---

//output omitted//
Enabling the Generation of the Process Core Dump File

If there might be insufficient storage space, you might want to reduce the number of process core dump files. To do that you must first enable the generation of the process core dump file by performing the following task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# config terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# exception coredump</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config)# exception coredump maximum-files x</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch# show exception information</td>
</tr>
</tbody>
</table>

This example shows how to generate the process core dump file, limit the number of process core dump files to 2, and to verify the configuration:

```bash
Switch# config t
Switch (config)# exception coredump
Switch (config)# exception coredump maximum files 2
Switch (config)# end
Switch# show exception information
```

Exception configuration information
Coredump file - enabled, compressed
Maximum number of files
  Core - 2 file(s)
  Process crashinfo - 10 file(s)
Configured storage devices
  1 - crashinfo:
  2 - not assigned
  3 - not assigned
Dump protocol - not configured
Saving Crash Files to a Secondary Devices

Assume that the system has an installed USB storage device and you want to save the crash files to the USB storage instead of deleting the old crash files from the default storage crashinfo: partition. The system starts saving the crash files to either installed and configured USB, when either the maximum number of files had been reached or there is in sufficient space on the crashinfo: partition.

To configure to save a crash file in a secondary device, perform the following task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# config terminal</td>
</tr>
<tr>
<td></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# exception dump second device x</td>
</tr>
<tr>
<td></td>
<td>Configures x as the storage devices to be searched for needed storage space.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td></td>
<td>Returns to global configuration mode.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch# show exception information</td>
</tr>
<tr>
<td></td>
<td>(optional) Verifies the configuration.</td>
</tr>
</tbody>
</table>

**Note** A portion of the output should indicate that the secondary device has been configured.

Configured storage devices
1 - crashinfo:
2 - usb0:
3 - not assigned

This example shows how to configure the USB to be searched for needed storage space and to verify the configuration:

Switch# config t
Switch(config)# exception dump second device usb0:
Switch# show exception information
Exception configuration information
Coredump file - disabled, compressed
Maximum number of files
- Core - 10 file(s)
- Process crashinfo - 10 file(s)
Configured storage devices
1 - crashinfo:
2 - usb0:
3 - not assigned
Dump protocol - not configured

Determining the Process that Crashed

Your system might have rebooted after a critical process had crashed. If so, you might want to determine the location of the latest crash file, the process that crashed, and the likely root cause. Cisco TAC requires the available crash files for root cause analysis. If the crash is due to some side-effects of another process that crashed earlier, the latest crash file may not contain the actual root cause information. We recommend that you provide Cisco TAC all the crash files that are generated around crash time.

To determine the process that crashed, perform this task:
### Configuring Crashinfo

The following examples show how to use these commands:

```plaintext
Switch# show exception information
Exception configuration information
Coredump file - disabled, compressed
Maximum number of files
  Core - 10 file(s)
  Process crashinfo - 10 file(s)
Configured storage devices
  1 - crashinfo:
  2 - not assigned
  3 - not assigned
Dump protocol - not configured
```

```plaintext
Switch# more crashinfo:last_crashinfo
```

```plaintext
Switch# more crashinfo:crashinfo_iosd_20100803-073408-UTC
```

```plaintext
Switch(config)# more crashinfo:koops.dat
```

```plaintext
Switch# copy crashinfo: tftp:
Source filename [}? Address or name of remote host []? remote_host Destination filename []? crashinfo_yyyymmdd-hhnmmss-UTC
```

### Command Purpose

<table>
<thead>
<tr>
<th>Step</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Switch# show exception information</td>
<td>Displays the configuration to determine where the crash files are saved.</td>
</tr>
<tr>
<td>2</td>
<td>Switch# more crashinfo:last_crashinfo</td>
<td>Locates the latest crashinfo file.</td>
</tr>
<tr>
<td>3</td>
<td>Switch# more crashinfo:crashinfo_yyyymmdd-hhnmmss-UTC</td>
<td>Displays the contents of the process crashinfo file.</td>
</tr>
<tr>
<td>4</td>
<td>Switch(config)# more crashinfo:koops.dat</td>
<td>Displays the contents of the kernel crashinfo file to determine whether the kernel had crashed.</td>
</tr>
<tr>
<td>5</td>
<td>Switch# copy crashinfo: tftp:</td>
<td>Copies a crash file to a TFTP server. When Cisco TAC requests a specific crash file for root cause analysis, you can copy the file to a TFTP server from the switch.</td>
</tr>
</tbody>
</table>

Command Purpose:

- **Step 1**:
  - Command: ```Switch# show exception information```
  - Purpose: Displays the configuration to determine where the crash files are saved.

- **Step 2**: 
  - Command: ```Switch# more crashinfo:last_crashinfo```
  - Purpose: Locates the latest crashinfo file.

- **Step 3**: 
  - Command: ```Switch# more crashinfo:crashinfo_yyyymmdd-hhnmmss-UTC```
  - Purpose: Displays the contents of the process crashinfo file.

- **Step 4**: 
  - Command: ```Switch(config)# more crashinfo:koops.dat```
  - Purpose: Displays the contents of the kernel crashinfo file to determine whether the kernel had crashed.

- **Step 5**: 
  - Command: ```Switch# copy crashinfo: tftp:```
  - Description: Copies a crash file to a TFTP server. When Cisco TAC requests a specific crash file for root cause analysis, you can copy the file to a TFTP server from the switch.
Switch# more crashinfo:koops.dat

Administering the Switch

This chapter describes how to perform one-time operations to administer the Catalyst 4500 Series switch.

This chapter also describes how to install and configure the Embedded CiscoView network management system to provide a graphical representation of a Catalyst 4500 series switch and to provide a GUI-based management and configuration interface.

This chapter includes the following major sections:

- Managing the System Time and Date, page 4-1
- Configuring a System Name and Prompt, page 4-14
- Creating a Banner, page 4-17
- Managing the MAC Address Table, page 4-19
- Managing the ARP Table, page 4-30
- Configuring Embedded CiscoView Support, page 4-30

For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it will be found in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

Managing the System Time and Date

You can configure the system time and date on your switch manually or automatically by using Network Time Protocol (NTP).

These sections contain this configuration information:

- System Clock, page 4-2
- Understanding Network Time Protocol, page 4-2
System Clock

The core of the time service is the system clock, which monitors the date and time. This clock starts when the system starts.

The system clock can provide time to these services:
- User `show` commands
- Logging and debugging messages

The system clock keeps track of whether the time is authoritative or not (whether it has been set by a time source considered to be authoritative). If it is not authoritative, the time is available only for display purposes and is not redistributed. For configuration information, see the “Configuring Time and Date Manually” section on page 4-11.

Understanding Network Time Protocol

The NTP is designed to synchronize a network of devices. NTP runs over User Datagram Protocol (UDP), which runs over IP. NTP is documented in RFC 1305.

An NTP network usually gets its time from an authoritative time source, such as a radio clock or an atomic clock attached to a time server. NTP then distributes this time across the network. NTP is extremely efficient; no more than one packet per minute is necessary to synchronize two devices to within a millisecond of one another.

NTP uses the concept of a stratum to describe how many NTP hops away a device is from an authoritative time source. A stratum 1 time server has a radio or atomic clock directly attached, a stratum 2 time server receives its time through NTP from a stratum 1 time server, and so on. A device running NTP automatically chooses as its time source the device with the lowest stratum number with which it communicates through NTP. This strategy effectively builds a self-organizing tree of NTP speakers.

NTP avoids synchronizing to a device whose time might not have been synchronized. NTP also compares the time reported by several devices and does not synchronize to a device whose time is significantly different than the others, even if its stratum is lower.

The communications between devices running NTP (known as associations) are usually statically configured; each device is given the IP address of all devices with which it should associate. Accurate timekeeping is possible by exchanging NTP messages between each pair of devices with an association. However, in a LAN environment, NTP can be configured to use IP broadcast messages instead. This alternative reduces configuration complexity because each device can simply be configured to send or receive broadcast messages; however, information flow is one-way only.

The time kept on a device is a critical resource; you should use the security features of NTP to avoid the accidental or malicious setting of an incorrect time. Two mechanisms are available: an access list-based restriction scheme and an encrypted authentication mechanism.
Cisco’s implementation of NTP does not support stratum 1 service; it is not possible to connect to a radio or atomic clock. We recommend that the time service for your network be derived from the public NTP servers available on the IP Internet.

Figure 4-1 shows a typical network example using NTP. Switch A is the NTP master, with Switches B, C, and D configured in NTP server mode, in server association with Switch A. Switch E is configured as an NTP peer to the upstream and downstream switches, Switch B and Switch F, respectively.

If the network is isolated from the Internet, Cisco’s implementation of NTP allows a device to act as if it is synchronized through NTP, when it is not. Other devices then synchronize to that device through NTP.

NTP time overrides the time set by any other method.

Several manufacturers include NTP software for their host systems, and a public version for systems running UNIX and its various derivatives is also available. This software allows host systems to be synchronized as well.

**Configuring NTP**

These sections contain this configuration information:

- Default NTP Configuration, page 4-4
- Configuring NTP Authentication, page 4-4
Default NTP Configuration

Table 4-1 shows the default NTP configuration.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>NTP authentication</td>
<td>Disabled. No authentication key is specified.</td>
</tr>
<tr>
<td>NTP peer or server associations</td>
<td>None configured.</td>
</tr>
<tr>
<td>NTP broadcast service</td>
<td>Disabled; no interface sends or receives NTP broadcast packets.</td>
</tr>
<tr>
<td>NTP access restrictions</td>
<td>No access control is specified.</td>
</tr>
<tr>
<td>NTP packet source IP address</td>
<td>The source address is set by the outgoing interface.</td>
</tr>
</tbody>
</table>

NTP is enabled on all interfaces by default. All interfaces receive NTP packets.

Configuring NTP Authentication

This procedure must be coordinated with the administrator of the NTP server; the information you configure in this procedure must be matched by the servers used by the switch to synchronize its time to the NTP server.

To authenticate the associations (communications between devices running NTP that provide for accurate timekeeping) with other devices for security purposes, perform this task:

```
Step 1 configure terminal
<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 2 ntp authenticate</td>
<td>Enables the NTP authentication feature, which is disabled by default.</td>
</tr>
<tr>
<td>Step 3 ntp authentication-key number md5 value</td>
<td>Defines the authentication keys. By default, none are defined.</td>
</tr>
<tr>
<td></td>
<td>- For number, specify a key number. The range is 1 to 4294967295.</td>
</tr>
<tr>
<td></td>
<td>- md5 specifies that message authentication support is provided by using the message digest algorithm 5 (MD5).</td>
</tr>
<tr>
<td></td>
<td>- For value, enter an arbitrary string of up to eight characters for the key.</td>
</tr>
</tbody>
</table>
```

The switch does not synchronize to a device unless both have one of these authentication keys, and the key number is specified by the ntp trusted-key key-number command.
To disable NTP authentication, use the **no ntp authenticate** global configuration command. To remove an authentication key, use the **no ntp authentication-key number** global configuration command. To disable authentication of the identity of a device, use the **no ntp trusted-key key-number** global configuration command.

This example shows how to configure the switch to synchronize only to devices providing authentication key 42 in the device’s NTP packets:

```
Switch# configure terminal
Switch(config)# ntp authenticate
Switch(config)# ntp authentication-key 42 md5 aNiceKey
Switch(config)# ntp trusted-key 42
Switch(config)# end
Switch#
```
Configuring NTP Associations

An NTP association can be a peer association (this switch can either synchronize to the other device or allow the other device to synchronize to it), or it can be a server association (meaning that only this switch synchronizes to the other device, and not the other way around).

To form an NTP association with another device, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>ntp peer ip-address [version number] [key keyid] [source interface] [prefer] or ntp server ip-address [version number] [key keyid] [source interface] [prefer]</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>end</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>show running-config</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>copy running-config startup-config</td>
</tr>
</tbody>
</table>

You need to configure only one end of an association; the other device can automatically establish the association. If you are using the default NTP version (Version 3) and NTP synchronization does not occur, try using NTP Version 2. Many NTP servers on the Internet run Version 2.

To remove a peer or server association, use the no ntp peer ip-address or the no ntp server ip-address global configuration command.

This example shows how to configure the switch to synchronize its system clock with the clock of the peer at IP address 172.16.22.44 using NTP Version 2:

```
Switch# configure terminal
Switch(config)# ntp server 172.16.22.44 version 2
Switch(config)# end
Switch#  
```
Configuring NTP Broadcast Service

The communications between devices running NTP (known as associations) are usually statically configured; each device is given the IP addresses of all devices with which it should form associations. Accurate timekeeping is possible by exchanging NTP messages between each pair of devices with an association. However, in a LAN environment, NTP can be configured to use IP broadcast messages instead. This alternative reduces configuration complexity because each device can simply be configured to send or receive broadcast messages. However, the information flow is one-way only.

The switch can send or receive NTP broadcast packets on an interface-by-interface basis if there is an NTP broadcast server, such as a router, broadcasting time information on the network. The switch can send NTP broadcast packets to a peer so that the peer can synchronize to it. The switch can also receive NTP broadcast packets to synchronize its own clock. This section provides procedures for both sending and receiving NTP broadcast packets.

To configure the switch to send NTP broadcast packets to peers so that they can synchronize their clock to the switch, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>interface interface-id</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>ntp broadcast [version number] [key keyid] [destination-address]</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>end</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>show running-config</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>copy running-config startup-config</td>
</tr>
</tbody>
</table>

To disable the interface from sending NTP broadcast packets, use the **no ntp broadcast** interface configuration command.

This example shows how to configure a port to send NTP Version 2 packets:

Switch# configure terminal
Switch(config)# interface gigabitethernet0/1
Switch(config-if)# ntp broadcast version 2
Switch(config-if)# end
Switch#
To configure the switch to receive NTP broadcast packets from connected peers, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><code>configure terminal</code> Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><code>interface interface-id</code> Specifies the interface to receive NTP broadcast packets, and enter interface configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><code>ntp broadcast client</code> Enables the interface to receive NTP broadcast packets. By default, no interfaces receive NTP broadcast packets.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><code>exit</code> Returns to global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><code>ntp broadcastdelay microseconds</code> (Optional) Changes the estimated round-trip delay between the switch and the NTP broadcast server. The default is 3000 microseconds; the range is 1 to 999999.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td><code>end</code> Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td><code>show running-config</code> Verifies your entries.</td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td><code>copy running-config startup-config</code> (Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

To disable an interface from receiving NTP broadcast packets, use the **no ntp broadcast client** interface configuration command. To change the estimated round-trip delay to the default, use the **no ntp broadcastdelay** global configuration command.

This example shows how to configure a port to receive NTP broadcast packets:

```
Switch# configure terminal
Switch(config)# interface gigabitethernet0/1
Switch(config-if)# ntp broadcast client
Switch(config-if)# end
Switch#
```

### Configuring NTP Access Restrictions

You can control NTP access on two levels as described in these sections:

- Creating an Access Group and Assigning a Basic IP Access List, page 4-9
- Disabling NTP Services on a Specific Interface, page 4-10
Creating an Access Group and Assigning a Basic IP Access List

To control access to NTP services by using access lists, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>configure terminal</td>
</tr>
<tr>
<td></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td>ntp access-group {query-only</td>
</tr>
<tr>
<td></td>
<td>Creates an access group, and apply a basic IP access list.</td>
</tr>
<tr>
<td></td>
<td>The keywords have these meanings:</td>
</tr>
<tr>
<td></td>
<td>• query-only—Allows only NTP control queries.</td>
</tr>
<tr>
<td></td>
<td>• serve-only—Allows only time requests.</td>
</tr>
<tr>
<td></td>
<td>• serve—Allows time requests and NTP control queries, but does not allow the switch to synchronize to the remote device.</td>
</tr>
<tr>
<td></td>
<td>• peer—Allows time requests and NTP control queries and allows the switch to synchronize to the remote device.</td>
</tr>
<tr>
<td></td>
<td>For access-list-number, enter a standard IP access list number from 1 to 99.</td>
</tr>
<tr>
<td>Step 3</td>
<td>access-list access-list-number</td>
</tr>
<tr>
<td></td>
<td>Creates the access list.</td>
</tr>
<tr>
<td></td>
<td>• For access-list-number, enter the number specified in Step 2.</td>
</tr>
<tr>
<td></td>
<td>• Enter the permit keyword to permit access if the conditions are matched.</td>
</tr>
<tr>
<td></td>
<td>• For source, enter the IP address of the device that is permitted access to the switch.</td>
</tr>
<tr>
<td></td>
<td>• (Optional) For source-wildcard, enter the wildcard bits to be applied to the source.</td>
</tr>
<tr>
<td></td>
<td>Note When creating an access list, remember that, by default, the end of the access list contains an implicit deny statement for everything if it did not find a match before reaching the end.</td>
</tr>
<tr>
<td>Step 4</td>
<td>end</td>
</tr>
<tr>
<td></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Step 5</td>
<td>show running-config</td>
</tr>
<tr>
<td></td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td>Step 6</td>
<td>copy running-config startup-config</td>
</tr>
<tr>
<td></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

The access group keywords are scanned in this order, from least restrictive to most restrictive:

1. peer—Allows time requests and NTP control queries and allows the switch to synchronize itself to a device whose address passes the access list criteria.
2. serve—Allows time requests and NTP control queries, but does not allow the switch to synchronize itself to a device whose address passes the access list criteria.
3. serve-only—Allows only time requests from a device whose address passes the access list criteria.
4. query-only—Allows only NTP control queries from a device whose address passes the access list criteria.

If the source IP address matches the access lists for more than one access type, the first type is granted. If no access groups are specified, all access types are granted to all devices. If any access groups are specified, only the specified access types are granted.
Managing the System Time and Date

To remove access control to the switch NTP services, use the
```
no ntp access-group {query-only | serve-only | serve | peer} global configuration command.
```

This example shows how to configure the switch to allow itself to synchronize to a peer from access list 99. However, the switch restricts access to allow only time requests from access list 42:

```
Switch# configure terminal
Switch(config)# ntp access-group peer 99
Switch(config)# ntp access-group serve-only 42
Switch(config)# access-list 99 permit 172.20.130.5
Switch(config)# access list 42 permit 172.20.130.6
Switch(config)# end
```

Disabling NTP Services on a Specific Interface

NTP services are enabled on all interfaces by default.

To disable NTP packets from being received on an interface, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>configure terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>interface interface-id</td>
</tr>
<tr>
<td>Step 3</td>
<td>ntp disable</td>
</tr>
<tr>
<td>Step 4</td>
<td>end</td>
</tr>
<tr>
<td>Step 5</td>
<td>show running-config</td>
</tr>
<tr>
<td>Step 6</td>
<td>copy running-config startup-config</td>
</tr>
</tbody>
</table>

Configuring the Source IP Address for NTP Packets

When the switch sends an NTP packet, the source IP address is normally set to the address of the interface through which the NTP packet is sent. Use the `ntp source` global configuration command when you want to use a particular source IP address for all NTP packets. The address is taken from the specified interface. This command is useful if the address on an interface cannot be used as the destination for reply packets.

To configure a specific interface from which the IP source address is to be taken, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>configure terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>ntp source type number</td>
</tr>
<tr>
<td>Step 3</td>
<td>end</td>
</tr>
<tr>
<td>Step 4</td>
<td>show running-config</td>
</tr>
<tr>
<td>Step 5</td>
<td>copy running-config startup-config</td>
</tr>
</tbody>
</table>
The specified interface is used for the source address for all packets sent to all destinations. If a source address is to be used for a specific association, use the `source` keyword in the `ntp peer` or `ntp server` global configuration command as described in the “Configuring NTP Associations” section on page 4-6.

**Displaying the NTP Configuration**

You can use two privileged EXEC commands to display NTP information:

- `show ntp associations [detail]`
- `show ntp status`

For detailed information about the fields in these displays, see the *Cisco IOS Configuration Fundamentals Command Reference, Release 12.3*.

**Configuring Time and Date Manually**

If no other source of time is available, you can manually configure the time and date after the system is restarted. The time remains accurate until the next system restart. We recommend that you use manual configuration only as a last resort. If you have an outside source to which the switch can synchronize, you do not need to manually set the system clock.

These sections contain this configuration information:

- Setting the System Clock, page 4-11
- Displaying the Time and Date Configuration, page 4-12
- Configuring the Time Zone, page 4-12
- Configuring Summer Time (Daylight Saving Time), page 4-13

**Setting the System Clock**

If you have an outside source on the network that provides time services, such as an NTP server, you do not need to manually set the system clock.

To set the system clock, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>clock set hh:mm:ss day month year</code> or <code>clock set hh:mm:ss month day year</code></td>
</tr>
<tr>
<td></td>
<td>• For <code>hh:mm:ss</code>, specify the time in hours (24-hour format), minutes, and seconds. The time specified is relative to the configured time zone.</td>
</tr>
<tr>
<td></td>
<td>• For <code>day</code>, specify the day by date in the month.</td>
</tr>
<tr>
<td></td>
<td>• For <code>month</code>, specify the month by name.</td>
</tr>
<tr>
<td></td>
<td>• For <code>year</code>, specify the year (no abbreviation).</td>
</tr>
</tbody>
</table>

This example shows how to manually set the system clock to 1:32 p.m. on July 23, 2001:

```
Switch# clock set 13:32:00 23 July 2001
```
Displaying the Time and Date Configuration

To display the time and date configuration, use the show clock [detail] privileged EXEC command.

The system clock keeps an authoritative flag that shows whether the time is authoritative (believed to be accurate). If the system clock has been set by a timing source such as NTP, the flag is set. If the time is not authoritative, it is used only for display purposes. Until the clock is authoritative and the authoritative flag is set, the flag prevents peers from synchronizing to the clock when the peers’ time is invalid.

The symbol that precedes the show clock display has the following meaning:
- Asterix(*)—Time is not authoritative.
- Blank—Time is authoritative.
- Period(.)—Time is authoritative, but NTP is not synchronized.

Configuring the Time Zone

To manually configure the time zone, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>configure terminal Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td>clock timezone zone hours-offset Sets the time zone.</td>
</tr>
<tr>
<td></td>
<td>[minutes-offset] To set the time to UTC, use the no clock timezone global configuration command.</td>
</tr>
<tr>
<td></td>
<td>The switch keeps internal time in universal time coordinated (UTC), so this command is used only for display purposes and when the time is manually set.</td>
</tr>
<tr>
<td></td>
<td>• For zone, enter the name of the time zone to be displayed when standard time is in effect. The default is UTC.</td>
</tr>
<tr>
<td></td>
<td>• For hours-offset, enter the hours offset from UTC.</td>
</tr>
<tr>
<td></td>
<td>• (Optional) For minutes-offset, enter the minutes offset from UTC.</td>
</tr>
<tr>
<td>Step 3</td>
<td>end Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Step 4</td>
<td>show running-config Verifies your entries.</td>
</tr>
<tr>
<td>Step 5</td>
<td>copy running-config startup-config (Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

The minutes-offset variable in the clock timezone global configuration command is available for those cases where a local time zone is a percentage of an hour different from UTC. For example, the time zone for some sections of Atlantic Canada (AST) is UTC-3.5, where the 3 means 3 hours and .5 means 50 percent. In this case, the necessary command is clock timezone AST -3 30.
Configuring Summer Time (Daylight Saving Time)

To configure summer time (daylight saving time) in areas where it starts and ends on a particular day of the week each year, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>clock summer-time zone recurring [week day month hh:mm week day month hh:mm [offset]]</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>end</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>show running-config</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>copy running-config startup-config</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode.</td>
</tr>
</tbody>
</table>
| **Step 2** | Configures summer time to start and end on the specified days every year. Summer time is disabled by default. If you specify clock summer-time zone recurring without parameters, the summer time rules default to the United States rules.  
- For zone, specify the name of the time zone (for example, PDT) to be displayed when summer time is in effect.  
- (Optional) For week, specify the week of the month (1 to 5 or last).  
- (Optional) For day, specify the day of the week (Sunday, Monday...).  
- (Optional) For month, specify the month (January, February...).  
- (Optional) For hh:mm, specify the time (24-hour format) in hours and minutes.  
- (Optional) For offset, specify the number of minutes to add during summer time. The default is 60. |
| **Step 3** | Returns to privileged EXEC mode. |
| **Step 4** | Verifies your entries. |
| **Step 5** | (Optional) Saves your entries in the configuration file. |

The first part of the clock summer-time global configuration command specifies when summer time begins, and the second part specifies when it ends. All times are relative to the local time zone. The start time is relative to standard time. The end time is relative to summer time. If the starting month is after the ending month, the system assumes that you are in the southern hemisphere.

This example shows how to specify that summer time starts on the first Sunday in April at 02:00 and ends on the last Sunday in October at 02:00:

```
Switch# configure terminal
Switch(config)# clock summer-time PDT recurring 1 Sunday April 2:00 last Sunday October 2:00
Switch(config)# end
Switch#
```
If summer time in your area does not follow a recurring pattern (configure the exact date and time of the next summer time events), perform this task:

```
Step 1  configure terminal
Enters global configuration mode.

Step 2  clock summer-time zone date [month
date year hh:mm month date year
hh:mm [offset]]
or
clock summer-time zone date [date
month year hh:mm date month month
hh:mm [offset]]
Configures summer time to start on the first date and end on the second date.
To disable summer time, use the no clock summer-time global configuration command.
Summer time is disabled by default.
• For zone, specify the name of the time zone (for example, PDT) to be displayed when summer time is in effect.
• (Optional) For week, specify the week of the month (1 to 5 or last).
• (Optional) For day, specify the day of the week (Sunday, Monday...).
• (Optional) For month, specify the month (January, February...).
• (Optional) For hh:mm, specify the time (24-hour format) in hours and minutes.
• (Optional) For offset, specify the number of minutes to add during summer time. The default is 60.

Step 3  end
Returns to privileged EXEC mode.

Step 4  show running-config
Verifies your entries.

Step 5  copy running-config startup-config
(Optional) Saves your entries in the configuration file.
```

The first part of the clock summer-time global configuration command specifies when summer time begins, and the second part specifies when it ends. All times are relative to the local time zone. The start time is relative to standard time. The end time is relative to summer time. If the starting month is after the ending month, the system assumes that you are in the southern hemisphere.

To disable summer time, use the no clock summer-time global configuration command.

This example shows how to set summer time to start on October 12, 2000, at 02:00, and end on April 26, 2001, at 02:00:
```
Switch# configure terminal
Switch(config)# clock summer-time pdt date 12 October 2000 2:00 26 April 2001 2:00
Switch#
```

**Configuring a System Name and Prompt**

You configure the system name on the switch to identify it. By default, the system name and prompt are Switch.

If you have not configured a system prompt, the first 20 characters of the system name are used as the system prompt. A greater-than symbol [>] is appended. The prompt is updated whenever the system name changes.
For complete syntax and usage information for the commands used in this section, see the Cisco IOS Configuration Fundamentals Command Reference, Release 12.3 and the Cisco IOS IP Command Reference, Volume 2 of 3: Routing Protocols, Release 12.3.

These sections contain this configuration information:
- Configuring a System Name, page 4-15
- Understanding DNS, page 4-15

## Configuring a System Name

To manually configure a system name, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 2 hostname name</td>
<td>Manually configures a system name.</td>
</tr>
<tr>
<td></td>
<td>The default setting is switch.</td>
</tr>
<tr>
<td></td>
<td>The name must follow the rules for ARPANET hostnames. They must start</td>
</tr>
<tr>
<td></td>
<td>with a letter, end with a letter or digit, and have as interior characters only</td>
</tr>
<tr>
<td></td>
<td>letters, digits, and hyphens. Names can be up to 63 characters.</td>
</tr>
<tr>
<td></td>
<td>To return to the default hostname, use the no hostname global configuration command.</td>
</tr>
<tr>
<td>Step 3 end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Step 4 show running-config</td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td>Step 5 copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

When you set the system name, it is also used as the system prompt.

## Understanding DNS

The DNS protocol controls the Domain Name System (DNS), a distributed database with which you can map hostnames to IP addresses. When you configure DNS on your switch, you can substitute the hostname for the IP address with all IP commands, such as ping, telnet, connect, and related Telnet support operations.

IP defines a hierarchical naming scheme that allows a device to be identified by its location or domain. Domain names are pieced together with periods (.) as the delimiting characters. For example, Cisco Systems is a commercial organization that IP identifies by a com domain name, so its domain name is cisco.com. A specific device in this domain, for example, the File Transfer Protocol (FTP) system is identified as ftp.cisco.com.

To keep track of domain names, IP has defined the concept of a domain name server, which holds a cache (or database) of names mapped to IP addresses. To map domain names to IP addresses, you must first identify the hostnames, specify the name server that is present on your network, and enable the DNS.
These sections contain this configuration information:

- Default DNS Configuration, page 4-16
- Setting Up DNS, page 4-16
- Displaying the DNS Configuration, page 4-17

**Default DNS Configuration**

Table 4-2 shows the default DNS configuration.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>DNS enable state</td>
<td>Enabled</td>
</tr>
<tr>
<td>DNS default domain name</td>
<td>None configured.</td>
</tr>
<tr>
<td>DNS servers</td>
<td>No name server addresses are configured.</td>
</tr>
</tbody>
</table>

**Setting Up DNS**

To set up your switch to use the DNS, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>configure terminal</td>
</tr>
<tr>
<td></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td>ip domain-name name</td>
</tr>
<tr>
<td></td>
<td>Defines a default domain name that the software uses to complete unqualified hostnames (names without a dotted-decimal domain name).</td>
</tr>
<tr>
<td></td>
<td>To remove a domain name, use the no ip domain-name name global configuration command.</td>
</tr>
<tr>
<td></td>
<td>Do not include the initial period that separates an unqualified name from the domain name.</td>
</tr>
<tr>
<td></td>
<td>At boot time, no domain name is configured; however, if the switch configuration comes from a BOOTP or Dynamic Host Configuration Protocol (DHCP) server, then the default domain name might be set by the BOOTP or DHCP server (if the servers were configured with this information).</td>
</tr>
<tr>
<td>Step 3</td>
<td>ip name-server server-address1 [server-address2 ... server-address6]</td>
</tr>
<tr>
<td></td>
<td>Specifies the address of one or more name servers to use for name and address resolution.</td>
</tr>
<tr>
<td></td>
<td>To remove a name server address, use the no ip name-server server-address global configuration command.</td>
</tr>
<tr>
<td></td>
<td>You can specify up to six name servers. Separate each server address with a space. The first server specified is the primary server. The switch sends DNS queries to the primary server first. If that query fails, the backup servers are queried.</td>
</tr>
</tbody>
</table>
Creating a Banner

If you use the switch IP address as its hostname, the IP address is used and no DNS query occurs. If you configure a hostname that contains no periods (.), a period followed by the default domain name is appended to the hostname before the DNS query is made to map the name to an IP address. The default domain name is the value set by the `ip domain-name` global configuration command. If there is a period (.) in the hostname, the Cisco IOS software looks up the IP address without appending any default domain name to the hostname.

Displaying the DNS Configuration

To display the DNS configuration information, use the `show running-config` privileged EXEC command.

Creating a Banner

You can configure a message-of-the-day (MOTD) and a login banner. The MOTD banner displays on all connected terminals at login and is useful for sending messages that affect all network users (such as impending system shutdowns).

The login banner also displays on all connected terminals. It appears after the MOTD banner and before the login prompts.

Note

For complete syntax and usage information for the commands used in this section, see the Cisco IOS Configuration Fundamentals Command Reference, Release 12.3.

These sections contain this configuration information:

- Default Banner Configuration, page 4-18
- Configuring a Message-of-the-Day Login Banner, page 4-18
- Configuring a Login Banner, page 4-19
Default Banner Configuration

The MOTD and login banners are not configured.

Configuring a Message-of-the-Day Login Banner

You can create a single or multiline message banner that appears on the screen when someone logs in to the switch.

To configure a MOTD login banner, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>configure terminal</strong></td>
</tr>
<tr>
<td></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><strong>banner motd c message c</strong></td>
</tr>
<tr>
<td></td>
<td>Specifies the message of the day.</td>
</tr>
<tr>
<td></td>
<td>To delete the MOTD banner, use the <strong>no banner motd</strong> global configuration command.</td>
</tr>
<tr>
<td></td>
<td>For <strong>c</strong>, enter the delimiting character of your choice, for example, a pound sign (#), and press the <strong>Return</strong> key. The delimiting character signifies the beginning and end of the banner text. Characters after the ending delimiter are discarded.</td>
</tr>
<tr>
<td></td>
<td>For <strong>message</strong>, enter a banner message up to 255 characters. You cannot use the delimiting character in the message.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><strong>end</strong></td>
</tr>
<tr>
<td></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><strong>show running-config</strong></td>
</tr>
<tr>
<td></td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><strong>copy running-config startup-config</strong></td>
</tr>
<tr>
<td></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

This example shows how to configure a MOTD banner for the switch by using the pound sign (#) symbol as the beginning and ending delimiter:

```
Switch(config)# banner motd #
This is a secure site. Only authorized users are allowed.
For access, contact technical support.
#
Switch(config)#
```

This example shows the banner that appears from the previous configuration:

```
Unix> telnet 172.2.5.4
Trying 172.2.5.4...
Connected to 172.2.5.4.
Escape character is '^]'.

This is a secure site. Only authorized users are allowed.
For access, contact technical support.

Managing the MAC Address Table

The MAC address table contains address information that the switch uses to forward traffic between ports. All MAC addresses in the address table are associated with one or more ports. The address table includes these types of addresses:

- Dynamic address—A source MAC address that the switch learns and then ages when it is not in use.
- Static address—A manually entered unicast address that does not age and that is not lost when the switch resets.

The address table lists the destination MAC address, the associated VLAN ID, and port number associated with the address and the type (static or dynamic).

Note

For complete syntax and usage information for the commands used in this section, see the command reference for this release.
These sections contain this configuration information:

- Building the Address Table, page 4-20
- MAC Addresses and VLANs, page 4-20

- Configuring MAC Threshold Notification Traps, page 4-26
- Adding and Removing Static Address Entries, page 4-27
- Configuring Unicast MAC Address Filtering, page 4-28
- Displaying Address Table Entries, page 4-30

**Building the Address Table**

With multiple MAC addresses supported on all ports, you can connect any port on the switch to individual workstations, repeaters, switches, routers, or other network devices. The switch provides dynamic addressing by learning the source address of packets it receives on each port and adding the address and its associated port number to the address table. As stations are added or removed from the network, the switch updates the address table, adding new dynamic addresses and aging out those that are not in use.

The aging interval is globally configured. However, the switch maintains an address table for each VLAN, and STP can accelerate the aging interval on a per-VLAN basis.

The switch sends packets between any combination of ports, based on the destination address of the received packet. Using the MAC address table, the switch forwards the packet only to the port associated with the destination address. If the destination address is on the port that sent the packet, the packet is filtered and not forwarded. The switch always uses the store-and-forward method: complete packets are stored and checked for errors before transmission.

**MAC Addresses and VLANs**

All addresses are associated with a VLAN. An address can exist in more than one VLAN and have different destinations in each. Unicast addresses, for example, could be forwarded to port 1 in VLAN 1 and ports 9, 10, and 1 in VLAN 5.

Each VLAN maintains its own logical address table. A known address in one VLAN is unknown in another until it is learned or statically associated with a port in the other VLAN.
When private VLANs are configured, address learning depends on the type of MAC address:

- Dynamic MAC addresses learned in one VLAN of a private VLAN are replicated in the associated VLANs. For example, a MAC address learned in a private-VLAN secondary VLAN is replicated in the primary VLAN.

- Static MAC addresses configured in a primary or secondary VLAN are not replicated in the associated VLANs. When you configure a static MAC address in a private VLAN primary or secondary VLAN, you should also configure the same static MAC address in all associated VLANs.

For more information about private VLANs, see Chapter 35, “Configuring Private VLANs.”

### Default MAC Address Table Configuration

Table 4-3 shows the default MAC address table configuration.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aging time</td>
<td>300 seconds</td>
</tr>
<tr>
<td>Dynamic addresses</td>
<td>Automatically learned</td>
</tr>
<tr>
<td>Static addresses</td>
<td>None configured</td>
</tr>
</tbody>
</table>

### Changing the Address Aging Time

Dynamic addresses are source MAC addresses that the switch learns and then ages when they are not in use. You can change the aging time setting for all VLANs or for a specified VLAN.

Setting too short an aging time can cause addresses to be prematurely removed from the table. Then when the switch receives a packet for an unknown destination, it floods the packet to all ports in the same VLAN as the receiving port. This unnecessary flooding can impact performance. Setting too long an aging time can cause the address table to be filled with unused addresses, which prevents new addresses from being learned. Flooding results, which can impact switch performance.

To configure the dynamic address table aging time, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Sets the length of time that a dynamic entry remains in the MAC address table after the entry is used or updated.</td>
</tr>
<tr>
<td>`mac address-table aging-time [0</td>
<td>10-1000000] vlan vlan-id]`</td>
</tr>
<tr>
<td></td>
<td>The range is 10 to 1000000 seconds. The default is 300. You can also enter 0, which disables aging. Static address entries are never aged or removed from the table.</td>
</tr>
<tr>
<td></td>
<td>For <code>vlan-id</code>, valid IDs are 1 to 4094.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><code>end</code></td>
<td></td>
</tr>
</tbody>
</table>
Removing Dynamic Address Entries

To remove all dynamic entries, use the `clear mac address-table dynamic` command in EXEC mode. You can also remove a specific MAC address (`clear mac address-table dynamic address mac-address`), remove all addresses on the specified physical port or port channel (`clear mac address-table dynamic interface interface-id`), or remove all addresses on a specified VLAN (`clear mac address-table dynamic vlan vlan-id`).

To verify that dynamic entries have been removed, use the `show mac address-table dynamic` privileged EXEC command.

Configuring MAC Change Notification Traps

MAC change notification enables you to track users on a network by storing the MAC change activity on the switch. Whenever the switch learns or removes a MAC address, an SNMP notification can be generated and sent to the network management system. If you have many users entering and exiting the network, you can set a trap interval time to bundle the notification traps and reduce network traffic. The MAC notification history table stores the MAC address activity for each hardware port for which the trap is enabled. MAC address notifications are generated for dynamic and static MAC addresses; events are not generated for self addresses or multicast addresses.

To send MAC change notification traps to an NMS host, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 4</td>
<td><code>show mac address-table aging-time</code> Verifies your entries.</td>
</tr>
<tr>
<td>Step 5</td>
<td><code>copy running-config startup-config</code> (Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>configure terminal</code> Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td>`snmp-server host host-addr [traps</td>
</tr>
</tbody>
</table>

- For `host-addr`, specify the name or address of the NMS.
- Specify `traps` (the default) to send SNMP traps to the host. Specify `informs` to send SNMP informs to the host.
- Specify the SNMP version to support. Version 1, the default, is not available with informs.
- For `community-string`, specify the string to send with the notification operation. Though you can set this string by using the `snmp-server host` command, we recommend that you define this string by using the `snmp-server community` command before using the `snmp-server host` command.
- For `notification-type`, use the `mac-notification` keyword.
### Managing the MAC Address Table

**Step 3**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>snmp-server enable traps mac-notification change</code></td>
<td>Enables the switch to send MAC change traps to the NMS. To disable the switch from sending MAC change notification traps, use the <code>no snmp-server enable traps mac-notification change</code> global configuration command.</td>
</tr>
</tbody>
</table>

**Step 4**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mac address-table notification change</code></td>
<td>Enables the MAC address change notification feature.</td>
</tr>
</tbody>
</table>

**Step 5**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| `mac address-table notification change [interval value] [history-size value]` | Enters the trap interval time and the history table size.  
  - (Optional) For `interval value`, specify the notification trap interval in seconds between each set of traps that are generated to the NMS. The range is 0 to 2147483647 seconds; the default is 1 second.  
  - (Optional) For `history-size value`, specify the maximum number of entries in the MAC notification history table. The range is 0 to 500; the default is 1. |

To disable the MAC change notification feature, use the `no mac address-table notification change` global configuration command.

**Step 6**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>interface interface-id</code></td>
<td>Enters interface configuration mode, and specify the interface on which to enable the SNMP MAC change notification trap.</td>
</tr>
</tbody>
</table>

**Step 7**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| `snmp trap mac-notification change {added | removed}` | Enables the MAC change notification trap.  
  - Enable the MAC change notification trap whenever a MAC address is `added` on this interface.  
  - Enable the MAC change notification trap whenever a MAC address is `removed` from this interface. |

To disable the MAC change notification traps on a specific interface, use the `no snmp trap mac-notification change {added | removed}` interface configuration command.

**Step 8**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>end</code></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
</tbody>
</table>

**Step 9**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show mac address-table notification change interface show running-config</code></td>
<td>Verifies your entries.</td>
</tr>
</tbody>
</table>

**Step 10**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>copy running-config startup-config</code></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>
This example shows how to specify 172.69.59.93 as the network management system, enable the switch to send MAC change notification traps to the network management system, enable the MAC change notification feature, set the interval time to 60 seconds, set the history-size to 100 entries, and enable traps whenever a MAC address is added on the specified port:

```
Switch# configure terminal
Switch(config)# snmp-server host 172.69.59.93 private mac-notification
Switch(config)# snmp-server enable traps mac-notification change
Switch(config)# mac address-table notification change
Switch(config)# mac address-table notification change interval 60
Switch(config)# mac address-table notification change history-size 100
Switch(config)# interface fastethernet0/2
Switch(config-if)# snmp trap mac-notification change added
Switch(config-if)# end
Switch# show mac address-table
MAC Notification Feature is Enabled on the switch
MAC Notification Flags For All Ethernet Interfaces:

<table>
<thead>
<tr>
<th>Interface</th>
<th>MAC Added Trap</th>
<th>MAC Removed Trap</th>
</tr>
</thead>
<tbody>
<tr>
<td>GigabitEthernet1/1</td>
<td>Enabled</td>
<td>Enabled</td>
</tr>
<tr>
<td>GigabitEthernet1/2</td>
<td>Enabled</td>
<td>Enabled</td>
</tr>
<tr>
<td>GigabitEthernet1/3</td>
<td>Enabled</td>
<td>Enabled</td>
</tr>
<tr>
<td>GigabitEthernet1/4</td>
<td>Enabled</td>
<td>Enabled</td>
</tr>
<tr>
<td>GigabitEthernet1/5</td>
<td>Enabled</td>
<td>Enabled</td>
</tr>
<tr>
<td>GigabitEthernet1/6</td>
<td>Enabled</td>
<td>Enabled</td>
</tr>
<tr>
<td>GigabitEthernet1/7</td>
<td>Enabled</td>
<td>Enabled</td>
</tr>
<tr>
<td>GigabitEthernet1/8</td>
<td>Enabled</td>
<td>Enabled</td>
</tr>
<tr>
<td>GigabitEthernet1/9</td>
<td>Enabled</td>
<td>Enabled</td>
</tr>
<tr>
<td>GigabitEthernet1/10</td>
<td>Enabled</td>
<td>Enabled</td>
</tr>
<tr>
<td>GigabitEthernet1/11</td>
<td>Enabled</td>
<td>Enabled</td>
</tr>
<tr>
<td>GigabitEthernet1/12</td>
<td>Enabled</td>
<td>Enabled</td>
</tr>
</tbody>
</table>
```

```
Switch#
```

**Configuring MAC Move Notification Traps**

When you configure MAC move notification, an SNMP notification is generated and sent to the network management system whenever a MAC address moves from one port to another within the same VLAN.
To configure MAC move notification, perform this task:

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
</tbody>
</table>

| Step 2 | snmp-server host host-addr [traps|informs] [version [1/2c/3]] [auth|noauth [priv] community-string [udp-port port]] [notification-type] | Specifies the recipient of the trap message. |
|        | | • For host-addr, specify the name or address of the NMS. |
|        | | • Specify traps (the default) to send SNMP traps to the host. Specify informs to send SNMP informs to the host. |
|        | | • Specify the SNMP version to support. Version 1, the default, is not available with informs. |
|        | | • For community-string, specify the string to send with the notification operation. Though you can set this string by using the snmp-server host command, we recommend that you define this string by using the snmp-server community command before using the snmp-server host command. |
|        | | • For notification-type, use the mac-notification keyword. |

| Step 3 | snmp-server enable traps mac-notification move | Enables the switch to send MAC move notification traps to the NMS. |
|        | | To disable the switch from sending MAC notification traps, use the no snmp-server enable traps mac-notification move global configuration command. |

| Step 4 | mac address-table notification mac-move | Enables the MAC-move notification feature. |
|        | | To disable this feature, use the no mac-address-table notification mac-move global configuration command. |

| Step 5 | end | Returns to privileged EXEC mode. |
|        | | |

| Step 6 | show mac address-table notification mac-move show running-config | Displays the MAC-move notification status. |

| Step 7 | copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

This example shows how to specify 172.69.59.93 as the network management system, enable the switch to send MAC move notification traps to the NMS, enable the MAC move notification feature, and enable traps whenever a MAC address moves from one port to another:

```
Switch# configure terminal
Switch(config)# snmp-server host 171.69.59.93 private mac-notification
Switch(config)# snmp-server enable traps mac-notification move
Switch(config)# mac address-table notification mac-move
Switch(config)# end
Switch# show mac address-table notification mac-move
MAC Move Notification: Enabled
```
### Configuring MAC Threshold Notification Traps

When you configure MAC threshold notification, an SNMP notification is generated and sent to the network management system when a MAC address table (MAT) threshold limit is reached or exceeded.

To configure MAC address threshold notification, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>snmp-server host host-addr [traps</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>snmp-server enable traps mac-notification threshold</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>mac address-table notification threshold</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>mac address-table notification threshold [limit percentage] [interval time]</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Managing the MAC Address Table

This example shows how to specify 172.69.59.93 as the network management system, enable the MAC threshold notification feature, enable the switch to send MAC threshold notification traps to the NMS, set the interval to 123 seconds, and set the limit to 78 per cent:

```
Switch# configure terminal
Switch(config)# snmp-server host 172.69.59.93 private mac-notification
Switch(config)# snmp-server enable traps mac-notification threshold
Switch(config)# mac address-table notification threshold
Switch(config)# mac address-table notification threshold interval 123
Switch(config)# mac address-table notification threshold limit 78
Switch(config)# end
```

```
Switch# show mac-address-table notification threshold
Status       limit        Interval
-------------+-----------+-------------
enabled        78           123
Switch#
```

Adding and Removing Static Address Entries

A static address has these characteristics:

- It is manually entered in the address table and must be manually removed.
- It can be a unicast or multicast address.
- It does not age and is retained when the switch restarts.

You can add and remove static addresses and define the forwarding behavior for them. The forwarding behavior defines how a port that receives a packet forwards it to another port for transmission. Because all ports are associated with at least one VLAN, the switch acquires the VLAN ID for the address from the ports that you specify. You can specify a different list of destination ports for each source port.

A packet with a static address that arrives on a VLAN where it has not been statically entered is flooded to all ports and not learned.

You add a static address to the address table by specifying the destination MAC unicast address and the VLAN from which it is received. Packets received with this destination address are forwarded to the interface specified with the interface-id option.

When you configure a static MAC address in a private-VLAN primary or secondary VLAN, you should also configure the same static MAC address in all associated VLANs. Static MAC addresses configured in a private-VLAN primary or secondary VLAN are not replicated in the associated VLAN. For more information about private VLANs, see Chapter 35, “Configuring Private VLANs.”
To add a static address, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>mac address-table static mac-addr vlan vlan-id interface interface-id</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>end</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>show mac address-table static</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>copy running-config startup-config</td>
</tr>
</tbody>
</table>

This example shows how to add the static address c2f3.220a.12f4 to the MAC address table. When a packet is received in VLAN 4 with this MAC address as its destination address, the packet is forwarded to the specified port:

```
Switch# configure terminal
Switch(config)# mac address-table static c2f3.220a.12f4 vlan 4 interface gigabitethernet0/1
Switch(config)# end
Switch#
```

### Configuring Unicast MAC Address Filtering

**Note**

Unicast MAC Address Filtering is not supported on Supervisor Engine 6-E.

When unicast MAC address filtering is enabled, the switch drops packets with specific source or destination MAC addresses. This feature is disabled by default and only supports unicast static addresses.

Follow these guidelines when using this feature:

- Multicast MAC addresses, broadcast MAC addresses, and router MAC addresses are not supported. If you specify one of these addresses when entering the `mac address-table static mac-addr vlan vlan-id drop` global configuration command, one of these messages appears:

  % Only unicast addresses can be configured to be dropped

  % CPU destined address cannot be configured as drop address
Packets that are forwarded to the CPU are also not supported.

If you add a unicast MAC address as a static address and configure unicast MAC address filtering, the switch either adds the MAC address as a static address or drops packets with that MAC address, depending on which command was entered last. The second command that you entered overrides the first command.

For example, if you enter the `mac address-table static mac-addr vlan vlan-id interface` global configuration command followed by the `mac address-table static mac-addr vlan vlan-id drop` command, the switch drops packets with the specified MAC address as a source or destination.

If you enter the `mac address-table static mac-addr vlan vlan-id drop` global configuration command followed by the `mac address-table static mac-addr vlan vlan-id interface` command, the switch adds the MAC address as a static address.

You enable unicast MAC address filtering and configure the switch to drop packets with a specific address by specifying the source or destination unicast MAC address and the VLAN from which it is received.

To configure the switch to drop a source or destination unicast static address, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>configure terminal</code> Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td><code>mac address-table static mac-addr vlan vlan-id drop</code> Enables unicast MAC address filtering and configure the switch to drop a packet with the specified source or destination unicast static address.</td>
</tr>
<tr>
<td></td>
<td>* For <code>mac-addr</code>, specify a source or destination unicast MAC address. Packets with this MAC address are dropped.</td>
</tr>
<tr>
<td></td>
<td>* For <code>vlan-id</code>, specify the VLAN for which the packet with the specified MAC address is received. Valid VLAN IDs are 1 to 4094.</td>
</tr>
<tr>
<td></td>
<td>To disable unicast MAC address filtering, use the <code>no mac address-table static mac-addr vlan vlan-id</code> global configuration command.</td>
</tr>
<tr>
<td>Step 3</td>
<td><code>end</code> Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Step 4</td>
<td><code>show mac address-table static</code> Verifies your entries.</td>
</tr>
<tr>
<td>Step 5</td>
<td><code>copy running-config startup-config</code> <em>(Optional)</em> Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

This example shows how to enable unicast MAC address filtering and to configure the switch to drop packets that have a source or destination address of `c2f3.220a.12f4`. When a packet is received in VLAN 4 with this MAC address as its source or destination, the packet is dropped:

```
Switch# configure terminal
Switch(config)# mac address-table static c2f3.220a.12f4 vlan 4 drop
Switch(config)# end
Switch# 
```
Displaying Address Table Entries

You can display the MAC address table by using one or more of the privileged EXEC commands described in Table 4-4:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ip igmp snooping groups</td>
<td>Displays the Layer 2 multicast entries for all VLANs or the specified VLAN.</td>
</tr>
<tr>
<td>show mac address-table address</td>
<td>Displays MAC address table information for the specified MAC address.</td>
</tr>
<tr>
<td>show mac address-table aging-time</td>
<td>Displays the aging time in all VLANs or the specified VLAN.</td>
</tr>
<tr>
<td>show mac address-table count</td>
<td>Displays the number of addresses present in all VLANs or the specified VLAN.</td>
</tr>
<tr>
<td>show mac address-table dynamic</td>
<td>Displays only dynamic MAC address table entries.</td>
</tr>
<tr>
<td>show mac address-table interface</td>
<td>Displays the MAC address table information for the specified interface.</td>
</tr>
<tr>
<td>show mac address-table notification</td>
<td>Displays the MAC notification parameters and history table.</td>
</tr>
<tr>
<td>show mac address-table static</td>
<td>Displays only static MAC address table entries.</td>
</tr>
<tr>
<td>show mac address-table vlan</td>
<td>Displays the MAC address table information for the specified VLAN.</td>
</tr>
</tbody>
</table>

Managing the ARP Table

To communicate with a device (over Ethernet, for example), the software first must learn the 48-bit MAC address or the local data link address of that device. The process of learning the local data link address from an IP address is called address resolution.

The Address Resolution Protocol (ARP) associates a host IP address with the corresponding media or MAC addresses and the VLAN ID. Using an IP address, ARP finds the associated MAC address. When a MAC address is found, the IP-MAC address association is stored in an ARP cache for rapid retrieval. Then the IP datagram is encapsulated in a link-layer frame and sent over the network. Encapsulation of IP datagrams and ARP requests and replies on IEEE 802 networks other than Ethernet is specified by the Subnetwork Access Protocol (SNAP). By default, standard Ethernet-style ARP encapsulation (represented by the arpa keyword) is enabled on the IP interface.

ARP entries added manually to the table do not age and must be manually removed.

For CLI procedures, see the Cisco IOS Release 12.3 documentation on Cisco.com.

Configuring Embedded CiscoView Support

The Catalyst 4500 series switch supports CiscoView web-based administration through the Catalyst Web Interface (CWI) tool. CiscoView is a device management application that can be embedded on the switch flash and provides dynamic status, monitoring, and configuration information for your switch. CiscoView displays a physical view of your switch chassis with color-coded modules and ports and monitoring capabilities that display the switch status, performance, and other statistics. Configuration capabilities allow comprehensive changes to devices, if the required security privileges have been granted. The configuration and monitoring capabilities for the Catalyst 4500 series of switches mirror those available in CiscoView in all server-based CiscoWorks solutions, including CiscoWorks LAN Management Solution (LMS) and CiscoWorks Routed WAN Management Solution (RWAN).
These sections describe the Embedded CiscoView support available with Cisco IOS Release 12.1(20)EW and later releases:

- Understanding Embedded CiscoView, page 4-31
- Installing and Configuring Embedded CiscoView, page 4-31
- Displaying Embedded CiscoView Information, page 4-33

**Understanding Embedded CiscoView**

The Embedded CiscoView network management system is a web-based interface that uses HTTP and SNMP to provide a graphical representation of the switch and to provide a GUI-based management and configuration interface.

**Installing and Configuring Embedded CiscoView**

To install and configure Embedded CiscoView, perform this task:

<table>
<thead>
<tr>
<th>Step</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Switch# <code>dir device_name</code></td>
<td>Displays the contents of the device. If you are installing Embedded CiscoView for the first time, or if the CiscoView directory is empty, skip to Step 5.</td>
</tr>
<tr>
<td>2</td>
<td>Switch# <code>delete device_name:cv/*</code></td>
<td>Removes existing files from the CiscoView directory.</td>
</tr>
<tr>
<td>3</td>
<td>Switch# <code>squeeze device_name:</code></td>
<td>Recovers the space in the file system.</td>
</tr>
<tr>
<td>4</td>
<td>Switch# <code>copy tftp bootflash</code></td>
<td>Copies the tar file to bootflash.</td>
</tr>
<tr>
<td>5</td>
<td>Switch# <code>archive tar /xtract tftp://ip address of tftp server/ciscoview.tar device_name:cv</code></td>
<td>Extracts the CiscoView files from the tar file on the TFTP server to the CiscoView directory.</td>
</tr>
<tr>
<td>6</td>
<td>Switch# <code>dir device_name:</code></td>
<td>Displays the contents of the device. In a redundant configuration, repeat Step 1 through Step 6 for the file system on the redundant supervisor engine.</td>
</tr>
<tr>
<td>7</td>
<td>Switch# <code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>8</td>
<td>Switch(config)# <code>ip http server</code></td>
<td>Enables the HTTP web server.</td>
</tr>
<tr>
<td>9</td>
<td>Switch(config)# <code>snmp-server community string ro</code></td>
<td>Configures the SNMP password for read-only operation.</td>
</tr>
<tr>
<td>10</td>
<td>Switch(config)# <code>snmp-server community string rw</code></td>
<td>Configures the SNMP password for read/write operation.</td>
</tr>
</tbody>
</table>

**Note**
The default password for accessing the switch web page is the enable-level password of the switch.

The following example shows how to install and configure Embedded CiscoView on your switch:

```

Configuring Supervisor Engine Redundancy Using RPR and SSO

Catalyst 4500 series switches allow a standby supervisor engine to take over if the active supervisor engine fails. In software, supervisor engine redundancy is enabled by running the redundant supervisor engine in route processor redundancy (RPR) or stateful switchover (SSO) operating mode.

The minimum ROMMON requirement for running SSO and RPR on Supervisor Engine 7-E is 15.0(1r)SG1.

This chapter describes how to configure supervisor engine redundancy on the Catalyst 4507R and Catalyst 4510R switches.

For information on Cisco nonstop forwarding (NSF) with SSO, see Chapter 9, “Configuring Cisco NSF with SSO Supervisor Engine Redundancy.”

This chapter contains these major sections:

- About Supervisor Engine Redundancy, page 5-2
- About Supervisor Engine Redundancy Synchronization, page 5-5
- Supervisor Engine Redundancy Guidelines and Restrictions, page 5-6
- Configuring Supervisor Engine Redundancy, page 5-7
- Performing a Manual Switchover, page 5-12
- Performing a Software Upgrade, page 5-13
- Manipulating Bootflash on the Standby Supervisor Engine, page 5-14
About Supervisor Engine Redundancy

These sections describe supervisor engine redundancy:

- Overview, page 5-2
- RPR Operation, page 5-3
- SSO Operation, page 5-3

Overview

With supervisor engine redundancy enabled, if the active supervisor engine fails or if a manual switchover is performed, the standby supervisor engine becomes the “new” active supervisor engine. The standby supervisor engine has been automatically initialized with the startup configuration of the active supervisor engine, shortening the switchover time (30 seconds or longer in RPR mode, depending on the configuration; subsecond in SSO mode).

In addition to the reduced switchover time, supervisor engine redundancy supports the following:

- Online insertion and removal (OIR) of the supervisor engine.
  Supervisor engine redundancy allows OIR of the redundant supervisor engine for maintenance. When the redundant supervisor engine is inserted, the active supervisor engine detects its presence, and the redundant supervisor engine boots into a partially-initialized state in RPR mode and a fully-initialized state in SSO mode.
- Software upgrade. (See the “Performing a Software Upgrade” section on page 5-13.)
  To minimize down time during software changes on the supervisor engine, load the new image on the standby supervisor engine, and conduct a switchover.

When power is first applied to a switch, the supervisor engine that boots first becomes the active supervisor engine and remains active until a switchover occurs.

A switchover will occur when one or more of the following events take place:

- The active supervisor engine fails (due to either hardware or software function) or is removed.
- A user forces a switchover.
- A user reloads the active supervisor engine.

Table 5-1 provides information about chassis and supervisor engine support for redundancy.
Chapter 5  Configuring Supervisor Engine Redundancy Using RPR and SSO

About Supervisor Engine Redundancy

RPR Operation

RPR is supported in Cisco IOS-XE Release 3.1.0 SG and later releases. When a standby supervisor engine runs in RPR mode, it starts up in a partially-initialized state and is synchronized with the persistent configuration of the active supervisor engine.

Note

Persistent configuration includes the following components: startup-config, boot variables, config-register, and VLAN database.

The standby supervisor engine pauses the startup sequence after basic system initialization, and in the event that the active supervisor engine fails, the standby supervisor engine becomes the new active supervisor engine.

In a supervisor engine switchover, traffic is disrupted because in the RPR mode all of the physical ports restart since there is no state maintained between supervisor engines relating to module types and statuses. Upon switchover, when the standby supervisor engine completes its initialization, it will read hardware information directly from the module and become the active supervisor engine.

SSO Operation

SSO is supported in Cisco IOS-XE Release 3.1.0 SG and later releases. When a standby supervisor engine runs in SSO mode, the standby supervisor engine starts up in a fully-initialized state and synchronizes with the persistent configuration and the running configuration of the active supervisor engine. It subsequently maintains the state on the protocols listed below, and all changes in hardware and software states for features that support stateful switchover are kept in synchronization. Consequently, it offers zero interruption to Layer 2 sessions in a redundant supervisor engine configuration.

Because the standby supervisor engine recognizes the hardware link status of every link, ports that were active before the switchover will remain active, including the uplink ports. However, because uplink ports are physically on the supervisor engine, they will be disconnected if the supervisor engine is removed.

If the active supervisor engine fails, the standby supervisor engine become active. This newly active supervisor engine uses existing Layer 2 switching information to continue forwarding traffic. Layer 3 forwarding will be delayed until the routing tables have been repopulated in the newly active supervisor engine.

</tbody>
</table>
SSO supports stateful switchover of the following Layer 2 features.

**Note** SSO is not supported if the IOS-XE software is running in the LAN Base mode.

The state of these features is preserved between both the active and standby supervisor engines:

- 802.3
- 802.3u
- 802.3x (Flow Control)
- 802.3ab (GE)
- 802.3z (Gigabit Ethernet including CWDM)
- 802.3ad (LACP)
- 802.1p (Layer 2 QoS)
- 802.1q
- 802.1X (Authentication)
- 802.1D (Spanning Tree Protocol)
- 802.3af (Inline power)
- PAgP
- VTP
- Dynamic ARP Inspection
- DHCP snooping
- IP source guard
- IGMP snooping (versions 1 and 2)
- DTP (802.1q and ISL)
- MST
- PVST+
- Rapid-PVST
- PortFast/UplinkFast/BackboneFast
- BPDU guard and filtering
- Voice VLAN
- Port security
- Unicast MAC filtering
- ACL (VACLs, PACLS, RACLs)
- QOS (DBL)
- Multicast storm control/broadcast storm control

SSO is compatible with the following list of features. However, the protocol database for these features is not synchronized between the standby and active supervisor engines:

- 802.1Q tunneling with Layer 2 Protocol Tunneling (L2PT)
- Baby giants
• Jumbo frame support
• CDP
• Flood blocking
• UDLD
• SPAN/RSPAN
• NetFlow

The following features are learned on the standby supervisor engine if the SSO feature is enabled:
• All Layer 3 protocols on Catalyst 4500 series switches (Switch Virtual Interfaces)

About Supervisor Engine Redundancy Synchronization

During normal operation, the persistent configuration (RPR and SSO) and the running configuration (SSO only) are synchronized by default between the two supervisor engines. In a switchover, the new active supervisor engine uses the current configuration.

Note
You cannot enter CLI commands on the standby supervisor engine console.

These sections describe supervisor engine redundancy synchronization:
• RPR Supervisor Engine Configuration Synchronization, page 5-5
• SSO Supervisor Engine Configuration Synchronization, page 5-6

RPR Supervisor Engine Configuration Synchronization

Because the standby supervisor engine is only partially initialized in RPR mode, it interacts with the active supervisor engine only to receive configuration changes at startup and upon saving the configuration changes.

When a standby supervisor engine is running in RPR mode, the following events trigger synchronization of the configuration information:
• When the standby supervisor engine boots, the auto-sync command synchronizes the persistent configuration. This command is enabled by default. For details, refer to “Synchronizing the Supervisor Engine Configurations” section on page 5-11.
• When the active supervisor engine detects the standby supervisor engine, the configuration information is synchronized from the active supervisor engine to the standby supervisor engine. This synchronization overwrites any existing startup configuration file on the standby supervisor engine.
• When you make changes to the configuration, you must use the write command to save and synchronize the startup configuration to the standby supervisor engine.
SSO Supervisor Engine Configuration Synchronization

When a standby supervisor engine runs in SSO mode, the following events trigger synchronization of the configuration information:

- When the active supervisor detects the standby supervisor engine, synchronization of the persistent and running configuration takes place, allowing the standby supervisor engine to arrive at a fully-initiated state.
- When real-time changes occur, the active supervisor engine synchronizes the running-config and (or) the persistent configuration (if necessary) with the standby supervisor engine.
- When you change the configuration, you must use the write command to allow the active supervisor engine to save and synchronize the startup configuration to the standby supervisor engine.

Supervisor Engine Redundancy Guidelines and Restrictions

The following guidelines and restrictions apply to supervisor engine redundancy:

- If SSO mode cannot be established between the active and standby supervisor engines because of an incompatibility in the configuration file, a mismatched command list (MCL) is generated at the active supervisor engine and a reload into RPR mode is forced for the standby supervisor engine. Subsequent attempts to establish SSO, after removing the offending configuration and rebooting the standby supervisor engine with the exact same image, might cause the C4K_REDUNDANCY-2-IOS_VERSION_CHECK_FAIL and ISSU-3-PEER_IMAGE_INCOMPATIBLE messages to appear because the peer image is listed as incompatible. If the configuration problem can be corrected, you can clear the peer image from the incompatible list with the redundancy config-sync ignore mismatched-commands EXEC command while the peer is in a standby cold (RPR) state. This action allows the standby supervisor engine to boot in standby hot (SSO) state when it reloads.

Here are the steps:

**Step 1** Clear the offending configuration (that caused an MCL) while the standby supervisor engine is in standby cold (RPR) state.

**Step 2** Enter the redundancy config-sync ignore mismatched-commands EXEC command at the active standby supervisor engine.

**Step 3** Perform write memory.

**Step 4** Reload the standby supervisor engine with the redundancy reload peer command.

- RPR and SSO requires Cisco IOS-XE Release 3.1.0 SG and later releases.
- SSO is not supported if the IOS-XE software is running in the LAN Base mode.
- WS-C4507R-E, WS-C4510R-E, WS-C4507R+E, and WS-C4510R+E are the only Catalyst 4500 series switches that support Supervisor Engine 7-E redundancy.
- SSO requires both supervisor engines in the chassis to have the same components (model and memory), and to use the same Cisco IOS XE software image.
- When you use WS-X45-SUP7-E in RPR or SSO mode, only the first two uplinks on each supervisor engine are available. The second two uplinks are unavailable.
• The active and standby supervisor engines in the chassis must be in slots 3 and 4 for 7-slot chassis and slot 5 and 6 for 10-slot chassis.
• Each supervisor engine in the chassis must have its own flash device and console port connections to operate the switch on its own.
• Each supervisor engine must have a unique console connection. Do not connect a Y cable to the console ports.
• Supervisor engine redundancy does not provide supervisor engine load balancing.
• The Cisco Express Forwarding (CEF) table is cleared on a switchover. As a result, routed traffic is interrupted until route tables reconverge. This reconvergence time is minimal because the SSO feature reduces the supervisor engine redundancy switchover time from 30+ seconds to subsecond, so Layer 3 also has a faster failover time if the switch is configured for SSO.
• Static IP routes are maintained across a switchover because they are configured from entries in the configuration file.
• Information about Layer 3 dynamic states that is maintained on the active supervisor engine is not synchronized to the standby supervisor engine and is lost on switchover.
• If configuration changes on a redundant switch are made through SNMP set operations, the changes are not synchronized to the standby supervisor engine even in SSO mode. You might experience unexpected behavior.
• After you configure the switch through SNMP in SSO mode, copy the running-config file to the startup-config file on the active supervisor engine to trigger synchronization of the startup-config file to the standby supervisor engine. Then, reload the standby supervisor engine so that the new configuration is applied on the standby supervisor engine.
• You cannot perform configuration changes during the startup (bulk) synchronization. If you attempt to make configuration changes during this process, the following message is generated:
  Config mode locked out till standby initializes
• If configuration changes occur at the same time as a supervisor engine switchover, these configuration changes are lost.
• If you remove a line card from a redundant switch and initiate an SSO switchover, then reinsert the line card, and all interfaces are shutdown. The rest of the original line card configuration is preserved.
  This situation only occurs if a switch had reached SSO before you removed the line card.

Configuring Supervisor Engine Redundancy

These sections describe how to configure supervisor engine redundancy:
• Configuring Redundancy, page 5-8
• Virtual Console for Standby Supervisor Engine, page 5-9
• Synchronizing the Supervisor Engine Configurations, page 5-11
Configuring Redundancy

Note

IOS XE software can be booted at three different levels (Enterprise Services, IP Base, and LAN Base), based on the licenses available on the supervisor engine. If you are booting the image in LAN Base mode, only RPR redundancy mode is available.

To configure redundancy, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch(config)# redundancy</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config-red)# mode {sso</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch# show running-config</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch# show redundancy [clients</td>
</tr>
</tbody>
</table>

This example shows how to configure the system for SSO and display the redundancy facility information:

```
Switch> enable
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# redundancy
Switch(config-red)# mode sso
Switch(config-red)# end

Switch# show redundancy
Redundant System Information :

-----------------------------
Available system uptime = 10 minutes Switchovers system experienced = 0
Standby failures = 1
Last switchover reason = none

Hardware Mode = Duplex
Configured Redundancy Mode = Stateful Switchover
Operating Redundancy Mode = Stateful Switchover
Maintenance Mode = Disabled
Communications = Up

Current Processor Information :

------------------------------
Active Location = slot 3
Current Software state = ACTIVE
Uptime in current state = 9 minutes

Image Version = Cisco IOS Software, Catalyst 4500 L3 Switch Software (cat4500e-UNIVERSALK9-M), Version 15.0(100)XO(1.42), INTERIM SOFTWARE Copyright (c) 1986-2010 by Cisco Systems, Inc.
Compiled Sun 01-Aug-10 04:12 by gsbuprod
Configuration register = 0x920

Peer Processor Information :

----------------------------
Standby Location = slot 4
```
This example shows how to display redundancy facility state information:

Switch# show redundancy states
    my state = 13 -ACTIVE
    peer state = 8 -STANDBY HOT
    Mode = Duplex
    Unit = Primary
    Unit ID = 3

Redundancy Mode (Operational) = Stateful Switchover
Redundancy Mode (Configured) = Stateful Switchover
Redundancy State = Stateful Switchover
Manual Swact = enabled

Communications = Up
    client count = 64
    client_notification_TMR = 240000 milliseconds
    keep_alive TMR = 9000 milliseconds
    keep_alive count = 1
    keep_alive threshold = 18
    RF debug mask = 0

This example shows how to change the system configuration from RPR to SSO mode:

Switch(config)# redundancy
Switch(config-red)# mode
Switch(config-red)# mode sso
Changing to sso mode will reset the standby. Do you want to continue?[confirm]
Switch(config-red)# end
Switch#
*Aug  1 13:11:16: %C4K_REDUNDANCY-3-COMMUNICATION: Communication with the peer Supervisor has been lost
*Aug  1 13:11:16: %C4K_REDUNDANCY-3-SIMPLEX_MODE: The peer Supervisor has been lost

This example shows how to change the system configuration from SSO to RPR mode:

Switch(config)# redundancy
Switch(config-red)# mode rpr
Changing to rpr mode will reset the standby. Do you want to continue?[confirm]
Switch(config-red)# end
*Aug  1 13:11:16: %C4K_REDUNDANCY-3-COMMUNICATION: Communication with the peer Supervisor has been lost
*Aug  1 13:11:16: %C4K_REDUNDANCY-3-SIMPLEX_MODE: The peer Supervisor has been lost

Virtual Console for Standby Supervisor Engine

Catalyst 4500 series switches can be configured with 2 supervisor engines to provide redundancy. When the switch is powered, one of the supervisor engines becomes active and remains active until a switchover occurs. The other supervisor engine remains in standby mode.

Each supervisor engine has its own console port. Access to the standby supervisor engine is possible only through the console port of the standby supervisor engine. Therefore, you must connect to the standby console to access, monitor or debug the standby supervisor.
Virtual Console for Standby Supervisor Engine enables you to access the standby console from the active supervisor engine without requiring a physical connection to the standby console. It uses IPC over EOBC to communicate with the standby supervisor engine and thus emulate the standby console on the active supervisor engine. Only one standby console session is active at any time.

The Virtual Console for Standby Supervisor Engine allows users who are logged onto the active supervisor engine to remotely execute `show` commands on the standby supervisor engine and view the results on the active supervisor engine. Virtual Console is available only from the active supervisor engine.

You can access the standby virtual console from the active supervisor engine with the `attach module`, `session module`, or `remote login` commands on the active supervisor engine. You must be in privilege EXEC mode (level 15) to run these commands to access the standby console.

Once you enter the standby virtual console, the terminal prompt automatically changes to `hostname-standby-console` where `hostname` is the configured name of the switch. The prompt is restored back to the original prompt when you exit the virtual console.

You exit the virtual console with the `exit` or `quit` commands. When the inactivity period of the terminal on the active supervisor engine where you logged in exceeds the configured idle time, you are automatically logged out of the terminal on the active supervisor engine. In such a case, the virtual console session is also terminated. Virtual console session is also automatically terminated when the standby is rebooted. After the standby boots up, you need to create another virtual console session.

To log in to the standby supervisor engine using a virtual console, do the following:

```
Switch# session module 4
Connecting to standby virtual console
Type "exit" or "quit" to end this session
Switch-standby-console# exit
Switch#
```

If the standby console is not enabled, the following message appears:

```
Switch-standby-console#
Standby console disabled.
Valid commands are: exit, logout
```

The standby virtual console provides the standard features that are available from the supervisor console such as command history, command completion, command help and partial command keywords.

The following limitations apply to the standby virtual console:

- All commands on the virtual console run to completion. It does not provide the auto-more feature; it behaves as if the `terminal length 0` command has been executed. It is also non-interactive. Therefore, a running command cannot be interrupted or aborted by any key sequence on the active supervisor engine. If a command produces considerable output, the virtual console displays it on the supervisor engine screen.
- The virtual console is non-interactive. Because the virtual console does not detect the interactive nature of a command, any command that requires user interaction causes the virtual console to wait until the RPC timer aborts the command.

The virtual console timer is set to 60 seconds. The virtual console returns to its prompt after 60 seconds. During this time, you cannot abort the command from the keyboard. You must wait for the timer to expire before you continue.
You cannot use virtual console to view debug and syslog messages that are being displayed on the standby supervisor engine. The virtual console only displays the output of commands that are executed from the virtual console. Other information that is displayed on the real standby console does not appear on the virtual console.

### Synchronizing the Supervisor Engine Configurations

To manually synchronize the configurations used by the two supervisor engines, perform this task on the active supervisor engine:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch(config)# redundancy</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config-red)# main-cpu</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config-r-mc)# auto-sync {startup-config</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config-r-mc)# end</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch# copy running-config startup-config</td>
</tr>
</tbody>
</table>

**Note** Configuration changes made to the active supervisor engine through SNMP are not synchronized to the redundant supervisor engine. For information on how to handle this situation, see the “Supervisor Engine Redundancy Guidelines and Restrictions” section on page 5-6.

**Note** The `auto-sync` command controls the synchronization of the config-reg, bootvar, and startup/private configuration files only. The calendar and VLAN database files are always synchronized when they change. In SSO mode, the running-config is always synchronized.

This example shows how to reenable the default automatic synchronization feature using the `auto-sync standard` command to synchronize the startup-config and config-register configuration of the active supervisor engine with the standby supervisor engine. Updates for the boot variables are automatic and cannot be disabled.

Switch(config)# redundancy
Switch(config-red)# main-cpu
Switch(config-r-mc)# auto-sync standard
Switch(config-r-mc)# end
Switch# copy running-config startup-config

**Note** To manually synchronize individual elements of the standard auto-sync configuration, disable the default automatic synchronization feature.
Performing a Manual Switchover

This section describes how to perform a manual switchover (from the active supervisor engine to the standby supervisor engine) for test purposes. We recommend that you perform a manual switchover prior to deploying SSO in your production environment.

Note
This discussion assumes that SSO has been configured as the redundant mode.

To perform a manual switchover, perform this task on the active supervisor engine:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# show redundancy</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch# redundancy force-switchover</td>
</tr>
</tbody>
</table>

Be aware of these usage guidelines:

- force a switchover, the redundant supervisor engine must be in a standby hot (SSO) or standby cold (RPR) state. You can verify the state with the `show redundancy` command. If the state is not standby hot or standby cold, the `redundancy force-switchover` command will not execute.

- Use the `redundancy force-switchover` command, rather than the `reload` command, to initiate a switchover. The `redundancy force-switchover` command will first check that the redundant supervisor engine is in the correct state. If you issue the `reload` command and the status is not standby hot or standby cold, the `reload` command will reset the current supervisor engine and the peer supervisor may not be able to take over because it was not in a terminsal state (standby hot or cold).

After a normal switchover, you might want to make the supervisor engine in a lower slot number of the chassis the active supervisor engine. Use the `show module` command to see which slot contains the active supervisor engine, and force another switchover if necessary.
Performing a Software Upgrade

This is useful only if IOS-XE software is running in LAN Base mode. For Enterprise Services or IP Base mode, use ISSU to upgrade software for both RPR and SSO redundant mode.

The software upgrade procedure supported by supervisor engine redundancy allows you to reload the Cisco IOS software image on the redundant supervisor engine, and once complete, reload the active supervisor engine once.

To perform a software upgrade, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# <code>copy source_device:source_filename slot0:target_filename</code>&lt;br&gt;Or:&lt;br&gt;Switch# <code>copy source_device:source_filename bootflash:target_filename</code></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch# <code>copy source_device:source_filename slaveslot0:target_filename</code>&lt;br&gt;Or:&lt;br&gt;Switch# <code>copy source_device:source_filename slavebootflash:target_filename</code></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch# <code>config terminal</code>&lt;br&gt;Switch(config)# <code>config-register 0x2</code>&lt;br&gt;Switch(config)# <code>boot system flash device:file_name</code></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config)# <code>redundancy</code></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch(config-red)# <code>main-cpu</code></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Switch(config-r-mc)# <code>auto-syn standard</code></td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>Switch(config-r-mc)# <code>end</code></td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>Switch# <code>copy running-config start-config</code></td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>Switch# <code>redundancy reload peer</code></td>
</tr>
<tr>
<td><strong>Step 10</strong></td>
<td>Switch# <code>redundancy force-switchover</code></td>
</tr>
</tbody>
</table>

This example shows how to perform a software upgrade:

Switch# `config terminal`<br>Switch(config)# `config-register 0x2`
Manipulating Bootflash on the Standby Supervisor Engine

Note: The console port on the standby supervisor engine is not available.

To manipulate the standby supervisor engine bootflash, perform one or more of the following tasks:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# dir slaveslot0:target_filename</td>
<td>Lists the contents of the slot0: device on the standby supervisor engine.</td>
</tr>
<tr>
<td>or Switch# dir slavebootflash:target_filename</td>
<td>Lists the contents of the bootflash: device on the standby supervisor engine.</td>
</tr>
<tr>
<td>Switch# delete slaveslot0:target_filename</td>
<td>Deletes specific files from the slot0: device on the standby supervisor engine.</td>
</tr>
<tr>
<td>or Switch# delete slave bootflash:target_filename</td>
<td>Deletes specific files from the bootflash: device on the standby supervisor engine.</td>
</tr>
<tr>
<td>Switch# squeeze slaveslot0:</td>
<td>Squeezes the slot0: device on the standby supervisor engine.</td>
</tr>
<tr>
<td>or Switch# squeeze slavebootflash:</td>
<td>Squeezes the bootflash: device on the standby supervisor engine.</td>
</tr>
</tbody>
</table>
## Manipulating Bootflash on the Standby Supervisor Engine

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Switch# format slaveslot0:</code></td>
<td>Formats the slot0: device on the standby supervisor engine.</td>
</tr>
<tr>
<td>or <code>Switch# format slavebootflash:</code></td>
<td>Formats the bootflash: device on the standby supervisor engine.</td>
</tr>
<tr>
<td><code>Switch# copy source_device:source_filename slaveslot0:target_filename</code></td>
<td>Copies a file from the active supervisor engine to the slot0: device on the standby supervisor engine.</td>
</tr>
<tr>
<td>or <code>Switch# copy source_device:source_filename slavebootflash:target_filename</code></td>
<td>Copies a file to the bootflash: device on a standby supervisor engine.</td>
</tr>
</tbody>
</table>

**Note**  
Source could be the active supervisor engine or a TFTP server.
ISSU is available in Cisco IOS XE 3.1.0.SG and later releases.

Operating on redundant systems, the In Service Software Upgrade (ISSU) process allows Cisco IOS XE software to be updated or otherwise modified while packet forwarding continues. In most networks, planned software upgrades are a significant cause of downtime. ISSU allows Cisco IOS XE software to be upgraded while packet forwarding continues. This increases network availability and reduces downtime caused by planned software upgrades. This document provides information about ISSU concepts and describes the steps taken to perform ISSU in a system.

Topics include:

- Prerequisites to Performing ISSU, page 6-2
- About Performing ISSU, page 6-3
- How to Perform the ISSU Process, page 6-15
- Cisco High Availability Features in Cisco IOS XE 3.1.0 SG, page 6-35

For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Cisco IOS Command Reference and related publications at this location:

Prerequisites to Performing ISSU

Before performing ISSU, you must meet these prerequisites:

- The type of the existing and target image must match. You cannot upgrade from a Universal Lite image to a Universal image (and vice versa) without experiencing several minutes of traffic loss. The same restriction applies between crypto and non-crypto images.

- The active and the standby supervisor engines must have the same supervisor engine hardware (same model, same memory, and so on).

- The new and old Cisco IOS XE software images must be loaded into the file systems (bootflash, SD card, or USB) of both the active and the standby supervisor engines before you begin the ISSU process.

  The old software image should be available either in bootflash, SD card, or USB and the system should have been booted from one of these locations because the boot variable must be changed before the ISSU process starts.

  **Note**  
  auto-boot must be enabled for ISSU to succeed.

  - Stateful Switchover (SSO) must be configured and the standby supervisor engine should be in STANDBY HOT state.

    These commands indicate whether SSO is enabled: `show module`, `show running-config`, `show redundancy state`.

    If you do not have SSO enabled, see the Stateful Switchover document for further information on how to enable and configure SSO.

  - Nonstop Forwarding (NSF) must be configured and working properly. If you do not have NSF enabled, see the Cisco Nonstop Forwarding document for further information on how to enable and configure NSF.

  - Before you perform ISSU, ensure that the file system for both the active and the standby supervisor engines contains the new ISSU-compatible IOS XE software. The current Cisco IOS XE version running in the system must also support ISSU.

    You can enter various commands on the Catalyst 4500 series switch to determine supervisor engine versioning and Cisco IOS XE software compatibility. Alternatively, you can use the ISSU application on Cisco Feature Navigator to determine this.
If you enter the `no ip routing` command, ISSU falls back from SSO to RPR mode, resulting in traffic loss.

Autoboot is turned on and the current booted image matches the one specified in the BOOT environmental variable. For details on how to configure and verify these, please refer to "Modifying the Boot Field and Using the boot Command, page 3-27.

If you enter the `no ip routing` command, ISSU falls back from SSO to RPR mode, resulting in traffic loss.

About Performing ISSU

**Note**

Do not make any hardware changes while performing ISSU.

Before you perform ISSU, you should understand the following concepts:

- Stateful Switchover, page 6-3
- NSF, page 6-5
- ISSU Process, page 6-6
- Performing an ISSU Upgrade: 2 Methods, page 6-11
- Changeversion Process, page 6-12
- Guidelines for Performing ISSU, page 6-13
- Compatibility Matrix, page 6-13
- SNMP Support for ISSU, page 6-14
- Compatibility Verification Using Cisco Feature Navigator, page 6-14

Stateful Switchover

Development of the SSO feature is an incremental step within an overall program to improve the availability of networks constructed with Cisco IOS XE switches.

In specific Cisco networking devices that support dual supervisor engines, SSO takes advantage of supervisor engine redundancy to increase network availability. SSO achieves this by establishing one of the supervisor engines as the active processor while the other supervisor engine is designated as the standby processor. Following an initial synchronization between the two supervisor engines, SSO dynamically synchronizes supervisor engine state information between them in real-time.

A switchover from the active to the standby supervisor engine occurs when the active supervisor engine fails or is removed from the networking device.

Cisco NSF is used with SSO. Cisco NSF allows the forwarding of data packets to continue along known routes while the routing protocol information is being restored following a switchover. With Cisco NSF, peer networking devices do not experience routing flaps, which reduce loss of service outages for customers.

**Figure 6-1** illustrates how SSO is typically deployed in service provider networks. In this example, Cisco NSF with SSO is enabled at the access layer (edge) of the service provider network. A fault at this point could result in loss of service for enterprise customers requiring access to the service provider network.
For Cisco NSF protocols that require neighboring devices to participate in Cisco NSF, Cisco NSF-aware software images must be installed on those neighboring distribution layer devices. Depending on your objectives, you may decide to deploy Cisco NSF and SSO features at the core layer of your network. Doing this can help reduce the time required to restore network capacity and service for certain failures, which leads to additional availability.

Figure 6-1  Cisco NSF with SSO Network Deployment: Service Provider Networks

Additional levels of availability may be gained by deploying Cisco NSF with SSO at other points in the network where a single point of failure exists. Figure 6-2 illustrates an optional deployment strategy that applies Cisco NSF with SSO at the enterprise network access layer. In this example, each access point in the enterprise network represents another single point of failure in the network design. In the event of a switchover or a planned software upgrade, enterprise customer sessions would continue uninterrupted through the network in this example.
Cisco NSF works with the SSO feature in Cisco IOS XE software. SSO is a prerequisite of Cisco NSF. NSF works with SSO to minimize the amount of time a network is unavailable to its users following a switchover. The main objective of Cisco NSF is to continue forwarding IP packets following a supervisor engine switchover.

Usually, when a networking device restarts, all routing peers of that device detect that the device went down and then came back up. This transition results in what is called a routing flap, which could spread across multiple routing domains. Routing flaps caused by routing restarts create routing instabilities, which are detrimental to the overall network performance. Cisco NSF helps to suppress routing flaps in SSO-enabled devices, thus reducing network instability.

Cisco NSF allows for the forwarding of data packets to continue along known routes while the routing protocol information is being restored following a switchover. With Cisco NSF, peer networking devices do not experience routing flaps. Data traffic is forwarded while the standby supervisor engine assumes control from the failed active supervisor engine during a switchover. The ability of physical links to remain up through a switchover and to be kept current with the Forwarding Information Base (FIB) on the active supervisor engine is key to Cisco NSF operation.

For further information on SSO, see the *Stateful Switchover* document.
ISSU Process

The ISSU process allows you to perform a Cisco IOS XE software upgrade or downgrade while the system continues to forward packets. (For an illustration of the commands used during the ISSU process, refer to Figure 6-8.) Cisco IOS XE ISSU takes advantage of the Cisco IOS XE high availability infrastructure—Cisco NSF with SSO and hardware redundancy—and eliminates downtime associated with software upgrades by allowing changes while the system remains in service (see Figure 6-3).

SSO and NSF mode support configuration and runtime state synchronization from the active to the standby supervisor engine. For this process, the IOS XE software image on both the active and the standby supervisor engines must be the same. When images on active and standby supervisor engines are different, ISSU allows the two supervisor engines to be kept in synchronization even when these two versions of Cisco IOS XE support different sets of features and commands.

Figure 6-3  High Availability Features and Hardware Redundancy in the ISSU Process
An ISSU-capable switch consists of two supervisor engines (active and standby) and 200 or more linecards. Before initiating the ISSU process, copy the Cisco IOS XE software into the file systems of both supervisor engines (see Figure 6-4).

**Note**

In the following figure, Cisco IOS XE 3.x.y SG represents the current version of Cisco IOS XE 3.z.y SG represents the image you are migrating to.

**Figure 6-4** Copy New Version of Cisco IOS XE Software on Both Supervisor Engines
After you have copied the Cisco IOS XE software to both file systems, load the new version of Cisco IOS XE software onto the standby supervisor engine (see Figure 6-5).

**Note**
Without the ISSU feature, SSO/NSF cannot function between the active and standby supervisor engines when they are running different versions of the Cisco IOS XE image.

**Figure 6-5 Load New Version of Cisco IOS XE Software on the Standby Supervisor Engine**
After a switchover (NSF/SSO, not RPR), the standby supervisor engine takes over as the new active supervisor engine (see Figure 6-6).

**Figure 6-6  Switch Over to Standby Supervisor Engine**
The former active supervisor engine is loaded with an old Cisco IOS XE image so that if the new active supervisor engine experiences problems, you can abort and conduct a switchover to the former active, which is already running the old software image. Next, the former active supervisor engine is loaded with the new version of Cisco IOS XE software and becomes the new standby supervisor engine (see Figure 6-7).

Figure 6-7 Load New Standby Supervisor Engine with New Cisco IOS XE Software
Figure 6-8 shows the steps during the ISSU process.

**Note**

*Acceptversion* stops the rollback timer.

### Performing an ISSU Upgrade: 2 Methods

There are two ways to perform an ISSU upgrade: manually, with four commands; or automatically, with one command.

The normal ISSU upgrade process involves issuing four separate ISSU exec commands (*issu loadversion*, *issu runversion*, *issu acceptversion*, *issue commitversion*) along with additional show command invocations to evaluate the success of each command before proceeding. Although the ISSU process is complicated, you should not expect disruption of service. The use of multiple ISSU commands dictates an additional level of care to ensure no service disruption. However, in some scenarios, this upgrade procedure might be cumbersome and of minimal value. A typical example is during a network upgrade that involves performing an ISSU upgrade on a large number of Catalyst 4500 switches. In these cases, we recommend that you first perform the normal (four command) ISSU upgrade procedure on one switch (possibly in a lab environment) to verify successful upgrade. Then, use a single *issu changeversion* command to perform an automatic ISSU on the rest of the Catalyst 4500 switches in the network.
Changeversion Process

The **issu changeversion** command launches a single-step complete ISSU upgrade cycle. It performs the logic for all four of the standard commands (**issu loadversion**, **issu runversion**, **issu acceptversion**, and **issu commitversion**) without user intervention, streamlining the upgrade through a single CLI step.

Additionally, **issu changeversion** allows the upgrade process to be scheduled for a future time. This enables you to stage a number of systems to perform upgrades sequentially when a potential disruption would be least harmful.

After the standby supervisor engine initializes and the system reaches a terminal state (RPR/SSO), the upgrade process is complete and the BOOT variable is permanently written with the new IOS XE software image. Hence, a reset on any RP will keep the system booting the new software image. Console and syslog messages will be generated to notify anyone monitoring the upgrade that the state transition has occurred.

Similar to the normal ISSU upgrade procedure, the in-progress upgrade procedure initiated by the **issu changeversion** command can be aborted with the **issu abortversion** command. If the system detects any problems or detects an unhealthy system during an upgrade, the upgrade might be automatically aborted.

When the **issu runversion** command is entered during the four step manual upgrade process, if any incompatible ISSU clients exist, the upgrade process reports them and their side effects, and allows the user to abort the upgrade. While performing a single-step upgrade process, when the process reaches the runversion state, it will either automatically continue with the upgrade provided the base clients are compatible, or automatically abort because of client incompatibility. If the user wants to continue the upgrade procedure in RPR mode, the user must use the normal ISSU command set and specify the **force** option when entering the **issu loadversion** command.

Changeversion: Quick Option (LV to INIT)

The **issu changeversion** command provides an optional quick command option that can reduce the time required to perform the automatic ISSU upgrade. When the **quick** command option is applied, the ISSU upgrade state transition differs from that described previously. With this option, the software logic up the loadversion stage remains the same as previously described, and the logic that performs runversion and commitversion is combined. This logic skips the step in the upgrade procedure that loads the old software version on the new standby (old active) supervisor, reducing the time required for the automatic ISSU upgrade by about a third.

Scheduled Changeversion: “in” and “at” Options

**issu changeversion** provides **in** and **at** command options that enable you to schedule a future automatic ISSU upgrade.

The **at** command option schedules an automatic ISSU upgrade to begin at a specific time. This option specifies an exact time (hh:mm, 24 hour format) in the next 24 hours at which the upgrade will occur.

The **in** command option schedules an automatic ISSU upgrade to begin after a certain amount of time has elapsed. This option specifies the number of hours and minutes (hh:mm format) that must elapse before an upgrade will occur, with a maximum value of 99:59.
Changeversion Deployment Scenario

The typical `issu changeversion` command usage scenario is for experienced users with a large installed base. These users typically validate a new image using a topology and configuration similar to their production network. The validation process should be done using both the existing multi-command process and the new `issu changeversion` command process. Once users certify an IOS XE software image and want to roll it out broadly, they can use the single command process to perform an efficient upgrade of their network.

Aborting an In-Progress Changeversion Procedure

The `issu changeversion` command functionality is designed to perform an ISSU software upgrade without user intervention. However, status messages are displayed to the console as the upgrade transitions through the various states. If any anomalies are noticed during the automatic upgrade, perhaps with peers or other parts of the network, you can use the `issu abortversion` command to manually abort the upgrade at any point in the process prior to the commitversion operation.

Guidelines for Performing ISSU

Be aware of the following guidelines while performing the ISSU process:

- Even with ISSU, it is recommended that upgrades be performed during a maintenance window.
- The new features should not be enabled (if they require change of configuration) during the ISSU process.

*Note* Enabling them will cause the system to enter RPR mode because commands are only supported on the new version.

- In a downgrade scenario, if any feature is not available in the downgrade revision of the Cisco IOS XE software handle, that feature should be disabled prior to initiating the ISSU process.

Compatibility Matrix

ISSU requires additional information to determine compatibility between software versions. Therefore, a compatibility matrix is defined that contains information about other IOS XE software image with respect to the one in question.

This compatibility matrix represents the compatibility of two software versions, one running on the active and the other on the standby supervisor engine, and to allow the system to determine the highest operating mode it can achieve. Incompatible versions will not be able to progress to SSO operational mode.
The compatibility matrix represents the compatibility relationship a Cisco IOS XE software image has with all of the other Cisco IOS XE software versions within the designated support window (for example, all of those software versions the IOS XE software image “knows” about) and is populated and released with every IOS XE software image. The matrix stores compatibility information between its own release and prior releases. It is always the newest release that contains the latest information about compatibility with existing releases in the field. The compatibility matrix is available within the Cisco IOS XE software image and on Cisco.com so that users can determine in advance whether an upgrade can be done using the ISSU process.

You can perform the ISSU process when the old and new Cisco IOS XE software are compatible. The compatibility matrix information stores the compatibility among releases as follows:

- **Compatible**—The base-level system infrastructure and all optional HA-aware subsystems are compatible. An in-service upgrade or downgrade between these versions will succeed with minimal service impact. The matrix entry designates the images to be compatible (C).

- **Base-level compatible**—One or more of the optional HA-aware subsystems is not compatible. An in-service upgrade or downgrade between these versions will succeed; however, some subsystems will not be able to maintain state always during the transition from the old to the new version of Cisco IOS XE. The matrix entry designates the images to be base-level compatible (B).

- **Incompatible**—A core set of system infrastructure exists in Cisco IOS XE that must be able to interoperate in a stateful manner for SSO to function correctly. If any of these required features or subsystems is not interoperable, then the two versions of the Cisco IOS XE software image are declared to be incompatible. An in-service upgrade or downgrade between these versions is not possible. The matrix entry designates the images to be incompatible (I). The system operates in RPR mode during the upgrade process when the versions of Cisco IOS XE at the active and standby supervisor engines are incompatible.

- **Cisco IOS XE determines the compatibility between the active and the standby IOS XE software dynamically during STANDBY boot up. The matrix is represented by “x”**.

To display the compatibility matrix data between two software versions on a given system, enter the `show issu comp-matrix stored` command.

**Note**  
This command is useful only for verification purposes because it is available only after the ISSU process has started. You might want to check the compatibility matrix prior to starting ISSU. Use the Feature Navigator to obtain the needed information

### SNMP Support for ISSU

SNMP for SSO provides a mechanism for synchronizing the SNMP configurations and the MIBs that support SSO from the active supervisor engine to the standby supervisor engine.

### Compatibility Verification Using Cisco Feature Navigator

The ISSU application on Cisco Feature Navigator allows you to:

- Select a specific software bundle.
- Identify which software images are compatible with the selected software image.
• Compare two IOS XE software images and understand the compatibility level of the software images (that is, compatible, base-level compatible, and incompatible), or dynamically determined.
• Compare two software images and see the client compatibility for each ISSU client.
• Provide links to release notes for the software image.

How to Perform the ISSU Process

Unlike SSO, which is a mode of operation for the device and a prerequisite for performing ISSU, the ISSU process is a series of steps performed while the switch is in operation. The steps result in an upgrade to new or modified Cisco IOS XE software, and have a minimal impact to traffic.

Note
For an illustration of the process flow for ISSU, refer to Figure 6-8 on page 6-11.

This section includes the following topics:
• Verifying the ISSU Software Installation, page 6-15
• Loading New Cisco IOS XE Software on the Standby Supervisor Engine, page 6-18 (required)
• Switching to the Standby Supervisor Engine, page 6-21 (required)
• Stopping the ISSU Rollback Timer (Optional), page 6-23 (optional)
• Loading New Cisco IOS XE Software on the New Standby Supervisor Engine, page 6-24 (required)
• Using changeversion to Automate an ISSU Upgrade, page 6-25
• Aborting a Software Upgrade During ISSU, page 6-31
• Configuring the Rollback Timer to Safeguard Against Upgrade Issues, page 6-32
• Displaying ISSU Compatibility Matrix Information, page 6-34

Verifying the ISSU Software Installation

During the ISSU process, there are five valid states: disabled, init, load version, run version, and system reset. Use the show issu state command to obtain the current ISSU state:
• Disabled state—The state for the standby supervisor engine while this engine is resetting.
• Init state—The initial state for two supervisor engines, one active and one standby, before the ISSU process is started. It is also the final state after the ISSU process completes.
• Load version (LV) state—The standby supervisor engine is loaded with the new version of Cisco IOS XE software.
• Run version (RV) state—The issu runversion command forces the switchover of the supervisor engines. The newly active supervisor engine runs the new Cisco IOS XE software image.
• While running ISSU, if both supervisor engines are reset due to power outage, for example, the ISSU context is lost and returns to the init state. Both supervisor engines return to the old software.
You can verify the ISSU software upgrade by entering `show` commands to provide information on the state of the during the ISSU process:

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 Switch&gt; enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td>Step 2 Switch# show issu state (detail)</td>
<td>Displays the state of the during the ISSU process.</td>
</tr>
<tr>
<td>Step 3 Switch# show redundancy</td>
<td>Displays current or historical status, mode, and related redundancy information about the device.</td>
</tr>
</tbody>
</table>

This example shows how to display the state and the current status of the supervisor engine during the ISSU process:

```bash
Switch> enable
Switch# show issu state
Switch# show redundancy
```

### Verifying Redundancy Mode Before Beginning the ISSU Process

Before you begin the ISSU process, verify the redundancy mode for the system and be sure to configure NSF and SSO.

The following example displays verification that the system is in SSO mode, that slot 3 is the active supervisor engine, and that slot 4 is the standby supervisor engine. Both supervisor engines are running the same Cisco IOS XE software release.

```bash
Switch# show redundancy states
my state = 13 -ACTIVE
peer state = 8 -STANDBY HOT
Mode = Duplex
Unit = Primary
Unit ID = 5

Redundancy Mode (Operational) = Stateful Switchover
Redundancy Mode (Configured) = Stateful Switchover
Redundancy State = Stateful Switchover
Manual Swact = enabled

Communications = Up
client count = 64
client_notification_TMR = 240000 milliseconds
keep_alive TMR = 9000 milliseconds
keep_alive count = 1
keep_alive threshold = 18
RF debug mask = 0

Switch# show redundancy
Redundant System Information :

----------------------------------------
Available system uptime = 12 minutes
Switchovers system experienced = 0
Standby failures = 0
Last switchover reason = none
```
Chapter 6  Configuring the Cisco IOS XE In Service Software Upgrade Process

How to Perform the ISSU Process

Hardware Mode = Duplex
Configured Redundancy Mode = Stateful Switchover
Operating Redundancy Mode = Stateful Switchover
Maintenance Mode = Disabled
Communications = Up

Current Processor Information:
----------------------------------------------
Active Location = slot 5
Current Software state = ACTIVE
Uptime in current state = 9 minutes
Image Version = Cisco IOS Software, IOS-XE Software, Catalyst 4500 L3
Switch Software (cat4500e-UNIVERSALK9-M), Version 03.00.00.1.68 CISCO UNIVERSAL
DEVELOPMENT K10 IOSD TEST VERSION
Copyright (c) 1986-2010 by Cisco Systems, Inc.
Compiled Sun 29-Aug-10 03:57 by gsbuprod
Configuration register = 0x2920

Peer Processor Information:
----------------------------------------------
Standby Location = slot 6
Current Software state = STANDBY HOT
Uptime in current state = 2 minutes
Image Version = Cisco IOS Software, IOS-XE Software, Catalyst 4500 L3
Switch Software (cat4500e-UNIVERSALK9-M), Version 03.00.00.1.68 CISCO UNIVERSAL

Verifying the ISSU State Before Beginning the ISSU Process

Ensure that the active and standby supervisor engines are up and in ISSU Init state and that both supervisor engines are running the same current image.

The following example displays the ISSU state before the process begins:

Switch# show issu state detail

Slot = 5
RP State = Active
ISSU State = Init
Operating Mode = Stateful Switchover
Current Image = bootflash:old_image
Pre-ISSU (Original) Image = N/A
Post-ISSU (Targeted) Image = N/A

Slot = 6
RP State = Standby
ISSU State = Init
Operating Mode = Stateful Switchover
Current Image = bootflash:old_image
Pre-ISSU (Original) Image = N/A
Post-ISSU (Targeted) Image = N/A

The new version of the Cisco IOS XE software must be present on both of the supervisor engines. The directory information displayed for each of the supervisor engines shows that the new version is present.

Switch# dir bootflash:
Directory of bootflash:/

5  -rw-  129923402  Aug 6 2010 09:32:33 +00:00  old_image
6  -rw-  127724184  Aug 6 2010 09:34:00 +00:00  new_image
61341696 bytes total (1111388 bytes free)

Switch# dir slavebootflash:
Directory of slavebootflash:

  4  -rw- 129923402   Aug 6 2006 09:40:10 +00:00  old_image
  5  -rw- 127724184   Aug 6 2006 09:42:13 +00:00  new_image

61341696 bytes total (1116224 bytes free)

Loading New Cisco IOS XE Software on the Standby Supervisor Engine

This task describes how to use ISSU to load a new version of Cisco IOS XE software to the standby supervisor engine.

Prerequisites

- Ensure that the new version of Cisco IOS XE software image is already present in the file system of both the active and standby supervisor engines. Also ensure that appropriate boot parameters (BOOT string and config-register) are set for the active and standby supervisor engines.

  __Note__

  The switch must boot with the BOOT string setting before the ISSU procedure is attempted.

  __Note__

  `auto-boot` must be enabled for ISSU to succeed.

- Optionally, perform additional tests and commands to determine the current state of peers and interfaces for later comparison.

- Ensure the system (both active and standby supervisor engines) is in SSO redundancy mode. If the system is in RPR mode, you can still upgrade the system using the ISSU CLI commands, but the system will experience extended packet loss during the upgrade.'

  Refer to the Stateful Switchover document for more details on how to configure SSO mode on supervisor engines.

- For ISSU to function, the IOS XE file names on the active and standby supervisor engines must match.
Perform the following steps at the active supervisor engine:

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>Switch&gt; enable</strong> Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><strong>Switch# issu loadversion</strong> (active-slot) &lt;br&gt;active-image-new (standby-slot) standby-image-new [forced] Starts the ISSU process and (optionally) overrides the automatic rollback when the new Cisco IOS XE software version is detected to be incompatible. It may take several minutes after entering the <code>issu loadversion</code> command for Cisco IOS XE software to load onto the standby supervisor engine and for the standby supervisor engine to transition to SSO mode. This causes the standby supervisor engine to reload with the new software image. If you use the <strong>forced</strong> option, the standby supervisor engine is booted with the new software image. After the software image is loaded on the standby supervisor engine, if the software image is incompatible, the system is forced to the RPR mode. Otherwise the system will continue in the SSO mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><strong>Switch# show issu state [detail]</strong> Displays the state of ISSU during the ISSU process. At this point in the ISSU process, use this command to check that the standby supervisor engine is loaded and is in SSO mode. It may take several minutes after entering the <code>issu loadversion</code> command for Cisco IOS XE software to load onto the standby supervisor engine and the standby supervisor engine to transition to SSO mode. If you enter the <code>show issu state</code> command too quickly, you may not see the information you need.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><strong>Switch# show redundancy [states]</strong> Displays redundancy facility state information.</td>
</tr>
</tbody>
</table>

This example shows how to start the ISSU process, boot the standby supervisor engine in the Standby Hot state, and load the standby supervisor engine slot (6) with the new IOS XE software image:

Switch> enable
Switch# issu loadversion 5 bootflash:new_image 6 slavebootflash:new_image
%issu loadversion executed successfully, Standby is being reloaded
Switch# show issu state detail
  Slot = 5
  RP State = Active
  ISSU State = Load Version
  Operating Mode = Stateful Switchover
  Current Image = bootflash:old_image
  Pre-ISSU (Original) Image = bootflash:old_image
  Post-ISSU (Targeted) Image = bootflash:new_image

  Slot = 6
  RP State = Standby
  ISSU State = Load Version
  Operating Mode = Stateful Switchover
Chapter 6    Configuring the Cisco IOS XE In Service Software Upgrade Process

How to Perform the ISSU Process

Current Image = bootflash:new_image
Pre-ISSU (Original) Image = bootflash:old_image
Post-ISSU (Targeted) Image = bootflash:new_image

Switch# show redundancy states
my state = 13 -ACTIVE
peer state = 8 -STANDBY HOT
Mode = Duplex
Unit = Primary
Unit ID = 5

Redundancy Mode (Operational) = Stateful Switchover
Redundancy Mode (Configured) = Stateful Switchover
Redundancy State = Stateful Switchover
Manual Swact = enabled

Communications = Up
client count = 64
client_notification_TMR = 240000 milliseconds
keep_alive TMR = 9000 milliseconds
keep_alive count = 1
keep_alive threshold = 18
RF debug mask = 0

The following example shows how the forced option places the system in RPR mode:

Switch> enable
Switch# issu loadversion 5 bootflash:new_image 6 slavebootflash:new_image forced
%issu loadversion executed successfully, Standby is being reloaded

Switch# show issu state detail
Slot = 5
RP State = Active
ISSU State = Init
Operating Mode = Stateful Switchover
Current Image = bootflash:old_image
Pre-ISSU (Original) Image = N/A
Post-ISSU (Targeted) Image = N/A

Slot = 6
RP State = Standby
ISSU State = Init
Operating Mode = Stateful Switchover
Current Image = bootflash:old_image
Pre-ISSU (Original) Image = N/A
Post-ISSU (Targeted) Image = N/A

The following example shows the redundancy mode as RPR:

Switch# show redundancy states
my state = 13 -ACTIVE
peer state = 4 -STANDBY COLD
Mode = Duplex
Unit = Primary
Unit ID = 3

Redundancy Mode (Operational) = RPR
Redundancy Mode (Configured) = Stateful Switchover
Redundancy State = RPR
Manual Swact = enabled
Communications = Up
Switching to the Standby Supervisor Engine

This task describes how to switch over to the standby supervisor engine, which is running the new Cisco IOS XE software image. Perform the following steps at the active supervisor engine.

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Switch&gt; <strong>enable</strong></td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Forces a switchover from the active to the standby supervisor engine and reloads the former active (current standby) supervisor engines with the old IOS XE image.</td>
</tr>
<tr>
<td>Switch# <strong>issu runversion</strong> [standby-slot] [standby-image-new]</td>
<td>When you enter the <strong>issu runversion</strong> command, an SSO switchover will be performed, and NSF procedures will be invoked if so configured.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Displays the state of the during the ISSU process. At this point in the ISSU process, use this command to check that a switchover occurs to slot 6.</td>
</tr>
<tr>
<td>Switch# <strong>show issu state</strong> [detail]</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Displays redundancy facility state information.</td>
</tr>
<tr>
<td>Switch# <strong>show redundancy</strong> [states]</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to cause a switchover to the former standby supervisor engine (slot 6), reset the former active supervisor engine and reload it with the old IOS XE software image so it becomes the standby supervisor engine:

```
Switch> **enable**
Switch# **issu runversion 6 slavebootflash:new_image**
%issu runversion initiated successfully
```

A switchover happens at this point. At the new active supervisor engine, do the following after old active supervisor engine comes up as standby.

```bash
Switch# **show issu state detail**
```

```
Slot = 6
RP State = Active
ISSU State = Run Version
Operating Mode = Stateful Switchover
Current Image = bootflash:new_image
Pre-ISSU (Original) Image = bootflash:old_image
Post-ISSU (Targeted) Image = bootflash:new_image
```

```
Slot = 5
RP State = Standby
ISSU State = Run Version
Operating Mode = Stateful Switchover
Current Image = bootflash:old_image
Pre-ISSU (Original) Image = bootflash:old_image
Post-ISSU (Targeted) Image = bootflash:new_image
```
The new active supervisor engine is now running the new version of software, and the standby supervisor engine is running the old version of software and is in the standby hot state.

```
Switch# show redundancy states
  my state = 13 -ACTIVE
  peer state = 8 -STANDBY HOT
    Mode = Duplex
    Unit = Primary
    Unit ID = 6

  Redundancy Mode (Operational) = Stateful Switchover
  Redundancy Mode (Configured) = Stateful Switchover
  Redundancy State = Stateful Switchover
    Manual Swact = enabled

  Communications = Up

  client count = 64
  client_notification_TMR = 240000 milliseconds
    keep_alive TMR = 9000 milliseconds
    keep_alive count = 0
    keep_alive threshold = 18
    RF debug mask = 0
```

Once Runversion has completed, the new active supervisor engine will be running the new version of software and the previously active supervisor engine will now become the standby supervisor engine. The standby will be reset and reloaded, but it will remain on the previous version of software and come back online in standbyhot status. The following example shows how to verify these conditions:

```
Switch# show redundancy
Redundant System Information :
---------------------------------
  Available system uptime = 12 minutes
  Switchovers system experienced = 0
  Standby failures = 0
  Last switchover reason = none

    Hardware Mode = Duplex
    Configured Redundancy Mode = Stateful Switchover
    Operating Redundancy Mode = Stateful Switchover
    Maintenance Mode = Disabled
    Communications = Up

Current Processor Information :
---------------------------------
  Active Location = slot 6
  Current Software state = ACTIVE
  Uptime in current state = 9 minutes
    Image Version = Cisco IOS Software, IOS-XE Software, Catalyst 4500 L3
      Switch Software (cat4500e-UNIVERSALK9-M), Version 03.00.00.1.68 CISCO UNIVERSAL
      DEVELOPMENT K10 IOSD TEST VERSION
    Copyright (c) 1986-2010 by Cisco Systems, Inc.
    Compiled Sun 29-Aug-10 03:57 by gsbuprod
    Configuration register = 0x2920

Peer Processor Information :
---------------------------------
  Standby Location = slot 5
  Current Software state = STANDBY HOT
  Uptime in current state = 2 minutes
```
Stopping the ISSU Rollback Timer (Optional)

This optional task describes how to stop the rollback timer.

If you do not run the following procedure before the rollback timer “timeout,” the system automatically aborts the ISSU process and reverts to the original Cisco IOS XE software version. By default the rollback timer is 45 minutes.

Use the following information to decide what action you should take:

- If you want to retain your switch in the runversion state for an extended period, you need to stop the rollback timer by entering the `acceptversion` command. Then validate the new software and enter the `commitversion` command (as described in the following section).

- If you want to proceed with the `commitversion` operation within the rollback timer window of 45 minutes (or the configured value), you do not need to use the `acceptversion` command to stop the roll-back timer.

**Note**

The `issu acceptversion` command may be optionally executed after the `issu runversion` command.

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Switch&gt; enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 2</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Switch# issu acceptversion [active-slot] [active-image-new]</td>
<td>Halts the rollback timer and ensures the new Cisco IOS XE ISSU process is not automatically aborted during the ISSU process. Enter the <code>issu acceptversion</code> command within the time period specified by the rollback timer to acknowledge that the supervisor engine has achieved connectivity to the outside world; otherwise, the ISSU process is terminated, when the rollback timer expires, and the system reverts to the previous version of Cisco IOS XE software by switching to the standby supervisor engine.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 3</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Switch# show issu rollback-timer</td>
<td>Displays the amount of time left before an automatic rollback will occur.</td>
</tr>
</tbody>
</table>

This example displays the Timer before you stop it. In the following example, the “Automatic Rollback Time” information indicates the amount of time remaining before an automatic rollback will occur.

```
Switch> enable
Switch# issu acceptversion 6 bootflash:new_image
```

```
Switch> enable
Switch# show issu rollback-timer
  Rollback Process State = 00:31:09 remaining
  Configured Rollback Time = 00:45:00

Switch# issu acceptversion 6 bootflash:new_image
```
Loading New Cisco IOS XE Software on the New Standby Supervisor Engine

This task explains how to load new version of Cisco IOS XE software to the new standby supervisor engine.

Perform the following steps at the active supervisor engine:

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1: Switch&gt; enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Step 2: Switch# issu commitversion [standby-slot] [standby-image-new]</td>
<td>Allows the new Cisco IOS XE software image to be loaded into the standby supervisor engine.</td>
</tr>
<tr>
<td>Step 3: Switch# show redundancy [states]</td>
<td>Displays redundancy facility state information.</td>
</tr>
<tr>
<td>Step 4: Switch# show issu state [detail]</td>
<td>Displays the state of the during the ISSU process. At this point in the ISSU process, use this command to check that the standby supervisor engine is loaded with the new image.</td>
</tr>
</tbody>
</table>

This example shows how to reset and reload the current standby supervisor engine (slot 1) with the new Cisco IOS XE software version. After you enter the `commitversion` command, the standby supervisor engine boots in the Standby Hot state.

Switch> enable
Switch# issu commitversion 5 slavebootflash:new_image
%issu commitversion executed successfully

Use the following to verify that the standby supervisor engine is reloaded with the new software.

Switch# show redundancy states
  my state = 13 -ACTIVE
  peer state = 8 -STANDBY HOT
  Mode = Duplex
  Unit = Primary
  Unit ID = 6

  Redundancy Mode (Operational) = Stateful Switchover
  Redundancy Mode (Configured) = Stateful Switchover
  Redundancy State = Stateful Switchover
  Manual Swact = enabled

  Communications = Up

  client count = 64
  client_notification_TMR = 240000 milliseconds
  keep_alive TMR = 9000 milliseconds
  keep_alive count = 1
  keep_alive threshold = 18
  RF debug mask = 0

Switch# show redundancy
Redundant System Information :

Pre-ISSU (Original) Image = N/A
Post-ISSU (Targeted) Image = N/A

The ISSU process has completed. At this stage, any further Cisco IOS XE software version upgrade or downgrade will require that a new ISSU process be invoked.

Using changeversion to Automate an ISSU Upgrade

This task describes how to use the issu changeversion command to perform a one step ISSU upgrade.
Prerequisites

- Ensure that the new version of Cisco IOS XE software image is already present in the file system of both the active and standby supervisor engines. Also ensure that appropriate boot parameters (BOOT string and config-register) are set for the active and standby supervisor engines.
- Optionally, perform additional tests and commands to determine the current state of peers and interfaces for later comparison.
- Ensure the system (both active and standby supervisor engines) is in SSO redundancy mode. If the system is in RPR mode, you can still upgrade the system using the ISSU CLI commands, but the system will experience extended packet loss during the upgrade.

Refer to the Stateful Switchover document for more details on how to configure SSO mode on supervisor engines (refer to Chapter 5, “Configuring Supervisor Engine Redundancy Using RPR and SSO”).
- For ISSU to function, the IOS XE software image file names on the active and standby supervisor engines must match.

Perform the following steps at the active supervisor engine:

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> Switch&gt; enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> Switch# issu changeversion [active-slot active-image-new] [standby-slot [standby-image-new]] [at hh:mm</td>
<td>in hh:mm] [quick]</td>
</tr>
<tr>
<td><strong>Step 3</strong> Switch# show issu state [detail]</td>
<td>Displays the state of the during the ISSU process. At this point in the ISSU process, use this command to check that the standby supervisor engine is loaded and is in SSO mode.</td>
</tr>
<tr>
<td><strong>Step 4</strong> Switch# show redundancy [states]</td>
<td>Displays redundancy facility state information.</td>
</tr>
</tbody>
</table>
This example shows how to initiate an ISSU upgrade process using the issu changefversion command on slot number 5, the slot for the current active supervisor engine. The show issu state detail and show redundancy command output is included to show the supervisor state before and after the upgrade procedure.

The success messages included in the output below is displayed after some delay because the ISSU upgrade procedure progresses through the ISSU states.

```
Switch> enable
Switch# show issu state detail
Slot = 5
  RP State = Active
  ISSU State = Init
  Operating Mode = Stateful Switchover
  Current Image = bootflash:x.bin
  Pre-ISSU (Original) Image = N/A
  Post-ISSU (Targeted) Image = N/A

Slot = 6
  RP State = Standby
  ISSU State = Init
  Operating Mode = Stateful Switchover
  Current Image = bootflash:x.bin
  Pre-ISSU (Original) Image = N/A
  Post-ISSU (Targeted) Image = N/A

Switch# show redundancy
Redundant System Information :

```
How to Perform the ISSU Process

Switch# **issu changeversion bootflash:y.bin**

% 'issu changeversion' is now executing 'issu loadversion'
% issu loadversion executed successfully, Standby is being reloaded

% changeversion finished executing loadversion, waiting for standby to reload and reach SSO ...

**Note**  Standby reloads with target image.

......

*Feb 25 20:41:00.479: %INSTALLER-7-ISSU_OP_SUCC: issu changeversion is now executing 'issu runversion'
*Feb 25 20:41:03.639: %INSTALLER-7-ISSU_OP_SUCC: issu changeversion successfully executed 'issu runversion'

**Note**  Switchover occurs.

......

Look at the console of new active supervisor engine.

*Feb 25 20:47:39.859: %RF-5-RF_TERMINAL_STATE: Terminal state reached for (SSO)
*Feb 25 20:47:39.971: %INSTALLER-7-ISSU_OP_SUCC: issu changeversion is now executing 'issu commitversion'

**Note**  The new standby supervisor engine reloads with target image; changeversion is successful upon SSO terminal state is reached.

*Feb 25 20:54:16.092: %HA_CONFIG_SYNC-6-BULK_CFGSYNC_SUCCEED: Bulk Sync succeeded
*Feb 25 20:54:16.094: %RF-5-RF_TERMINAL_STATE: Terminal state reached for (SSO)

Switch#

Switch# **show issu state detail**

```
Slot = 6
RP State = Active
ISSU State = Init
Operating Mode = Stateful Switchover
Current Image = bootflash:y.bin
Pre-ISSU (Original) Image = N/A
Post-ISSU (Targeted) Image = N/A
```

```
Slot = 5
RP State = Standby
ISSU State = Init
Operating Mode = Stateful Switchover
Current Image = bootflash:y.bin
Pre-ISSU (Original) Image = N/A
Post-ISSU (Targeted) Image = N/A
```
This example shows how to use issu changeversion with the at command option to schedule an ISSU upgrade procedure to automatically start at the specified time. This example specifies that the ISSU upgrade should be started at 16:30 (24 hour format). The show issu state detail and show redundancy command output is included to show the supervisor state before and after the issu changeversion command was entered.

Switch# show redundancy

Aborting a Software Upgrade During ISSU

You can abort the ISSU process at any stage manually (prior to entering the `issu commitversion` command) by entering the `issu abortversion` command. The `issu abortversion` command may also be issued after entering the `issu changeversion` command while the automatic ISSU upgrade is still in progress. The ISSU process also aborts on its own if the software detects a failure.

**Note**

If you enter the `issu abortversion` command before the standby supervisor engine becomes hot, the traffic might be disrupted.

If you abort the process after you issue the `issu loadversion` command, the standby supervisor engine is reset and reloaded with the original software.

If the process is aborted after you enter either the `issu runversion` or `issu acceptversion` command, then a second switchover is performed to the new standby supervisor engine that is still running the original software version. The supervisor engine that had been running the new software is reset and reloaded with the original software version.

**Note**

Ensure that the standby supervisor is fully booted before issuing the `abortversion` command on an active supervisor engine.

The following task describes how to abort the ISSU process before you complete the ISSU process with the `issu commitversion` command.

Perform the following task on the active supervisor engine.

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Switch&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2** | Cancels the ISSU upgrade or downgrade process in progress and restores the switch to its state before the process had started. |
| Switch# issu abortversion [active slot [active-image-new]] | |

This example shows how to abort the ISSU process on slot number 6, the slot for the current active supervisor engine. In this example, the ISSU upgrade process is in the Runversion state when the `issu abortversion` command is entered:

```
Switch> enable
Switch# show issu state detail
Slot = 6
RP State = Active
ISSU State = Run Version
Operating Mode = Stateful Switchover
Current Image = bootflash:x.bin
Pre-ISSU (Original) Image = bootflash:y.bin
Post-ISSU (Targeted) Image = bootflash:x.bin
Slot = 5
```
How to Perform the ISSU Process

RP State = Standby
ISSU State = Run Version
Operating Mode = Stateful Switchover
Current Image = bootflash:y.bin
Pre-ISSU (Original) Image = bootflash:y.bin
Post-ISSU (Targeted) Image = bootflash:x.bin

Switch# issu abortversion 6
% issu abortversion initiated successfully
Switch# show issu state detail

Slot = 5
RP State = Active
ISSU State = Init
Operating Mode = Stateful Switchover
Current Image = bootflash:y.bin
Pre-ISSU (Original) Image = N/A
Post-ISSU (Targeted) Image = N/A

Slot = 6
RP State = Standby
ISSU State = Init
Operating Mode = Stateful Switchover
Current Image = bootflash:y.bin
Pre-ISSU (Original) Image = N/A
Post-ISSU (Targeted) Image = N/A

Switch#

Configuring the Rollback Timer to Safeguard Against Upgrade Issues

Cisco IOS XE software maintains an ISSU rollback timer, to safeguard against an upgrade that may leave the new active supervisor engine in a state in which communication with the standby supervisor engine is severed.

You may want to configure the rollback timer to fewer than 45 minutes (the default) so that the user need not wait in case the new software is not committed or the connection to the switch was lost while it was in runversion mode. A user may want to configure the rollback timer to more than 45 minutes in order to have enough time to verify the operation of the new Cisco IOS XE software before committing the new software image.

Note
The valid timer value range is from 0 to 7200 seconds (two hours). A value of 0 seconds disables the rollback timer.

Once you are satisfied that the new image at the active supervisor engine has been successful and you want to remain in the current state, you may indicate acceptance by issuing the **issu acceptversion** command, which stops the rollback timer.

Issuing the **issu commitversion** command at this stage is equal to entering both the **issu acceptversion** and the **issu commitversion** commands. Use the **issu commitversion** command if you do not intend to run in the current state for a period of time and are satisfied with the new software version.

Note
The rollback timer can be configured only in the ISSU Init state.

This task explains how to configure the rollback timer:
Chapter 6 Configuring the Cisco IOS XE In Service Software Upgrade Process

How to Perform the ISSU Process

This example shows how to set the rollback timer to 3600 seconds:

Switch> enable
Switch# configure terminal
Enter configuration commands, one per line. End with CNTRL/Z.
Switch(config)# issu set rollback-timer 3600
% Rollback timer value set to [ 3600 ] seconds
Switch(config)# exit
Switch# show issu rollback-timer
Rollback Process State = Not in progress
Configured Rollback Time = 60:00

The Rollback Timer cannot be set in loadversion or runversion state, as the following example illustrates:

Switch# show issu state detail
Slot = 5
   RP State = Active
   ISSU State = Load Version
   Operating Mode = Stateful Switchover
   Current Image = bootflash:old_image
   Pre-ISSU (Original) Image = bootflash:old_image
   Post-ISSU (Targeted) Image = bootflash:new_image

   Slot = 6
   RP State = Standby
   ISSU State = Load Version
   Operating Mode = Stateful Switchover
   Current Image = bootflash:new_image
   Pre-ISSU (Original) Image = bootflash:old_image
   Post-ISSU (Targeted) Image = bootflash:new_image

Switch# show issu rollback-timer
Rollback Process State = Not in progress
Configured Rollback Time = 60:00

Switch# configure terminal
Enter configuration commands, one per line. End with CNTRL/Z.
Switch(config)# issu set rollback-timer 20
% ISSU state should be [ init ] to set the rollback timer
Displaying ISSU Compatibility Matrix Information

The ISSU compatibility matrix contains information about other IOS XE software releases and the version in question. This compatibility matrix represents the compatibility of the two software versions, one running on the active and the other on the standby supervisor engine, and the matrix allows the system to determine the highest operating mode it can achieve. This information helps the user identify whether to use ISSU.

This task shows how to display information about the ISSU compatibility matrix.

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>Step 2</strong></td>
</tr>
<tr>
<td>Switch&gt; enable</td>

<td>Comp(3)</td>
</tr>
</tbody>
</table>

Switch#

Dynamic Image Version Compatibility (DIVC) feature is supported in IOS XE releases. With DIVC, we store Dynamic(0) rather than Incomp(1), Base(2), or Comp(3), and determine compatibility during run-time when two different DIVC-capable IOS XE software images are running in the active and standby supervisor engines during ISSU.

For Catalyst 4500 switches, a value of Dynamic(0) in the stored compatibility-matrix normally results in Base(2) or Comp(3) upon run-time negotiation between the two IOS XE software images; as of today, you never observe Incomp(1) as long as the other IOS XE name is present in the stored compatibility-matrix.

This example shows how to display negotiated information regarding non-IOSd clients:

Switch# `show package compatibility`

Cisco High Availability Features in Cisco IOS XE 3.1.0 SG

This section provides a list of High Availability software features that are supported in Cisco IOS XE 3.1.0SG. Links to the feature documentation are included.

Feature guides may contain information about more than one feature. To find information about a specific feature within a feature guide, see the Feature Information table at the end of the guide.

Feature guides document features that are supported on many different software releases and platforms. Your Cisco software release or platform may not support all the features documented in a feature guide. See the Feature Information table at the end of the feature guide for information about which features in...
that guide are supported in your software release. Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

**Enhanced High System Availability**

CHAPTER 7

Configuring Interfaces

This chapter describes how to configure interfaces for the Catalyst 4500 series switches. It also provides guidelines, procedures, and configuration examples.

This chapter includes the following major sections:

- About Interface Configuration, page 7-2
- Using the interface Command, page 7-2
- Configuring a Range of Interfaces, page 7-4
- Defining and Using Interface-Range Macros, page 7-6
- Deploying SFP+ in X2 Ports, page 7-7
- Deploying 10-Gigabit Ethernet or Gigabit Ethernet Ports on WS-X4606-10GE-E, page 7-7
- Internal Management Port and Supervisor Engine 7-E, page 7-10
- Limitation and Restrictions on Supervisor Engine 7-E, page 7-10
- Digital Optical Monitoring Transceiver Support, page 7-10
- Configuring Optional Interface Features, page 7-11
- Understanding Online Insertion and Removal, page 7-23
- Monitoring and Maintaining the Interface, page 7-24

Note

For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

About Interface Configuration

By default, all interfaces are enabled. The 10/100-Mbps Ethernet interfaces autonegotiated connection speed and duplex. The 10/100/1000-Mbps Ethernet interfaces negotiate speed, duplex, and flow control. The 1000-Mbps Ethernet interfaces negotiate flow control only. Autonegotiation automatically selects the fastest speed possible on that port for the given pair. If a speed is explicitly stated for an interface, that interface defaults to half duplex unless it is explicitly set for full duplex.

Many features are enabled on a per-interface basis. When you enter the `interface` command, you must specify the following:

- Interface type:
  - Fast Ethernet (use the `fastethernet` keyword)
  - Gigabit Ethernet (use the `gigabitethernet` keyword)
  - 10-Gigabit Ethernet (use the `tengigabitethernet` keyword)

- Slot number—The slot in which the interface module is installed. Slots are numbered starting with 1, from top to bottom.

- Interface number—The interface number on the module. The interface numbers always begin with 1. When you are facing the front of the switch, the interfaces are numbered from left to right.

You can identify interfaces by physically checking the slot/interface location on the switch. You can also use the Cisco IOS `show` commands to display information about a specific interface or all the interfaces.

The interfaces on WS-X45-SUP7-E and WS-X4712-SFP+E support both Gigabit Ethernet SFPs and Ten Gigabit Ethernet SFP+s but are always termed Ten Gigabit Ethernet interfaces.

Using the `interface` Command

These general instructions apply to all interface configuration processes:

**Step 1**
At the privileged EXEC prompt, enter the `configure terminal` command to enter global configuration mode:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)#
```

**Step 2**
In global configuration mode, enter the `interface` command. Identify the interface type and the number of the connector on the interface card. The following example shows how to select Fast Ethernet, slot 5, interface 1:

```
Switch(config)# interface fastethernet 5/1
Switch(config-if)#
```

**Step 3**
Interface numbers are assigned at the factory at the time of installation or when modules are added to a system. Enter the `show interfaces` EXEC command to see a list of all interfaces installed on your switch. A report is provided for each interface that your switch supports, as shown in this display:

```
Switch(config-if)#Ctrl-Z
Switch#show interfaces
Vlan1 is up, line protocol is down
  Hardware is Ethernet SVI, address is 0004.dd46.7aff (bia 0004.dd46.7aff)
  MTU 1500 bytes, BW 1000000 Kbit, DLY 10 usec,
  reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
```
Chapter 7 Configuring Interfaces

Using the interface Command

ARP type: ARPA, ARP Timeout 04:00:00

0 babbles, 0 late collision, 0 deferred
0 lost carrier, 0 no carrier
0 output buffer failures, 0 output buffers swapped out

--More--

<...output truncated...>
Configuring a Range of Interfaces

The interface-range configuration mode allows you to configure multiple interfaces with the same configuration parameters. When you enter the interface-range configuration mode, all command parameters you enter are attributed to all interfaces within that range until you exit interface-range configuration mode.

To configure a range of interfaces with the same configuration, perform this task:

**Step 4**
To begin configuring Fast Ethernet interface 5/5, as shown in the following example, enter the `interface` keyword, interface type, slot number, and interface number in global configuration mode:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fastethernet 5/5
Switch(config-if)#
```

*Note*  Adding a space between the interface type and interface number is not needed. For example, in the preceding line you can specify either fastethernet 5/5 or fastethernet/5/5.

**Step 5**
Follow each `interface` command with the interface configuration commands your particular interface requires. The commands you enter define the protocols and applications that will run on the interface. The commands are collected and applied to the `interface` command until you enter another `interface` command or press Ctrl-Z to exit interface configuration mode and return to privileged EXEC mode.

*Note* On the Supervisor, WS-X45-SUP7-E and the linecard, WS-X4712-SFP+E, the interfaces can support both Gigabit Ethernet SFPs and 10-Gigabit Ethernet SFP+s. For simplicity, these interfaces are always termed 10-Gigabit Ethernet interfaces. All Gigabit Ethernet and 10-Gigabit Ethernet parameters can be configured on these interfaces. However, the actual interface configuration parameters that are valid for an interface depend on which transceiver type (SFP or SFP+) is loaded. When an SFP is loaded, only the Gigabit Ethernet parameters are applicable and the interface behaves exactly like a Gigabit Ethernet port. Similarly, when an SFP+ is loaded, only the 10-Gigabit Ethernet parameters are applicable and the interface behaves exactly like a 10-Gigabit Ethernet port.

**Step 6**
After you configure an interface, check its status by using the EXEC `show` commands listed in the “Monitoring and Maintaining the Interface” section on page 7-24.
### Note
When you use the `interface range` command, you must add a space between the `vlan`, `fastethernet`, `gigabitethernet`, `tengigabitethernet`, or `macro` keyword and the dash. For example, the command `interface range fastethernet 5/1 - 5` specifies a valid range; the command `interface range fastethernet 5/1-5` does not contain a valid range command.

### Note
The `interface range` command works only with VLAN interfaces that have been configured with the `interface vlan` command (the `show running-configuration` command displays the configured VLAN interfaces). VLAN interfaces that are not displayed by the `show running-configuration` command cannot be used with the `interface range` command.

---

**Command**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# <strong>interface range</strong> (vlan vlan_ID - vlan_ID)</td>
<td>Selects the range of interfaces to be configured. Note the following:</td>
</tr>
<tr>
<td>Switch(config)# <strong>interface range</strong> (fastethernet</td>
<td>• You are required to enter a space before the dash.</td>
</tr>
<tr>
<td>Switch(config)# <strong>interface range</strong> (gigabitethernet</td>
<td>• You can enter up to five comma-separated ranges.</td>
</tr>
<tr>
<td>Switch(config)# <strong>interface range</strong> (tengigabitethernet</td>
<td>• You are not required to enter spaces before or after the comma.</td>
</tr>
<tr>
<td>Switch(config)# <strong>interface range</strong> (macro macro_name)</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# <strong>interface range</strong> (slot/interface - interface)</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# <strong>interface range</strong> (vlan vlan_ID - vlan_ID)</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# <strong>interface range</strong> (fastethernet</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# <strong>interface range</strong> (gigabitethernet</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# <strong>interface range</strong> (tengigabitethernet</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# <strong>interface range</strong> (macro macro_name)</td>
<td></td>
</tr>
<tr>
<td>Switch(config)# <strong>interface range</strong> (slot/interface - interface)</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to re-enable all Fast Ethernet interfaces 5/1 to 5/5:

```
Switch(config)# interface range fastethernet 5/1 - 5
Switch(config-if-range)# no shutdown
```

```
*Oct  6 08:24:35: %LINK-3-UPDOWN: Interface FastEthernet5/1, changed state to up
*Oct  6 08:24:35: %LINK-3-UPDOWN: Interface FastEthernet5/2, changed state to up
*Oct  6 08:24:35: %LINK-3-UPDOWN: Interface FastEthernet5/3, changed state to up
*Oct  6 08:24:35: %LINK-3-UPDOWN: Interface FastEthernet5/4, changed state to up
*Oct  6 08:24:36: %LINK-3-UPDOWN: Interface FastEthernet5/5, changed state to up
*Oct  6 08:24:36: %LINEPROTO-5-UPDOWN: Line protocol on Interface FastEthernet5/5, changed state to up
*Oct  6 08:24:36: %LINEPROTO-5-UPDOWN: Line protocol on Interface FastEthernet5/3, changed state to up
*Oct  6 08:24:36: %LINEPROTO-5-UPDOWN: Line protocol on Interface FastEthernet5/4, changed state to up
*Oct  6 08:24:36: %LINEPROTO-5-UPDOWN: Line protocol on Interface FastEthernet5/2, changed state to up
```

This example shows how to use a comma to add different interface type strings to the range to re-enable all Fast Ethernet interfaces ranging from 5/1 to 5/5 and both Gigabit Ethernet interfaces 1/1 and 1/2:

```
Switch(config-if)# interface range fastethernet 5/1 - 5, gigabitethernet 1/1 - 2
Switch(config-if)# no shutdown
```

```
*Oct  6 08:29:28: %LINK-3-UPDOWN: Interface FastEthernet5/1, changed state to up
*Oct  6 08:29:28: %LINK-3-UPDOWN: Interface FastEthernet5/2, changed state to up
*Oct  6 08:29:28: %LINK-3-UPDOWN: Interface FastEthernet5/3, changed state to up
*Oct  6 08:29:28: %LINK-3-UPDOWN: Interface FastEthernet5/4, changed state to up
*Oct  6 08:29:28: %LINK-3-UPDOWN: Interface FastEthernet5/5, changed state to up
*Oct  6 08:29:28: %LINK-3-UPDOWN: Interface GigabitEthernet1/1, changed state to up
*Oct  6 08:29:28: %LINK-3-UPDOWN: Interface GigabitEthernet1/2, changed state to up
```
Note

If you enter multiple configuration commands while you are in interface-range configuration mode, each command is run as it is entered (they are not batched together and run after you exit interface-range configuration mode). If you exit interface-range configuration mode while the commands are being run, some commands might not be run on all interfaces in the range. Wait until the command prompt is displayed before exiting interface-range configuration mode.

Defining and Using Interface-Range Macros

You can define an interface-range macro to automatically select a range of interfaces for configuration. Before you can use the `macro` keyword in the `interface-range` macro command string, you must define the macro.

To define an interface-range macro, perform this task:

Table 7-1

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`define interface-range macro_name (vlan vlan_ID - vlan_ID)</td>
<td>(fastethernet</td>
</tr>
<tr>
<td>Switch(config)# define interface-range enet_list fastethernet 5/1 - 4</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to define an interface-range macro named `enet_list` to select Fast Ethernet interfaces 5/1 through 5/4:

```
Switch(config)# define interface-range enet_list fastethernet 5/1 - 4
```

To show the defined interface-range macro configuration, perform this task:

Table 7-2

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show running-config</code></td>
<td>Shows the defined interface-range macro configuration.</td>
</tr>
</tbody>
</table>

This example shows how to display the defined interface-range macro named `enet_list`:

```
Switch# show running-config | include define
define interface-range enet_list FastEthernet5/1 - 4
Switch#
```
To use an interface-range macro in the `interface range` command, perform this task:

Table 7-3

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# interface range macro name</td>
<td>Selects the interface range to be configured using the values saved in a named interface-range macro.</td>
</tr>
</tbody>
</table>

This example shows how to change to the interface-range configuration mode using the interface-range macro `enet_list`:

```
Switch(config)# interface range macro enet_list
Switch(config-if)#
```

## Deploying SFP+ in X2 Ports

**Note**

This feature is supported on WS-X4606-X2-E.

To use an SFP+ in an X2 port to obtain 10-Gigabit Ethernet bandwidth, the Catalyst 4500 series switch supports OneX Convertor modules. When you plug a OneX Converter module into an X2 port, it converts the X2 port into an SFP+ port into which you can plug an SFP+. An SFP+ in a OneX Convertor module provides the same functionality as an X2 and maintains the same port numbering.

The output for the `show idprom tengigabitethernet slot/interface` command displays the contents of both the SFP+ and the OneX Convertor module seeproms when an SFP+ in a OneX Convertor module is plugged into an X2 port.

## Deploying 10-Gigabit Ethernet or Gigabit Ethernet Ports on WS-X4606-10GE-E

To increase the flexibility of X2 ports on WS-X4606-10GE-E, the Catalyst 4500 switch supports TwinGig Convertor modules. When you plug a TwinGig Convertor module into an X2 hole, it converts a single X2 hole (capable of holding one pluggable X2 optic) into two SFP holes (capable of holding two pluggable SFP optics). This enables you to have 10 Gigabit ports and 1-Gigabit ports on the same linecard. It also allows you to use Gigabit ports, and then switch to a 10-Gigabit port, when needed.

Topics include:

- Port Numbering TwinGig Convertors, page 7-7
- Selecting X2/TwinGig Convertor Mode, page 7-8

## Port Numbering TwinGig Convertors

When a TwinGig Convertor is enabled or disabled, the number and type of ports on the linecard change dynamically. The terminology must reflect this behavior. In Cisco IOS, 10-Gigabit ports are named `TenGigabit` and 1-Gigabit ports are named `Gigabit`. To avoid having two ports named `TenGigabit1/1` and
Gigabit1/1, the 10-Gigabit and 1-Gigabit port numbers are independent. For example, for a WS-X4606-10GE-E module with six X2 holes, the X2 ports are named TenGigabit slot-num/<1-6>, and the SFP ports are named Gigabit slot-num/<7-18>.

In Cisco IOS, ports 1 through 18 always exist. This means that you can apply configurations on them and they display in the CLI output. However, only the X2 or the SFP ports can be active at any particular time. For example, if an X2 is plugged into the second hole, the X2 port 2 is active and SFP ports 9 and 10 are inactive. If a TwinGig Convertor is plugged into the second hole, the X2 port 2 is inactive, and the SFP ports 9 and 10 are active.

When using both TwinGig and X2 transceivers on the WS-X4606-X2-E module, place ports 1-3 in one group and ports 4-6 in another. (The mode selected with the show hw-module module port-group command determines the behavior. See “Selecting X2/TwinGig Convertor Mode.”) Mixing within a port group will not work. For example, you cannot have an X2 in port 1 and a TwinGig in port 2 and expect both of them to function.

**Selecting X2/TwinGig Convertor Mode**

The default configuration mode is X2. So, if you plan to deploy 10-Gigabit interfaces, you don’t need to configure anything. However, if you want to deploy Gigabit interfaces (that is, use TwinGig Convertors), you must configure the associated port-group:

- To determine how the X2 holes on a module are grouped, enter the show hw-module module m port-group p command.

*Note* For a 10-Gigabit port that accepts a HAMM, you must place it into 1-Gigabit mode instead of 10-Gigabit mode.

If you configure a 10-Gigabit port as 1-Gigabit port, an output similar to the following displays:

```
Switch# show hw-module module 5 port-group
Module Port-group Active Inactive
------------------------------------------
 5   1   Gi5/3-6       Te5/1-2
```

Instead, if the port is set to the default, 10-Gigabit mode, an output similar to the following displays:

```
Switch# show hw-module module 6 port-group
Module Port-group Active Inactive
------------------------------------------
 6   1   Te6/1-2       Gi5/3-6
```
To configure the modes of operation for each X2 port group in which you want to deploy Gigabit, enter the `hw-module module m port-group p select gigabitethernet` command. This configuration is preserved across power cycles and reloads.

To deploy Gigabit Ethernet interfaces using the TwinGig Convertor, perform this task:

This example shows how to select Gigabit Ethernet interfaces on a WS-X4606-10GE-E using the TwinGig Convertor:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# hw-module module 1 port-group 1 select gigabitethernet
Switch(config)# exit
Switch# show int status mod 1
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# hw-module module m port-group p select [gigabitethernet</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config)# exit</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch# show int status mod n</td>
</tr>
</tbody>
</table>

This example shows how to select Gigabit Ethernet interfaces on a WS-X4606-10GE-E using the TwinGig Convertor:
Internal Management Port and Supervisor Engine 7-E

The Internal Management Port is not supported on WS-X45-SUP-7E. The configuration for the internal management port always appears in the running configuration in shutdown state. The configuration cannot be changed to the no shut state. One of the front panel ports on the WS-X45-SUP-7E or on a linecard in the chassis can be configured and used as a management port.

Limitation and Restrictions on Supervisor Engine 7-E

Please note the following:

- When you use WS-X45-SUP7-E in RPR or SSO mode, only the first two uplinks on each supervisor engine are available. The second two uplinks are unavailable.

Digital Optical Monitoring Transceiver Support

Command line interface (CLI) commands (show inventory, show idprom interface) are used on transceivers to obtain serial number, model name, inventory information.

The following commands are specific to the transceivers that support the DOM capability:

- Displays current values and thresholds for all sensor on a particular interface transceiver:

  ```
  show interfaces <int-name> transceiver [detail] [threshold]
  ```

- Enables or disables the `entSensorThresholdNotification` for all sensors in all the transceivers:

  ```
  snmp-server enable trap transceiver
  ```

- Enables or disables transceiver monitoring:

  ```
  transceiver type all monitoring
  ```

**Note**

This feature is only available when a DOM capable transceiver is present and configured for monitoring. The frequency at which the sensor information is refreshed depends on default values configured in the transceiver SEEPROM (Serial Electrically Erasable Programmable Read Only Memory).

**Note**

For details on transceiver module compatibility, refer to this URL:

Configuring Optional Interface Features

The following subsections describe optional procedures:

- Configuring Ethernet Interface Speed and Duplex Mode, page 7-11
- Configuring Flow Control, page 7-14
- Configuring Jumbo Frame Support, page 7-16
- Interacting with Baby Giants, page 7-20
- Configuring the Port Debounce Timer, page 7-20
- Configuring auto-MDIX on a Port, page 7-21

Configuring Ethernet Interface Speed and Duplex Mode

- Speed and Duplex Mode Configuration Guidelines, page 7-11
- Setting the Interface Speed, page 7-11
- Setting the Interface Duplex Mode, page 7-12
- Displaying the Interface Speed and Duplex Mode Configuration, page 7-13
- Adding a Description for an Interface, page 7-13

Speed and Duplex Mode Configuration Guidelines

Note

You do not configure the client device for autonegotiation. Rather, you configure the switch with the speed, or range of speeds, that you want to autonegotiate.

You can configure the interface speed and duplex mode parameters to **auto** and allow the Catalyst 4500 series switch to negotiate the interface speed and duplex mode between interfaces. If you decide to configure the interface **speed** and **duplex** commands manually, consider the following:

- If you enter the **no speed** command, the switch automatically configures both interface **speed** and **duplex** to **auto**.
- When you set the interface speed to **1000** (Mbps) or **auto 1000**, the duplex mode is full duplex. You cannot change the duplex mode.
- If the interface speed is set to **10** or **100**, the duplex mode is set to half duplex by default unless you explicitly configure it.

Caution

Changing the interface speed and duplex mode configuration might shut down and restart the interface during the reconfiguration.

Setting the Interface Speed

If you set the interface speed to **auto** on a 10/100-Mbps Ethernet interface, speed and duplex are autonegotiated. The forced 10/100 autonegotiation feature allows you to limit interface speed auto negotiation up to 100 Mbps on a 10/100/1000BASE-T port.
To set the port speed for a 10/100-Mbps Ethernet interface, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch(config)# interface fastethernet slot/interface</td>
</tr>
<tr>
<td></td>
<td>Specifies the interface to be configured.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config-if)# speed [10</td>
</tr>
<tr>
<td></td>
<td>Sets the interface speed of the interface.</td>
</tr>
</tbody>
</table>

This example shows how to set the interface speed to 100 Mbps on the Fast Ethernet interface 5/4:

```
Switch(config)# interface fastethernet 5/4
Switch(config-if)# speed 100
```

This example shows how to allow Fast Ethernet interface 5/4 to autonegotiate the speed and duplex mode:

```
Switch(config)# interface fastethernet 5/4
Switch(config-if)# speed auto
```

**Note**

This is analogous to specifying `speed auto 10 100`.

This example shows how to limit the interface speed to 10 and 100 Mbps on the Gigabit Ethernet interface 1/1 in auto-negotiation mode:

```
Switch(config)# interface gigabitethernet 1/1
Switch(config-if)# speed auto 10 100
```

This example shows how to limit speed negotiation to 100 Mbps on the Gigabit Ethernet interface 1/1:

```
Switch(config)# interface gigabitethernet 1/1
Switch(config-if)# speed auto 100
```

**Note**

Turning off autonegotiation on a Gigabit Ethernet interface will result in the port being forced into 1000 Mbps and full-duplex mode.

To turn off the port speed autonegotiation for Gigabit Ethernet interface 1/1, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch(config)# interface gigabitethernet1/1</td>
</tr>
<tr>
<td></td>
<td>Specifies the interface to be configured.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config-if)# speed nonegotiate</td>
</tr>
<tr>
<td></td>
<td>Disables autonegotiation on the interface.</td>
</tr>
</tbody>
</table>

To restore autonegotiation, enter the `no speed nonegotiate` command in the interface configuration mode.

**Note**

For the blocking ports on the WS-X4416 module, do not set the speed to autonegotiate.

## Setting the Interface Duplex Mode

**Note**

When the interface is set to 1000 Mbps, you cannot change the duplex mode from full duplex to half duplex.
To set the duplex mode of a Fast Ethernet interface, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch(config)# interface fastethernet slot/interface</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config-if)# duplex [auto</td>
</tr>
</tbody>
</table>

This example shows how to set the interface duplex mode to full on Fast Ethernet interface 5/4:

```
Switch(config)# interface fastethernet 5/4
Switch(config-if)# duplex full
```

### Displaying the Interface Speed and Duplex Mode Configuration

To display the interface speed and duplex mode configuration for an interface, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Switch# show interfaces [fastethernet</td>
</tr>
</tbody>
</table>

This example shows how to display the interface speed and duplex mode of Fast Ethernet interface 6/1:

```
Switch# show interface fastethernet 6/1
FastEthernet6/1 is up, line protocol is up
    Hardware is Fast Ethernet Port, address is 0050.547a.dee0 (bia 0050.547a.dee0)
    MTU 1500 bytes, BW 100000 Kbit, DLY 100 usec,
        reliability 255/255, txload 1/255, rxload 1/255
    Encapsulation ARPA, loopback not set
    Keepalive set (10 sec)
    Full-duplex, 100Mb/s
    ARP type: ARPA, ARP Timeout 04:00:00
    Last input 00:00:54, output never, output hang never
    Last clearing of "show interface" counters never
    Input queue: 50/2000/0/0 (size/max/drops/flushes); Total output drops: 0
    Queueing strategy: fifo
    Output queue: 0/40 (size/max)
    5 minute input rate 0 bits/sec, 0 packets/sec
    5 minute output rate 0 bits/sec, 0 packets/sec
    50 packets input, 11300 bytes, 0 no buffer
    Received 50 broadcasts, 0 runts, 0 giants, 0 throttles
    0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
    0 input packets with dribble condition detected
    1456 packets output, 111609 bytes, 0 underruns
    0 output errors, 0 collisions, 0 interface resets
    0 packets, 0 late collision, 0 deferred
    1 lost carrier, 0 no carrier
    0 output buffer failures, 0 output buffers swapped out
```

### Adding a Description for an Interface

You can add a description about an interface to help you remember its function. The description appears in the output of the following commands: `show configuration`, `show running-config`, and `show interfaces`.
To add a description for an interface, enter the following command:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config-if)# description string</td>
<td>Adds a description for an interface.</td>
</tr>
</tbody>
</table>

This example shows how to add a description on Fast Ethernet interface 5/5:

```
Switch(config)# interface fastethernet 5/5
Switch(config-if)# description Channel-group to "Marketing"
```

### Configuring Flow Control

Gigabit Ethernet ports use Flow Control to slow-down the transmission of incoming packets. If a buffer on a Gigabit Ethernet port runs out of space, the port transmits a special packet that requests remote ports to delay sending packets for a period of time. The port can also receive this special packet from its link-partner for the same purpose. This special packet is called a pause frame.

The default settings for Gigabit Ethernet interfaces are as follows:

- Sending pause frames is off—non-oversubscribed Gigabit Ethernet interfaces.
- Receiving pause frames is desired—non-oversubscribed Gigabit Ethernet interfaces.
- Sending pause frames is on—Oversubscribed Gigabit Ethernet interfaces.
- Receiving pause frames is desired—Oversubscribed Gigabit Ethernet interfaces.

The default settings for Tengigabit Ethernet interfaces are as follows:

- Sending pause frames is off.
- Receiving pause frames is on.

**Note**

*desired* is not a flow control option on the Tengigabit Ethernet interfaces.

To configure flow control, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1  Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 2  Switch(config)# interface interface-id</td>
<td>Enters interface configuration mode and specifies the interface to be enabled for flowcontrol.</td>
</tr>
<tr>
<td>Step 3  Switch(config-if)# flowcontrol receive</td>
<td>Configures a Gigabit Ethernet port to send or receive pause frames.</td>
</tr>
<tr>
<td></td>
<td>send</td>
</tr>
<tr>
<td>Step 4  Switch(config-if)# end</td>
<td>Returns to configuration mode.</td>
</tr>
<tr>
<td>Step 5  Switch(config)# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
</tbody>
</table>

This example shows how to configure flow control on an oversubscribed Gigabit Ethernet port 7/5:

```
Switch# configure terminal
Switch(config)# interface g7/5
Switch(config-if)# flowcontrol send on
Switch(config-if)# end
Switch)# show interfaces gigabitEthernet 7/5 capabilities
```
### Configuring Optional Interface Features

**GigabitEthernet7/5**
- **Model:** WS-X4548-GB-RJ45-RJ-45
- **Type:** 10/100/1000-TX
- **Speed:** 10,100,1000,auto
- **Duplex:** half,full,auto
- **Trunk encap. type:** 802.1Q,ISL
- **Trunk mode:** on,off,desirable,nonegotiate
- **Channel:** yes
- **Broadcast suppression:** percentage(0-100), hw

**Flowcontrol:** rx-(off,on,desired), tx-(off,on,desired)

**VLAN Membership:** static, dynamic

**Fast Start:** yes

**Queueing:** rx-(N/A), tx-(1p3q1t, Sharing/Shaping)

**CoS rewrite:** yes

**ToS rewrite:** yes

**Inline power:** no

**SPAN:** source/destination

**UDLD:** yes

**Link Debounce:** no

**Link Debounce Time:** no

**Port Security:** yes

**Dot1x:** yes

**Maximum MTU:** 1552 bytes (Baby Giants)

**Multiple Media Types:** no

**Diagnostic Monitoring:** N/A

```
Switch# show flowcontrol interface GigabitEthernet 7/5
Port       Send FlowControl  Receive FlowControl  RxPause TxPause
---------  -------- -------- -------- --------    ------- -------
Gi7/5      on        off      desired  off       0    0
```

This example shows the output of the `show interfaces` and `show flowcontrol` commands on a non-oversubscribed Gigabit Ethernet port 5/5:

```
Switch# show interfaces gigabitEthernet 5/5 capabilities
GigabitEthernet5/5
Model:     WS-X4306-GB-Gbic
Type:      No Gbic
Speed:     1000
Duplex:    full
Trunk encap. type: 802.1Q,ISL
Trunk mode: on,off,desirable,nonegotiate
Channel:   yes
Broadcast suppression: percentage(0-100), hw

**Flowcontrol:** rx-(off,on,desired), tx-(off,on,desired)

**VLAN Membership:** static, dynamic

**Fast Start:** yes

**Queueing:** rx-(N/A), tx-(1p3q1t, Sharing/Shaping)

**CoS rewrite:** yes

**ToS rewrite:** yes

**Inline power:** no

**SPAN:** source/destination

**UDLD:** yes

**Link Debounce:** no

**Link Debounce Time:** no

**Port Security:** yes

**Dot1x:** yes

**Maximum MTU:** 9198 bytes (Jumbo Frames)

**Multiple Media Types:** no

**Diagnostic Monitoring:** N/A

Switch# show flowcontrol interface gigabitEthernet 5/5
Port       Send FlowControl  Receive FlowControl  RxPause TxPause
---------  -------- -------- -------- --------    ------- -------
Gi5/5      on        off      desired  off       0    0
```
Chapter 7  Configuring Interfaces

Configuring Optional Interface Features

This example shows the output of the `show interfaces` and `show flowcontrol` commands on an unsupported Fast Ethernet port 3/5:

```
Switch# show interfaces fa3/5 capabilities
FastEthernet3/5
  Model:                 WS-X4148-RJ-45
  Type:                  10/100BaseTX
  Speed:                 10,100,auto
  Duplex:                half,full,auto
  Trunk encap. type:     802.1Q,ISL
  Trunk mode:            on,off,desirable,nonegotiate
  Channel:               yes
  Broadcast suppression: percentage(0-100), sw
Flowcontrol:           rx-(none),tx-(none)
VLAN Membership:       static, dynamic
Fast Start:            yes
Queuing:               rx-(N/A), tx-(1p3qlt, Shaping)
CoS rewrite:           yes
ToS rewrite:           yes
Inline power:          no
SPAN:                  source/destination
UDLD:                  yes
Link Debounce:         no
Link Debounce Time:    no
Port Security:         yes
Dot1x:                 yes
Maximum MTU:           1552 bytes (Baby Giants)
Multiple Media Types:  no
Diagnostic Monitoring: N/A
```

```
Switch# show flowcontrol interface fa3/5
Port       Send FlowControl  Receive FlowControl  RxPause TxPause
admin      oper     admin    oper     ---------  -------- -------- -------- ------- -------
Fa3/5      Unsupp.  Unsupp.  Unsupp.  Unsupp.      0       0
```

Note

Although all interfaces are termed 10-Gigabit interfaces on WS-X45-SUP7+E and WS-X4712-SFP+E, if an interface has an SFP, the interface is treated as a Gigabit Ethernet interface.

Configuring Jumbo Frame Support

These subsections describe jumbo frame support:

- **Ports and Modules that Support Jumbo Frames, page 7-16**
- **Jumbo Frame Support, page 7-17**
- **Configuring MTU Sizes, page 7-19**

**Ports and Modules that Support Jumbo Frames**

The following ports and modules support jumbo frames:

- Supervisor uplink ports
- WS-X4306-GB: all ports
Chapter 7 Configuring Interfaces

Configuring Optional Interface Features

- WS-X4232-GB-RJ: ports 1-2
- WS-X4418-GB: ports 1-2
- WS-X4412-2GB-TX: ports 13-14
- WS-X4506-GB-T
- WS-X4606-X2-E
- WS-X4648-RJ45-E
- WS-X4648-RJ45V+E
- WS-X4648-RJ45V-E
- WS-X4712-SFP+E
- WS-X4748-UPOE+E
- WS-X4748-RJ45-E
- WS-X4748-RJ45V+E

Jumbo Frame Support

These sections describe jumbo frame support:
- Maximum Transmission Units, page 7-17
- Jumbo Frame Support Overview, page 7-17
- Ethernet Ports, page 7-18
- VLAN Interfaces, page 7-18

Maximum Transmission Units

The Catalyst 4500 series switch allows you to configure a maximum of 32 different maximum transmission unit (MTU) sizes system wide. This means that the maximum number of different MTU sizes that you can configure with the `system mtu`, `mtu`, `ip mtu`, and `ipv6 mtu` command on all Layer 2 and Layer 3 interfaces combined is 32.

Also, the system stores the ipv4 and ipv6 MTU sizes configured on an interface separately. So, for every `system mtu` command or per interface `mtu` command, two separate MTU values are stored, one for ipv4 and one for ipv6. This further reduces the number of slots available (out of 32). However, only a single MTU value is stored for each `ip mtu` and `ipv6 mtu` commands.

If the new MTU value you are configuring is already present in the system (that is, configured on some other interface), then no new slot(s) will be allocated to store it again.

If the maximum limit of 32 is reached and an attempt is made to configure a new MTU size on a new interface, the system will only allow configuration to proceed if the new MTU size has previously been configured on some interface. Otherwise, an error message will be displayed and the default MTU size will be assigned to the interface being configured.

Jumbo Frame Support Overview

A jumbo frame is a frame larger than the default Ethernet size. Enable jumbo frame support by configuring a larger-than-default MTU size on a port or interface.
Catalyst 4500 series switch Ethernet LAN ports configured with a nondefault MTU size accept frames containing packets with a size between 1500 and 9216 bytes (including Ethernet payload, header and trailer). (The maximum MTU size for a Catalyst 4948 series switch is 9198 bytes (not including header and trailer.).) With a nondefault MTU size configured, the packet size of ingress frames is checked. If the packet is larger than the configured MTU, it is dropped.

For traffic that needs to be routed, the MTU of the egress port is checked. If the MTU is smaller than the packet size, the packet is forwarded to the CPU. If the “do not fragment bit” is not set, it is fragmented. Otherwise, the packet is dropped.

**Note**

Jumbo frame support does not fragment Layer 2 switched packets.

The Catalyst 4500 series switch does not compare the packet size with the MTU at the egress port, but jumbo frames are dropped in ports that do not support them. The frames can be transmitted in ports that do support jumbo frames, even though the MTU is not configured to jumbo size.

**Note**

Jumbo frame support is only configured per interface; jumbo frame support cannot be configured globally.

### Ethernet Ports

These sections describe configuring nondefault MTU sizes on Ethernet ports:

- Ethernet Port Overview, page 7-18
- Layer 3 and Layer 2 EtherChannels, page 7-18

#### Ethernet Port Overview

Configuring a nondefault MTU size on certain Ethernet ports limits the size of ingress packets. The MTU does not impact the egress packets.

#### Layer 3 and Layer 2 EtherChannels

You can configure all the interfaces in an EtherChannel provided that they have the same MTU. Changing the MTU of an EtherChannel changes the MTU of all member ports. If the MTU of a member port cannot be changed to the new value, that port is suspended (administratively shut down). A port cannot join an EtherChannel if the port has a different MTU. If a member port of an EtherChannel changes MTU, the member port is suspended.

### VLAN Interfaces

If switch ports reside in the same VLAN, either configure all of the switch ports to handle jumbo frames and support the same MTU size, or configure none of them. However, such uniformity of MTU size in the same VLAN is not enforced.

When a VLAN has switch ports with different MTU size, packets received from a port with a larger MTU might be dropped when they are forwarded to a port with a smaller MTU.

If the switch ports in a VLAN have jumbo frames enabled, the corresponding SVI can have jumbo frames enabled. The MTU of an SVI should always be smaller than the smallest MTU among all the switch ports in the VLAN, but this condition is not enforced.
The MTU of a packet is not checked on the ingress side for an SVI; it is checked on the egress side of an SVI. If the MTU of a packet is larger than the MTU of the egress SVI, the packet will be sent to the CPU for fragmentation processing. If the “do not fragment” bit is not set, the packet is fragmented. Otherwise, the packet is dropped.

**Configuring MTU Sizes**

To configure the MTU size, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> Switch(config)# interface {{ (vlan vlan_ID)</td>
<td>(((type slot/port)</td>
</tr>
<tr>
<td><strong>Step 2</strong> Switch(config-if)# mtu mtu_size</td>
<td>Configures the MTU size.</td>
</tr>
<tr>
<td>Switch(config-if)# no mtu</td>
<td>Reverts to the default MTU size (1500 bytes).</td>
</tr>
<tr>
<td><strong>Step 3</strong> Switch(config-if)# end</td>
<td>Exits configuration interface mode.</td>
</tr>
<tr>
<td><strong>Step 4</strong> Switch(config)# end</td>
<td>Exits configuration mode.</td>
</tr>
<tr>
<td><strong>Step 5</strong> Switch# show running-config interface [{fastethernet</td>
<td>gigabitethernet) slot/port]}</td>
</tr>
</tbody>
</table>

1. *type = fastethernet, gigabitethernet, or tengigabitethernet*

**Note** When you remove a linecard, and then reinset the card, some or all of the MTU values configured on the ports of that linecard may be unconfigured. This will happen if the system wide limit of 32 different MTUs is reached while the card is removed. Upon reinserting the linecard, the system attempts to reapply the MTU configuration on the ports. If this attempt fails, the MTU values are set to the default.

**Note** When configuring the MTU size for VLAN interfaces and Layer 3 and Layer 2 Ethernet ports, note that the supported MTU values are from 1500 to 9198 bytes.

This example shows how to configure the MTU size on Gigabit Ethernet port 1/1:

```
switch# conf terminal
switch(config)# interface gi1/1
switch(config-if)# mtu 9198
switch(config-if)# end
switch(config)# end
switch# show interface gigabitethernet 1/2
GigabitEthernet1/2 is administratively down, line protocol is down
  Hardware is C6k 1000Mb 802.3, address is 0030.9629.9f88 (bia 0030.9629.9f88)
  MTU 9216 bytes, BW 1000000 Kbit, DLY 10 usec,
  <...Output Truncated...>
switch#
```

For details on how to configure IP MTU size, refer to **Configuring MTU Sizes, page 7-19.**
Interacting with Baby Giants

The baby giants feature uses the global command `system mtu <size>` to set the global baby giant MTU. This feature also allows certain interfaces to support Ethernet payload size of up to 1552 bytes.

Both the `system mtu` command and the per-interface `mtu` command can operate on interfaces that can support jumbo frames, but the per-interface `mtu` command takes precedence.

For example, before setting the per-interface MTU for interface gi1/1, you issue the `system mtu 1550` command to change the MTU for gi1/1 to 1550 bytes. Next, you issue the per-interface `mtu` command to change the MTU for gi1/1 to 9198 bytes. Now, if you change the baby giant MTU to 1540 bytes with the command `system mtu 1540`, the MTU for gi1/1 remains unchanged at 9198 bytes.

Configuring the Port Debounce Timer

The port debounce timer delays notification of a link change, which can decrease traffic loss due to network reconfiguration. You can configure the port debounce timer separately on each LAN port.

**Note**

You can only configure Port Debounce on 10GE ports.

**Caution**

Enabling the port debounce timer causes link up and link down detections to be delayed, resulting in loss of traffic during the debouncing period. This situation might affect the convergence and reconvergence of some Layer 2 and Layer 3 protocols.

To configure the debounce timer on a port, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch(config)# interface tengigabitethernet slot/port</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config-if)# link debounce [time debounce_time] Switch(config-if)# no link debounce</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch# show interfaces debounce</td>
</tr>
</tbody>
</table>

When configuring the debounce timer on a port, you can increase the port debounce timer value between 10 milliseconds and 5000 milliseconds on the tengigabitethernet ports.

**Note**

By default, debounce is disabled. If you configure debounce without a time, the value is set at 100ms.

This example shows how to enable the port debounce timer on TenGigabit Ethernet port 2/1 and to accept the default value (10 ms):

```
Switch# config terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface tengigabitEthernet 2/1
Switch(config-if)# link debounce
Warning: Enabling debounce feature causes link down detection to be delayed
Switch(config-if)# exit
```
This example shows how to enable the port debounce timer of 5000 ms on TenGigabit Ethernet port 2/2 and to verify the setting:

Switch# config terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface tenGigabitEthernet 2/2
Switch(config-if)# link debounce time 5000
Warning: Enabling debounce feature causes link down detection to be delayed
Switch(config-if)# end
Switch#
Switch# show interfaces debounce | include enable
Te2/1 enable 10
Te2/2 enable 5000
Switch#

Configuring auto-MDIX on a Port

When automatic medium-dependent-interface crossover (auto-MDIX) is enabled on a port, the port automatically detects the required cable connection type (straight through or crossover) and configures the connection appropriately. When connecting switches without the auto-MDIX feature, you must use straight-through cables to connect to devices such as servers, workstations, or routers and crossover cables to connect to other switches or repeaters. With auto-MDIX enabled, you can use either type of cable to connect to other devices, and the interface automatically corrects for any incorrect cabling. For more information about cabling requirements, see the hardware installation guide.

Auto-MDIX is enabled by default. When you enable auto-MDIX, you must also set the speed on the port to auto so that for the feature to operate correctly. auto-MDIX is supported on copper media ports. It is not supported on fiber media ports.

---

**Note**
The following linecards support Auto-MDIX by default, when port auto-negotiation is enabled:

---

**Note**
The following linecards do not support Auto-MDIX, neither by default nor by CLI:

---

**Note**
The following linecards support Auto-MDIX through the CLI on their copper media ports:
WS-X4124-RJ45, WS-X4148-RJ45 (hardware revision 3.0 or higher), and WS-X4232-GB-RJ45 (hardware revision 3.0, or higher), WS-X4920-GE-RJ45 and WS-4648-RJ45V+E (Auto-MDIX support when inline power is disabled on the port).

*Table 7-1* shows the link states that results from auto-MDIX settings and correct and incorrect cabling.

<table>
<thead>
<tr>
<th>Local Side auto-MDIX</th>
<th>Remote Side auto-MDIX</th>
<th>With Correct Cabling</th>
<th>With Incorrect Cabling</th>
</tr>
</thead>
<tbody>
<tr>
<td>On</td>
<td>On</td>
<td>Link up</td>
<td>Link up</td>
</tr>
<tr>
<td>On</td>
<td>Off</td>
<td>Link up</td>
<td>Link up</td>
</tr>
</tbody>
</table>
To configure auto-MDIX on a port, perform the following task:

**Table 7-1** Link Conditions and auto-MDIX Settings (continued)

<table>
<thead>
<tr>
<th>Local Side auto-MDIX</th>
<th>Remote Side auto-MDIX</th>
<th>With Correct Cabling</th>
<th>With Incorrect Cabling</th>
</tr>
</thead>
<tbody>
<tr>
<td>Off</td>
<td>On</td>
<td>Link up</td>
<td>Link up</td>
</tr>
<tr>
<td>Off</td>
<td>Off</td>
<td>Link up</td>
<td>Link down</td>
</tr>
</tbody>
</table>

To display the interface auto-MDIX configuration, perform this task:

**Displaying the Interface auto-MDIX Configuration**

To disable auto-MDIX, use the `no mdix auto` interface configuration command.

Depending on how the `speed auto` and the `mdix auto` commands are configured on a supported linecard interface, the `show interfaces` command displays the following possible auto-MDIX statuses:

Table 7-2 shows the auto-MDIX setting and operational state and the status of auto-MDIX.
This example shows how to display the auto-MDI-X configuration setting and its operational state on Fast Ethernet interface 6/1:

```
Switch# show interfaces fastethernet 6/1
FastEthernet6/1 is up, line protocol is up (connected)
Hardware is Fast Ethernet Port, address is 0001.64fe.e5d0 (bia 0001.64fe.e5d0)
MTU 1500 bytes, BW 100000 Kbit, DLY 100 usec,
   reliability 255/255, txload 1/255, rxload 1/255
Encapsulation ARPA, loopback not set
Keepalive set (10 sec)
Full-duplex, 100Mb/s, link type is auto, media type is 10/100BaseTX
input flow-control is unsupported output flow-control is unsupported
Auto-MDI-X on (operational: on)
ARP type: ARPA, ARP Timeout 04:00:00
Last input 00:00:16, output never, output hang never
Last clearing of "show interface" counters never
Input queue: 0/2000/0/0 (size/max/drops/flushes); Total output drops: 0
Queueing strategy: fifo
Output queue: 0/40 (size/max)
5 minute input rate 0 bits/sec, 0 packets/sec
5 minute output rate 0 bits/sec, 0 packets/sec
   511 packets input, 74464 bytes, 0 no buffer
   Received 511 broadcasts (511 multicasts)
   0 runts, 0 giants, 0 throttles
   0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
   0 input packets with dribble condition detected
   3552 packets output, 269088 bytes, 0 underruns
   0 output errors, 0 collisions, 0 interface resets
   0 babbles, 0 late collision, 0 deferred
   1 lost carrier, 0 no carrier
   0 output buffer failures, 0 output buffers swapped out
Switch#
```

### Understanding Online Insertion and Removal

The online insertion and removal (OIR) feature supported on the Catalyst 4500 series switch allows you to remove and replace modules while the system is online. You can shut down the module before removal and restart it after insertion without causing other software or interfaces to shut down.
You do not need to enter a command to notify the software that you are going to remove or install a module. The system notifies the supervisor engine that a module has been removed or installed and scans the system for a configuration change. The newly installed module is initialized, and each interface type is verified against the system configuration; then the system runs diagnostics on the new interface. There is no disruption to normal operation during module insertion or removal.

If you remove a module and then replace it, or insert a different module of the same type into the same slot, no change to the system configuration is needed. An interface of a type that has been configured previously will be brought online immediately. If you remove a module and insert a module of a different type, the interface(s) on that module will be administratively up with the default configuration for that module.

## Monitoring and Maintaining the Interface

The following sections describe how to monitor and maintain the interfaces:

- Monitoring Interface and Controller Status, page 7-24
- Clearing and Resetting the Interface, page 7-25
- Shutting Down and Restarting an Interface, page 7-25
- Configuring Interface Link Status and Trunk Status Events, page 7-26
- Resetting the Interface to the Default Configuration, page 7-28

### Monitoring Interface and Controller Status

The Cisco IOS software for the Catalyst 4500 series switch contains commands that you can enter at the EXEC prompt to display information about the interface, including the version of the software and the hardware, the controller status, and statistics about the interfaces. The following table lists some of the interface monitoring commands. (You can display the full list of show commands by entering the `show ?` command at the EXEC prompt.) These commands are fully described in the Interface Command Reference.

To display information about the interface, perform this task:

<table>
<thead>
<tr>
<th>Step</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Switch# <code>show interfaces [type slot/interface]</code></td>
<td>Displays the status and configuration of all interfaces or of a specific interface.</td>
</tr>
<tr>
<td>2</td>
<td>Switch# <code>show running-config</code></td>
<td>Displays the configuration currently running in RAM.</td>
</tr>
<tr>
<td>3</td>
<td>Switch# <code>show protocols [type slot/interface]</code></td>
<td>Displays the global (system-wide) and interface-specific status of any configured protocol.</td>
</tr>
<tr>
<td>4</td>
<td>Switch# <code>show version</code></td>
<td>Displays the hardware configuration, software version, the names and sources of configuration files, and the boot images.</td>
</tr>
</tbody>
</table>

This example shows how to display the status of Fast Ethernet interface 5/5:

```
Switch# `show protocols fastethernet 5/5`
FastEthernet5/5 is up, line protocol is up
Switch#
```
Clearing and Resetting the Interface

To clear the interface counters shown with the `show interfaces` command, enter the following command:

```
Command Purpose
Switch# clear counters (type slot/interface) Clears interface counters.
```

This example shows how to clear and reset the counters on Fast Ethernet interface 5/5:

```text
Switch# clear counters fastethernet 5/5
Clear *show interface* counters on this interface [confirm] y
Switch#
*Sep 30 08:42:55: %CLEAR-5-COUNTERS: Clear counter on interface FastEthernet5/5
by vty1 (171.69.115.10)
Switch#
```

The `clear counters` command (without any arguments) clears all the current interface counters from all interfaces.

**Note**
The `clear counters` command does not clear counters retrieved with SNMP; it clears only those counters displayed with the EXEC `show interfaces` command.

Shutting Down and Restarting an Interface

You can disable an interface, which disables all functions on the specified interface and marks the interface as unavailable on all monitoring command displays. This information is communicated to other network servers through all dynamic routing protocols. The interface will not be mentioned in any routing updates.

To shut down an interface and then restart it, perform this task:

```
Command Purpose
Step 1 Switch(config)# interface {vlan vlan_ID} | {
((fastethernet | gigabitethernet |
tengigabitethernet) slot/port) | {port-channel
port_channel_number} Specifies the interface to be configured.
Step 2 Switch(config-if)# shutdown Shuts down the interface.
Step 3 Switch(config-if)# no shutdown Reenables the interface.
```

This example shows how to shut down Fast Ethernet interface 5/5:

```text
Switch(config)# interface fastethernet 5/5
Switch(config-if)# shutdown
Switch(config-if)#
*Sep 30 08:33:47: %LINK-5-CHANGED: Interface FastEthernet5/5, changed state to a
administratively down
Switch(config-if)#
```
This example shows how to reenable Fast Ethernet interface 5/5:

Switch(config-if)# no shutdown
Switch(config-if)#

*Sep 30 08:36:00: %LINK-3-UPDOWN: Interface FastEthernet5/5, changed state to up
Switch(config-if)#

To verify whether an interface is disabled, enter the EXEC `show interfaces` command. An interface that has been shut down will appear as “administratively down.”

### Configuring Interface Link Status and Trunk Status Events

You can configure interface link status and trunk status events. On the Catalyst 4500 series switch, the following interface logging event notifications are supported both globally and per interface:

- Enable/disable notification on the interface whenever its data link status is changed.
- Enable/disable notification on the trunk interface whenever its trunking status is changed.

Use the `[no] logging event link-status [use-global]` command to enable/disable the interface link status event. Use the `[no] logging event trunk-status [use-global]` command to enable/disable the interface trunk status event.

Each interface link status logging event can be configured in one of the following states:

- **logging event link-status** - Link status logging event is enabled explicitly on the interface regardless of the switch global setting.
- **no logging event link-status** - Link status logging event is disabled explicitly on the interface regardless of the switch global setting.
- **logging event link-status use-global** - This is the default link status logging event configuration on the interface; its configuration should follow the switch global link status logging event setting.

The interface trunk status logging event can be configured in the same configuration states.

### Configuring Link Status Event Notification for an Interface

To enable/disable a link status logging event, enter one of the following commands:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config-if)# <code>logging event link-status</code></td>
<td>Enables interface link status logging.</td>
</tr>
<tr>
<td>Switch(config-if)# <code>no logging event link-status</code></td>
<td>Disables interface link status logging.</td>
</tr>
<tr>
<td>Switch(config-if)# <code>logging event link-status use-global</code></td>
<td>Specifies the global default setting for interface link status logging.</td>
</tr>
</tbody>
</table>

### Global Settings

You can also provide a global configuration for the corresponding logging event. A global configuration provides default logging settings for all interfaces. The `[no] logging event link-status global` command lets you enable/disable the interface link status logging for the entire switch. The `[no] logging event trunk-status global` command lets you enable/disable interface trunk status logging for the entire switch.
Each interface link status logging event, if not configured at the interface level, will use the following global logging event setting:

- **logging event link-status global** - Link status logging event is enabled, if not configured on the interface.
- **no logging event link-status global** - Link status logging event is disabled, if not configured on the interface.

The interface trunk status logging event has similar global configurations.

### Configuring a Switch Global Link Status Logging Event

To enable/disable the global link status logging event, enter one of the following commands:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config-if)# <strong>logging event link-status global</strong></td>
<td>Enables global link status logging.</td>
</tr>
<tr>
<td>Switch(config-if)# <strong>no logging event link-status global</strong></td>
<td>Disables global link status logging.</td>
</tr>
</tbody>
</table>

### Result

The following example displays a summary of the operating states for the interface logging event under different combinations of global and interface logging settings:

<table>
<thead>
<tr>
<th>global setting</th>
<th>interface setting</th>
<th>actual logging state</th>
</tr>
</thead>
<tbody>
<tr>
<td>on</td>
<td>on</td>
<td>on</td>
</tr>
<tr>
<td>off</td>
<td>on</td>
<td>on</td>
</tr>
<tr>
<td>on</td>
<td>off</td>
<td>off</td>
</tr>
<tr>
<td>off</td>
<td>off</td>
<td>off</td>
</tr>
<tr>
<td>on</td>
<td>default(use-global)</td>
<td>on</td>
</tr>
<tr>
<td>off</td>
<td>default(use-global)</td>
<td>off</td>
</tr>
</tbody>
</table>

The following example displays the configuration and logging message output for link status and trunk status logging events:

```
//
// The global link status and trunk status logging events are enabled.
//
Switch# **show running | include logging**
show running | include logging
logging event link-status global
logging event trunk-status global
Switch#

//
// The interface link status and trunk status logging settings
// are set to default values, which follow regardless of the global
// setting.
//
Switch# **show running interface g1/4**
Building configuration...

Current configuration: 97 bytes
!
interface GigabitEthernet1/4
  switchport trunk encapsulation dot1q
  switchport mode trunk
end
```
Switch#

//
// The trunk status logging messages for the interface are
// displayed whenever the interface trunking status is changed.
// Here we change the other end node's trunking encapsulation
// from dot1q to isl.
//
3d00h: %DTP-5-ILGLCFG: Illegal config(on,isl--on,dot1q) on Gi1/4
3d00h: %DTP-5-ILGLCFG: Illegal config(on,isl--on,dot1q) on Gi1/4
3d00h: %DTP-5-ILGLCFG: Illegal config(on,isl--on,dot1q) on Gi1/4

//
// The link and trunk status logging message for the interface
// are displayed whenever the interface link status is changed.
// Here we do a "shut" and "no shut" on the other end link node.
//
3d00h: %DTP-5-NONTRUNKPORTON: Port Gi1/4 has become non-trunk
3d00h: %LINEPROTO-5-UPDOWN: Line protocol on Interface
GigabitEthernet1/4, changed state to down
3d00h: %LINK-3-UPDOWN: Interface GigabitEthernet1/4, changed state to
down
3d00h: %LINK-3-UPDOWN: Interface GigabitEthernet1/4, changed state to up
3d00h: %DTP-5-TRUNKPORTON: Port Gi1/4 has become dot1q trunk
3d00h: %LINEPROTO-5-UPDOWN: Line protocol on Interface
GigabitEthernet1/4, changed state to up

---

**Resetting the Interface to the Default Configuration**

If you have configured a interface with many command lines and you want to clear all the configuration
on that interface, you can use the **default interface** global configuration command, as follows:

Switch(config)# default interface fastEthernet 3/5
Interface FastEthernet3/5 set to default configuration

This command will clear all the configurations and shutdown the interface:

Switch# show run interface fastethernet 3/5
Building configuration...

Current configuration : 58 bytes

!  interface FastEthernet3/5
    no ip address
    shutdown
end
This chapter describes how to check switch port status and connectivity on the Catalyst 4500 series switch.

This chapter includes the following major sections:

- Checking Module Status, page 8-2
- Checking Interfaces Status, page 8-2
- Displaying MAC Addresses, page 8-3
- Checking Cable Status Using Time Domain Reflectometer, page 8-3
- Using Telnet, page 8-5
- Changing the Logout Timer, page 8-6
- Monitoring User Sessions, page 8-6
- Using Ping, page 8-7
- Using IP Traceroute, page 8-8
- Using Layer 2 Traceroute, page 8-10
- Configuring ICMP, page 8-12

For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

Checking Module Status

The Catalyst 4500 series switch is a multimodule system. You can see which modules are installed, as well as the MAC address ranges and version numbers for each module, by using the `show module` command. You can use the `[mod_num]` argument to specify a particular module number to see detailed information on that module.

This example shows how to check module status for all modules on your switch:

```
Switch# show module all
```

<table>
<thead>
<tr>
<th>Mod</th>
<th>Ports</th>
<th>Card Type</th>
<th>Model</th>
<th>Serial No.</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>1000BaseX (GBIC) Supervisor Module</td>
<td>WS-X4014</td>
<td>JAB012345AB</td>
</tr>
<tr>
<td>5</td>
<td>24</td>
<td>10/100/1000BaseTX (RJ45)</td>
<td>WS-X4424-GB-RJ45</td>
<td>JAB045304EY</td>
</tr>
<tr>
<td>6</td>
<td>48</td>
<td>10/100BaseTX (RJ45)</td>
<td>WS-X4148</td>
<td>JAB023402QK</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>MAC addresses</th>
<th>Hw</th>
<th>Fw</th>
<th>Sw</th>
<th>Stat</th>
</tr>
</thead>
<tbody>
<tr>
<td>0004.dd46.9f00 to 0004.dd46.a2ff</td>
<td>0.0</td>
<td>12.1(10r)EW(1.21)</td>
<td>12.1(10)EW(1)</td>
<td>Ok</td>
</tr>
<tr>
<td>0050.3e7e.1d70 to 0050.3e7e.1d87</td>
<td>0.0</td>
<td></td>
<td></td>
<td>Ok</td>
</tr>
<tr>
<td>0050.0f10.2370 to 0050.0f10.239f</td>
<td>1.0</td>
<td></td>
<td></td>
<td>Ok</td>
</tr>
</tbody>
</table>

Checking Interfaces Status

You can view summary or detailed information on the switch ports using the `show interfaces status` command. To see summary information on all ports on the switch, enter the `show interfaces status` command with no arguments. Specify a particular module number to see information on the ports on that module only. Enter both the module number and the port number to see detailed information about the specified port.

To apply configuration commands to a particular port, you must specify the appropriate logical module. For more information, see the “Checking Module Status” section on page 8-2.

This example shows how to display the status of all interfaces on a Catalyst 4500 series switch, including transceivers. Output of this command displays “Unapproved GBIC” for non-Cisco transceivers:

```
Switch# show interfaces status
```

<table>
<thead>
<tr>
<th>Port</th>
<th>Name</th>
<th>Status</th>
<th>Vlan</th>
<th>Duplex</th>
<th>Speed</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gi1/1</td>
<td></td>
<td>notconnect</td>
<td>1</td>
<td>auto</td>
<td>auto</td>
<td>No GBic</td>
</tr>
<tr>
<td>Gi1/2</td>
<td></td>
<td>notconnect</td>
<td>1</td>
<td>auto</td>
<td>auto</td>
<td>No GBic</td>
</tr>
<tr>
<td>Gi5/1</td>
<td></td>

<td>auto</td>
<td>10/100BaseTX</td>
</tr>
</tbody>
</table>

Switch#
This example shows how to display the status of interfaces in error-disabled state:

```
Switch# show interfaces status err-disabled
Port  Name          Status      Reason
Fa9/4                      err-disabled  link-flap
```

Displaying MAC Addresses

In addition to displaying the MAC address range for a module using the `show module` command, you can display the MAC address table information of a specific MAC address or a specific interface in the switch using the `show mac-address-table address` and `show mac-address-table interface` commands.

This example shows how to display MAC address table information for a specific MAC address:

```
Switch# show mac-address-table address 0050.3e8d.6400
  vlan  mac address     type    protocol  qos             ports
       ------+---------------+--------+---------+---+--------------------------------
       200  0050.3e8d.6400  static   assigned  --  Switch
       100  0050.3e8d.6400  static   assigned  --  Switch
        5  0050.3e8d.6400  static   assigned  --  Switch
         4  0050.3e8d.6400  static        ipx  --  Switch
            1  0050.3e8d.6400  static        ipx  --  Switch
            1  0050.3e8d.6400  static   assigned  --  Switch
            5  0050.3e8d.6400  static        ipx  --  Switch
            100 0050.3e8d.6400  static        ipx  --  Switch
            200 0050.3e8d.6400  static        ipx  --  Switch
            100 0050.3e8d.6400  static      other  --  Switch
            200 0050.3e8d.6400  static      other  --  Switch
            5  0050.3e8d.6400  static      other  --  Switch
             4  0050.3e8d.6400  static         ip  --  Switch
             1  0050.3e8d.6400  static         ip  --  Route
            1  0050.3e8d.6400  static      other  --  Switch
             4  0050.3e8d.6400  static      other  --  Switch
             5  0050.3e8d.6400  static         ip  --  Switch
            200 0050.3e8d.6400  static         ip  --  Switch
            100 0050.3e8d.6400  static         ip  --  Switch
Switch#
```

This example shows how to display MAC address table information for a specific interface:

```
Switch# show mac-address-table interface gigabit 1/1
  vlan  mac address     type    ports
       -------+---------------+------------------------------------------
        1    ffff.ffff.ffff system  Switch,Gi6/1,Gi6/2,Gi6/9,Gi1/1
Switch#
```

Checking Cable Status Using Time Domain Reflectometer

The Time Domain Reflectometer (TDR) feature allows you to determine if cable is OPEN or SHORT when it is at fault.
Overview

With TDR, you can check the status of copper cables on the 48-port 10/100/1000 BASE-T modules for the Catalyst 4500 series switch. TDR detects a cable fault by sending a signal through the cable and reading the signal that is reflected back. All or part of the signal can be reflected back either by cable defects or by the end of the cable.

Note

Four pairs of standard category 5 cable exist. Each pair can assume one of the following states: open (not connected), broken, shorted, or terminated. The TDR test detects all four states and displays the first three as “Fault” conditions, and displays the fourth as “Terminated.” Although the CLI output is shown, the cable length is displayed only if the state is “Faulty.”

TDR feature is supported on the following modules:
WS-X4524-GB-RJ45V
WS-X4548-GB-RJ45
WS-X4548-GB-RJ45V
WS-X4548-GB-RJ45V+
WS-X4548-RJ45V+
WS-X4748-RJ45+E
WS-X4748-RJ45V+E
WS-C4948E

TDR detects a cable fault by sending a signal along its wires and depending on the reflected signal it can determine roughly where a cable fault could be. The variations on how TDR signal is reflected back determine the results on TDR. On cat4k products, we only support cable fault types: OPEN or SHORT. We do display Terminated status in case cable is proper terminated and this is done for illustrative purpose.

Running the TDR Test

To start the TDR test, perform this task in privileged mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# test cable-diagnostics tdr {interface interface interface-number}</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch# show cable-diagnostics tdr {interface interface interface-number}</td>
</tr>
</tbody>
</table>

This example shows how to start the TDR test on port 1 on module 2:

Switch# test cable-diagnostics tdr int gi2/1
Switch#

This example shows the message that displays when the TDR test is not supported on a module:

Switch# test cable-diagnostics tdr int gi2/1 |
00:03:15: %C4K_IOSDIAGMAN-4-TESTNOTSUPPORTEDONMODULE: Online cable diag tdr test is not supported on this module
Switch#
This example shows how to display TDR test results for a port:

```
Switch# show cable-diagnostics tdr interface gi4/13

Interface Speed  Local pair  Cable length  Remote channel  Status
Gi4/13  0Mbps      1-2        +2m            Unknown       Fault
         3-6        +2m            Unknown       Fault
         4-5        +2m            Unknown       Fault
         7-8        +2m            Unknown       Fault
```

**Note**

After this command is deprecated, use the diagnostic start and the `show diagnostic result` commands to run the TDR test and display the test results.

**Note**

TDR is a port test; the port cannot handle traffic for the duration of the test (generally, 1 minute).

### TDR Guidelines

The following guidelines apply to the use of TDR:

- If you connect a port undergoing a TDR test to an Auto-MDIX enabled port, the TDR result might be invalid. In those instances, the port on the WS-X4148-RJ45V should be administratively down before the start of the TDR test.

- If you connect a port undergoing a TDR test to a 100BASE-T port such as that on the WS-X4148-RJ45V, the unused pairs (4-5 and 7-8) will be reported as faulty because the remote end does not terminate these pairs.

- Do not change the port configuration while the TDR test is running.

- Due to cable characteristics, you should run the TDR test multiple times to get accurate results.

- Do not change port status (for example, remove the cable at the near or far end) because the results might be inaccurate.

- TDR works best if the test cable is disconnected from the remote port. Otherwise, it might be difficult for you to interpret results correctly.

- TDR operates across four wires. Depending on the cable conditions, the status might show one pair is OPEN or SHORT while all other wire pairs display as faulty. This operation is acceptable because you should declare a cable faulty provided one pair of wires is found to be OPEN or SHORT.

- TDR determines how poor a cable is functioning rather than where a faulty cable is located.

- When TDR locates a faulty cable, you should still use an offline cable diagnosis tool to better diagnose the problem.

- TDR results might differ between runs on different Catalyst 4500 modules because of resolution difference in TDR implementations. When this occurs, you should refer to offline cable diagnosis tool.

### Using Telnet

You can access the switch command-line interface (CLI) using Telnet. In addition, you can use Telnet from the switch to access other devices in the network. You can have up to eight simultaneous Telnet sessions.
Before you can open a Telnet session to the switch, you must first set the IP address (and in some cases the default gateway) for the switch. For information about setting the IP address and default gateway, see Chapter 3, “Configuring the Switch for the First Time.”

To establish a Telnet connection to a host by using the hostname, configure and enable DNS.

To establish a Telnet connection to another device on the network from the switch, perform this task:

```
Switch# telnet labsparc
Trying 172.16.10.3...
Connected to labsparc.
Escape character is '^[].'
UNIX(r) System V Release 4.0 (labsparc)
login:
```

### Changing the Logout Timer

The logout timer automatically disconnects a user from the switch when the user is idle for longer than the specified time. To set the logout timer, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# logoutwarning number</td>
<td>Changes the logout timer value (a timeout value of 0 prevents idle sessions from being disconnected automatically). Use the no keyword to return to the default value.</td>
</tr>
</tbody>
</table>

### Monitoring User Sessions

You can display the currently active user sessions on the switch using the `show users` command. The command output lists all active console port and Telnet sessions on the switch.

To display the active user sessions on the switch, perform this task in privileged EXEC mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# show users [all]</td>
<td>Displays the currently active user sessions on the switch.</td>
</tr>
</tbody>
</table>
This example shows the output of the show users command when local authentication is enabled for console and Telnet sessions (the asterisk [*] indicates the current session):

```plaintext
Switch# show users
Line       User       Host(s)              Idle       Location
*  0 con 0                idle                 00:00:00

Interface      User        Mode                     Idle     Peer Address
Switch#
```

```plaintext
Switch# show users all
Line       User       Host(s)              Idle       Location
*  0 con 0                idle                 00:00:00
  1 vty 0                                     00:00:00
  2 vty 1                                     00:00:00
  3 vty 2                                     00:00:00
  4 vty 3                                     00:00:00
  5 vty 4                                     00:00:00

Interface      User        Mode                     Idle     Peer Address
Switch#
```

To disconnect an active user session, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Switch# disconnect (console | Disconnects an active user session on the switch.
| ip_addr)                     |                                              |

This example shows how to disconnect an active console port session and an active Telnet session:

```plaintext
Switch> disconnect console
Console session disconnected.
Console> (enable) disconnect tim-nt.bigcorp.com
Telnet session from tim-nt.bigcorp.com disconnected. (1)
Switch# show users
Session  User             Location
-------- ---------------- -------------------------
telnet   jake             jake-mac.bigcorp.com
* telnet   suzy             suzy-pc.bigcorp.com
Switch#
```

---

**Using Ping**

These sections describe how to use IP ping:

- Understanding How Ping Works, page 8-7
- Running Ping, page 8-8

---

**Understanding How Ping Works**

You can use the ping command to verify connectivity to remote hosts. If you attempt to ping a host in a different IP subnetwork, you must define a static route to the network or configure a router to route between those subnets.
The **ping** command is configurable from normal executive and privileged EXEC mode. Ping returns one of the following responses:

- Normal response—The normal response (*hostname* is alive) occurs in 1 to 10 seconds, depending on network traffic.
- Destination does not respond—If the host does not respond, a No Answer message is returned.
- Unknown host—If the host does not exist, an Unknown Host message is returned.
- Destination unreachable—If the default gateway cannot reach the specified network, a Destination Unreachable message is returned.
- Network or host unreachable—If there is no entry in the route table for the host or network, a Network or Host Unreachable message is returned.

To stop a ping in progress, press **Ctrl-C**.

### Running Ping

To ping another device on the network from the switch, perform this task in normal executive and privileged EXEC mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# ping</td>
<td>Checks connectivity to a remote host.</td>
</tr>
</tbody>
</table>

This example shows how to ping a remote host from normal executive mode:

```
Switch# ping labsparc
labsparc is alive
Switch> ping 72.16.10.3
12.16.10.3 is alive
Switch#
```

This example shows how to enter a **ping** command in privileged EXEC mode specifying the number of packets, the packet size, and the timeout period:

```
Switch# ping
Target IP Address [ ]: 12.20.5.19
Number of Packets [5]: 10
Datagram Size [56]: 100
Timeout in seconds [2]: 10
Source IP Address [12.20.2.18]: 12.20.2.18
!!!!!!!!!!!

---12.20.2.19 PING Statistics-----
10 packets transmitted, 10 packets received, 0% packet loss
round-trip (ms) min/avg/max = 1/1/1
Switch
```

### Using IP Traceroute

These sections describe how to use IP traceroute feature:

- **Understanding How IP Traceroute Works**, page 8-9
- **Running IP Traceroute**, page 8-9
Understanding How IP Traceroute Works

You can use IP traceroute to identify the path that packets take through the network on a hop-by-hop basis. The command output displays all network layer (Layer 3) devices, such as routers, that the traffic passes through on the way to the destination.

Layer 2 switches can participate as the source or destination of the `trace` command but will not appear as a hop in the `trace` command output.

The `trace` command uses the Time To Live (TTL) field in the IP header to cause routers and servers to generate specific return messages. Traceroute starts by sending a User Datagram Protocol (UDP) datagram to the destination host with the TTL field set to 1. If a router finds a TTL value of 1 or 0, it drops the datagram and sends back an Internet Control Message Protocol (ICMP) Time-Exceeded message to the sender. Traceroute determines the address of the first hop by examining the source address field of the ICMP Time-Exceeded message.

To identify the next hop, traceroute sends a UDP packet with a TTL value of 2. The first router decrements the TTL field by 1 and sends the datagram to the next router. The second router sees a TTL value of 1, discards the datagram, and returns the Time-Exceeded message to the source. This process continues until the TTL is incremented to a value large enough for the datagram to reach the destination host or until the maximum TTL is reached.

To determine when a datagram reaches its destination, traceroute sets the UDP destination port in the datagram to a very large value that the destination host is unlikely to be using. When a host receives a datagram with an unrecognized port number, it sends an ICMP Port Unreachable error message to the source. The Port Unreachable error message indicates to traceroute that the destination has been reached.

Running IP Traceroute

To trace the path that packets take through the network, perform this task in EXEC or privileged EXEC mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# <code>trace [protocol] [destination]</code></td>
<td>Runs IP traceroute to trace the path that packets take through the network.</td>
</tr>
</tbody>
</table>

This example shows use the `trace` command to display the route a packet takes through the network to reach its destination:

```
Switch# trace ip ABA.NYC.mil
Type escape sequence to abort.
Tracing the route to ABA.NYC.mil (26.0.0.73)
  1 DEBRIS.CISCO.COM (192.180.1.6) 1000 msec 8 msec 4 msec
  2 BARENET-GW.CISCO.COM (192.180.16.2) 8 msec 8 msec 8 msec
  3 EXTERNAL-A-GATEWAY.STANFORD.EDU (192.42.110.225) 8 msec 4 msec 4 msec
  4 BB2.SU.BARRNET.NET (192.200.254.6) 8 msec 8 msec 8 msec
  5 SU.ARC.BARRNET.NET (192.200.3.8) 12 msec 12 msec 8 msec
  6 MOFFETT-FLD-MB.in.MIL (192.52.195.1) 216 msec 120 msec 132 msec
  7 ABA.NYC.mil (26.0.0.73) 412 msec 628 msec 664 msec
Switch# 
```
**Using Layer 2 Traceroute**

The Layer 2 traceroute feature allows the switch to identify the physical path that a packet takes from a source device to a destination device. Layer 2 traceroute supports only unicast source and destination MAC addresses. It determines the path by using the MAC address tables of the switches in the path. When the switch detects a device in the path that does not support Layer 2 traceroute, the switch continues to send Layer 2 trace queries and lets them time out.

If you want the switch to trace the path from a host on a source device to a host on a destination device, the switch can identify only the path from the source device to the destination device. It cannot identify the path that a packet takes from source host to the source device or from the destination device to the destination host.

These sections describe how to use the Layer 2 traceroute feature:

- Layer 2 Traceroute Usage Guidelines, page 8-10
- Running Layer 2 Traceroute, page 8-11

**Layer 2 Traceroute Usage Guidelines**

These are the Layer 2 traceroute usage guidelines:

- CDP must be enabled on all the devices in the network. For Layer 2 traceroute to functional properly, do not disable CDP.
  - If any devices in the physical path are transparent to CDP, the switch cannot identify the path through these devices.
  
  **Note**  
  For more information about enabling CDP, see Chapter 20, “Configuring CDP.”

- All switches in the physical path must have IP connectivity. When a switch is reachable from another switch, you can test connectivity by using the **ping** command in privileged EXEC mode.

- The maximum number of hops identified in the path is ten.

- You can enter the **traceroute mac** or the **traceroute mac ip** command in privileged EXEC mode on a switch that is not in the physical path from the source device to the destination device. All switches in the path must be reachable from this switch.

- The **traceroute mac** command output shows the Layer 2 path only when the specified source and destination MAC addresses belong to the same VLAN. If you specify source and destination MAC addresses that belong to different VLANs, the Layer 2 path is not identified, and an error message appears.

- If you specify a multicast source or destination MAC address, the path is not identified, and an error message appears.

- If the source or destination MAC address belongs to multiple VLANs, you must specify the VLAN to which both the source and destination MAC addresses belong. If the VLAN is not specified, the path is not identified, and an error message appears.
The `traceroute mac ip` command output shows the Layer 2 path when the specified source and destination IP addresses belong to the same subnet. When you specify the IP addresses, the switch uses Address Resolution Protocol (ARP) to associate the IP address with the corresponding MAC address and the VLAN ID.

- If an ARP entry exists for the specified IP address, the switch uses the associated MAC address and identifies the physical path.
- If an ARP entry does not exist, the switch sends an ARP query and tries to resolve the IP address. If the IP address is not resolved, the path is not identified, and an error message appears.

When multiple devices are attached to one port through hubs (for example, multiple CDP neighbors are detected on a port), the Layer 2 traceroute feature is not supported. When more than one CDP neighbor is detected on a port, the Layer 2 path is not identified, and an error message appears.

This feature is not supported in Token Ring VLANs.

### Running Layer 2 Traceroute

To display the physical path that a packet takes from a source device to a destination device, perform either one of these tasks in privileged EXEC mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# <code>traceroute mac {source-mac-address} {destination-mac-address}</code></td>
<td>Runs Layer 2 traceroute to trace the path that packets take through the network.</td>
</tr>
</tbody>
</table>

or

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# <code>traceroute mac ip {source-mac-address} {destination-mac-address}</code></td>
<td>Runs IP traceroute to trace the path that packets take through the network.</td>
</tr>
</tbody>
</table>

These examples show how to use the `traceroute mac` and `traceroute mac ip` commands to display the physical path a packet takes through the network to reach its destination:

Switch# `traceroute mac 0000.0201.0601 0000.0201.0201`

Source 0000.0201.0601 found on con6[WS-C2950G-24-EI] (2.2.6.6)
con6 (2.2.6.6) :Fa0/1 => Fa0/3
con5 (2.2.5.5) : Fa0/3 => G10/1
con1 (2.2.1.1) : G10/1 => G10/2
con2 (2.2.2.2) : G10/2 => Fa0/1
Destination 0000.0201.0201 found on con2[WS-C3550-24] (2.2.2.2)
Layer 2 trace completed
Switch#

Switch# `traceroute mac ip 2.2.66.66 2.2.22.22 detail`

Translating IP to mac ..... 2.2.66.66 => 0000.0201.0601
2.2.22.22 => 0000.0201.0201
Configuring ICMP

Internet Control Message Protocol (ICMP) provides many services that control and manage IP connections. ICMP messages are sent by routers or access servers to hosts or other routers when a problem is discovered with the Internet header. For detailed information on ICMP, refer to RFC 792.

Enabling ICMP Protocol Unreachable Messages

If the Cisco IOS software receives a nonbroadcast packet that uses an unknown protocol, it sends an ICMP Protocol Unreachable message back to the source.

Similarly, if the software receives a packet that it is unable to deliver to the ultimate destination because it knows of no route to the destination address, it sends an ICMP Host Unreachable message to the source. This feature is enabled by default.

To enable the generation of ICMP Protocol Unreachable and Host Unreachable messages, enter the following command in interface configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch (config-if)# [no] ip unreachables</td>
<td>Enables ICMP destination unreachable messages. Use the no keyword to disable the ICMP destination unreachable messages.</td>
</tr>
</tbody>
</table>

⚠️ Caution

If you enter the no ip unreachables command, you will break the path MTU discovery functionality. Routers in the middle of the network might be forced to fragment packets.

To limit the rate that Internet Control Message Protocol (ICMP) destination unreachable messages are generated, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch (config)# [no] ip icmp rate-limit unreachable [df] milliseconds</td>
<td>Limits the rate that ICMP destination messages are generated. Use the no keyword to remove the rate limit and reduce the CPU usage.</td>
</tr>
</tbody>
</table>
Enabling ICMP Redirect Messages

Data routes are sometimes less than optimal. For example, it is possible for the router to be forced to resend a packet through the same interface on which it was received. If this occurs, the Cisco IOS software sends an ICMP Redirect message to the originator of the packet telling the originator that the router is on a subnet directly connected to the receiving device, and that it must forward the packet to another system on the same subnet. The software sends an ICMP Redirect message to the packet's originator because the originating host presumably could have sent that packet to the next hop without involving this device at all. The Redirect message instructs the sender to remove the receiving device from the route and substitute a specified device representing a more direct path. This feature is enabled by default.

However, when Hot Standby Router Protocol (HSRP) is configured on an interface, ICMP Redirect messages are disabled (by default) for the interface. For more information on HSRP, refer to the following URL:

To enable the sending of ICMP Redirect messages if the Cisco IOS software is forced to resend a packet through the same interface on which it was received, enter the following command in interface configuration mode:

```
Switch (config-if)# [no] ip redirects
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch (config-if)# [no] ip redirects</td>
<td>Enables ICMP Redirect messages. Use the no keyword to disable the ICMP Redirect messages and reduce CPU usage.</td>
</tr>
</tbody>
</table>

Enabling ICMP Mask Reply Messages

Occasionally, network devices must know the subnet mask for a particular subnetwork in the internetwork. To obtain this information, devices can send ICMP Mask Request messages. These messages are responded to by ICMP Mask Reply messages from devices that have the requested information. The Cisco IOS software can respond to ICMP Mask Request messages if the ICMP Mask Reply function is enabled.

To have the Cisco IOS software respond to ICMP mask requests by sending ICMP Mask Reply messages, perform this task:

```
Switch (config-if)# [no] ip mask-reply
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch (config-if)# [no] ip mask-reply</td>
<td>Enables response to ICMP destination mask requests. Use the no keyword to disable this functionality.</td>
</tr>
</tbody>
</table>
CHAPTER 9

Configuring Cisco NSF with SSO Supervisor Engine Redundancy

This chapter describes how to configure supervisor engine redundancy using Cisco nonstop forwarding (NSF) with stateful switchover (SSO).

This chapter consists of these sections:

- About NSF with SSO Supervisor Engine Redundancy, page 9-1
- Configuring NSF with SSO Supervisor Engine Redundancy, page 9-7
- Cisco High Availability Features in Cisco IOS XE 3.1.0SG, page 9-13

For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

About NSF with SSO Supervisor Engine Redundancy

These sections describe supervisor engine redundancy using NSF with SSO:

- About Cisco IOS NSF-Aware and NSF-Capable Support, page 9-2
- NSF with SSO Supervisor Engine Redundancy Overview, page 9-3

About Cisco IOS NSF-Aware and NSF-Capable Support

Cisco IOS Nonstop Forwarding (NSF) has two primary components:

- NSF-awareness—If neighboring router devices detect that an NSF router can still forward packets when a supervisor engine switchover happens, this capability is referred to as NSF-awareness. Cisco IOS enhancements to the Layer 3 routing protocols (OSPF, BGP, and EIGRP) are designed to prevent route-flapping so that the CEF routing table does not time out or the NSF router does not drop routes. An NSF-aware router helps to send routing protocol information to the neighboring NSF router.

- NSF-capability—NSF works with SSO to minimize the amount of time that a Layer 3 network is unavailable following a supervisor engine switchover by continuing to forward IP packets. Reconvergence of Layer 3 routing protocols (BGP, EIGRP, and OSPF v2) is transparent to the user and happens automatically in the background. The routing protocols recover routing information from neighbor devices and rebuild the Cisco Express Forwarding (CEF) table.

Note: NSF does not support IPv6 and is IPv4 Unicast only.

Note: NSF capable devices include Catalyst 4500 series switches, Catalyst 6500 series switches, Cisco 7500 series routers, Cisco 10000 series routers, and Cisco 12000 series routers.

A typical topology for NSF and NSF-aware routers is given below.

Figure 9-1 Topology for NSF and NSF-Capable Switches

The Catalyst 4500 series switch supports NSF capability and NSF-awareness for the EIGRP, OSPF, and BGP protocols in Enterprise Services mode and NSF-awareness for the EIGRP-stub in IP Base mode. NSF-awareness is turned on by default for EIGRP-stub, EIGRP, and OSPF protocols. For BGP, you need to turn it on manually.

If the supervisor engine is configured for BGP (with the graceful-restart command), EIGRP, or OSPF routing protocols, routing updates are automatically sent during the supervisor engine switchover of a neighboring NSF capable switch.

Table 9-1 lists the supervisor engines and Catalyst 4500 series switches that support NSF-capable.
Chapter 9      Configuring Cisco NSF with SSO Supervisor Engine Redundancy

About NSF with SSO Supervisor Engine Redundancy

NSF with SSO Supervisor Engine Redundancy Overview

Catalyst 4500 series switches support fault resistance by allowing a standby supervisor engine to take over if the active supervisor engine fails. NSF works with SSO to minimize the amount of time a network is unavailable to its users following a switchover.

NSF provides these benefits:

- Improved network availability
  NSF continues forwarding network traffic and application state information so that user session information is maintained after a switchover.
- Overall network stability
  Network stability may be improved with the reduction in the number of route flaps, which were created when routers in the network failed and lost their routing tables.
- Neighboring routers do not detect a link flap
  Because the interfaces remain up during a switchover, neighboring routers do not detect a link flap (the link does not go down and come back up).
- Prevents routing flaps
  Because SSO continues forwarding network traffic during a switchover, routing flaps are avoided.
- Maintains user sessions established prior to the switchover

Catalyst 4500 series switches also support route processor redundancy (RPR). For information about these redundancy modes, see Chapter 5, “Configuring Supervisor Engine Redundancy Using RPR and SSO.”

SSO Operation

SSO establishes one of the supervisor engines as active while the other supervisor engine is designated as standby, and then SSO synchronizes information between them. A switchover from the active to the standby supervisor engine occurs when the active supervisor engine fails, or is removed from the switch, or is manually shut down for maintenance.

In networking devices running SSO, both supervisor engines must be running the same Cisco IOS software version (except during the ISSU upgrade/downgrade process) and ROMMON version so that the standby supervisor engine is always ready to assume control following a fault on the active supervisor engine. SSO switchover also preserves FIB and adjacency entries and can forward Layer 3 traffic after a switchover. Configuration information and data structures are synchronized from the active

About NSF with SSO Supervisor Engine Redundancy

to the standby supervisor engine and whenever changes to the active supervisor engine configuration occur. Following an initial synchronization between the two supervisor engines, SSO maintains state information between them, including forwarding information.

During switchover, system control and routing protocol execution is transferred from the active supervisor engine to the standby supervisor engine.

Note

Be aware that you can use the [no] service slave-log configuration command to forward all error messages from the standby supervisor engine to the active engine. By default, this capability is enabled.

NSF Operation

NSF always runs with SSO and provides redundancy for Layer 3 traffic. NSF is supported by the BGP, OSPF, and EIGRP routing protocols and is supported by Cisco Express Forwarding (CEF) for forwarding. The routing protocols have been enhanced with NSF-capability and awareness, which means that routers running these protocols can detect a switchover and take the necessary actions to continue forwarding network traffic and to recover route information from the peer devices.

A networking device is NSF-aware if it is running NSF-compatible software. A device is NSF-capable if it has been configured to support NSF; it rebuilds routing information from NSF-aware or NSF-capable neighbors.

Each protocol depends on CEF to continue forwarding packets during switchover while the routing protocols rebuild the Routing Information Base (RIB) tables. After the routing protocols have converged, CEF updates the FIB table and removes stale route entries. CEF then updates the hardware with the new FIB information.

Cisco Express Forwarding

A key element of NSF is packet forwarding. In a Cisco networking device, packet forwarding is provided by Cisco Express Forwarding (CEF). CEF maintains the FIB and uses the FIB information that was current at the time of the switchover to continue forwarding packets during a switchover. This feature reduces traffic interruption during the switchover.

During normal NSF operation, CEF on the active supervisor engine synchronizes its current FIB and adjacency databases with the FIB and adjacency databases on the standby supervisor engine. Upon switchover, the standby supervisor engine initially has FIB and adjacency databases that are mirror images of those that were current on the active supervisor engine. CEF keeps the forwarding engine on the standby supervisor engine current with changes that are sent to it by CEF on the active supervisor engine. The forwarding engine can continue forwarding after a switchover as soon as the interfaces and a data path are available.

As the routing protocols start to repopulate the RIB on a prefix-by-prefix basis, the updates cause prefix-by-prefix updates to CEF, which it uses to update the FIB and adjacency databases. Existing and new entries receive the new version ("epoch") number, indicating that they have been refreshed. The forwarding information is updated on the forwarding engine during convergence. The supervisor engine signals when the RIB has converged. The software removes all FIB and adjacency entries that have an epoch older than the current switchover epoch. The FIB now represents the newest routing protocol forwarding information.
Routing Protocols

**Note**
Use of the routing protocols require the Enterprise Services (entservices) level of Cisco IOS-XE Software for the Catalyst 4500 series switch. EIGRP-stub and OSPF for routed access are supported on IP Base level of Cisco IOS-XE.

The routing protocols run only on the active supervisor engine, and they receive routing updates from their neighbor routers. Routing protocols do not run on the standby supervisor engine. Following a switchover, the routing protocols request that the NSF-aware neighbor devices send state information to help rebuild the routing tables. NSF supports the BGP, OSPF, and EIGRP protocols.

**Note**
For NSF operation, the routing protocols depend on CEF to continue forwarding packets while the routing protocols rebuild the routing information.

BGP Operation

When an NSF-capable router begins a BGP session with a BGP peer, it sends an OPEN message to the peer. Included in the message is a statement that the NSF-capable device has “graceful” restart capability. Graceful restart is the mechanism by which BGP routing peers avoid a routing flap following a switchover. If the BGP peer has received this capability, it is aware that the device sending the message is NSF-capable. Both the NSF-capable router and its BGP peers need to exchange the graceful restart capability in their OPEN messages at the time of session establishment. If both the peers do not exchange the graceful restart capability, the session will not be capable of a graceful restart.

If the BGP session is lost during the supervisor engine switchover, the NSF-aware BGP peer marks all the routes associated with the NSF-capable router as stale; however, it continues to use these routes to make forwarding decisions for a set period of time. This functionality prevents packets from being lost while the newly active supervisor engine is waiting for convergence of the routing information with the BGP peers.

After a supervisor engine switchover occurs, the NSF-capable router reestablishes the session with the BGP peer. In establishing the new session, it sends a new graceful restart message that identifies the NSF-capable router as having restarted.

At this point, the routing information is exchanged between the two BGP peers. After this exchange is complete, the NSF-capable device uses the routing information to update the RIB and the FIB with the new forwarding information. The NSF-aware device uses the network information to remove stale routes from its BGP table; the BGP protocol then is fully converged.

If a BGP peer does not support the graceful restart capability, it ignores the graceful restart capability in an OPEN message but establishes a BGP session with the NSF-capable device. This function allows interoperability with non-NSF-aware BGP peers (and without NSF functionality), but the BGP session with non-NSF-aware BGP peers is not capable of a graceful restart.

**Note**
BGP support in NSF requires that neighbor networking devices be NSF-aware; that is, the devices must have the graceful restart capability and advertise that capability in their OPEN message during session establishment. If an NSF-capable router discovers that a particular BGP neighbor does not have graceful restart capability, it does not establish an NSF-capable session with that neighbor. All other neighbors that have graceful restart capability continue to have NSF-capable sessions with this NSF-capable networking device.
OSPF Operation

When an OSPF NSF-capable router performs a supervisor engine switchover, it must perform the following tasks in order to resynchronize its link state database with its OSPF neighbors:

- Relearn the available OSPF neighbors on the network without causing a reset of the neighbor relationship
- Reacquire the contents of the link state database for the network

As quickly as possible after a supervisor engine switchover, the NSF-capable router sends an OSPF NSF signal to neighboring NSF-aware devices. Neighbor networking devices recognize this signal as an indicator that the neighbor relationship with this router should not be reset. As the NSF-capable router receives signals from other routers on the network, it can begin to rebuild its neighbor list.

After neighbor relationships are reestablished, the NSF-capable router begins to resynchronize its database with all of its NSF-aware neighbors. At this point, the routing information is exchanged between the OSPF neighbors. Once this exchange is complete, the NSF-capable device uses the routing information to remove stale routes, update the RIB, and update the FIB with the new forwarding information. The OSPF protocols are then fully converged.

Note
OSPF support in NSF requires that all neighbor networking devices be NSF-aware. If an NSF-capable router discovers that it has non-NSF-aware neighbors on a particular network segment, it disables NSF capabilities for that segment. Other network segments composed entirely of NSF-capable or NSF-aware routers continue to provide NSF capabilities.

EIGRP Operation

When an EIGRP NSF-capable router initially re-boots after an NSF restart, it has no neighbor and its topology table is empty. The router is notified by the standby (now active) supervisor engine when it needs to bring up the interfaces, reacquire neighbors, and rebuild the topology and routing tables. The restarting router and its peers must accomplish these tasks without interrupting the data traffic directed toward the restarting router. EIGRP peer routers maintain the routes learned from the restarting router and continue forwarding traffic through the NSF restart process.

To prevent an adjacency reset by the neighbors, the restarting router uses a new Restart (RS) bit in the EIGRP packet header to indicate a restart. The RS bit is set in the hello packets and in the initial INIT update packets during the NSF restart period. The RS bit in the hello packets allows the neighbors to be quickly notified of the NSF restart. Without seeing the RS bit, the neighbor can only detect an adjacency reset by receiving an INIT update or by the expiration of the hello hold timer. Without the RS bit, a neighbor does not know if the adjacency reset should be handled using NSF or the normal startup method.

When the neighbor receives the restart indication, either by receiving the hello packet or the INIT packet, it recognizes the restarting peer in its peer list and maintains the adjacency with the restarting router. The neighbor then sends it topology table to the restarting router with the RS bit set in the first update packet indicating that it is NSF-aware and is helping out the restarting router. The neighbor does not set the RS bit in their hello packets, unless it is also a NSF restarting neighbor.

Note
A router may be NSF-aware but may not be helping the NSF restarting neighbor because booting from a cold start.
If at least one of the peer routers is NSF-aware, the restarting router would then receive updates and rebuild its database. The restarting router must then find out if it had converged so that it can notify the routing information base (RIB). Each NSF-aware router is required to send an end of table (EOT) marker in the last update packet to indicate the end of the table content. The restarting router knows it has converged when it receives the EOT marker. The restarting router can then begin sending updates.

An NSF-aware peer would know when the restarting router had converged when it receives an EOT indication from the restarting router. The peer then scans its topology table to search for the routes with the restarted neighbor as the source. The peer compares the route timestamp with the restart event timestamp to determine if the route is still available. The peer then goes active to find alternate paths for the routes that are no longer available through the restarted router.

When the restarting router has received all EOT indications from its neighbors or when the NSF converge timer expires, EIGRP notifies the RIB of convergence. EIGRP waits for the RIB convergence signal and then floods its topology table to all awaiting NSF-aware peers.

NSF Guidelines and Restrictions

NSF with SSO has these restrictions:

- For NSF operation, you must have SSO configured on the device.
- NSF with SSO supports IP Version 4 traffic and protocols only; NSF with SSO does not support IPv6 traffic.
- The Virtual Redundancy Routing Protocols (VRRP) is not SSO-aware, meaning state information is not maintained between the active and standby supervisor engine during normal operation. VRRP and SSO can coexist but both features work independently. Traffic that relies on VRRP may switch to the VRRP standby in the event of a supervisor engine switchover.
- All neighboring devices participating in BGP NSF must be NSF-capable and configured for BGP graceful restart.
- OSPF NSF for virtual links is not supported.
- All OSPF networking devices on the same network segment must be NSF-aware (running an NSF software image).
- For IETF, all neighboring devices must be running an NSF-aware software image.

Configuring NSF with SSO Supervisor Engine Redundancy

The following sections describe the configuration tasks for the NSF feature:

- Configuring SSO, page 9-8
- Configuring CEF NSF, page 9-8
- Verifying CEF NSF, page 9-9
- Configuring BGP NSF, page 9-9
- Verifying BGP NSF, page 9-10
- Configuring OSPF NSF, page 9-11
- Verifying OSPF NSF, page 9-11
- Configuring EIGRP NSF, page 9-12
- Verifying EIGRP NSF, page 9-13
Configuring SSO

You must configure SSO in order to use NSF with any supported protocol. To configure SSO, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch(config)# redundancy</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config-red)# mode sso</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config-red)# end</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch# show running-config</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch# show redundancy states</td>
</tr>
</tbody>
</table>

Note

The `sso` keyword is not supported if the IOS-XE software is running in LAN Base level.

This example shows how to configure the system for SSO and display the redundancy state:

```
Switch> enable
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# redundancy
Switch(config-red)# mode sso
Switch(config-red)# end
Switch# show running-config
Verifies that SSO is enabled.
Switch# show redundancy states
Displays the operating redundancy mode.
```

Configuring CEF NSF

The CEF NSF feature operates by default while the networking device is running in SSO mode. No configuration is necessary.
Verifying CEF NSF

To verify that CEF is NSF-capable, enter the `show cef state` command:

```
Switch# show cef state
CEF Status:
 RP instance
 common CEF enabled
IPv4 CEF Status:
 CEF enabled/running
dCEF enabled/running
CEF switching enabled/running
universal per-destination load sharing algorithm, id DEA83012
IPv6 CEF Status:
 CEF disabled/not running
dCEF disabled/not running
universal per-destination load sharing algorithm, id DEA83012
RRP state:
 I am standby RRP: no
 RF Peer Presence: yes
 RF PeerComm reached: yes
 RF Progression blocked: never
 Redundancy mode: rpr(1)
 CEF NSF sync: disabled/not running
CEF ISSU Status:
 FIBHWIDB broker
   No slots are ISSU capable.
 FIBIDB broker
   No slots are ISSU capable.
 FIBHWIDB Subblock broker
   No slots are ISSU capable.
 FIBIDB Subblock broker
   No slots are ISSU capable.
 Adjacency update
   No slots are ISSU capable.
 IPv4 table broker
   No slots are ISSU capable.
 CEF push
   No slots are ISSU capable.
```

Configuring BGP NSF

**Note**

You must configure BGP graceful restart on all peer devices participating in BGP NSF.

To configure BGP for NSF, perform this task (repeat this procedure on each of the BGP NSF peer devices):

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
</tbody>
</table>
Configuring NSF with SSO Supervisor Engine Redundancy

Chapter 9      Configuring Cisco NSF with SSO Supervisor Engine Redundancy

Verifying BGP NSF

To verify BGP NSF, you must check that BGP graceful restart is configured on the SSO-enabled networking device and on the neighbor devices. To verify, follow these steps:

Step 1  Verify that “bgp graceful-restart” appears in the BGP configuration of the SSO-enabled switch by entering the `show running-config` command:

```
Switch# show running-config

router bgp 120

bgp graceful-restart

neighbor 10.2.2.2 remote-as 300
```

Step 2  Repeat Step 1 on each of the BGP neighbors.

Step 3  On the SSO device and the neighbor device, verify that the graceful restart function is shown as both advertised and received, and confirm the address families that have the graceful restart capability. If no address families are listed, BGP NSF does not occur either:

```
Switch# show ip bgp neighbors
BGP neighbor is 31.31.31.7,  remote AS 1, internal link
  BGP version 4, remote router ID 7.7.7.7
  BGP state = Established, up for 00:02:38
  Last read 00:00:38, last write 00:00:35, hold time is 180, keepalive interval is 60 seconds
  Neighbor capabilities:
    Route refresh: advertised and received(new)
    Address family IPv4 Unicast: advertised and received
  Message statistics:
    InQ depth is 0
    OutQ depth is 0
    Sent                     Rcvd
    Opens:                   1   1
    Notifications:          0   0
```

Verifying BGP NSF

To verify BGP NSF, you must check that BGP graceful restart is configured on the SSO-enabled networking device and on the neighbor devices. To verify, follow these steps:

Step 1  Verify that “bgp graceful-restart” appears in the BGP configuration of the SSO-enabled switch by entering the `show running-config` command:

```
Switch# show running-config

router bgp 120

bgp graceful-restart

neighbor 10.2.2.2 remote-as 300
```

Step 2  Repeat Step 1 on each of the BGP neighbors.

Step 3  On the SSO device and the neighbor device, verify that the graceful restart function is shown as both advertised and received, and confirm the address families that have the graceful restart capability. If no address families are listed, BGP NSF does not occur either:

```
Switch# show ip bgp neighbors
BGP neighbor is 31.31.31.7,  remote AS 1, internal link
  BGP version 4, remote router ID 7.7.7.7
  BGP state = Established, up for 00:02:38
  Last read 00:00:38, last write 00:00:35, hold time is 180, keepalive interval is 60 seconds
  Neighbor capabilities:
    Route refresh: advertised and received(new)
    Address family IPv4 Unicast: advertised and received
  Message statistics:
    InQ depth is 0
    OutQ depth is 0
    Sent                     Rcvd
    Opens:                   1   1
    Notifications:          0   0
```
Configuring OSPF NSF

Note

All peer devices participating in OSPF NSF must be made OSPF NSF-aware, which happens automatically when you install an NSF software image on the device.

To configure OSPF NSF, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# router ospf processID</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config-router)# nsf</td>
</tr>
</tbody>
</table>

Verifying OSPF NSF

To verify OSPF NSF, you must check that the NSF function is configured on the SSO-enabled networking device. To verify OSPF NSF, follow these steps:

Step 1  Verify that `nsf` appears in the OSPF configuration of the SSO-enabled device by entering the `show running-config` command:

```
Switch# show running-config

route ospf 120
log-adjacency-changes
nsf
network 192.168.20.0 0.0.0.255 area 0
network 192.168.30.0 0.0.0.255 area 1
network 192.168.40.0 0.0.0.255 area 2
```

Step 2  Enter the `show ip ospf` command to verify that NSF is enabled on the device:

```
Switch> show ip ospf
Routing Process "ospf 1" with ID 187.1.1.1
Start time: 00:02:07.532, Time elapsed: 00:39:05.052
Supports only single TOS(TOS0) routes
Supports opaque LSA
Supports Link-local Signaling (LLS)
```
Supports area transit capability
Router is not originating router-LSAs with maximum metric
Initial SPF schedule delay 5000 msecs
Minimum hold time between two consecutive SPF's 10000 msecs
Maximum wait time between two consecutive SPF's 10000 msecs
Incremental-SPF disabled
Minimum LSA interval 5 secs
Minimum LSA arrival 1000 msecs
LSA group pacing timer 240 secs
Interface flood pacing timer 33 msecs
Retransmission pacing timer 66 msecs
Number of external LSA 0. Checksum Sum 0x000000
Number of opaque AS LSA 0. Checksum Sum 0x000000
Number of DoNotAge external and opaque AS LSA 0
Number of areas in this router is 1. 1 normal 0 stub 0 nssa
Number of areas transit capable is 0
External flood list length 0
IETF Non-Stop Forwarding enabled
  restart-interval limit: 120 sec
IETF NSF helper support enabled
Cisco NSF helper support enabled
Reference bandwidth unit is 100 mbps
  Area BACKBONE(0)
    Number of interfaces in this area is 3 (1 loopback)
    Area has no authentication
    SPF algorithm last executed 00:08:53.760 ago
    SPF algorithm executed 2 times
    Area ranges are
    Number of LSA 3. Checksum Sum 0x025BE0
    Number of opaque link LSA 0. Checksum Sum 0x000000
    Number of DCbitless LSA 0
    Number of indication LSA 0
    Number of DoNotAge LSA 0
    Flood list length 0

Switch#

### Configuring EIGRP NSF

To configure EIGRP NSF, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# router eigrp as-number</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config-router)# nsf</td>
</tr>
</tbody>
</table>
Verifying EIGRP NSF

To verify EIGRP NSF, you must check that the NSF function is configured on the SSO-enabled networking device. To verify EIGRP NSF, follow these steps:

---

**Step 1** Verify that “nsf” appears in the EIGRP configuration of the SSO-enabled device by entering the `show running-config` command:

```
Switch# show running-config
  ..
  router eigrp 100
    auto-summary
    nsf
  ..
```

**Step 2** Enter the `show ip protocols` command to verify that NSF is enabled on the device:

```
Switch# show ip protocols
*** IP Routing is NSF aware ***
Routing Protocol is "ospf 1"
  Outgoing update filter list for all interfaces is not set
  Incoming update filter list for all interfaces is not set
  Router ID 187.1.1.1
  Number of areas in this router is 1. 1 normal 0 stub 0 nssa
  Maximum path: 1
  Routing for Networks:
    Routing on Interfaces Configured Explicitly (Area 0):
      Loopback0
      GigabitEthernet5/3
      TenGigabitEthernet3/1
    Routing Information Sources:
      Gateway         Distance      Last Update
      121.1.1.1            110      00:01:02
      Distance: (default is 110)

Routing Protocol is "bgp 601"
  Outgoing update filter list for all interfaces is not set
  Incoming update filter list for all interfaces is not set
  IGP synchronization is disabled
  Automatic route summarization is disabled
  Neighbor(s):
    Address          FiltIn FiltOut DistIn DistOut Weight RouteMap
    150.1.1.1
    Maximum path: 1
    Routing Information Sources:
      Gateway         Distance      Last Update
      150.1.1.1            20      00:01:03
      Distance: external 20 internal 200 local 200

Switch#
```

Cisco High Availability Features in Cisco IOS XE 3.1.0SG

This section provides a list of High Availability software features that are supported in Cisco IOS XE 3.1.0SG. Links to the feature documentation are included.
Feature guides may contain information about more than one feature. To find information about a specific feature within a feature guide, see the Feature Information table at the end of the guide.

Feature guides document features that are supported on many different software releases and platforms. Your Cisco software release or platform may not support all the features documented in a feature guide. See the Feature Information table at the end of the feature guide for information about which features in that guide are supported in your software release. Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

The following high availability features were introduced with Cisco IOS XE 3.1.0SG:

- Enhanced High System Availability
- NSF - Graceful Restart (GR) and Non Stop Routing (NSR) for IS-IS
- NSF - OSPF
- NSF/SSO (Nonstop Forwarding with Stateful Switchover)
- SSO - HDLC
- SSO - HSRP
- SSO - Multilink PPP (MLP)
- SSO - PPP

For details on Cisco High Availability, refer to the following URL:

Before reading this chapter, read the “Preparing for Installation” section of the Catalyst 4500 Series Installation Guide. It is important to ensure that your installation site has enough power and cooling to accommodate the additional electrical load and heat introduced by Power over Ethernet (PoE).

This chapter describes power management and environmental monitoring features in the Catalyst 4500 series switches. It provides guidelines, procedures, and configuration examples.

This chapter consists of the following major sections:

- About Environmental Monitoring, page 10-1
- Power Management, page 10-5

For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

About Environmental Monitoring

This section contains the following subsections:

- Using CLI Commands to Monitor your Environment, page 10-2
- Displaying Environment Conditions, page 10-2
- Emergency Actions, page 10-3
- System Alarms, page 10-4
Environmental monitoring of chassis components provides early warning indications of possible component failure. This warning helps you to ensure the safe and reliable operation of your system and avoid network interruptions.

This section describes how to monitor critical system components so that you can identify and rapidly correct hardware-related problems.

### Using CLI Commands to Monitor your Environment

Use the `show environment` CLI command to monitor the system. This section gives a basic overview of the command and keywords you need.

Enter the `show environment [alarm | status | temperature]` command to display system status information. Keyword descriptions are listed in Table 10-1.

#### Table 10-1 show environment Keyword Descriptions

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>alarm</td>
<td>Displays environmental alarms for the system.</td>
</tr>
<tr>
<td>status</td>
<td>Displays field-replaceable unit (FRU) operational status and power and power supply fan sensor information.</td>
</tr>
<tr>
<td>temperature</td>
<td>Displays temperature of the chassis.</td>
</tr>
</tbody>
</table>

### Displaying Environment Conditions

Supervisor Engine 7-E and its associated linecards support multiple temperature sensors per card. The environment condition output includes the temperature reading from each sensor and the temperature thresholds for each sensor. These linecards support three thresholds: warning, critical, and shutdown. The following example illustrates how to display the environment condition on a Supervisor Engine 7-E. The thresholds appear within parentheses.

```
Switch# show environment
Module Sensor                     Temperature          Status
------+--------------------------+--------------------+------------
1      Xgstub A                   39C (48C,62C,65C)              ok
1      Xgstub B                   32C (45C,60C,63C)              ok
1      XPP                        47C (62C,75C,78C)              ok
1      VFE2                       59C (74C,85C,88C)              ok
1      NFE                        44C (63C,75C,78C)              ok
1      CPU                        55C (57C,72C,75C)              ok
1      FPGA                       37C (52C,66C,69C)              ok

Emergency Actions

Chassis with Supervisor Engine 7-E can power down a single card, providing a detailed response to over-temperature conditions on linecards. However, Supervisor Engine 7-E \textit{cannot} safely operate when the temperature of the supervisor itself exceeds the critical threshold. Therefore, the supervisor engine turns off the chassis’ power supplies to protect itself from overheating. When this happens, you can recover the switch only by cycling the power on and off switches on the power supplies or by cycling the AC or DC inputs to the power supplies.

Critical and shutdown temperature emergencies trigger the same action. Table 10-2 lists temperature emergencies but does not distinguish between critical and shutdown emergencies.

| Case 1. Complete fan failure emergency. | Power down the chassis. |
| Case 2. Temperature emergency on a linecard. | Power down the linecard. |
| Case 3. Temperature emergency on the standby supervisor engine. | Power down the standby supervisor engine. |
| Case 4. Temperature emergency on the active supervisor engine with the standby supervisor engine in the hot standby or cold standby redundancy state. | Reset the active supervisor engine. |
| Case 5. Temperature emergency on the active supervisor engine with no standby supervisor engine or with a standby supervisor engine that is not in hot standby or cold standby redundancy state. | Power down the chassis. |

In Case 4, the standby supervisor engine takes over when the active engine resets itself. Then, if the temperature emergency remains, the newly active supervisor engine resets the standby supervisor engine.

Case 5 applies to nonredundant chassis and to chassis with a standby supervisor engine that has been shutdown or which has not fully booted.
System Alarms

Any system has two types of alarms: major and minor. A major alarm indicates a critical problem that could lead to system shutdown. A minor alarm is informational—it alerts you to a problem that could become critical if corrective action is not taken.

Table 10-3 lists the possible environment alarms.

**Table 10-3 Possible Environmental Alarms**

<table>
<thead>
<tr>
<th>Event</th>
<th>Alarm Type</th>
<th>Color</th>
<th>Timeout</th>
<th>Description and Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>A temperature sensor over its warning threshold</td>
<td>minor</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>A temperature sensor over its critical threshold</td>
<td>major</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>A temperature sensor over its shutdown threshold</td>
<td>major</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>A partial fan failure</td>
<td>minor</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>A complete fan failure</td>
<td>major</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Fan failure alarms are issued as soon as the fan failure condition is detected and are canceled when the fan failure condition clears. Temperature alarms are issued as soon as the temperature reaches the threshold temperature and are canceled when the temperature drops more than 5 degree C below the threshold. 5 degree C is a hysteresis value designed to prevent toggling alarms.

An LED on the supervisor engine indicates whether an alarm has been issued.

When the system issues a major alarm, it starts a timer whose duration depends on the alarm. If the alarm is not canceled before the timer expires, the system takes emergency action to protect itself from the effects of overheating. The timer values and the emergency actions depend on the type of supervisor engine.

Refer to the *Catalyst 4500 Series Switch Module Installation Guide* for information on LEDs, including the startup behavior of the supervisor engine system LED.

Table 10-4 describes the alarms on Supervisor Engine 7-E.

**Table 10-4 Alarms on Supervisor Engine 7-E**

Chapter 10      Environmental Monitoring and Power Management

Power Management

This section describes the power management feature in the Catalyst 4500 series switches. It includes the following topics:

- Power Management for the Catalyst 4500 Series Switches, page 10-5
- Powering Down a Module, page 10-18

Note

For power consumption of all Catalyst 4000/4500 family modules, see “Appendix A, Specifications,” in the Catalyst 4500 Series Module Installation Guide. Enter the `show power` command to display the current power redundancy and the current system power usage.

### Power Management for the Catalyst 4500 Series Switches

This section includes the following subsections:

- Supported Power Supplies, page 10-5
- Power Management Modes for the Catalyst 4500 Switch, page 10-7
- Selecting a Power Management Mode, page 10-7
- Power Management Limitations in Catalyst 4500 Series Switches, page 10-8
- Available Power for Catalyst 4500 Series Switches Power Supplies, page 10-12
- Special Considerations for the 4200 W AC and 6000 W AC Power Supplies, page 10-13
- Combined Mode Power Resiliency, page 10-15
- Special Considerations for the 1400 W DC Power Supply, page 10-16
- Special Considerations for the 1400 W DC SP Triple Input Power Supply, page 10-17

### Supported Power Supplies

You can select from several different power supplies to ensure that you have enough power for the modules installed in your switch.

### Table 10-4 Alarms on Supervisor Engine 7-E

</tbody>
</table>
You should select a power supply based on the modules and the amount of PoE desired using the Cisco Power Calculator:

http://tools.cisco.com/cpc/

The choice between 1000 AC and 1400 AC should depend on the type of linecards that the customer plans to use in the chassis.

The Catalyst 4500 series switches support the following power supplies:

- **Fixed Wattage**—These power supplies always deliver a fixed amount of PoE and system power.
  - 1000 W AC—Supports up to 1050 W of system power. (Not recommended on the Catalyst 4510R switch, PoE not supported)
  - 1400 W AC—Supports up to 1400 W system power. (PoE not supported)
  - 2800 W AC—Supports up to 1400 W of system power and up to 1400 W of PoE.

- **Variable Wattage**—These power supplies automatically adjust the wattage to accommodate PoE and system power requirements.
  - 1300 W AC—Supports up to 1050 W of system power and 800 W of PoE, limited to a total of 1300 W.
  - 1400 W DC—Supports up to 1400 W of system power and variable amounts of PoE, depending on the input feed to the power supply. See “Special Considerations for the 1400 W DC Power Supply” section on page 10-16 for more information.
  - 1400 W DC Service Provider—Uses up to three lines (12.5 A, 15 A, 15 A) of DC input and delivers varying amounts of system power ranging from 400 W to 1400 W depending on the lines powered. See “Special Considerations for the 1400 W DC SP Triple Input Power Supply” section on page 10-17 for more information. (PoE not supported)
  - 4200 W AC and 6000 W AC—Supports varying amounts of system power and PoE depending on the number of inputs powered and input voltage.

All Catalyst 4500 series switch AC-input power supplies require single-phase source AC. The source AC can be out of phase between multiple power supplies or multiple AC-power plugs on the same power supply because all AC power supply inputs are isolated. Each chassis power supply should ideally have its own dedicated branch circuit sized to local and national codes.

When you insert power supplies in your switch, use power supplies that are of the same wattage. Multi-input power supplies such as 1400 W DC triple-input, 4200 W AC, and 6000 W AC have additional restrictions. Read the sections on special considerations for these power supplies. If you mix power supplies, the switch uses the one with the higher wattage and ignores the other power supply. The power supply status displays as err-disable and the summary displays as all zeros (0) for wattage values in the output for the `show power` command. The following example shows the output for the `show power` command for mixed power supplies:

```
Switch# show power

Power Supply  Model No  Type  Status  Fan  Sensor  Inline
-------------  -----------  ------  ------  -----  -------  ----
PWR-C45-2800AC  2800W  good  good  good

PS1             PWR-C45-1000AC  1000W  err-disable  good  n.a.
```

When you insert power supplies in your switch, use power supplies that are of the same wattage. **Power Management Modes for the Catalyst 4500 Switch**

The Catalyst 4500 series switches support two power management modes:

- **Redundant mode**—Redundant mode uses one power supply as a primary power supply and the second power supply as a back-up. If the primary power supply fails, the second power supply immediately supports the switch without any disruption in the network. Both power supplies must be the same wattage. A single power supply must have enough power to support the switch configuration.

- **Combined mode**—Combined mode uses the power from all installed power supplies to support the switch configuration power requirements. However, combined mode has no power redundancy. If a power supply fails, one or more modules might shut down.

**Note**
On the Catalyst 4510R switch, the 1000 W AC power supply is not enough to support redundant mode for all possible configurations. It is able to support redundant mode for limited configurations that require less than 1050 W.

**Note**
The 1400 W DC power supply supports combined mode for data power. It does not support combined mode for PoE power.

**Selecting a Power Management Mode**

By default, a switch is set to redundant mode. In the show power command, if the power supplies needed by system is 1, the switch is in redundant mode; if the power supplies needed by system is 2, the switch is in combined mode.

Your switch hardware configuration dictates which power supply or supplies you should use. For example, if your switch configuration requires more power than a single power supply provides, use the combined mode. In combined mode, however, the switch has no power redundancy. Consider the following possibilities:

- The supervisor engine consumes 110 W, the fan boxes for the Catalyst 4503 switch consume 30 W each, the fan boxes for the Catalyst 4506 and Catalyst 4507 switches consume 50 W each, the backplane for the Catalyst 4503 and Catalyst 4506 switches consumes 10 W, and the backplane for the Catalyst 4507 switch consumes 40 W.

- 1000 W can support a fully loaded Catalyst 4503 switch with no powered device support.
• 1300 W can support a fully loaded Catalyst 4503 switch with Cisco powered devices.
• Each PoE port on a WS-X4148-RJ45V module requires 6.3 W. Five fully loaded WS-X4148-RJ45V modules in a switch comprise 240 ports. This configuration requires 1512 W of PoE, plus 300 W for the modules.

Power Management Limitations in Catalyst 4500 Series Switches

Limitation 1

It is possible to configure a switch that requires more power than the power supplies provide. The two ways you could configure a switch to exceed the power capabilities are as follows:
• The power requirements for the installed modules exceed the power provided by the power supplies.
  
  If you insert a single power supply and then set the switch to combined mode, the switch displays this error message:
  
  Insufficient power supplies present for specified configuration.

  This error message also displays in the output for the show power command. This error message displays because, by definition, combined mode requires that two working power supplies be installed in your switch.

  If the power requirements for the installed modules exceeds the power provided by the power supplies, the switch displays this error message:
  
  Insufficient power available for the current chassis configuration.

  This error message also appears in the show power command output.

  If you attempt to insert additional modules into your switch and exceed the power supply, the switch immediately places the newly inserted module into reset mode, and the switch displays these error messages:
  
  Module has been inserted
  Insufficient power supplies operating.

  Additionally, if you power down a functioning switch and insert an additional module or change the module configuration so that the power requirements exceed the available power, one or more modules enter reset mode when you power on the switch again.

• The power requirements for the PoE exceed the PoE provided by the power supplies.

  If you have too many IP phones drawing power from the system, power to IP phones is cut, and some phones may be powered down to reduce the power requirements to match the power supplies.

  In the first scenario (power requirements exceed the power supplied), the system attempts to resolve this power usage limitation by evaluating the type and number of modules installed. During the evaluation cycle, beginning from the bottom of the chassis, the system puts the modules that it is unable to support (for lack of power) into reset mode. The supervisor engine and modules for which there is adequate power always remain enabled, with no disruption of network connectivity. Modules placed in reset mode still consume some power and can be removed from the chassis to further reduce power requirements. If you configure the chassis correctly, the system does not enter the evaluation cycle.

  A module in reset mode continues to draw power as long as it is installed in the chassis; use the show power module command to determine how much power is required to bring the module online.
To compute the power requirements for your system and verify that your system has enough power, add the power consumed by the supervisor engine module(s), the fan box(es), and the installed modules (including PoE). For PoE, total the requirements for all the phones. See the “Powering Down a Module” section on page 10-18 for more information on the power consumption for the various components of your switch.

The 802.3af-compliant PoE modules can consume up to 20 W of PoE to power FPGAs and other hardware components on the module. Be sure to add at least 20 W to your PoE requirements for each 802.3af-compliant PoE module to ensure that the system has adequate power for the PDs connected to the switch.

On the WS-X4148-RJ45V PoE module, PoE consumption cannot be measured. Therefore, for all PoE calculations, the PoE consumption on this module is presumed to be equal to its administrative PoE.

Use the `show module` command to verify which modules are active and which, if any, have been placed in reset.

The following example shows the `show module` command output for a system with inadequate power for all installed modules. The system does not have enough power for Module 5; the `Status` displays it as `PwrDeny`.

If the PoE that is consumed by the module is more than 50 W above the PoE you allocated using the `power inline consumption default` command, the Status displays as `PwrOver`. If the PoE consumed by the module is more than 50 W above the PoE module limit, the Status displays as `PwrFault`.

**Limitation 2**

Certain configurations on the Catalyst 4507R and Catalyst 4510R chassis exceeds the maximum amount of data power available. These configurations include the combination of the follow PIDs:

- 7-slot configuration
- Chassis: WS-C4507R-E, WS-C4510R-E
- Dual supervisor engines: WS-X45-Sup6-E
- One or more: WS-X4448-GB-RJ45 or WS-X4148-FX-MT

To maximize the 10/100/1000 port density of 7 and 10 slot chassis when using redundant Supervisor engine 6-E install WS-X4548-GB-RJ45 linecards instead of WS-X4448-GB-RJ45 linecards. If WS-X4448-GB-RJ45 linecards are required two options are available.

- Option 1
  - Only 4 linecard slots can be used on the Cat4507R and 6 linecard slots on the Cat4510R chassis.
**Power Management**

- **Option 2**
  
  When all slots are required only one WS-X4448-GB-RJ45 linecard can be used.

To maximize the 100-BASE-FX port density of 7 and 10 slot chassis when using Supervisor engine 6-E install WS-4248-FE-SFP linecards with FX optics instead of WS-X4148-FX-MT linecards. If WS-X4148-FX-MT linecards are required two options are available.

- **Option 1**
  
  Only 4 linecard slots can be used on the Cat4507R and 6 linecard slots on the Cat4510R chassis.

- **Option 2**
  
  When all slots are required only one WS-X4448-GB-RJ45 linecard can be used.

---

### Configuring Redundant Mode on a Catalyst 4500 Series Switch

By default, the power supplies in a Catalyst 4500 series switch are set to operate in redundant mode. To effectively use redundant mode, follow these guidelines:

- Use two power supplies of the same type.
- If you have the power management mode set to redundant mode and only one power supply installed, your switch accepts the configuration but operates without redundancy.

---

**Caution**

If you have power supplies with different types or different wattages installed in your switch, the switch does not recognize one of the power supplies and does not have power redundancy.

- For fixed power supplies, choose a power supply that by itself is powerful enough to support the switch configuration.
- For variable power supplies, choose a power supply that provides enough power so that the chassis and PoE requirements are less than the maximum available power. Variable power supplies automatically adjust the power resources at startup to accommodate the chassis and PoE requirements. Modules are brought up first, followed by IP phones.
- The maximum available power for chassis and PoE for each power supply are listed in Table 10-5 on page 10-12.

To configure redundant mode on your Catalyst 4500 series switch, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>Step 2</strong></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td>Switch(config)# power redundancy-mode redundant</td>
</tr>
<tr>
<td>Enters configuration mode.</td>
<td>Sets the power management mode to redundant mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><strong>Step 4</strong></td>
</tr>
<tr>
<td>Switch(config)# end</td>
<td>Switch# show power supplies</td>
</tr>
<tr>
<td>Exits configuration mode.</td>
<td>Verifies the power redundancy mode for the switch.</td>
</tr>
</tbody>
</table>

The following example shows how to set the power management mode to redundant mode.

```bash
Switch (config)# power redundancy-mode redundant
Switch (config)# end
Switch#
```
Chapter 10  Environmental Monitoring and Power Management

Power Management

The following example shows how to display the current power redundancy mode. The power supplies needed by system: 1 indicates that the switch is in redundant mode.

```
Switch# show power supplies
Power supplies needed by system:1
```

An option in the combined mode provides a form of redundancy available with only the 4200 W AC and 6000 W AC power supplies. Refer to the section “Combined Mode Power Resiliency” on page 15.

Configuring Combined Mode on a Catalyst 4500 Series Switch

If your switch configuration requires more power than a single power supply can provide, set the power management mode to combined mode. Combined mode utilizes the available power for both power supplies; however, your switch has no power redundancy.

To effectively use combined mode, follow these guidelines:

- Use power supplies of the same type and wattage (fixed or variable and AC or DC).
- If you use power supplies with different types or wattages, the switch utilizes only one of the power supplies.
- For variable power supplies, choose a power supply that provides enough power so that the chassis and PoE requirements are less than the maximum available power. Variable power supplies automatically adjust the power resources at startup to accommodate the chassis and PoE requirements.
- If you have the power management mode set to combined mode and only one power supply installed, your switch accepts the configuration, but power is available from only one power supply.
- When your switch is configured to combined mode, the total available power is not the mathematical sum of the individual power supplies. The power supplies have a predetermined current sharing ratio (See Table 10-5 on page 10-12 for more information.)
- The maximum available power for chassis and PoE for each power supply are listed in Table 10-5 on page 10-12.

To configure combined mode on your Catalyst 4500 series switch, perform this task:

```
Step 1
Switch# configure terminal  
Purpose: Enters configuration mode.

Step 2
Switch(config)# power redundancy-mode combined
Purpose: Sets the power management mode to combined mode.

Step 3
Switch(config)# end
Purpose: Exits configuration mode.

Step 4
Switch# show power supplies
Purpose: Verifies the power redundancy mode for the switch.
```

The following example shows how to set the power management mode to combined mode.

```
Switch (config)# power redundancy-mode combined
Switch (config)# end
Switch#
```
The following example shows how to display the current power redundancy mode. The power supplies needed by system: 2 indicates that the switch is in combined mode.

```
Switch# show power supplies
Power supplies needed by system: 2
Switch#
```

### Available Power for Catalyst 4500 Series Switches Power Supplies

Table 10-5 lists the power available for use in the various Catalyst 4500 series switches power supplies. When your switch is configured to combined mode, the total available power in not the mathematical sum of the individual power supplies. The power supplies have a sharing ratio predetermined by the hardware. In combined mode, the total power available is \( P + (P \times \text{sharing-ratio}) \), where \( P \) is the amount of power in the power supply.

<table>

</tr>
</tbody>
</table>

1. Chassis power includes power for the supervisor(s), all linecards, and the fan tray.
2. The efficiency for the 1400 W DC power supply is 0.75, and 0.96 is applied to PoE.
3. DC input can vary for the 1400 W DC power supply and is configurable. For more information, see “Special Considerations for the 1400 W DC Power Supply” on page 16.
4. Not available for PoE.
5. Not available for PoE.
6. No voice power.
7. Data-only.
8. Inline power.
Special Considerations for the 4200 W AC and 6000 W AC Power Supplies

The 4200 W AC and 6000 W AC power supply has two inputs: each can be powered at 110 or 220 V.

The output of the `show power` command for the 4200 W AC and 6000 W AC power supplies are similar to that of 1400 W DC triple-input power supply (that is, the status of the sub-modules (multiple inputs) is displayed). With these two power supplies, you can distinguish sub-module “failed” versus “off,” and the status of the sub-modules (good, bad, or off):

</tbody>
</table>

Power supplies needed by system : 1
Power supplies currently available : 2

As with other power supplies, the two power supplies must be of the same type (6000 W AC or 4200 W AC or 1400 W DC). Otherwise, the right power supply are put in err-disable state and the left one is selected. In addition, all the inputs to the chassis must be at the same voltage. In redundant mode, the inputs to the left and right power supplies must be identical. If the left and right power supplies are powered in redundant mode, the power values are based on the power supply that has higher output wattage.

**Note**

When the system is powered with a 4200 W or 6000 W power supply either in 110 V or 220 V combined mode operation, the available power is determined by the configuration of the system (the type of linecards, the number of linecards, number of ports consuming inline power etc.) and does not reflect the absolute maximum power.

**Note**

In a matched redundant power supply configuration, if a power supply sub-module fails, the other (good) power supply provides power to its full capability.

Table 10-6 illustrates how the 4200 W AC power supply is evaluated in redundant mode.
Table 10-6 Power Output in Redundant Mode for the 4200 W AC Power Supply

Combined Mode Power Resiliency

This feature only applies in combined mode when both power supply bays contain the 4200 W AC or 6000 W AC power supply.

Using the combined mode power resiliency feature, you can limit the power usage to a maximum of two or three (configurable) inputs.

With two 4200 W AC or 6000 W AC power supplies, a maximum of four inputs are available. This feature allows you to cap the power usage to that of two or three inputs. If one of the power supplies fails, no loss of power occurs because you have capped its usage to a smaller number of inputs.

To configure the combined mode resiliency feature, perform this task:

Let’s say that you have max inputs 3 configured with 4 “good” (220 V) inputs and you limit the user to 5500 W instead of 7600 W with the following configuration. If one sub-unit fails or is powered off, the user would have three “good” inputs providing 5500 W and the chassis is powered at the same rate as it was prior to the failure event.

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# power redundancy combined max inputs {2 | 3}
Switch(config)# end
Switch# 14:32:01: %SYS-5-CONFIG_I: Configured from console by console

Here is the output of the show power command prior to invoking this feature:

Switch# show power
Power
Supply Model No Type Status Fan Sensor Inline
------ ----------- --------- --------- ------- ------ ------
PS1     PWR-C45-4200ACV AC 4200W good 10V good good
PS1-1                           110V good
PS1-2                           110V good
PS2     PWR-C45-4200ACV AC 4200W good 10V good good
PS2-1                           110V good

Switch#

Special Considerations for the 1400 W DC Power Supply

⚠️ Caution

Do not mix the 1400 W DC power supply with any other power supply, even for a hot swap or other
short-term emergency. Doing so can seriously damage your switch.

Keep in mind the following guidelines when using a 1400 W DC power supply with your Catalyst 4500
series switch:

- The 1400 W DC power supply works with a variety of DC sources. The DC input can vary from
  300 W to 7500 W. Refer to the power supply documentation for additional information.
- The supervisor engine cannot detect the DC source plugged into the 1400 W DC power supply. If
  you are using the 1400 W DC power supply, use the power dc input command to set the DC input
  power. For more information on this command, see the “Configuring the DC Input for a Power
  Supply” section on page 10-17.
• The software automatically adjusts between system power (for modules, backplane, and fans) and PoE. Although PoE is 96 percent efficient, system power has only 75 percent efficiency. For example, each 120 W of system power requires 160 W from the DC input. This requirement is reflected in the “Power Used” column of the output for the show power available command.

• The 1400 W DC power supply has a separate power on or off switch for PoE. The power supply fan status and main power supply status are tied together. If either of them fails, both the power supply and its fan report as bad/off. You should verify that the main power is on before turning on the power for the inline switch. In addition, you should verify that the power for the inline switch is off before turning off the main power.

Configuring the DC Input for a Power Supply

To configure the DC input power for the 1400 W DC power supply or a power shelf, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal Enters configuration mode</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# power dc input watts Sets the capacity of the DC input source.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config)# end Exits configuration mode.</td>
</tr>
</tbody>
</table>

The same configuration is applied to both power slots. For example, if you set the dc power input to 1000 W, the switch expects 1000 W as the external DC source for both slot 1 and slot 2 (if present) respectively.

The following example shows how to set the external DC power source to 1000 W:

Switch# configure terminal
Switch (config)# power dc input 1000
Switch (config)# end
Switch#

If you use the 1400 W DC SP power supply in combined mode, the inputs do not have to match.

Special Considerations for the 1400 W DC SP Triple Input Power Supply

Unlike the 1400 W DC power supply, the 1400 W DC SP power supply has sub-modules (multiple inputs) that can be powered on or off. With Cisco IOS Release 12.2(25)EW, output of the show power command is modified to display the status of these sub-modules:

<table>
<thead>
<tr>
<th>Power Supply</th>
<th>Model No</th>
<th>Type</th>
<th>Status</th>
<th>Fan Sensor Status</th>
<th>Inline Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>PS1</td>
<td>PWR-C45-1400DC</td>
<td>DCSP1400W</td>
<td>good</td>
<td>good</td>
<td>n.a.</td>
</tr>
<tr>
<td>PS1-1</td>
<td></td>
<td>12.5A</td>
<td>good</td>
<td></td>
<td></td>
</tr>
<tr>
<td>PS1-2</td>
<td></td>
<td>15.0A</td>
<td>bad</td>
<td></td>
<td></td>
</tr>
<tr>
<td>PS1-3</td>
<td></td>
<td>15.0A</td>
<td>off</td>
<td></td>
<td></td>
</tr>
<tr>
<td>PS2</td>
<td>none</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Observe the following guidelines when using a 1400 W DC SP power supply with your Catalyst 4500 series switch:

- When you use two 48 V power rails to drive two power supplies, you might employ cross-wiring to connect the power supplies (to rails) to minimize the inrush current drawn during an initial power up. In this situation, you should configure the switch in combined mode before you take a rail down for maintenance.

- Ordinarily, when configured for redundancy, two power supplies must be matched (have identical inputs). For example, you might provide power to inputs 1 and 3 on both PS1 and PS2. If power supplies are mismatched upon bootup, the right (second) power supply is in err-disable state.

In a matched redundant power supply configuration, if a power supply sub-module fails, the other (good) power supply provides maximum power.

**Powering Down a Module**

If your system does not have enough power for all modules installed in the switch, you can power down a module, and place it in low power mode. To power down a module, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# no hw-module module num power</td>
<td>Turns power down to the specified module by placing it in low power mode.</td>
</tr>
</tbody>
</table>

To power on a module that has been powered down, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# hw-module module num power</td>
<td>Turns power on to the specified module.</td>
</tr>
</tbody>
</table>

This example shows how to power down module 6:

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# no hw-module module 6 power
Switch(config)# end
Switch#
Note
Before reading this chapter, read the "Preparing for Installation” section of the Catalyst 4500 Series Installation Guide. You must ensure that your installation site has enough power and cooling to accommodate the additional electrical load and heat introduced by PoE.

This chapter describes how to configure Power over Ethernet (PoE) on the Catalyst 4500 series switch. This chapter contains the following sections:

- About Power over Ethernet, page 11-1
- Power Management Modes, page 11-3
- Configuring Power Consumption for Powered Devices on an Interface, page 11-5
- Displaying the Operational Status for an Interface, page 11-6
- Displaying the PoE Consumed by a Module, page 11-7
- PoE Policing and Monitoring, page 11-11
- Enhanced Power PoE Support on the E-Series Chassis, page 11-15

Note
For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

About Power over Ethernet

The Catalyst 4500 series switch provides support for Power over Ethernet (PoE) for both Cisco Prestandard PoE and the IEEE 802.3af standard. Certain linecards also support the higher 802.3at standard. PoE is supported by all Catalyst 4500+E series chassis and requires a PoE module and power
About Power over Ethernet

supply. The amount of PoE power available depends on the PoE capabilities of individual power supplies. Support for PoE enables the system to power inline devices, such as IP phones, IP video phones, and wireless access points over standard copper cabling (Category 5, 5e, or 6 cabling).

In addition, with PoE, you do not need to provide wall power for each PoE enabled device. This action eliminates the cost for additional electrical cabling that would otherwise be necessary for connected devices. Moreover, PoE enables you to isolate critical devices on a single power system, enabling the entire system to be supported by UPS backup.

You typically deploy a Catalyst 4500 series switch in one of two deployment scenarios. The first scenario is data-only, which requires power to operate the switch and the associated modules. The second scenario supports data and PoE (also termed “inline power”) for deployments where the attached device derives power from the Ethernet port.

Catalyst 4500 series switches can sense if a powered device is connected to a PoE module. They can supply PoE to the powered device if there is no power on the circuit. (If there is power on the circuit, the switch does not supply it.) The powered device can also be connected to an AC power source and supply its own power to the voice circuit.

Note

You should select the amount of PoE desired using the Cisco Power Calculator:

http://tools.cisco.com/cpc/

Hardware Requirements

To power a device using PoE, your chassis must use at least one of the power supplies listed in Table 11-1, and connect the device to at least one of the switching modules listed in Table 11-1.

<table>

</tbody>
</table>
Power Management Modes

If your switch has a module capable of providing PoE to end stations, you can set each interface on the module to automatically detect and apply PoE if the end station requires power.

The Catalyst 4500 series switch has three PoE modes:

- **auto**—PoE interface. The supervisor engine directs the switching module to power up the interface only if the switching module discovers the phone and the switch has enough power. You can specify the maximum wattage that is allowed on the interface. If you do not specify a wattage, then the switch delivers no more than the hardware-supported maximum value. This mode has no effect if the interface is not capable of providing PoE.

- **static**—High priority PoE interface. The supervisor engine preallocates power to the interface, even when nothing is connected, guaranteeing that power exists for the interface. You can specify the maximum wattage that is allowed on the interface. If you do not specify a wattage, then the switch preallocates the hardware-supported maximum value. If the switch does not have enough power for the allocation, the command fails. The supervisor engine directs the switching module to power up the interface only if the switching module discovers the powered device.

- **never**—Data interface only. The supervisor engine never powers up the interface, even if an unpowered phone is connected. This mode is only needed when you want to make sure power is never applied to a PoE-capable interface.

The switch can measure the actual PoE consumption for an 802.3af-compliant PoE module, and displays this consumption in the `show power module` command.

PoE consumption cannot be measured on the WS-X4148-RJ45V PoE module. Therefore, for all PoE calculations, the PoE consumption on this module is presumed to be equal to its administrative PoE.

For more information, see the “Displaying the PoE Consumed by a Module” section on page 11-7.

For most users, the default configuration of “auto” works well, providing plug and play capability. No further configuration is required. However, to make an interface higher priority or data only, or to specify a maximum wattage, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Selects the interface to configure.</td>
</tr>
<tr>
<td>Switch(config)# interface {fastethernet</td>
<td>gigabitethernet} slot/port</td>
</tr>
<tr>
<td>Step 2</td>
<td>The auto keyword sets the interface to automatically detect and supply power to the powered device. This is the default configuration.</td>
</tr>
<tr>
<td>Switch(config-if)# power inline {auto</td>
<td>static</td>
</tr>
</tbody>
</table>
**Power Management Modes**

### EFT Draft - Confidential

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config-if)# end</td>
<td>Exits configuration mode.</td>
</tr>
</tbody>
</table>

| Step 4 | Switch# show power inline (fastethernet | gigabitethernet) slot/port | Displays the PoE state for the switch. |

**Note**

If you set a non-PoE-capable interface to automatically detect and apply power, an error message indicates that the configuration is not valid.

The following example shows how to set the Fast Ethernet interface 4/1 to automatically detect PoE and send power through that interface, and to verify the PoE configuration:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fastethernet 4/1
Switch(config-if)# power inline auto
Switch(config-if)# end
Switch# show power inline fastethernet 4/1
Available:677(w) Used:11(w) Remaining:666(w)

<table>
<thead>
<tr>
<th>Interface</th>
<th>Admin</th>
<th>Oper</th>
<th>Power(Watts)</th>
<th>Device</th>
<th>Class</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fa4/1</td>
<td>auto</td>
<td>on</td>
<td>11.2</td>
<td>10.0</td>

<th>AdminPowerMax</th>
<th>AdminConsumption</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fa4/1</td>
<td>15.4</td>
<td>10.0</td>
</tr>
</tbody>
</table>
```

The following example shows how to configure an interface so that it never supplies power through the interface:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fastethernet 5/2
Switch(config-if)# power inline never
Switch(config-if)# end
Switch#
```

### Intelligent Power Management

All Catalyst 4500 PoE-capable modules use Intelligent Power Management to provide power on each interface. When a powered device (PD) is attached to a PoE-capable port, the port detects the PD and provision power accordingly. If a Cisco PD is used, the switch and PD negotiate power using CDP packets to determine the precise amount of power needed by the PD. If the PD is 802.3af or 802.3at compatible, the switch and the PD negotiate using LLDP-MED or LLDP Power-Management TLVs if the TLV is enabled and present. The difference of power in the class-based power allocation and power negotiation is returned back to the switch power budget for use by other attached devices. So, power negotiation enables customers to stretch their power budget and use it more effectively.

Power negotiation also enables the interoperability of newer Cisco powered devices with older legacy PoE-capable ports from Cisco. Newer Cisco PDs do not consume more than what the switch port can provide.
Configuring Power Consumption for Powered Devices on an Interface

By default, when the switch detects a powered device on an interface, it assumes the powered device consumes the maximum the port can provide (7 W on a legacy Power over Ethernet (PoE) module and 15.4W on the IEEE PoE modules introduced in Cisco IOS Release 12.2(18)EW). Then, when the switch receives a CDP/LLDP packet from the powered device, the wattage automatically adjusts downward to the specific amount required by that device. Normally, this automatic adjustment works well, and no further configuration is required or recommended. However, you can specify the powered device’s consumption for a particular interface to provide extra functionality from your switch. This behavior is useful when CDP/LLDP is disabled or not available.

Note

When manually configuring the consumption for powered devices, you need to account for the power loss over the cable between the switch and the powered device.

To change the power consumption of a single powered device, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch(config)# interface {fastethernet</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config-if)# [no] power inline consumption milli-watts</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config-if)# end</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch# show power inline consumption {fastethernet</td>
</tr>
</tbody>
</table>

This example shows how to set the PoE consumption to 5000 milliwatts for interface gi 7/1 regardless what is mandated by the 802.3af class of the discovered device, or by any CDP packet received from the powered device. This example also verifies the PoE consumption on interface gi 7/1.

The following output displays the initial power consumption of the interface.

Switch# show power inline gi 7/1
Available:627(w) Used:267(w) Remaining:360(w)

<table>
<thead>
<tr>
<th>Interface</th>
<th>Admin</th>
<th>Oper</th>
<th>Power (Watts)</th>
<th>Device</th>

<td>on</td>
<td>7.9</td>
<td>7.0</td>
<td>IP Phone 7941</td>
</tr>
</tbody>
</table>

Switch# conf terminal
Enter configuration commands, one per line. End with CNTL/Z.
Chapter 11 Configuring Power over Ethernet

Displaying the Operational Status for an Interface

Each interface has an operational status which reflects the PoE status for an interface. The operational status for an interface is defined as one of the following:

- **on**—Power is supplied by the port.
- **off**—Power is not supplied by the port. If a powered device is connected to an interface with external power, the switch does not recognize the powered device. The “Device” column in the `show power inline` command displays as n/a.
- **Power-deny**—The supervisor engine does not have enough power to allocate to the port, or the power that is configured for the port is less than the power required by the port; power is not being supplied by the port.
- **err-disable**—The port is unable to provide power to the connected device that is configured in static mode.
- **faulty**—The port failed diagnostics tests.

Use the `show power inline` command to view the operational status for an interface.

This example shows how to display the operational status for all interfaces on module 3.

Switch# `show power inline module 3`
Available: 677(w) Used: 117(w) Remaining: 560(w)

<table>
<thead>
<tr>
<th>Interface</th>
<th>Admin</th>
<th>Oper</th>

</table>
Displaying the PoE Consumed by a Module

A Catalyst 4500 series switch can measure the actual PoE consumption for an 802.3af-compliant PoE module. You can observe this consumption with the `show power module` and `show power detail` commands. For all PoE calculations, presume that the PoE consumption on the WS-X4148-RJ45V module equals its administrative PoE.

The 802.3af-compliant PoE modules can consume up to 20 W of PoE to power FPGAs and other hardware components on the module. To ensure that the system has sufficient power for the PDs connected to the switch, add at least 20 W to your PoE requirements for each 802.3af-compliant PoE module.
The following example uses the `show power module` command to display the PoE consumption for an 802.3af-compliant module:

```
Switch# show power module

Watts Used of System Power (12V)
Mod  Model               currently  out of reset  in reset
----  -----------------   ---------  ------------  --------
 1    WS-X4013+TS             330         330         330
 2    WS-X4548-GB-RJ45V       60          60          20
 3    WS-X4548-GB-RJ45V       60          60          20
  --  Fan Tray                30          --          --
------  -----------------   ---------  ------------   -------
     Total                 480         450         370
```

```
Watts used of Chassis Inline Power (-50V)
Mod  Model                PS     Device       PS     Device     Efficiency
----  -----------------  ----------------    ----------------    ----------
 2    WS-X4548-GB-RJ45V    138      123         73       65          89
 3    WS-X4548-GB-RJ45V      0        0         22       20          89
------  -----------------  ----------------    ----------------    ----------
     Total               138      123         95       85
```

```
Watts used of Module Inline Power (12V -> -50V)
Mod  Model                PS     Device       PS     Device     Efficiency
----  -----------------  ----------------    ----------------    ----------
 1    WS-X4013+TS         128      128         63       63         100
------  -----------------  ----------------    ----------------    ----------
```

Switch#

The Inline Power Oper column displays the amount of PoE consumed by the powered devices that are attached to the module, in addition to the PoE consumed by the FPGAs and other hardware components on the module.

The Inline Power Admin column displays only the amount of PoE allocated by the powered devices attached to the module.

```
Note
The operating PoE consumption for an 802.3af-compliant module can be non-zero, even when there are no powered devices attached to the module, because of the PoE consumed by FPGAs and other hardware components on the module. In addition, the operating PoE can vary because of fluctuations in the PoE consumed by the hardware components.
```

The following example uses the `show power detail` and `show power inline` commands to display the PoE consumption for an 802.3af-compliant module:

```
Switch# show power detail

Power Supply  Model No  Type  Status  Fan Sensor  Inline Status
-------  -----------  ------  --------  ----------  -------

## PoE Policing and Monitoring

PoE policing protects a switch from faulty inline powered devices that may draw more current than they were designed for. When a device is connected to a port, a linecard detects the type of device connected and allocates the appropriate amount of power. It sets a PoE policing threshold to a value 5 per cent greater than the allocated power. If the device consumes more power than specified by the policing threshold for more than 1 second, the port shuts down. Depending on the policing action configured, the port may then be error-disabled, or a message might be logged to the console and the port restarted.

### Note

This functionality is supported on the WS-X4548-RJ45V+, WS-X4648-RJ45V-E, and WS-X4648-RJ45V+E linecards.

**Totals:**  12 on  138.2  123.0
PoE monitoring lets you display the true power consumption of inline powered devices attached to the switch, allowing you determine your actual power consumption.

Topics include:

- PoE Policing Modes, page 11-12
- Configuring Power Policing on an Interface, page 11-12
- Displaying Power Policing on an Interface, page 11-13
- Configuring Errdisable Recovery, page 11-14

PoE Policing Modes

PoE policing comprises two modes, which determine the action to take on the interface after a port shuts down because of an inline-power policing violation:

- **Logging** - An error message is logged to the console and the interface restarts; the device powers up.
- **Errdisable** (Default) - In addition to logging an error message to the console, the interface is placed in an errdisable state so that the device attached to the port does not receive inline-power until you restart the port or configure an errdisable autorecovery mechanism.

**Note**

After an inline-power policing violation occurs and the port shuts down, PoE policing automatically turns on again when the port restarts. So, if the connected device exceeds its allocated power again, the port once again shuts down.

Configuring Power Policing on an Interface

The default policing levels are determined by the discovery and power allocation methods (listed in order of priority):

- Configured consumption values, in case any exist
- CDP/LDP allocated values (for Cisco devices using CDP, or IEEE devices using LLDP)
- Allocated power from IEEE discovery (for devices using this mechanism)

To activate default PoE policing, enter the following:

```
Switch# conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# int g2/1
Switch(config-if)# power inline police
Switch(config-if)# end
Switch# show power inline police g2/1
```

Available: 800 (w)  Used: 32 (w)  Remaining: 768 (w)

<th>Oper Power</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gi2/1</td>
<td>auto on</td>
<td>errdisable ok</td>
<td></td>
<td></td>
<td>17.2</td>
<td>16.7</td>
</tr>
</tbody>
</table>
The default action for power policing is to set the port to errdisable; the **power inline police** command is equivalent to the **power inline police action errdisable** command, as the above example illustrates. The following example illustrates how to configure the logging policing action:

```plaintext
Switch# conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# int g2/1
Switch(config-if)# power inline police action log
Switch(config-if)# end
Switch# show power inline police g2/1
Available:800(w) Used:32(w) Remaining:768(w)

Interface Admin Oper Admin Oper Cutoff Oper
--------- ------ ---------- ---------- ------ ------
Gi2/1 auto on log ok 17.2 16.7
```

When a PD consumes more than its allocated power, the port shuts down and a warning message similar to the following appears on the console:

For the WS-X4648-GB-RJ45V and WS-X4648-GB-RJ45V+:

```
```

For the WS-X4548-RJ45V+:

```
```

For actions of Log type, the port restarts itself and the device reboots. In contrast, when the action is to set the port in an errdisable state, a log message like the following appears:

```
*Sep 26 09:30:20.463: %PM-4-ERR_DISABLE: inline-power error detected on Gi2/1, putting Gi2/1 in err-disable state
```

Switch# show power inline police g2/1
Available:800 (w) Used:16 (w) Remaining:784 (w)

<table>
<thead>
<tr>
<th>Interface</th>
<th>Admin State</th>
<th>Oper State</th>
<th>Admin Police</th>
<th>Oper Police</th>
<th>Cutoff Power</th>
<th>Oper Power</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gi2/1</td>
<td>auto</td>
<td>errdisable</td>
<td>errdisable</td>
<td>overdrown</td>
<td>0.0</td>
<td>0.0</td>
</tr>
</tbody>
</table>
```

**Displaying Power Policing on an Interface**

You can display power policing on an interface, on a module, or for all the PoE-capable linecards in a chassis.

The following example shows output for the **show power inline police** command:

```plaintext
Switch# show power inline police
Available:623 (w) Used:6 (w) Remaining:617 (w)

<table>
<thead>
<tr>
<th>Interface</th>
<th>Admin State</th>
<th>Oper State</th>
<th>Admin Police</th>
<th>Oper Police</th>
<th>Cutoff Power</th>
<th>Oper Power</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gi2/1</td>
<td>auto</td>
<td>off</td>
<td>none</td>
<td>n/a</td>
<td>n/a</td>
<td>0.0</td>
</tr>
<tr>
<td>Gi2/2</td>
<td>auto</td>
<td>on</td>
<td>none</td>
<td>n/a</td>
<td>n/a</td>
<td>16.7</td>
</tr>
<tr>
<td>Gi2/3</td>
<td>auto</td>
<td>off</td>
<td>errdisable</td>
<td>n/a</td>
<td>0.0</td>
<td>0.0</td>
</tr>
</tbody>
</table>
```

The default action for power policing is to set the port to errdisable; the **power inline police** command is equivalent to the **power inline police action errdisable** command, as the above example illustrates. The following example illustrates how to configure the logging policing action:
Chapter 11  Configuring Power over Ethernet

### Configuring Power over Ethernet

#### PoE Policing and Monitoring

The following table lists the interface and the status.

<table>
<thead>
<tr>
<th>Interface Configuration</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gi2/1</td>
<td>No PD connected, no policing configured.</td>
</tr>
<tr>
<td>Gi2/2</td>
<td>PD connected, no policing configured.</td>
</tr>
<tr>
<td>Gi2/3</td>
<td>No PD connected, policing configured (gets enabled when PD is connected). Policing action is errdisable.</td>
</tr>
<tr>
<td>Gi2/4</td>
<td>PD connected, policing configured. Configured policing action is errdisable. Port is currently operating within policing limits.</td>
</tr>
<tr>
<td>Gi2/5</td>
<td>PD connected, policing configured. Configured policing action is log. Port is currently operating within policing limits.</td>
</tr>
<tr>
<td>Gi2/6</td>
<td>PD connected, policing configured. Configured policing action is errdisable. Port is currently in errdisable state as it has overdrawn its policed power level.</td>
</tr>
</tbody>
</table>

If you enter the `show power inline` command at the global level (`show power inline police`), the last line of the output under the Oper Power field displays the total of true inline power consumption of all devices connected to the switch.

### Configuring Errdisable Recovery

By default, errdisable auto recovery for inline-power is disabled; when an interface is placed in an errdisable state because of an inline-power policing violation, it remains in that state. You must enter `shut` and `no shut` on the affected interface to revive it.

The errdisable autorecovery mechanism allows you to configure a timer for errdisable recovery so that when an interface enters errdisable state (after the timer expires), the interface returns from the errdisable state.

#### errdisable detection

By default, errdisable detection for inline-power is enabled, as the following example illustrates:

```
Switch# show errdisable detect
ErrDisable Reason  Detection  Mode
-----------------  ---------  ----
inline-power     Enabled  port
```

**Note**

If detection is disabled (through the `errdisable detect cause inline-power` command), the port is not placed in errdisable state when it exceeds its power policing threshold.
errdisable recovery

By default, errdisable recovery for inline-power is disabled. To enable errdisable recovery, enter the `errdisable detect cause line-power` command:

```
Switch# conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# errdisable detect cause line-power
Switch(config)# end
Switch#
```

```
show errdisable recovery

ErrDisable Reason            Timer Status
-----------------            --------------
-----------                  ----------
inline-power                 Enabled
```

**Enhanced Power PoE Support on the E-Series Chassis**

The WS-X4648-RJ45V-E, WS-X4648-RJ45V+E, and WS-X4548-RJ45V+ switching modules support IEEE 802.3af PoE as well as the Cisco proprietary Inline Power standard. With Cisco IOS Release 12.2(44)SG, the WS-X4648-RJ45V+E linecard can also support the IEEE 802.3at standard with up to 30 W available per port. Furthermore, the WS-X4648-RJ45V-E linecard supports up to 20 W. The WS-X4548-RJ45V+ switching module is supported with Cisco IOS Release 12.2(50)SG and can provide up to 30 W of inline power per port. The WS-X4747-RJ45V+ linecard introduced in Cisco IOS Release 15.0(1)XO provides up to 30 watts per port.

For these switching modules, the valid milliwatt ranges for the `power inline` command have been increased appropriately for the module, as the following table illustrates:

<table>
<thead>
<tr>
<th>Linecard</th>
<th>Standard</th>
<th>Max Power/Port</th>
<th>Cisco IOS Release</th>
</tr>
</thead>
<tbody>
<tr>
<td>WS-X4648-RJ45V-E</td>
<td>IEEE 802.3af</td>
<td>20 W</td>
<td>12.2(44)SG</td>
</tr>
<tr>
<td>WS-X4648-RJ45V-E</td>
<td>IEEE 802.3af</td>
<td>30 W</td>
<td>12.2(44)SG</td>
</tr>
<tr>
<td>WS-X4648-RJ45V-E</td>
<td>IEEE 802.3af</td>
<td>30 W</td>
<td>12.2(50)SG</td>
</tr>
<tr>
<td>WS-X4747-RJ45V+</td>
<td>IEEE 802.3af</td>
<td>30 W</td>
<td>15.0(1)XO</td>
</tr>
</tbody>
</table>

Ordinarily, the default power inline configurations suffice; no additional configuration is required even for high power consumption Cisco powered devices (for example, a Cisco AP1250 Wireless Access Point). When a high power consumption device is attached to a port on a WS-X4648-RJ45V-E or WS-X4648-RJ45V+E linecard, the switch and device negotiate power using CDP/LLDP packets to automatically determine the extended amount of power needed by the device.

Depending on the deployment requirements and design, you specify a specific configuration with the `power inline` command.

The following example shows how to pre-allocate PoE allocation to 16500 mW for Gi 2/1, regardless of what is mandated either by the 802.3af class of the discovered device or by any CDP packet that is received from the powered device:

```
Switch# configure terminal
```
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface gigabitethernet 2/1
Switch(config-if)# power inline static max 16500
Switch(config-if)# end
Switch#
This chapter describes VLANs on Catalyst 4500 series switches. It also describes how to enable the VLAN Trunking Protocol (VTP) and to configure the Catalyst 4500 series switch as a VMPS client.

This chapter includes the following major sections:

- VLANs, page 12-1
- VLAN Trunking Protocol, page 12-7
- VLAN Membership Policy Server, page 12-20

For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

VLANs

This section includes the following major subsections:

- About VLANs, page 12-1
- VLAN Configuration Guidelines and Restrictions, page 12-3
- VLAN Default Configuration, page 12-4
- Configuring VLANs, page 12-5

About VLANs

A VLAN is a group of devices on one or more LANs that are configured to communicate as if they were attached to the same wire, when in fact they are located on a number of different LAN segments. Because VLANs are based on logical instead of physical connections, they are extremely flexible.
VLANs define broadcast domains in a Layer 2 network. A broadcast domain is the set of all devices that receives broadcast frames originating from any device within the set. Broadcast domains are typically bounded by switches because switches do not forward broadcast frames. Layer 2 switches create broadcast domains based on the configuration of the switch. Switches are multiport bridges that allow you to create multiple broadcast domains. Each broadcast domain is like a distinct virtual bridge within a switch.

You can define one or many virtual bridges within a switch. Each virtual bridge you create in the switch defines a new broadcast domain (VLAN). Traffic cannot pass directly to another VLAN (between broadcast domains) within the switch or between two switches. To interconnect two different VLANs, you must use switches or Layer 3 switches. See the “Overview of Layer 3 Interfaces” section on page 26-1 for information on inter-VLAN routing on Catalyst 4500 series switches.

Figure 12-1 shows an example of three VLANs that create logically defined networks.

VLANs are often associated with IP subnetworks. For example, all of the end stations in a particular IP subnet belong to the same VLAN. Traffic between VLANs must be routed. You must assign LAN interface VLAN membership on an interface-by-interface basis (this is known as interface-based or static VLAN membership).

You can set the following parameters when you create a VLAN in the management domain:

- VLAN number
- VLAN name
- VLAN type
Chapter 12      Configuring VLANs, VTP, and VMPS

VLANs

- VLAN state (active or suspended)
- Maximum transmission unit (MTU) for the VLAN
- Security Association Identifier (SAID)
- VLAN number to use when translating from one VLAN type to another

**Note** When the software translates from one VLAN type to another, it requires a different VLAN number for each media type.

**VLAN Configuration Guidelines and Restrictions**

Follow these guidelines and restrictions when creating and modifying VLANs in your network:

- Before creating a VLAN, put the Catalyst 4500 series switch in VTP server mode or VTP transparent mode. If the Catalyst 4500 series switch is a VTP server, you must define a VTP domain. For information on configuring VTP, see the section **VLAN Trunking Protocol**, page 12-7.
- The Cisco IOS **end** command is not supported in VLAN database mode.
- You cannot use **Ctrl-Z** to exit VLAN database mode.
- If a Catalyst 4948 switch running MSTP and configured with all possible VLANs (4094) is in the path of two HSRP peers with the timeout set below 500 ms., HSRP flaps.
  **Workarounds:**
  - Use fewer VLANs.
  - Set the timers greater than 600 ms.
  - Enter the commands **no igmp snooping** (globally) and **access-list hardware capture mode VLAN**.

**VLAN Ranges**

**Note** You must enable the extended system ID to use 4094 VLANs. See the “Understanding the Bridge ID” section on page 16-2.

With Cisco IOS Release 12.2(25)EWA and later, Catalyst 4500 series switches support 4096 VLANs in compliance with the IEEE 802.1Q standard. These VLANs are organized into three ranges: reserved, normal, and extended.

Some of these VLANs are propagated to other switches in the network when you use the VLAN Trunking Protocol (VTP). The extended-range VLANs are not propagated, so you must configure extended-range VLANs manually on each network device.
Table 12-1 describes the uses for VLAN ranges.

### Table 12-1  VLAN Ranges

<table>
<thead>
<tr>
<th>VLANs</th>
<th>Range</th>
<th>Usage</th>
<th>Prop by VTX</th>
</tr>
</thead>
<tbody>
<tr>
<td>0, 4095</td>
<td>Reserved</td>
<td>For system use only. You cannot see or use these VLANs.</td>
<td>—</td>
</tr>
<tr>
<td>1</td>
<td>Normal</td>
<td>Cisco default. You can use this VLAN but you cannot delete it.</td>
<td>Yes</td>
</tr>
<tr>
<td>2–1001</td>
<td>Normal</td>
<td>Used for Ethernet VLANs; you can create, use, and delete these VLANs.</td>
<td>Yes</td>
</tr>
<tr>
<td>1002–1005</td>
<td>Normal</td>
<td>Cisco defaults for FDDI and Token Ring. You cannot delete VLANs 1002–1005.</td>
<td>Yes</td>
</tr>
<tr>
<td>1006–4094</td>
<td>Extended</td>
<td>For Ethernet VLANs only. When configuring extended-range VLANs, note the following:</td>
<td>No</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Layer 3 ports and some software features require internal VLANs. Internal VLANs are allocated from 1006 and up. You cannot use a VLAN that has been allocated for such use. To display the VLANs used internally, enter the <code>show vlan internal usage</code> command.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Switches running Catalyst product family software do not support configuration of VLANs 1006–1024. If you configure VLANs 1006–1024, ensure that the VLANs do not extend to any switches running Catalyst product family software.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• You must enable the extended system ID to use extended range VLANs.</td>
<td></td>
</tr>
</tbody>
</table>

### Configurable Normal-Range VLAN Parameters

**Note**

Ethernet VLANs 1 and 1006 through 4094 use only default values.

You can configure the following parameters for VLANs 2 through 1001:

- VLAN name
- VLAN type
- VLAN state (active or suspended)
- SAID
- STP type for VLANs

### VLAN Default Configuration

Table 12-2 shows the default VLAN configuration values.

### Table 12-2  Ethernet VLAN Defaults and Ranges

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Valid Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>VLAN ID</td>
<td>1</td>
<td>1–4094</td>
</tr>
<tr>
<td>VLAN name</td>
<td>VLANx, where x is a number assigned by the software.</td>
<td>No range</td>
</tr>
</tbody>
</table>
Table 12-2  Ethernet VLAN Defaults and Ranges (continued)

<table>
<thead>
<tr>

<td>0–1005</td>
</tr>
<tr>
<td>VLAN state</td>
<td>active</td>
<td>active; suspend; shutdown</td>
</tr>
</tbody>
</table>

Note: Catalyst 4500 series switches do not support Token Ring or FDDI media. The switch does not forward FDDI, FDDI-NET, TrCRF, or TrBRF traffic, but it does propagate the VLAN configuration via VTP. The software reserves parameters for these media types, but they are not truly supported.

Configuring VLANs

Note: Before you configure VLANs, you must use VLAN Trunking Protocol (VTP) to maintain global VLAN configuration information for your network. For complete information on VTP, see the “VLAN Trunking Protocol” section on page 7.

Note: VLANs support a number of parameters that are not discussed in detail in this section. For complete information, refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference.

Note: The VLAN configuration is stored in the vlan.dat file, which is stored in nonvolatile memory. You can cause inconsistency in the VLAN database if you manually delete the vlan.dat file. If you want to modify the VLAN configuration or VTP, use the commands described in the following sections and in the Catalyst 4500 Series Switch Cisco IOS Command Reference.

The following sections describe how to configure VLANs:

- Configuring VLANs in Global Configuration Mode, page 12-5
- Assigning a Layer 2 LAN Interface to a VLAN, page 12-7

Configuring VLANs in Global Configuration Mode

If the switch is in VTP server or transparent mode (see the “VLAN Trunking Protocol” section on page 12-7), you can configure VLANs in global and VLAN configuration modes. When you configure VLANs in global and config-vlan configuration modes, the VLAN configuration is saved in the vlan.dat files, not the running-config or startup-config files. To display the VLAN configuration, enter the show vlan command.
If the switch is in VLAN transparent mode, use the `copy running-config startup-config` command to save the VLAN configuration to the `startup-config` file. After you save the running configuration as the startup configuration, the `show running-config` and `show startup-config` commands display the VLAN configuration.

**Note**

When the switch boots, if the VTP domain name and VTP mode in the `startup-config` and `vlan.dat` files do not match, the switch uses the configuration in the `vlan.dat` file.

You use the interface configuration command mode to define the port membership mode and add and remove ports from a VLAN. The results of these commands are written to the `running-config` file, and you can display the contents of the file by entering the `show running-config` command.

User-configured VLANs have unique IDs from 1 to 4094. To create a VLAN, enter the `vlan` command with an unused ID. To verify whether a particular ID is in use, enter the `show vlan id ID` command. To modify a VLAN, enter the `vlan` command for an existing VLAN.

See the “VLAN Default Configuration” section on page 12-4 for the list of default parameters that are assigned when you create a VLAN. If you do not use the `media` keyword when specifying the VLAN type, the VLAN is an Ethernet VLAN.

To create a VLAN, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# vlan vlan_ID</td>
</tr>
<tr>
<td></td>
<td>Adds an Ethernet VLAN.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> You cannot delete the default VLANs for these media types: Ethernet VLAN 1 and FDDI or Token Ring VLANs 1002 to 1005.</td>
</tr>
<tr>
<td></td>
<td>When you delete a VLAN, any LAN interfaces configured as access ports assigned to that VLAN become inactive. They remain associated with the VLAN (and thus inactive) until you assign them to a new VLAN.</td>
</tr>
<tr>
<td></td>
<td>You can use the <code>no</code> keyword to delete a VLAN.</td>
</tr>
<tr>
<td></td>
<td>When the prompt reads <code>Switch(config-vlan)#</code>, you are in vlan-configuration mode. If you wish to change any of the parameters for the newly created VLAN, use this mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config-vlan)# end</td>
</tr>
<tr>
<td></td>
<td>Returns to enable mode from vlan-configuration mode.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch# show vlan [id</td>
</tr>
<tr>
<td></td>
<td>Verifies the VLAN configuration.</td>
</tr>
</tbody>
</table>

When you create or modify an Ethernet VLAN, note the following:

- Because Layer 3 ports and some software features require internal VLANs allocated from 1006 and up, configure extended-range VLANs starting with 4094 and work downward.
- You can configure extended-range VLANs only in global configuration mode. You cannot configure extended-range VLANs in VLAN database mode.
- Layer 3 ports and some software features use extended-range VLANs. If the VLAN you are trying to create or modify is being used by a Layer 3 port or a software feature, the switch displays a message and does not modify the VLAN configuration.
VLAN Trunking Protocol

When you create VLANs with the VLAN configuration command, they are automatically added to the existing VTP domain; no action is required of the user.

This example shows how to create an Ethernet VLAN in global configuration mode and verify the configuration:

```
Switch# configure terminal
Switch(config)# vlan 3
Switch(config-vlan)# end
Switch# show vlan id 3

VLAN Name                             Status    Ports
---- -------------------------------- --------- -------------------------------
3    VLAN0003                         active

VLAN Type  SAID       MTU   Parent RingNo BridgeNo Stp   BrdgMode   Trans1   Trans2
---- ----- ---------- ----- ------ ------ -------- ---- -------- ------ -----
3    enet  100003     1500  -    -      -        -    -        0      0

Primary Secondary Type Interfaces
------- --------- ----------------- -------------------------------------------
Switch#
```

Assigning a Layer 2 LAN Interface to a VLAN

A VLAN created in a management domain remains unused until you assign one or more LAN interfaces to the VLAN.

**Note** Make sure you assign LAN interfaces to a VLAN of the proper type. Assign Fast Ethernet, Gigabit Ethernet, and 10-Gigabit Ethernet interfaces to Ethernet-type VLANs.

To assign one or more LAN interfaces to a VLAN, complete the procedures in the “Configuring Ethernet Interfaces for Layer 2 Switching” section on page 14-5.

VLAN Trunking Protocol

This section describes the VLAN Trunking Protocol (VTP) on the Catalyst 4500 series switches.

This section includes the following major subsections:

- **About VTP**, page 12-7
- **VTP Configuration Guidelines and Restrictions**, page 12-12
- **VTP Default Configuration**, page 12-13
- **Configuring VTP**, page 12-14

About VTP

VTP is a Layer 2 messaging protocol that maintains VLAN configuration consistency by managing the addition, deletion, and renaming of VLANs within a VTP domain. A VTP domain (also called a VLAN management domain) is made up of one or more network devices that share the same VTP domain name and that are interconnected with trunks. VTP minimizes misconfigurations and configuration inconsistencies that can result in a number of problems, such as duplicate VLAN names, incorrect VLAN-type specifications, and security violations.
Before you create VLANs, you must decide whether you want to use VTP in your network. With VTP, you can make configuration changes centrally on one or more network devices and have those changes automatically communicated to all the other network devices in the network. For details on configuring VLANs, see VLANs, page 12-1

These sections describe how VTP works:

- Understanding the VTP Domain, page 12-8
- Understanding VTP Modes, page 12-8
- Understanding VTP Advertisements, page 12-9
- Understanding VTP Versions, page 12-9
- Understanding VTP Pruning, page 12-11

### Understanding the VTP Domain

A VTP domain is made up of one or more interconnected network devices that share the same VTP domain name. A network device can be configured to be in only one VTP domain. You make global VLAN configuration changes for the domain using either the command-line interface (CLI) or Simple Network Management Protocol (SNMP).

By default, the Catalyst 4500 series switch is in VTP server mode and the domain is set to NULL until the switch receives an advertisement for a domain over a trunk link or you configure a management domain. You cannot create or modify VLANs on a VTP server until the management domain name is specified or learned.

If the switch receives a VTP advertisement over a trunk link, it inherits the management domain name and the VTP configuration revision number. The switch ignores advertisements with a different management domain name or an earlier configuration revision number.

If you configure the switch as VTP transparent, you can create and modify VLANs, but the changes affect only the individual switch.

When you make a change to the VLAN configuration on a VTP server, the change is propagated to all network devices in the VTP domain. VTP advertisements are transmitted out all Inter-Switch Link (ISL) and IEEE 802.1Q trunk connections.

VTP maps VLANs dynamically across multiple LAN types with unique names and internal index associations. Mapping eliminates unnecessary device administration for network administrators.

### Understanding VTP Modes

You can configure a Catalyst 4500 series switch to operate in any one of these VTP modes:

- **Server**—In VTP server mode, you can create, modify, and delete VLANs and specify other configuration parameters (such as VTP version and VTP pruning) for the entire VTP domain. VTP servers advertise their VLAN configuration to other network devices in the same VTP domain and synchronize their VLAN configuration with other network devices based on advertisements received over trunk links. VTP server is the default mode.

  **Note** In VTP version 3, manipulation of VLANs can be done only to primary servers.

- **Client**—VTP clients behave the same way as VTP servers, but you cannot create, change, or delete VLANs on a VTP client.
Chapter 12  Configuring VLANs, VTP, and VMPS

VLAN Trunking Protocol

- **Transparent**—VTP transparent network devices do not participate in VTP. A VTP transparent network device does not advertise its VLAN configuration and does not synchronize its VLAN configuration based on received advertisements. However, in VTP version 2, transparent network devices do forward VTP advertisements that they receive on their trunking LAN interfaces.
- **Off**—In VTP off mode, a network device functions in the same manner as a VTP transparent device except that it does not forward VTP advertisements.

**Note**
Catalyst 4500 series switches automatically change from VTP server mode to VTP client mode if the switch detects a failure while writing configuration to NVRAM. If this happens, the switch cannot be returned to VTP server mode until the NVRAM is functioning.

**Understanding VTP Advertisements**

Each network device in the VTP domain sends periodic advertisements out each trunking LAN interface to a reserved multicast address. VTP advertisements are received by neighboring network devices, which update their VTP and VLAN configurations as necessary.

The following global configuration information is distributed in VTP advertisements:
- VLAN IDs (ISL and 802.1Q)
- Emulated LAN names (for ATM LANE)
- 802.10 SAID values (FDDI)
- VTP domain name
- VTP configuration revision number
- VLAN configuration, including maximum transmission unit (MTU) size for each VLAN
- Frame format

**Understanding VTP Versions**

**VTP Version 2**

If you use VTP in your network, you must decide whether to use VTP version 1 or version 2.

**Note**
Catalyst 4500 series switches do not support Token Ring or FDDI media. The switch does not forward FDDI, FDDI-Net, Token Ring Concentrator Relay Function [TrCRF], or Token Ring Bridge Relay Function [TrBRF] traffic, but it does propagate the VLAN configuration via VTP.

VTP version 2 supports the following features, which are not supported in version 1:
- Token Ring support—VTP version 2 supports Token Ring LAN switching and VLANs (TrBRF and TrCRF).
- Unrecognized Type-Length-Value (TLV) Support—A VTP server or client propagates configuration changes to its other trunks, even for TLVs it is not able to parse. The unrecognized TLV is saved in NVRAM.
- Version-Dependent Transparent Mode—In VTP version 1 and version 2, a VTP transparent network device forwards VTP messages in transparent mode without checking the version.
Chapter 12 Configuring VLANs, VTP, and VMPS

VLAN Trunking Protocol

- Consistency Checks—In VTP version 2, VLAN consistency checks (such as VLAN names and values) are performed only when you enter new information through the CLI or SNMP. Consistency checks are not performed when new information is obtained from a VTP message or when information is read from NVRAM. If the digest on a received VTP message is correct, its information is accepted without consistency checks.

VTP Version 3

VTP version 3 supports the following features not supported in version 1 or version 2:

- Hidden Password Support—VTP version 3 supports the option of configuring the password as hidden or secret.
  When the hidden keyword is specified, that password must be reentered if a takeover command is issued in the domain. The secret key generated from the password string is saved in the const_nvram:vlan.dat file. When configured with this option, the password does not appear in plain text in the configuration. Instead, the secret key associated with the password is saved in hexadecimal format in the running configuration. If the hidden keyword is not specified, the password is saved in clear text in the const_nvram:vlan.dat file as in VTP version 1 and VTP version 2.
  When the secret keyword is specified, the password secret key can be directly configured.

- Support for extended VLAN Database Propagation—In VTP version 2, VLAN configuration information is propagated only for VLANs numbered 1 to 1000. In VTP version 3, information also is propagated for extended-range VLANs (VLANs numbered 1006 to 4094).

- On Catalyst 4500 series switches running VTP version 1, VTP version 2, or VTP version 3, default VLANs 1 and 1002 to 1005 cannot be modified.

Note VTP pruning continues to apply only to VLANs numbered 1 to 1000.

- Propagation of Any Database in a Domain—In addition to propagating VLAN database information, VTP can propagate Multiple Spanning Tree (MST) protocol database information.

- Disabling VTP—When VTP is disabled on a trunking port, it applies to all VTP instances on that port. When VTP is disabled globally, the setting applies to all the trunking ports in the system.

- In VTP version 1 and VTP version 2, the role of a VTP server is to back up the database to NVRAM and to allow the administrator to change database information. VTP version 3 introduces the roles of VTP Primary Server and VTP Secondary Server. A VTP Primary Server is used to update the database information. The updates sent out are honored by all the devices in the system. A VTP Secondary Server can only back up to its NVRAM the VTP configuration received via updates from the VTP Primary Server.

The status of primary and secondary servers is a runtime status and is not a configurable option. By default, all devices are initiated as secondary servers. Primary server status is needed only when database updates are needed, and is obtained when the administrator issues a takeover message in the domain. (See the “Starting a Takeover” section on page 12-19.)

Primary server status is lost upon reload of the device, or when switchover or domain parameters change. Secondary servers back up the configuration and continue to propagate it. Because of that, it is possible to have a working VTP domain without any primary servers.
Understanding VTP Pruning

VTP pruning enhances network bandwidth use by reducing unnecessary flooded traffic, such as broadcast, multicast, and unicast packets. VTP pruning increases available bandwidth by restricting flooded traffic to those trunk links that the traffic must use to access the appropriate network devices. By default, VTP pruning is disabled.

For VTP pruning to be effective, all devices in the management domain must either support VTP pruning or, on devices that do not support VTP pruning, you must manually configure the VLANs allowed on trunks.

Figure 12-2 shows a switched network without VTP pruning enabled. Interface 1 on Switch 1 and Interface 2 on Switch 4 are assigned to the Red VLAN. A broadcast is sent from the host connected to Switch 1. Switch 1 floods the broadcast and every network device in the network receives it, even though Switches 3, 5, and 6 have no interfaces in the Red VLAN.

You can enable pruning globally on the Catalyst 4500 series switch (see the “Enabling VTP Pruning” section on page 12-15).

Figure 12-2  Flooding Traffic without VTP Pruning

Figure 12-3 shows the same switched network with VTP pruning enabled. The broadcast traffic from Switch 1 is not forwarded to Switches 3, 5, and 6 because traffic for the Red VLAN has been pruned on the links indicated (Interface 5 on Switch 2 and Interface 4 on Switch 4).
Enabling VTP pruning on a VTP server enables pruning for the entire management domain. VTP pruning takes effect several seconds after you enable it. By default, VLANs 2 through 1000 are eligible for pruning. VTP pruning does not prune traffic from pruning-ineligible VLANs. VLAN 1 is always ineligible for pruning; traffic from VLAN 1 cannot be pruned.

To configure VTP pruning on a trunking LAN interface, use the `switchport trunk pruning vlan` command. VTP pruning operates when a LAN interface is trunking. You can set VLAN pruning eligibility regardless of whether VTP pruning is enabled or disabled for the VTP domain, whether any given VLAN exists, and regardless of whether the LAN interface is currently trunking.

### VTP Configuration Guidelines and Restrictions

Follow these guidelines and restrictions when implementing VTP in your network:

- Supervisor engine redundancy does not support nondefault VLAN data file names or locations. Do not enter the `vtp file file_name` command on a switch that has a redundant supervisor engine.
- Before installing a redundant supervisor engine, enter the `no vtp file` command to return to the default configuration.
- When a VTP version 3 device on a trunk port receives messages from a VTP version 2 device, it sends a scaled-down version of the VLAN database on that particular trunk in a VTP version 2 format. A VTP version 3 device does not send out VTP version 2 formatted packets on a trunk port unless it first receives VTP version 2 packets on that trunk.
- Even when a VTP version 3 device detects a VTP version 2 device on a trunk port, it continues to send VTP version 3 packets in addition to VTP version 2 packets, to allow co-existence of two kinds of neighbors off the trunk.
- A VTP version 3 device does not accept configuration information from a VPT version 2 or version 1 device.
- Unlike in VPT version 2, when VTP is configured to be version 3, this does not configure all the version-3-capable devices in the domain to start behaving as VPT version 3 systems.
- When a VTP version 1 device, capable of version 2 or version 3, receives a VTP version 3 packet, the device is configured as a VTP version 2 device provided a VTP version 2 conflict does not exist.
- Devices that are only VTP version 1 capable cannot interoperate with VTP version 3 devices.
In a Token Ring environment, you must enable VTP version 2 or version 3 for Token Ring VLAN switching to function properly.

Two VPT version 3 regions can only communicate in transparent mode over a VTP version 1 or VTP version 2 region.

All network devices in a VTP domain must run the same VTP version.

You must configure a password on each network device in the management domain when VTP is in secure mode.

Caution

If you configure VTP in secure mode, the management domain does not function properly if you do not assign a management domain password to each network device in the domain.

A VTP version 2-capable network device can operate in the same VTP domain as a network device running VTP version 1 if VTP version 2 is disabled on the VTP version 2-capable network device (VTP version 2 is disabled by default).

Do not enable VTP version 2 on a network device unless all of the network devices in the same VTP domain are version 2-capable. When you enable VTP version 2 on a server, all of the version 2-capable network devices in the domain enable VTP version 2.

Enabling or disabling VTP pruning on a VTP server enables or disables VTP pruning for the entire management domain.

Configuring VLANs as eligible for pruning on a Catalyst 4500 series switch affects pruning eligibility for those VLANs on that switch only, not on all network devices in the VTP domain.

The VLAN database is saved in the NVRAM file in a format compliant with the VTP version running on the system. Since older images supporting only VTP version 2 do not recognize the VTP version 3 file format, the NVRAM VLAN database information is lost if the system is downgraded from a new image supporting VTP to one that does not.

VTP Default Configuration

Table 12-3 shows the default VTP configuration.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>VTP domain name</td>
<td>Null</td>
</tr>
<tr>
<td>VTP mode</td>
<td>Server</td>
</tr>
<tr>
<td>VTP version 2 enable state</td>
<td>Version 2 is disabled</td>
</tr>
<tr>
<td>VTP password</td>
<td>None</td>
</tr>
<tr>
<td>VTP pruning</td>
<td>Disabled</td>
</tr>
</tbody>
</table>

The default VTP mode for newly manufactured Catalyst 4500 supervisor engines, Catalyst 4900 series switches, and the Cisco ME 4924-10GE switch is transparent. Deleting vlan.dat or issuing the `erase cat4000_flash:` command, and resetting the switch changes the VTP mode to server.
Configuring VTP

These sections describe how to configure VTP:

- Configuring VTP Global Parameters, page 12-14
- Configuring the VTP Mode, page 12-16
- Starting a Takeover, page 12-19
- Displaying VTP Statistics, page 12-19
- Displaying VTP Devices in a Domain, page 12-20

Configuring VTP Global Parameters

These sections describe configuring the VTP global parameters:

- Configuring a VTP Password, page 12-14
- Enabling VTP Pruning, page 12-15
- Enabling the VTP Version Number, page 12-15

Note

You can enter the VTP global parameters in either global configuration mode or in EXEC mode.

Configuring a VTP Password

To configure the VTP global parameters, use these commands:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`Switch(config)# vtp password password_string [hidden</td>
<td>secret]`</td>
</tr>
<tr>
<td><code>Switch(config)# no vtp password</code></td>
<td>Clears the password.</td>
</tr>
</tbody>
</table>

This example shows one way to configure a VTP password in global configuration mode:

```
Switch# configure terminal
Switch(config)# vtp password WATER
Setting device VLAN database password to WATER.
Switch#
```

This example shows how to configure a VTP password in EXEC mode:
Switch# vtp password WATER
Setting device VLAN database password to WATER.
Switch#

Note
The password is not stored in the running-config file.

This example shows how to configure a hidden password:

Switch# configure terminal
Switch(config)# vtp password WATER hidden
Generating the secret associated to the password.
Switch(config)#

This example shows how the password WATER is displayed when it is configured with the hidden keyword.

Switch# show vtp password
VTP Password: 89914640C8D90868B6A0D8103847A733
Switch#

Enabling VTP Pruning

To enable VTP pruning in the management domain, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 Switch(config)# vtp pruning</td>
<td>Enables VTP pruning in the management domain.</td>
</tr>
<tr>
<td>Step 2 Switch# show vtp status</td>
<td>include pruning</td>
</tr>
</tbody>
</table>

This example shows one way to enable VTP pruning in the management domain:

Switch# configure terminal
Switch(config)# vtp pruning
Pruning switched ON

This example shows how to enable VTP pruning in the management domain with any release:

Switch# vtp pruning
Pruning switched ON

This example shows how to verify the configuration:

Switch# show vtp status | include Pruning
VTP Pruning Mode: Enabled
Switch#

For information about configuring prune eligibility, see the “Understanding VTP Pruning” section on page 12-11.

Enabling the VTP Version Number

VTP version 2 is disabled by default on VTP version-2-capable network devices. When you enable VTP version 2 on a network device, every VTP version-2-capable network device in the VTP domain enables version 2.
VTP version 1 and VTP version 2 are not interoperable on network devices in the same VTP domain. Every network device in the VTP domain must use the same VTP version. Do not enable VTP version 2 unless every network device in the VTP domain supports version 2.

Caution

In a Token Ring environment, you must enable VTP version 2 or VTP version 3 for Token Ring VLAN switching to function properly on devices that support Token Ring interfaces.

To enable the VTP version, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch(config)# vtp version {1</td>
</tr>
<tr>
<td></td>
<td>Enables the VTP version.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch# show vtp status</td>
</tr>
<tr>
<td></td>
<td>(Optional) Verifies the configuration.</td>
</tr>
</tbody>
</table>

This example shows one way to enable VTP version 2:

```
Switch# configure terminal
Switch(config)# vtp version 2
V2 mode enabled.
Switch(config)#
```

This example shows how to enable VTP version 2 with any release:

```
Switch# vtp version 2
V2 mode enabled.
Switch#
```

This example shows how to verify the configuration:

```
Switch# show vtp status | include V2
VTP V2 Mode: Enabled
Switch#
```

Configuring the VTP Mode

To configure the VTP mode, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch(config)# vtp mode (client</td>
</tr>
<tr>
<td></td>
<td>Configures the VTP mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# vtp domain domain_name</td>
</tr>
<tr>
<td></td>
<td>(Optional; for server mode only) Defines the VTP domain name, which can be up to 32 characters long. VTP server mode requires a domain name. If the switch has a trunk connection to a VTP domain, the switch learns the domain name from the VTP server in the domain.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> You cannot clear the domain name.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td></td>
<td>Exits VLAN configuration mode.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch# show vtp status</td>
</tr>
<tr>
<td></td>
<td>(Optional) Verifies the configuration.</td>
</tr>
</tbody>
</table>
Chapter 12      Configuring VLANs, VTP, and VMPS

VLAN Trunking Protocol

When VTP is disabled, you can enter VLAN configuration commands in configuration mode instead of the VLAN database mode and the VLAN configuration is stored in the startup configuration file.

This example shows how to configure the switch as a VTP server:

Switch# configure terminal
Switch(config)# vtp mode server
Setting device to VTP SERVER mode.
Switch(config)# vtp domain Lab_Network
Setting VTP domain name to Lab_Network
Switch(config)# end
Switch#

This example shows how to configure the switch as a VTP client:

Switch# configure terminal
Switch(config)# vtp mode client
Setting device to VTP CLIENT mode.
Switch(config)# end
Switch#

This example shows how to disable VTP on the switch:

Switch# configure terminal
Switch(config)# vtp mode transparent
Setting device to VTP TRANSPARENT mode.
Switch(config)# end
Switch#

This example shows how to disable VTP on the switch and to disable VTP advertisement forwarding:

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# vtp mode off
Setting device to VTP OFF mode.
Switch(config)# end
Switch#

This example shows an example of the VTP configuration parameters when the device is running VTP version 1:

Switch# show vtp status
VTP Version capable : 1 to 3
VTP version running : 1
VTP Domain Name : Lab_Network
VTP Pruning Mode : Enabled
VTP Traps Generation : Disabled
Device ID : 0016.9c6d.5300
Configuration last modified by 127.0.0.12 at 10-18-07 10:12:42
Local updater ID is 127.00.12 at 10-18-07 10:2:42

Feature VLAN:
---------------
VTP Operating Mode : Server
Maximum number of existing VLANs : 5
Configuration Revision : 1
MD5 digest : 0x92 0xF1 0x52 0x2E 0x5C 0x36 0x10 0x70 0x61 0xB8 0x24 0xB6 0x93 0x21 0x09
Switch#
This example shows an example of the VTP configuration parameters when the device is running VTP version 2:

Switch# show vtp status
VTP Version capable      : 1 to 3
VTP version running      : 2
VTP Domain Name          : Lab_Network
VTP Pruning Mode         : Disabled
VTP Traps Generation     : Disabled
Device ID                : 0012.44dc.b800
Configuration last modified by 127.0.0.12 at 10-18-07 10:38:45
Local updater ID is 127.0.0.12 on interface E0 0/0 (first interface found)

Feature VLAN:
--------------
VTP Operating Mode      : Server
Maximum VLANs supported locally: 1005
Number of existing VLANs: 1005
Configuration Revision  : 1
MD5 digest              : 0x2E 0x6B 0x99 0x58 0xA2 0x4F 0xD5 0x15 0x70 0xB8 0x24 0xB6 0x93 0x21 0x09

Switch#

This example shows an example of the VTP configuration parameters when the device is running VTP version 3:

Switch# show vtp status
VTP Version capable      : 1 to 3
VTP version running      : 3
VTP Domain Name          : Lab_Network
VTP Pruning Mode         : Disabled
VTP Traps Generation     : Disabled
Device ID                : 0012.44dc.b800

Feature VLAN:
--------------
VTP Operating Mode      : Server
Number of existing VLANs: 1005
Number of existing extended VLANs: 3074
Configuration Revision  : 18
Primary ID              : 0012.4371.9ec0
Primary Description     :
Starting a Takeover

This process applies to VTP version 3 only. To start a takeover, perform this task:

```
Switch# vtp primary-server [vlan | mst] | force
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# vtp primary-server [vlan</td>
<td>mst]</td>
</tr>
</tbody>
</table>

**Note** Using the force keyword overwrites the configuration of any conflicting servers. If not using the force keyword, you are prompted for confirmation prior to proceeding with the takeover.

Specify where to direct the takeover by selecting the appropriate feature (vlan or mst). If no feature is selected, the takeover is directed to the VLAN database.

This example shows how to start a takeover and direct it to the vlan database:

```
Switch# vtp primary-server vlan
Enter VTP password:password
This system is becoming primary for feature vlan

VTP Feature Conf Revision Primary Server Device ID      Description
----------- -------------      -------------- -------- -------------------
MST         Yes 4         0012.4371.9ec0=0012.4371.9ec0 R1
Do you want to continue? (confirm)
Switch#
```

Displaying VTP Statistics

To display VTP statistics, including VTP advertisements sent and received and VTP errors, perform this task:

```
Switch# show vtp counters
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# show vtp counters</td>
<td>Displays VTP statistics.</td>
</tr>
</tbody>
</table>

This example shows how to display VTP statistics:

```
Switch# show vtp counters
VTP statistics:
Summary advertisements received : 7
Subset advertisements received : 5
Request advertisements received : 0
Summary advertisements transmitted : 997
Subset advertisements transmitted : 13
```
VLAN Membership Policy Server

This section describes how to configure dynamic port VLAN membership through the VLAN Membership Policy Server (VMPS).

This section includes the following subsections:

- About VMPS, page 12-21
- Overview of VMPS Clients, page 12-23
- Dynamic Port VLAN Membership Configuration Example, page 12-29
- VMPS Database Configuration File Example, page 12-32
About VMPS

These subsections describe what a VMPS server does and how it operates:

- VMPS Server, page 12-21
- Security Modes for VMPS Server, page 12-22
- Fallback VLAN, page 12-23
- Illegal VMPS Client Requests, page 12-23

VMPS Server

A VLAN Membership Policy Server (VMPS) provides a centralized server for selecting the VLAN for a port dynamically based on the MAC address of the device connected to the port. When the host moves from a port on one switch in the network to a port on another switch in the network, that switch dynamically assigns the new port to the proper VLAN for that host.

A Catalyst 4500 series switch running Cisco IOS software does not support the functionality of a VMPS. It can only function as a VLAN Query Protocol (VQP) client, which communicates with a VMPS through the VQP. For VMPS functionality, you need to use a Catalyst 4500 series switch (or Catalyst 6500 series switch) running Catalyst operating system (OS) software.

VMPS uses a UDP port to listen to VQP requests from clients, so, it is not necessary for VMPS clients to know if the VMPS resides on a local or remote device on the network. Upon receiving a valid request from a VMPS client, a VMPS server searches its database for an entry of a MAC-address to VLAN mapping.

In response to a request, the VMPS takes one of the following actions:

- If the assigned VLAN is restricted to a group of ports, the VMPS verifies the requesting port against this group and responds as follows:
  - If the VLAN is allowed on the port, the VMPS sends the VLAN name to the client in response.
  - If the VLAN is not allowed on the port and the VMPS is not in secure mode, the VMPS sends an “access-denied” response.
  - If the VLAN is not allowed on the port and the VMPS is in secure mode, the VMPS sends a “port-shutdown” response.

- If the VLAN in the database does not match the current VLAN on the port and there are active hosts on the port, the VMPS sends an “access-denied” (open), a “fallback VLAN name” (open with fallback VLAN configured), a “port-shutdown” (secure), or a “new VLAN name” (multiple) response, depending on the secure mode setting of the VMPS.

If the switch receives an “access-denied” response from the VMPS, the switch continues to block traffic from the MAC address to or from the port. The switch continues to monitor the packets directed to the port and sends a query to the VMPS when it identifies a new address. If the switch receives a “port-shutdown” response from the VMPS, the switch disables the port. The port must be manually re-enabled by using the CLI, Cisco Visual Switch Manager (CVSM), or SNMP.

You can also use an explicit entry in the configuration table to deny access to specific MAC addresses for security reasons. If you enter the none keyword for the VLAN name, the VMPS sends an “access-denied” or “port-shutdown” response.
Security Modes for VMPS Server

VMPS operates in three different modes. The way a VMPS server responds to illegal requests depends on the mode in which the VMPS is configured:

- **Open Mode, page 12-22**
- **Secure Mode, page 12-22**
- **Multiple Mode, page 12-22**

**Open Mode**

If no VLAN is assigned to this port, VMPS verifies the requesting MAC address against this port:

- If the VLAN associated with this MAC address is allowed on the port, the VLAN name is returned to the client.
- If the VLAN associated with this MAC address is not allowed on the port, the host receives an “access denied” response.

If a VLAN is already assigned to this port, VMPS verifies the requesting MAC address against this port:

- If the VLAN associated with this MAC address in the database does not match the current VLAN assigned on the port, and a fallback VLAN name is configured, VMPS sends the fallback VLAN name to the client.
- If a VLAN associated with this MAC address in the database does not match the current VLAN assigned on the port, and a fallback VLAN name is not configured, the host receives an “access denied” response.

**Secure Mode**

If no VLAN is assigned to this port, VMPS verifies the requesting MAC address against this port:

- If the VLAN associated with this MAC address is allowed on the port, the VLAN name is returned to the client.
- If the VLAN associated with this MAC address is not allowed on the port, the port is shut down.

If a VLAN is already assigned to this port, VMPS verifies the requesting MAC address against this port:

- If a VLAN associated with this MAC address in the database does not match the current VLAN assigned on the port, the port is shutdown, even if a fallback VLAN name is configured.

**Multiple Mode**

Multiple hosts (MAC addresses) can be active on a dynamic port if they are all in the same VLAN. If the link fails on a dynamic port, the port returns to the unassigned state. Any hosts that come online through the port are checked again with VMPS before the port is assigned to a VLAN.

If multiple hosts connected to a dynamic port belong to different VLANs, the VLAN matching the MAC address in the last request is returned to the client provided that multiple mode is configured on the VMPS server.

**Note**

Although Catalyst 4500 series and Catalyst 6500 series switches running Catalyst operating system software support VMPS in all three operation modes, the User Registration Tool (URT) supports open mode only.
Chapter 12 Configuring VLANs, VTP, and VMPS

VLAN Membership Policy Server

**Fallback VLAN**

You can configure a fallback VLAN name on a VMPS server.

If no VLAN has been assigned to this port, VMPS compares the requesting MAC address to this port:

- If you connect a device with a MAC address that is not in the database, the VMPS sends the fallback VLAN name to the client.
- If you do not configure a fallback VLAN name and the MAC address does not exist in the database, the VMPS sends an “access-denied” response.

If a VLAN is already assigned to this port, VMPS compares the requesting MAC address to this port:

- If the VMPS is in secure mode, it sends a “port-shutdown” response, whether a fallback VLAN has been configured on the server.

**Illegal VMPS Client Requests**

Two examples of illegal VMPS client requests are as follows:

- When a MAC-address mapping is not present in the VMPS database and “no fallback” VLAN is configured on the VMPS.
- When a port is already assigned a VLAN (and the VMPS mode is not “multiple”) but a second VMPS client request is received on the VMPS for a different MAC-address.

**Overview of VMPS Clients**

The following subsections describe how to configure a switch as a VMPS client and configure its ports for dynamic VLAN membership.

The following topics are included:

- Understanding Dynamic VLAN Membership, page 12-23
- Default VMPS Client Configuration, page 12-24
- Configuring a Switch as a VMPS Client, page 12-24
- Administrating and Monitoring the VMPS, page 12-28
- Troubleshooting Dynamic Port VLAN Membership, page 12-29

**Understanding Dynamic VLAN Membership**

When a port is configured as “dynamic,” it receives VLAN information based on the MAC-address that is on the port. The VLAN is not statically assigned to the port; it is dynamically acquired from the VMPS based on the MAC-address on the port.

A dynamic port can belong to one VLAN only. When the link becomes active, the switch does not forward traffic to or from this port until the port is assigned to a VLAN. The source MAC address from the first packet of a new host on the dynamic port is sent to the VMPS as part of the VQP request, which attempts to match the MAC address to a VLAN in the VMPS database. If there is a match, the VMPS sends the VLAN number for that port. If there is no match, the VMPS either denies the request or shuts down the port (depending on the VMPS security mode setting). See the “About VMPS” section on page 12-21 for a complete description of possible VMPS responses.
Multiple hosts (MAC addresses) can be active on a dynamic port if all are in the same VLAN. If the link goes down on a dynamic port, the port returns to the unassigned state and does not belong to a VLAN. Any hosts that come online through the port are checked again with the VMPS before the port is assigned to a VLAN.

For this behavior to work, the client device must be able to reach the VMPS. A VMPS client sends VQP requests as UDP packets, trying a certain number of times before giving up. For details on how to set the retry interval, refer to section “Configuring the Retry Interval” on page 27.

The VMPS client also periodically reconfirms the VLAN membership. For details on how to set the reconfirm frequency, refer to section “Administering and Monitoring the VMPS” on page 28.

A maximum of 50 hosts are supported on a given port at any given time. After this maximum is exceeded, the port is shut down, irrespective of the operating mode of the VMPS server.

**Note**

The VMPS shuts down a dynamic port if more than 50 hosts are active on that port.

### Default VMPS Client Configuration

*Table 12-4* shows the default VMPS and dynamic port configuration on client switches.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMPS domain server</td>
<td>None</td>
</tr>
<tr>
<td>VMPS reconfirm interval</td>
<td>60 minutes</td>
</tr>
<tr>
<td>VMPS server retry count</td>
<td>3</td>
</tr>
<tr>
<td>Dynamic ports</td>
<td>None configured</td>
</tr>
</tbody>
</table>

### Configuring a Switch as a VMPS Client

This section contains the following topics:

- Configuring the IP Address of the VMPS Server, page 12-24
- Configuring Dynamic Access Ports on a VMPS Client, page 12-25
- Reconfirming VLAN Memberships, page 12-26
- Configuring Reconfirmation Interval, page 12-26
- Reconfirming VLAN Memberships, page 12-26

### Configuring the IP Address of the VMPS Server

To configure a Catalyst 4500 series switch as a VMPS client, you must enter the IP address or hostname of the switch acting as the VMPS.
Chapter 12 Configuring VLANs, VTP, and VMPS

VLAN Membership Policy Server

To define the primary and secondary VMPS on a Catalyst 4500 series switch, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td>Switch(config)# vmps server (ipaddress</td>
<td>Specifies the IP address or hostname of the switch acting as the primary VMPS server.</td>
</tr>
<tr>
<td>hostname) primary</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td></td>
</tr>
<tr>
<td>Switch(config)# vmps server (ipaddress</td>
<td>Specifies the IP address or hostname of the switch acting as a secondary VMPS server.</td>
</tr>
<tr>
<td>hostname)</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td></td>
</tr>
<tr>
<td>Switch(config)# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td></td>
</tr>
<tr>
<td>Switch# show vmps</td>
<td>Verifies the VMPS server entry.</td>
</tr>
</tbody>
</table>

This example shows how to define the primary and secondary VMPS devices:

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# vmps server 172.20.128.179 primary
Switch(config)# vmps server 172.20.128.178
Switch(config)# end

**Note**
You can configure up to four VMPS servers using this CLI on the VMPS client.

Switch# show vmps
VQP Client Status:
-------------------------------
VMPS VQP Version: 1
Reconfirm Interval: 60 min
Server Retry Count: 3
VMPS domain server: 172.20.128.179 (primary, current)
172.20.128.178

Reconfirmation status
-------------------------------
VMPS Action: No Dynamic Port

Configuring Dynamic Access Ports on a VMPS Client

To configure a dynamic access port on a VMPS client switch, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td>Switch(config)# interface interface</td>
<td>Enters interface configuration mode and specifies the port to be configured.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td></td>
</tr>
<tr>
<td>Switch(config-if)# switchport mode access</td>
<td>Sets the port to access mode.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td></td>
</tr>
<tr>
<td>Switch(config-if)# switchport access vlan dynamic</td>
<td>Configures the port as eligible for dynamic VLAN access.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td></td>
</tr>
<tr>
<td>Switch(config-if)# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td></td>
</tr>
<tr>
<td>Switch# show interface interface switchport</td>
<td>Verifies the entry.</td>
</tr>
</tbody>
</table>
This example shows how to configure a dynamic access port and to verify the entry:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fa0/1
Switch(config-if)# switchport mode access
Switch(config-if)# switchport access vlan dynamic
Switch(config-if)# end

Switch# show interface fa0/1 switchport
Name: Fa0/1
Switchport: Enabled
Administrative mode: dynamic auto
Operational Mode: dynamic access
Administrative Trunking Encapsulation: isl
Operational Trunking Encapsulation: isl
Negotiation of Trunking: Disabled
Access Mode VLAN: 0 ((Inactive))
Trunking Native Mode VLAN: 1 (default)
Trunking VLANs Enabled: NONE
Pruning VLANs Enabled: NONE
```

**Voice Ports**

If a VVID (voice VLAN ID) is configured on a dynamic access port, the port can belong to both an access VLAN and a voice VLAN. Consequently, an access port configured for connecting an IP phone can have separate VLANs for the following:

- Data traffic to and from the PC that is connected to the switch through the access port of the IP phone (access VLAN)
- Voice traffic to and from the IP phone (voice VLAN)

**Reconfirming VLAN Memberships**

To confirm the dynamic port VLAN membership assignments that the switch has received from the VMPS, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# vmps reconfirm</td>
<td>Reconfirms dynamic port VLAN membership.</td>
</tr>
<tr>
<td>Switch# show vmps</td>
<td>Verifies the dynamic VLAN reconfirmation status.</td>
</tr>
</tbody>
</table>

**Configuring Reconfirmation Interval**

VMPS clients periodically reconfirm the VLAN membership information received from the VMPS. You can set the number of minutes the VMPS client waits before reconfirming the VLAN-to-MAC-address assignments.

To configure the reconfirmation interval, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Switch(config)# vmps reconfirm minutes</td>
<td>Specifies the number of minutes between reconfirmations of the dynamic VLAN membership.</td>
</tr>
</tbody>
</table>
Chapter 12 Configuring VLANs, VTP, and VMPS

VLAN Membership Policy Server

This example shows how to change the reconfirmation interval to 60 minutes and verify the change:

```plaintext
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# vmps reconfirm 60
Switch(config)# end
Switch# show vmps
VQP Client Status:
--------------------
VMPS VQP Version:   1
Reconfirm Interval: 60 min
Server Retry Count: 10
VMPS domain server: 172.20.130.50 (primary, current)

Reconfirmation status
---------------------
VMPS Action:         No Host
```

Configuring the Retry Interval

You can set the number of times that the VMPS client attempts to contact the VMPS before querying the next server.

To configure the retry interval, perform this task:

```
Step 1
Switch# configure terminal
Enters global configuration mode.

Step 2
Switch(config)# vmps retry count
Specifies the retry count for the VPQ queries. Default is 3. Range is from 1 to 10.

Step 3
Switch(config)# end
Returns to privileged EXEC mode.

Step 4
Switch# show vmps
Verifies the retry count.
```

This example shows how to change the retry count to 5 and to verify the change:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# vmps retry 5
Switch(config)# end

Switch# show vmps
VQP Client Status:
--------------------
VMPS VQP Version:   1
Reconfirm Interval: 60 min
Server Retry Count: 5
VMPS domain server: 172.20.130.50 (primary, current)

Reconfirmation status
---------------------
VMPS Action:         No Host
```
Administering and Monitoring the VMPS

You can display the following information about the VMPS with the `show vmps` command:

- **VQP Version**: The version of VQP used to communicate with the VMPS. The switch queries the VMPS using VQP Version 1.
- **Reconfirm Interval**: The number of minutes the switch waits before reconfirming the VLAN-to-MAC-address assignments.
- **Server Retry Count**: The number of times VQP resends a query to the VMPS. If no response is received after this many tries, the switch starts to query the secondary VMPS.
- **VMPS domain server**: The IP address of the configured VLAN membership policy servers. The switch currently sends queries to the one marked “current.” The one marked “primary” is the primary server.
- **VMPS Action**: The result of the most-recent reconfirmation attempt. This action can occur automatically when the reconfirmation interval expired, or you can force it by entering the `vmps reconfirm` command or its CVSM or SNMP equivalent.

The following example shows how to display VMPS information:

```
Switch# show vmps
VQP Client Status: ------------------------
VQP VQP Version: 1
Reconfirm Interval: 60 min
Server Retry Count: 3
VMPS domain server:

Reconfirmation status
---------------------
VMPS Action: other
```

The following example shows how to display VMPS statistics:

```
Switch# show vmps statistics
VMPS Client Statistics
----------------------
VQP Queries: 0
VQP Responses: 0
VMPS Changes: 0
VQP Shutdowns: 0
VQP Denied: 0
VQP Wrong Domain: 0
VQP Wrong Version: 0
VQP Insufficient Resource: 0
```

---

**Note**: Refer to the *Catalyst 4500 Series Switch Cisco IOS Command Reference* for details on VMPS statistics.
Troubleshooting Dynamic Port VLAN Membership

VMPS errdisables a dynamic port under the following conditions:

- The VMPS is in secure mode, and it does not allow the host to connect to the port. The VMPS errdisables the port to prevent the host from connecting to the network.
- More than 50 active hosts reside on a dynamic port.

For information on how to display the status of interfaces in error-disabled state, refer to Chapter 8, “Checking Port Status and Connectivity.” To recover an errdisabled port, use the `errdisable recovery cause vmps` global configuration command.

Dynamic Port VLAN Membership Configuration Example

Figure 12-4 on page 12-30 shows a network with a VMPS servers and VMPS client switches with dynamic ports. In this example, these assumptions apply:

- The VMPS server and the VMPS client are separate switches.
- The Catalyst 4000 family Switch 1 (running CatOS) is the primary VMPS server.
- The Catalyst 6000 family Switch 3 (running CatOS) and the URT are secondary VMPS servers.
- End stations are connected to these clients:
  - Catalyst 4500 series XL Switch 2 (running Catalyst IOS)
  - Catalyst 4500 series XL Switch 9 (running Catalyst IOS)
- The database configuration file is called Bldg-G.db and is stored on the TFTP server with the IP address 172.20.22.7.
Two topologies are possible. Figure 12-5 illustrates a topology with one end station attached directly to a Catalyst 4500 series switch operating as a VMPS client. Figure 12-6 illustrates a topology with an end station attached to a Cisco IP Phone, which is attached to a Catalyst 4500 series switch.
In the following procedure, the Catalyst 4000 and Catalyst 6000 series switches (running CatOS) are the VMPS servers. Use this procedure to configure the Catalyst 4500 series switch clients in the network:

**Step 1** Configure the VMPS server addresses on Switch 2, the client switch.

a. Starting from privileged EXEC mode, enter global configuration mode:

   `switch# configuration terminal`

b. Enter the primary VMPS server IP address:

   `switch(config)# vmps server 172.20.26.150 primary`

c. Enter the secondary VMPS server IP addresses:

   `switch(config)# vmps server 172.20.26.152`

d. To verify your entry of the VMPS IP addresses, return to privileged EXEC mode:

   `switch(config)# exit`

e. Display VMPS information configured for the switch:

   `switch# show vmps`

<table>
<thead>
<tr>
<th>VQP Client Status:</th>
</tr>
</thead>
<tbody>
<tr>
<td>-------------------</td>
</tr>
<tr>
<td>VMPS VQP Version: 1</td>
</tr>
<tr>
<td>Reconfirm Interval: 60 min</td>
</tr>
<tr>
<td>Server Retry Count: 3</td>
</tr>
<tr>
<td>VMPS domain server: 172.20.26.152</td>
</tr>
<tr>
<td>172.20.26.150 (primary, current</td>
</tr>
</tbody>
</table>

**Step 2** Configure port Fa0/1 on Switch 2 as a dynamic port.

a. Return to global configuration mode:

   `switch# configure terminal`

b. Enter interface configuration mode:

   `switch(config)# interface fa2/1`

c. Configure the VLAN membership mode for static-access ports:

   `switch(config-if)# switchport mode access`
**VLAN Membership Policy Server**

**Chapter 12  Configuring VLANs, VTP, and VMPS**

**Step 3**
Connect End Station 2 on port Fa2/1. When End Station 2 sends a packet, Switch 2 sends a query to the primary VMPS server, Switch 1. Switch 1 responds with the VLAN ID for port Fa2/1. If spanning-tree PortFast mode is enabled on Fa2/1, port Fa2/1 connects immediately and begins forwarding.

**Step 4**
Set the VMPS reconfirmation period to 60 minutes. The reconfirmation period is the number of minutes the switch waits before reconfirming the VLAN to MAC address assignments.

```
switch# config terminal
switch(config)# vmps reconfirm 60
```

**Step 5**
Confirm the entry from privileged EXEC mode:

```
switch# show vmps
VQP Client Status:
-------------------
VQP VQP Version:   1
Reconfirm Interval: 60 min
Server Retry Count: 3
VQP domain server:

Reconfirmation status
---------------------
VQP Action:         No Dynamic Port
```

**Step 6**
Repeat Steps 1 and 2 to configure the VMPS server addresses, and assign dynamic ports on each VMPS client switch.

---

**VMPS Database Configuration File Example**

This example shows a sample VMPS database configuration file as it appears on a VMPS server. A VMPS database configuration file is an ASCII text file that is stored on a TFTP server accessible to the switch that functions as the VMPS server.

```
!vmps domain <domain-name>
! The VMPS domain must be defined.
!vmps mode { open | secure }
! The default mode is open.
!vmps fallback <vlan-name>
!vmps no-domain-req { allow | deny }
! The default value is allow.
vmps domain WBU
vmps mode open
vmps fallback default
vmps no-domain-req deny
```

Configuring IP Unnumbered Interface

This chapter discusses the IP Unnumbered Interface feature, which allows you to enable IP processing on an interface without assigning an explicit IP address.

This chapter contains these sections:
- About IP Unnumbered Support, page 13-2
- Limitations and Restrictions, page 13-4
- Configuring IP Unnumbered Interface Support with DHCP Server, page 13-5
- Configuring IP Unnumbered Interface Support with Connected Host Polling, page 13-7
- Displaying IP Unnumbered Interface Settings, page 13-8
- Troubleshooting IP Unnumbered, page 13-9

Note

For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

Chapter 13      Configuring IP Unnumbered Interface

About IP Unnumbered Support

Before you configure VLANs and LAN interfaces with IP unnumbered interfaces, you should understand the following concepts:

- IP Unnumbered Interface Support with DHCP Server and Relay Agent, page 13-2
- IP Unnumbered with Connected Host Polling, page 13-4

IP Unnumbered Interface Support with DHCP Server and Relay Agent

The IP unnumbered interface configuration allows you to enable IP processing on an interface without assigning it an explicit IP address. The IP unnumbered interface can “borrow” the IP address from another interface that is already configured on the Catalyst 4500 series switch, thereby conserving network and address space. When employed with the DHCP server/relay agent, this feature allows a host address assigned by the DHCP server to be learned dynamically at the DHCP relay agent.

Figure 13-1 shows a sample network topology implementing the IP Unnumbered Interface feature. In this topology, IP routes are dynamically established by the aggregation switch when the DHCP server assigns IP addresses to the hosts.
Figure 13-1  Sample Network Topology Using the VLANs over IP Unnumbered Interfaces Feature

DHCP Option 82

DHCP provides a framework for passing configuration information to hosts on a TCP/IP network. Configuration parameters and other control information are carried in tagged data items that are stored in the options field of the DHCP message. The data items are also called options. Option 82 is organized as a single DHCP option that contains information known by the relay agent.

The IP Unnumbered Interface feature communicates information to the DHCP server using a suboption of the DHCP relay agent information option called *agent remote ID*. The information sent in the agent remote ID includes an IP address identifying the relay agent and information about the interface and the connection over which the DHCP request entered. The DHCP server can use this information to make IP address assignments and security policy decisions.

Figure 13-2 shows the agent remote ID suboption format that is used with the IP Unnumbered Interfaces feature.

| Table 13-1 describes the agent remote ID suboption fields displayed in Figure 13-2. |
Limitations and Restrictions

Limitations and restrictions include:

- For IP unnumbered interfaces, the following features are not supported:
  - Dynamic routing protocols
  - HSRP/VRRP
  - Static arp
  - Unnumbered interface and Numbered interface in different VRFs
- The option to add dhcp host routes as connected routes is available in Cisco IOS. When using connected mode, however, the `clear ip route *` command deletes the dhcp host connected routes permanently.

  **Workarounds:**
  - For a layer 3 interface (SVI), enter `shut` then `no shut`.
  - To enable IP unnumbered to use static routes, enter the `ip dhcp route static` command.

- IP Redirect is not sent by an interface configured with IP unnumbered. (CSCse75660).
- An IP unnumbered interface is unable to forward multicast source packets. (CSCse61766)
**Configuring IP Unnumbered Interface Support with DHCP Server**

**Note**

DHCP must be configured and operational.

This section contains the following procedures:

- Configuring IP Unnumbered Interface Support on LAN and VLAN Interfaces, page 13-5
- Configuring IP Unnumbered Interface Support on a Range of Ethernet VLANs, page 13-6

**Configuring IP Unnumbered Interface Support on LAN and VLAN Interfaces**

To configure IP unnumbered interface support on a single LAN or VLAN interface, perform this task.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface [fastethernet | gigabitethernet | tengigabitethernet | vlan vlan | port-channel | loopback]`
4. `ip unnumbered type number`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# <code>enable</code> Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch# <code>configure terminal</code> Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config)# `interface [fastethernet</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config-if)# <code>ip unnumbered type number</code> Enables IP processing on an interface without assigning an explicit IP address to the interface. The <code>type</code> and <code>number</code> arguments specify another interface on which the switch has an assigned IP address. The interface specified cannot be another unnumbered interface.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch(config-if)# <code>exit</code> Returns to global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Switch(config)# <code>end</code> Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>Switch# <code>show running-config</code> Verifies that IP unnumbered support has been configured correctly.</td>
</tr>
</tbody>
</table>
In the following example, Ethernet VLAN 10 is configured as an IP unnumbered interfaces:

Switch> enable
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface vlan 10
Switch(config-if)# ip unnumbered Lookback 0

Configuring IP Unnumbered Interface Support on a Range of Ethernet VLANs

To configure IP unnumbered interface support on a range of Ethernet VLAN interfaces, perform this task:

SUMMARY STEPS

1. enable
2. configure terminal
3. interface range {{fastethernet | gigabitethernet | vlan vlan} slot/interface {fastethernet | gigabitethernet | vlan vlan} slot/interface macro macro-name}
4. ip unnumbered type number

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# enable</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config)# interface range {{fastethernet</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config-if)# ip unnumbered type number</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch(config-if)# exit</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>Switch# show running-config</td>
</tr>
</tbody>
</table>
Chapter 13 Configuring IP Unnumbered Interface

In the following example, Vlan in the range from 1 to 10 are configured as IP unnumbered interfaces, sharing ip address of fastethernet 3/1:

```
Switch> enable
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface range vlan 1 - 10
Switch(config-if)# ip unnumbered fastethernet 3/1
Switch(config-if)# exit
Switch(config)# end
```

### Configuring IP Unnumbered Interface Support with Connected Host Polling

To configure IP unnumbered interface support with connected host polling, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
Switch# enable | Enables privileged EXEC mode.
Enter your password if prompted. |
| **Step 2**
Switch# configure terminal | Enters global configuration mode. |
| **Step 3**
Switch(config)# interface vlan vlan-id | Enters interface configuration mode and the interface to be configured as a tunnel port. |
| **Step 4**
Switch(config-if)# ip unnumbered type number poll | Enables IP processing and connected host polling on an interface without assigning an explicit IP address to the interface.

The *type* and *number* specify another interface on which the switch has an assigned IP address. The interface specified cannot be another unnumbered interface.
The *type* argument can have the values: *loopback*, *fastethernet*, *gigabitethernet*, *svi*, and *portchannel*.

| **Step 5**
Switch(config-if)# exit | Returns to global configuration mode. |
| **Step 6**
Switch(config)# ip arp poll queue <10-10000> | Configures the global backlog queue of host addresses to be discovered.
Default for the queue size is 1000 |
| **Step 7**
Switch(config)# ip arp poll rate <10-10000> | Configures the maximum number of arp requests sent over unnumbered interfaces.
Default number of arp requests is 1000 packet per second |
| **Step 8**
Switch(config)# end | Returns to privileged EXEC mode. |
| **Step 9**
Switch# show running-config | Verifies that IP unnumbered support has been configured correctly. |
The following example shows how to enable IP processing and connected host polling on Fast Ethernet interface 6/2. It also shows how to set the global backlog queue to 2000 and the maximum number of arp requests to 500:

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fastEthernet 6/2
Switch(config-if)# no switchport
Switch(config-if)# ip unnumbered loopback 0 poll
Warning: dynamic routing protocols will not work on non-point-to-point interfaces with IP unnumbered configured.
Switch(config-if)# exit
Switch(config)# ip arp poll queue 2000
Switch(config)# ip arp poll rate 500
Switch(config)# end

Displaying IP Unnumbered Interface Settings

Use the show ip interface unnumbered command to display status of an unnumbered interface with connected host polling for the switch.

To display status of an unnumbered interface, perform one or more of these tasks:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# show ip interface [type number] unnumbered [detail]</td>
<td>Displays the status of unnumbered interface with connected host polling for the Catalyst 4500 series switch.</td>
</tr>
</tbody>
</table>

The following example shows how to display the status of unnumbered interface with connected host polling:

Switch# show ip interface loopback 0 unnumbered detail
Number of unnumbered interfaces with polling: 1
Number of IP addresses processed for polling: 2
10.1.1.7
10.1.1.8
Number of IP addresses in queue for polling: 2(high water mark: 3)
10.1.1.17
10.1.1.18

To display key statistic for the backlog of unnumbered interface with connected host polling for the switch, use the show ip arp poll command:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# show ip arp poll [detail]</td>
<td>display key statistic for the backlog of unnumbered interface with connected host polling for the switch</td>
</tr>
</tbody>
</table>
The following example shows how to display key statistic for the backlog of unnumbered interface with connected host polling:

Switch# `show ip arp poll`
Number of IP addresses processed for polling: 439
Number of IP addresses in queue for polling: 3 (high water mark: 0, max: 1000)
Number of requests dropped:
  Queue was full: 0
  Request was throttled by incomplete ARP: 0
  Duplicate request was found in queue: 0

To clear the key statistic for the backlog of unnumbered interface, use the `clear ip arp poll statistic` command, as follows:

Switch# `clear ip arp poll statistic`
Switch# `show ip arp poll`
Number of IP addresses processed for polling: 0
Number of IP addresses in queue for polling: 0 (high water mark: 0, max: 1000)
Number of requests dropped:
  Queue was full: 0
  Request was throttled by incomplete ARP: 0
  Duplicate request was found in queue: 0

**Troubleshooting IP Unnumbered**

To understand how to debug connect host polling, see the IOS documentation of the `debug arp` command on cisco.com.

When an IP unnumbered interface shares the IP address of a loopback interface whose prefix is advertised in an OSPF network, you must modify the loopback interface as a point to point interface. Otherwise, only the loopback interface host route is advertised to an OSPF neighbor.

Switch(config)# `int loopback 0`
Switch(config-if)# `ip address`
Switch(config-if)# `ip address 10.1.0.1 255.255.0.0`
Switch(config-if)# `ip ospf network point-to-point`
Switch(config-if)# `end`
Chapter 13  Configuring IP Unnumbered Interface

Troubleshooting IP Unnumbered
CHAPTER 14

Configuring Layer 2 Ethernet Interfaces

This chapter describes how to use the command-line interface (CLI) to configure Fast Ethernet and Gigabit Ethernet interfaces for Layer 2 switching on Catalyst 4500 series switches. It also provides guidelines, procedures, and configuration examples. The configuration tasks in this chapter apply to Fast Ethernet and Gigabit Ethernet interfaces on any module, including the uplink ports on the supervisor engine.

This chapter includes the following major sections:

- About Layer 2 Ethernet Switching, page 14-1
- Default Layer 2 Ethernet Interface Configuration, page 14-4
- Layer 2 Interface Configuration Guidelines and Restrictions, page 14-5
- Configuring Ethernet Interfaces for Layer 2 Switching, page 14-5

Note
To configure Layer 3 interfaces, see Chapter 26, “Configuring Layer 3 Interfaces.”

Note
For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

About Layer 2 Ethernet Switching

The following sections describe how Layer 2 Ethernet switching works on Catalyst 4500 series switches:

- Layer 2 Ethernet Switching, page 14-2
- VLAN Trunks, page 14-3
- Layer 2 Interface Modes, page 14-4
Layer 2 Ethernet Switching

Catalyst 4500 series switches support simultaneous, parallel connections between Layer 2 Ethernet segments. Switched connections between Ethernet segments last only for the duration of the packet. New connections can be made between different segments for successive packets.

Note

With release 12.1(13)EW, the Catalyst 4500 series switches can handle packets of 1600 bytes, rather than treat them as “oversized” and discard them. This size is larger than the usual IEEE Ethernet Maximum Transmission Unit (MTU) (1518 bytes) and 802.1q MTU (1522 bytes). The ability to handle larger packets is required to support two nested 802.1q headers and Multiprotocol Label Switching (MPLS) on a network.

The Catalyst 4500 series solves congestion problems caused by high-bandwidth devices and a large number of users by assigning each device (for example, a server) to its own 10-, 100-, or 1000-Mbps segment. Because each Ethernet interface on the switch represents a separate Ethernet segment, servers in a properly configured switched environment achieve full access to the bandwidth.

Because collisions are a major bottleneck in Ethernet networks, an effective solution is full-duplex communication. Normally, Ethernet operates in half-duplex mode, which means that stations can either receive or transmit. In full-duplex mode, two devices can transmit and receive at the same time. When packets can flow in both directions simultaneously, effective Ethernet bandwidth doubles to 20 Mbps for 10-Mbps interfaces and to 200 Mbps for Fast Ethernet interfaces. Gigabit Ethernet interfaces on the Catalyst 4500 series switch are full-duplex mode only, providing 2-Gbps effective bandwidth.

Switching Frames Between Segments

Each Ethernet interface on a Catalyst 4500 series switch can connect to a single workstation or server, or to a hub through which workstations or servers connect to the network.

On a typical Ethernet hub, all ports connect to a common backplane within the hub, and the bandwidth of the network is shared by all devices attached to the hub. If two devices establish a session that uses a significant level of bandwidth, the network performance of all other stations attached to the hub is degraded.

To reduce degradation, the switch treats each interface as an individual segment. When stations on different interfaces need to communicate, the switch forwards frames from one interface to the other at wire speed to ensure that each session receives full bandwidth.

To switch frames between interfaces efficiently, the switch maintains an address table. When a frame enters the switch, it associates the MAC address of the sending station with the interface on which it was received.

Building the MAC Address Table

The Catalyst 4500 series builds the MAC address table by using the source address of the frames received. When the switch receives a frame for a destination address not listed in its MAC address table, it floods the frame to all interfaces of the same VLAN except the interface that received the frame. When the destination device replies, the switch adds its relevant source address and interface ID to the address table. The switch then forwards subsequent frames to a single interface without flooding to all interfaces.

The address table can store at least 32,000 address entries without flooding any entries. The switch uses an aging mechanism, defined by a configurable aging timer, so if an address remains inactive for a specified number of seconds, it is removed from the address table.
VLAN Trunks

A trunk is a point-to-point link between one or more Ethernet switch interfaces and another networking device such as a router or a switch. Trunks carry the traffic of multiple VLANs over a single link and allow you to extend VLANs across an entire network.

Two trunking encapsulations are available on all Ethernet interfaces:

- Inter-Switch Link (ISL) Protocol—ISL is a Cisco-proprietary trunking encapsulation.

**Note** Supervisor Engine 7-E does not support ISL trunking, so the `switchport trunk encapsulate` command is not supported.

- 802.1Q—802.1Q is an industry-standard trunking encapsulation.

You can configure a trunk on a single Ethernet interface or on an EtherChannel bundle. For more information about EtherChannel, see Chapter 19, “Configuring EtherChannel.”

Ethernet trunk interfaces support different trunking modes (see Table 14-2). You can specify whether the trunk uses ISL encapsulation, 802.1Q encapsulation, or if the encapsulation type is autonegotiated.

To autonegotiate trunking, make sure your interfaces are in the same VTP domain. Use the `trunk` or `nonegotiate` keywords to force interfaces in different domains to trunk. For more information on VTP domains, see Chapter 12, “Configuring VLANs, VTP, and VMPS.”

Trunk negotiation is managed by the Dynamic Trunking Protocol (DTP). DTP supports autonegotiation of both ISL and 802.1Q trunks.

Encapsulation Types

Table 14-1 lists the Ethernet trunk encapsulation types.

<table>
<thead>
<tr>
<th>Encapsulation Type</th>
<th>Encapsulation Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISL</td>
<td><code>switchport trunk encapsulation isl</code></td>
<td>Specifies ISL encapsulation on the trunk link.</td>
</tr>
<tr>
<td>802.1Q</td>
<td><code>switchport trunk encapsulation dot1q</code></td>
<td>Specifies 802.1Q encapsulation on the trunk link.</td>
</tr>
<tr>
<td>Negotiate</td>
<td><code>switchport trunk encapsulation negotiate</code></td>
<td>Specifies that the interface negotiate with the neighboring interface to become an ISL (preferred) or 802.1Q trunk, depending on the configuration and capabilities of the neighboring interface.</td>
</tr>
</tbody>
</table>

The trunking mode, the trunk encapsulation type, and the hardware capabilities of the two connected interfaces determine whether a link becomes an ISL or 802.1Q trunk.
Layer 2 Interface Modes

Table 14-2 lists the Layer 2 interface modes and describes how they function on Ethernet interfaces.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>switchport mode access</td>
<td>Puts the interface into permanent nontrunking mode and negotiates to convert the link into a nontrunking link. The interface becomes a nontrunk interface even if the neighboring interface does not change.</td>
</tr>
<tr>
<td>switchport mode dynamic desirable</td>
<td>Makes the interface actively attempt to convert the link to a trunking link. The interface becomes a trunk interface if the neighboring interface is set to trunk, desirable, or auto mode.</td>
</tr>
<tr>
<td>switchport mode dynamic auto</td>
<td>Makes the interface convert the link to a trunking link if the neighboring interface is set to trunk or desirable mode. This is the default mode for all Ethernet interfaces.</td>
</tr>
<tr>
<td>switchport mode trunk</td>
<td>Puts the interface into permanent trunking mode and negotiates to convert the link into a trunking link. The interface becomes a trunk interface even if the neighboring interface does not change.</td>
</tr>
<tr>
<td>switchport nonegotiate</td>
<td>Puts the interface into permanent trunking mode but prevents the interface from generating DTP frames. You must configure the neighboring interface manually as a trunk interface to establish a trunking link.</td>
</tr>
</tbody>
</table>

Note

DTP is a point-to-point protocol. However, some internetworking devices might forward DTP frames improperly. To avoid this problem, ensure that interfaces connected to devices that do not support DTP are configured with the access keyword if you do not intend to trunk across those links. To enable trunking to a device that does not support DTP, use the nonegotiate keyword to cause the interface to become a trunk without generating DTP frames.

Default Layer 2 Ethernet Interface Configuration

Table 14-3 shows the Layer 2 Ethernet interface default configuration.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interface mode</td>
<td>switchport mode dynamic auto</td>
</tr>
<tr>
<td>Trunk encapsulation</td>
<td>switchport trunk encapsulation negotiate</td>
</tr>
<tr>
<td>Allowed VLAN range</td>
<td>VLANs 1–1005</td>
</tr>
<tr>
<td>VLAN range eligible for pruning</td>
<td>VLANs 2–1001</td>
</tr>
<tr>
<td>Default VLAN (for access ports)</td>
<td>VLAN 1</td>
</tr>
</tbody>
</table>
Layer 2 Interface Configuration Guidelines and Restrictions

Keep the following guidelines and restrictions in mind when you configure Layer 2 interfaces:

- In a network of Cisco switches connected through 802.1Q trunks, the switches maintain one instance of spanning tree for each VLAN allowed on the trunks. Non-Cisco 802.1Q switches maintain only one instance of spanning tree for all VLANs allowed on the trunks.

When you connect a Cisco switch to a non-Cisco device through an 802.1Q trunk, the Cisco switch combines the spanning tree instance of the native VLAN of the trunk with the spanning tree instance of the non-Cisco 802.1Q switch. However, spanning tree information for each VLAN is maintained by Cisco switches separated by a cloud of non-Cisco 802.1Q switches. The non-Cisco 802.1Q cloud separating the Cisco switches is treated as a single trunk link between the switches.

- Make sure the native VLAN for an 802.1Q trunk is the same on both ends of the trunk link. If the VLAN on one end of the trunk is different from the VLAN on the other end, spanning tree loops might result.

- Disabling spanning tree on any VLAN of an 802.1Q trunk can cause spanning tree loops.

Configuring Ethernet Interfaces for Layer 2 Switching

The following sections describe how to configure Layer 2 switching on a Catalyst 4500 series switch:

- Configuring an Ethernet Interface as a Layer 2 Trunk, page 14-6
- Configuring an Interface as a Layer 2 Access Port, page 14-8
- Clearing Layer 2 Configuration, page 14-9

<sup>1</sup> STP = Spanning Tree Protocol
Configuring an Ethernet Interface as a Layer 2 Trunk

The default for Layer 2 interfaces is `switchport mode dynamic auto`. If the neighboring interface supports trunking and is configured to trunk mode or dynamic desirable mode, the link becomes a Layer 2 trunk. By default, trunks negotiate encapsulation. If the neighboring interface supports ISL and 802.1Q encapsulation and both interfaces are set to negotiate the encapsulation type, the trunk uses ISL encapsulation.

Supervisor Engine 7-E does not support ISL trunking.

To configure an interface as a Layer 2 trunk, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>`Switch(config)# interface {fastethernet</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><code>Switch(config-if)# shutdown</code></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>`Switch(config-if)# switchport trunk encapsulation {isl</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>`Switch(config-if)# switchport mode {dynamic {auto</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><code>Switch(config-if)# switchport access vlan vlan_num</code></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td><code>Switch(config-if)# switchport trunk native vlan vlan_num</code></td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>`Switch(config-if)# switchport trunk allowed vlan {add</td>
</tr>
</tbody>
</table>
Configuring Ethernet Interfaces for Layer 2 Switching

### Chapter 14
Configuring Layer 2 Ethernet Interfaces

#### Step 8
```
Switch(config-if)# switchport trunk pruning vlan (add | except | none | remove) vlan_num[,vlan_num[,vlan_num[,...]]]
```
(Optional) Configures the list of VLANs allowed to be pruned from the trunk (see the “VLAN Trunking Protocol” section on page 12-7). The default list of VLANs allowed to be pruned contains all VLANs, except for VLAN 1.

#### Step 9
```
Switch(config-if)# no shutdown
```
Activates the interface. (Required only if you shut down the interface.)

#### Step 10
```
Switch(config-if)# end
```
Exits interface configuration mode.

#### Step 11
```
Switch# show running-config interface 
{fastethernet | gigabitethernet | tengigabitethernet} slot/port
```
Displays the running configuration of the interface.

#### Step 12
```
Switch# show interfaces [fastethernet | gigabitethernet | tengigabitethernet]
slot/port switchport
```
Displays the switch port configuration of the interface.

#### Step 13
```
Switch# show interfaces [{fastethernet | gigabitethernet | tengigabitethernet}
slot/port] trunk
```
Displays the trunk configuration of the interface.

This example shows how to configure the Fast Ethernet interface 5/8 as an 802.1Q trunk. This example assumes that the neighbor interface is configured to support 802.1Q trunking and that the native VLAN defaults to VLAN 1:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fastethernet 5/8
Switch(config-if)# shutdown
Switch(config-if)# switchport mode dynamic desirable
Switch(config-if)# switchport trunk encapsulation dot1q
Switch(config-if)# no shutdown
Switch(config-if)# end
Switch# exit
```

This example shows how to verify the running configuration:

```
Switch# show running-config interface fastethernet 5/8
Building configuration...
Current configuration:
!
interface FastEthernet5/8
 switchport mode dynamic desirable
 switchport trunk encapsulation dot1q
end
```

This example shows how to verify the switch port configuration:

```
Switch# show interfaces fastethernet 5/8 switchport
Name: Fa5/8
Switchport: Enabled
Administrative Mode: dynamic desirable
Operational Mode: trunk
Administrative Trunking Encapsulation: negotiate
Operational Trunking Encapsulation: dot1q
Negotiation of Trunking: Enabled
Access Mode VLAN: 1 (default)
Trunking Native Mode VLAN: 1 (default)
Trunking VLANs Enabled: ALL
Pruning VLANs Enabled: 2-1001
```
This example shows how to verify the trunk configuration:

```
Switch# show interfaces fastethernet 5/8 trunk

<table>
<thead>
<tr>
<th>Port</th>
<th>Mode</th>
<th>Encapsulation</th>
<th>Status</th>
<th>Native vlan</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fa5/8</td>
<td>desirable</td>
<td>n-802.1q</td>
<td>trunking</td>
<td>1</td>
</tr>
</tbody>
</table>
```

```
Port       Vlans allowed on trunk
Fa5/8 1-1005

Port       Vlans allowed and active in management domain
Fa5/8 1-6,10,20,50,100,152,200,300,303-305,349-351,400,500,521,524,570,801-802,850,917,999,1002-1005

Port       Vlans in spanning tree forwarding state and not pruned
Fa5/8 1-6,10,20,50,100,152,200,300,303-305,349-351,400,500,521,524,570,801-802,850,917,999,1002-1005
```

Configuring an Interface as a Layer 2 Access Port

**Note**

If you assign an interface to a VLAN that does not exist, the interface is not operational until you create the VLAN in the VLAN database (see the “Configuring VLANs in Global Configuration Mode” section on page 12-5).

To configure an interface as a Layer 2 access port, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>`Switch(config)# interface {fastethernet</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><code>Switch(config-if)# shutdown</code></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><code>Switch(config-if)# switchport</code></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><code>Switch(config-if)# switchport mode access</code></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><code>Switch(config-if)# switchport access vlan &lt;vlan_num&gt;</code></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td><code>Switch(config-if)# no shutdown</code></td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td><code>Switch(config-if)# end</code></td>
</tr>
</tbody>
</table>
Chapter 14  Configuring Layer 2 Ethernet Interfaces

Configuring Ethernet Interfaces for Layer 2 Switching

Chapter 14      Configuring Layer 2 Ethernet Interfaces

Configuring Ethernet Interfaces for Layer 2 Switching

This example shows how to configure the Fast Ethernet interface 5/6 as an access port in VLAN 200:

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fastethernet 5/6
Switch(config-if)# shutdown
Switch(config-if)# switchport mode access
Switch(config-if)# switchport access vlan 200
Switch(config-if)# no shutdown
Switch(config-if)# end
Switch# exit

This example shows how to verify the running configuration:

Switch# show running-config interface fastethernet 5/6
Building configuration...
!
Current configuration :33 bytes
interface FastEthernet 5/6
  switchport access vlan 200
  switchport mode access
end

This example shows how to verify the switch port configuration:

Switch# show interface fastethernet 5/6 switchport
Name:Fa5/6
Switchport:Enabled
Administrative Mode:dynamic auto
Operational Mode:static access
Administrative Trunking Encapsulation:negotiate
Operational Trunking Encapsulation:native
Negotiation of Trunking:On
Access Mode VLAN:1 (default)
Trunking Native Mode VLAN:1 (default)
Administrative private-vlan host-association:none
Administrative private-vlan mapping:none
Operational private-vlan:none
Trunking VLANS Enabled:ALL
Pruning VLANS Enabled:2-1001
Switch#

Clearing Layer 2 Configuration

To clear the Layer 2 configuration on an interface, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Specifies the interface to clear.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Exits interface configuration mode.</td>
</tr>
</tbody>
</table>

Software Configuration Guide—Release 15.0(1)XO

OL-22250-01
Configuring Ethernet Interfaces for Layer 2 Switching

Chapter 14      Configuring Layer 2 Ethernet Interfaces

Step 3
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# default interface fastethernet 5/6
Switch(config)# end
Switch# exit

This example shows how to clear the Layer 2 configuration on the Fast Ethernet interface 5/6:

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# default interface fastethernet 5/6
Switch(config)# end
Switch# exit

Step 4
Switch# show interfaces {{fastethernet | gigabitethernet | tengigabitethernet} slot/port | switchport
Displays the switch port configuration of the interface.

This example shows how to verify the Layer 2 configuration was cleared:

Switch# show running-config interface fastethernet 5/6
Building configuration...
Current configuration:
!
interface FastEthernet5/6
end

This example shows how to verify the switch port configuration:

Switch# show interfaces fastethernet 5/6 switchport
Name: Fa5/6
Switchport: Enabled
Switch#
### Configuring SmartPort Macros

This chapter describes how to configure and apply SmartPort macros on your switch. It consists of these sections:

- **About SmartPort Macros, page 15-1**
- **Configuring SmartPort Macros, page 15-2**
- **Displaying SmartPort Macros, page 15-12**

---

**Note**

For complete syntax and usage information for the switch commands used in this chapter, look at the *Cisco Catalyst 4500 Series Switch Command Reference* and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the *Catalyst 4500 Series Switch Cisco IOS Command Reference* and related publications at this location:

---

### About SmartPort Macros

SmartPort macros provide a convenient way to save and share common configurations. They enable features and settings based on the location of a switch in the network and for mass configuration deployments across the network.

Each SmartPort macro is a set of CLI commands that you define. SmartPort macro sets do not contain new CLI commands; each SmartPort macro is a group of existing CLI commands.

When you apply a SmartPort macro on an interface, the CLI commands contained within the macro are configured on the interface. When the macro is applied to an interface, the existing interface configurations are not lost. The new commands are added to interface and are saved in the running configuration file.

There are Cisco-default SmartPorts macros embedded in the switch software (see Table 15-1). You can display these macros and the commands they contain by using the `show parser macro` user EXEC command.
Configuring SmartPort Macros

Cisco also provides a collection of pretested, Cisco-recommended baseline configuration templates for Catalyst switches. The online reference guide templates provide the CLI commands that you use to create SmartPorts macros based on the usage of the port. The configuration templates allow you to create SmartPorts macros to build and deploy Cisco-recommended network designs and configurations.

### Table 15-1 Cisco-Default SmartPorts Macros

<table>
<thead>
<tr>
<th>Macro Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cisco-global</td>
<td>Use this global configuration macro to enable rapid PVST+, loop guard, and dynamic port error recovery for link state failures.</td>
</tr>
<tr>
<td>cisco-desktop</td>
<td>Use this interface configuration macro for increased network security and reliability when connecting a desktop device, such as a PC, to a switch port.</td>
</tr>
<tr>
<td>cisco-phone</td>
<td>Use this interface configuration macro when connecting a desktop device such as a PC with a Cisco IP Phone to a switch port. This macro is an extension of the cisco-desktop macro and provides the same security and resiliency features, but with the addition of dedicated voice VLANs to ensure proper treatment of delay-sensitive voice traffic.</td>
</tr>
<tr>
<td>cisco-switch</td>
<td>Use this interface configuration macro when connecting an access switch and a distribution switch or between access switches connected using GigaStack modules or GBICs.</td>
</tr>
<tr>
<td>cisco-router</td>
<td>Use this interface configuration macro when connecting the switch and a WAN router.</td>
</tr>
</tbody>
</table>

1. Cisco-default SmartPorts macros vary depending on the software version running on your switch.

### Configuring SmartPort Macros

You can create a new SmartPort macro or use an existing macro as a template to create a new macro that is specific to your application. After you create the macro, you can apply it to an interface or a range of interfaces.

This section includes information about these topics:

- Passing Parameters Through the Macro, page 15-2
- Default SmartPort Macro Configuration, page 15-3
- SmartPort Macro Configuration Guidelines, page 15-6
- Creating SmartPorts Macros, page 15-7
- Applying SmartPorts Macros, page 15-8

### Passing Parameters Through the Macro

Some commands might not be sufficiently generic for all the interfaces; for example, VLAN ID for Layer 2 interfaces and the IP address for Layer 3 interface. Retaining such commands in macro definitions requires that you change the value of such parameters (like VLAN ID or IP address) before applying the macro to different interfaces. Alternatively, it requires that you create different macros for each possible value of its parameters.
The macro infrastructure can be enhanced to support accepting parameters while applying a macro. The parameters are passed as keyword-value pairs.

The CLI limits the number of keyword-value pairs to a maximum of three, where the first parameter must be the keyword, the second is its corresponding value, and the third parameter would be the keyword for the second keyword-value pair. Here is an example of how to pass parameters to a command-macro:

```
Switch(config)# macro name parameter-test
Enter macro commands one per line. End with the character '@'.
switchport mode access
switchport access vlan $VLANID
switchport port-security
switchport port-security maximum $MAXHOST
```

If the above macro is applied to some interface without parameters, the invalid commands fail. Instead, you should apply the macro with appropriate keyword-value pair parameters, as follows:

```
Switch(config-if)# macro apply parameter-test $VLANID 1 $MAXHOST 5
```

The above command applies the macro after replacing $VLANID with 1 and $MAXHOST with 5. Be aware that you can specify any string in the macro as a keyword.

**Macro Parameter Help**

It is often difficult to remember the macro keywords while applying a macro to an interface or switch. Macros can contain the definitions for mandatory keywords. If you apply a macro without those keyword values, the commands are considered invalid and they fail.

You can enhance the macro infrastructure to provide help on keywords defined in macros. While creating a macro, you can specify a help string (as a comment) to list the mandatory keywords for that macro.

The following example illustrates how to specify the help string for the keywords:

```
Switch(config)# macro name test
switchport access vlan $VLANID
switchport port-security maximum $MAX
#macro keywords $VLANID $MAX
```

Help string can be anywhere in the macro. The following example illustrates an alternate way to specify the help string:

```
Switch(config)# macro name test
switchport access vlan $VLANID
#macro keywords $VLANID
switchport port-security maximum $MAX
#macro keywords $MAX
```

**Default SmartPort Macro Configuration**

This section illustrates the default configurations for the four supported macros. These macros can only be viewed and applied; they cannot be modified by the user.

- cisco-global, page 15-4
- cisco-desktop, page 15-4
- cisco-phone, page 15-4
- cisco-router, page 15-5
- cisco-switch, page 15-5
Chapter 15 Configuring SmartPort Macros

cisco-global

This is the example for the cisco-global macro:

```
# Enable dynamic port error recovery for link state failures.
erd disable recovery cause link-flap
erd disable recovery interval 60

# VTP requires Transparent mode for future 802.1x Guest VLAN
# and current Best Practice
vtp domain [smartports]
vtp mode transparent

# Enable aggressive mode UDLD on all fiber uplinks
udld aggressive

# Enable Rapid PVST+ and Loopguard
spanning-tree mode rapid-pvst
spanning-tree loopguard default
spanning-tree extend system-id
```

cisco-desktop

This is the example for the cisco-desktop macro:

```
# Basic interface - Enable data VLAN only
# Recommended value for access vlan (AVID) should not be 1
switchport access vlan $AVID
switchport mode access
# Enable port security limiting port to a single
# MAC address -- that of desktop
switchport port-security
# Ensure port-security age is greater than one minute
# and use inactivity timer
# "Port-security maximum 1" is the default and will not
# Show up in the config
switchport port-security violation restrict
switchport port-security aging time 2
switchport port-security aging type inactivity
# Configure port as an edge network port
spanning-tree portfast
spanning-tree bpdu-guard enable
```

cisco-phone

This is the example for the cisco-phone macro:

```
# VoIP enabled interface - Enable data VLAN
# and voice VLAN (VVID)
# Recommended value for access vlan (AVID) should not be 1\nswitchport access vlan $AVID
switchport mode access
# Update the Voice VLAN (VVID) value which should be
# different from data VLAN
# Recommended value for voice vlan (VVID) should not be 1
switchport voice vlan $VVID
# Enable port security limiting port to a 2 MAC
# addressess -- One for desktop and two for phone
switchport port-security
switchport port-security maximum 2
# Ensure port-security age is greater than one minute
# and use inactivity timer
```
Chapter 15  Configuring SmartPort Macros

### Configuring SmartPort Macros

```
switchport port-security violation restrict
switchport port-security aging time 2
switchport port-security aging type inactivity
# Enable auto-qos to extend trust to attached Cisco phone
auto qos voip cisco-phone
# Configure port as an edge network port
spanning-tree portfast
spanning-tree bpduguard enable
```

**cisco-router**

This is the example for the cisco-router macro:

```
# Access Uplink to Distribution
switchport trunk encapsulation dot1q
# Define unique Native VLAN on trunk ports
# Recommended value for native vlan (NVID) should not be 1
switchport trunk native vlan $NVID
# Update the allowed VLAN range (VRANGE) such that it
# includes data, voice and native VLANs
switchport trunk allowed vlan $VRANGE
# Hardcode trunk and disable negotiation to
# speed up convergence
# Hardcode speed and duplex to router
switchport mode trunk
switchport nonegotiate
speed 100
duplex full
# Configure qos to trust this interface
auto qos voip trust
qos trust dscp
# Ensure fast access to the network when enabling the interface.
# Ensure that switch devices cannot become active on the interface.
spanning-tree portfast
spanning-tree bpduguard enable
```

**cisco-switch**

This is the example for the cisco-switch macro:

```
# Access Uplink to Distribution
switchport trunk encapsulation dot1q
# Define unique Native VLAN on trunk ports
# Recommended value for native vlan (NVID) should not be 1
switchport trunk native vlan $NVID
# Update the allowed VLAN range (VRANGE) such that it
# includes data, voice and native VLANs
switchport trunk allowed vlan $VRANGE
# Hardcode trunk and disable negotiation to
# speed up convergence
switchport mode trunk

# Configure qos to trust this interface
auto qos voip trust
# 802.1w defines the link as pt-pt for rapid convergence
spanning-tree link-type point-to-point
```
SmartPort Macro Configuration Guidelines

Follow these guidelines when configuring macros on your switch:

- If a command fails when you apply a macro, either due to a syntax error or to a configuration error, the macro continues to apply the remaining commands to the interface.
- `cisco-global` needs to be applied at the global configuration mode. Cisco recommends that you apply this macro before any other interface level macro.
- Specific keywords are required when you apply the system-defined macros (`cisco-desktop`, `cisco-phone`, `cisco-switch`, and `cisco-router`) on an interface.
- When using the `cisco-phone` macro to apply port security, the port security maximum is 2 (switchport port-security maximum 2).
- At most, 3 keyword-value pairs are allowed per system-defined macro.
- When creating a macro, do not use the `exit` or `end` commands or change the command mode by using `interface interface-id`. This could cause commands that follow `exit`, `end`, or `interface interface-id` to execute in a different command mode.
- When creating a macro, ensure that all CLI commands are in the same configuration mode.
- When creating a macro that requires the assignment of unique values, use the `parameter value` keywords to designate values specific to the interface. Keyword matching is case sensitive. All matching occurrences of the keyword are replaced with the corresponding value. Any full match of a keyword, even if it is part of a larger string, is considered a match and is replaced by the corresponding value.
- Macro names are case sensitive. For example, the commands macro name Sample-Macro and macro name sample-macro result in two separate macros.
- Some macros might contain keywords that require a parameter value. Use the `macro global apply macro-name ?` global configuration command or the `macro apply macro-name ?` interface configuration command to display a list of any required values in the macro. If you apply a macro without entering the keyword values, the commands are invalid and are not applied.
- When a macro is applied globally to a switch or to a switch interface, all existing configuration on the interface is retained. This is helpful when applying an incremental configuration.
- If you modify a macro definition by adding or deleting commands, the changes are not reflected on the interface where the original macro was applied. You need to reapply the updated macro on the interface to apply the new or changed commands.
- Use the `macro global trace macro-name` global configuration command or the `macro trace macro-name` interface configuration command to apply and debug a macro to find any syntax or configuration errors. If a command fails because of a syntax error or a configuration error, the macro continues to apply the remaining commands.
- Some CLI commands are specific to certain interface types. If a macro is applied to an interface that does not accept the configuration, the macro fails the syntax check or the configuration check, and the switch returns an error message.
- Applying a macro to an interface range is the same as applying a macro to a single interface. When you use an interface range, the macro is applied sequentially to each interface within the range. If a macro command fails on one interface, it is still applied to the remaining interfaces.
When you apply a macro to a switch or a switch interface, the macro name is automatically added to the macro description of the switch or interface. You can display the applied commands and macro names by using the `show parser macro description` user EXEC command.

The user-configurable macro has a buffer that can take commands and comments up to 3000 characters. Each newline would take 2 characters and empty lines are counted as is.

There are Cisco-default SmartPorts macros embedded in the switch software (see Table 15-1). You can display these macros and the commands they contain by using the `show parser macro` user EXEC command.

Follow these guidelines when you apply a Cisco-default SmartPorts macro on an interface:

- Display all macros on the switch by using the `show parser macro` user EXEC command. Display the contents of a specific macro by using the `show parser macro macro-name` user EXEC command.
- Keywords that begin with `$` mean that a unique parameter value is required. Append the Cisco-default macro with the required values by using the `parameter` value keywords.
- The Cisco-default macros use the `$` character to help identify required keywords. There is no restriction on using the `$` character to define keywords when you create a macro.

**Creating SmartPorts Macros**

To create a SmartPorts macro, perform this task:

<table>
<thead>
<tr>
<th>Step</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>2</td>
<td>Switch(config)# macro name macro-name</td>
<td>Creates a macro definition, and enter a macro name. A macro definition can contain up to 3000 characters. Enter the macro commands with one command per line. Use the @ character to end the macro. Use the # character at the beginning of a line to enter comment text within the macro. Macro names are case sensitive. For example, the commands <code>macro name Sample-Macro</code> and <code>macro name sample-macro</code> result in two separate macros. We recommend that you do not use the <code>exit</code> or <code>end</code> commands or change the command mode by using <code>interface interface-id</code> in a macro. This could cause any commands following <code>exit</code>, <code>end</code>, or <code>interface interface-id</code> to execute in a different command mode. For best results, all commands in a macro should be in the same configuration mode. <strong>Note</strong> The <code>no</code> form of the <code>macro name</code> global configuration command only deletes the macro definition. It does not affect the configuration of those interfaces on which the macro is already applied.</td>
</tr>
<tr>
<td>3</td>
<td>Switch(config)# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>4</td>
<td>Switch# show parser macro name macro-name</td>
<td>Verifies that the macro was created.</td>
</tr>
</tbody>
</table>
Applying SmartPorts Macros

To apply a SmartPorts macro, follow these steps:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# macro global {apply</td>
</tr>
<tr>
<td></td>
<td>[parameter {value}]</td>
</tr>
<tr>
<td></td>
<td>[value}]</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config)# macro global description text</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config-if)# interface interface-id</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch(config-if)# default interface interface-id</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Switch(config-if)# macro {apply</td>
</tr>
<tr>
<td></td>
<td>[parameter {value}]</td>
</tr>
<tr>
<td></td>
<td>[value}]</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>Switch(config-if)# macro description text</td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>Switch(config-if)# end</td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>Switch# show parser macro description [interface interface-id]</td>
</tr>
<tr>
<td><strong>Step 10</strong></td>
<td>Switch# copy running-config startup-config</td>
</tr>
</tbody>
</table>
You can delete a global macro-applied configuration on a switch only by entering the `no` version of each command that is in the macro. You can delete a macro-applied configuration on an interface by entering the `default interface interface-id` interface configuration command.

The `no` form of the `macro name` global configuration command deletes only the macro definition. It does not affect the configuration of those interfaces on which the macro is already applied. You can delete a macro-applied configuration on an interface by entering the `default interface interface-id` interface configuration command. Alternatively, you can create an `anti-macro` for an existing macro that contains the `no` form of all the corresponding commands in the original macro. Then, apply the anti-macro to the interface.

The following sections illustrate how to apply and display the attachments on each of the supported macros:

- `cisco-global`, page 15-9
- `cisco-desktop`, page 15-9
- `cisco-phone`, page 15-10
- `cisco-switch`, page 15-11
- `cisco-router`, page 15-11

### cisco-global

This example shows how to use the system-defined macro `cisco-global`:

```
Switch(config)# macro global apply cisco-global
Changing VTP domain name from gsg-switch to [smartports]
Setting device to VTP TRANSPARENT mode.
Switch(config)# end
Switch(config)# show parser macro name cisco-global
Macro name : cisco-global
Macro type : default global
# Enable dynamic port error recovery for link state failures.
erdisable recovery cause link-flap
errdisable recovery interval 60

# VTP requires Transparent mode for future 802.1x Guest VLAN
# and current Best Practice vtp domain [smartports] vtp mode transparent

# Enable aggressive mode UDLD on all fiber uplinks udld aggressive

# Enable Rapid PVST+ and Loopguard
spanning-tree mode rapid-pvst
spanning-tree loopguard default
spanning-tree extend system-id
```

### cisco-desktop

This example shows how to use the system-defined macro `cisco-desktop` to assign a value of 35 to the access VLAN of the Fast Ethernet interface 2/9.

```
Note
This macro requires the `$AVID` keyword, which is the access VLAN of the port.
```

```
Switch(config)# interface fastethernet2/9
Switch(config-if)# macro apply cisco-desktop $AVID 35
Switch(config-if)# end
```
Chapter 15 Configuring SmartPort Macros

Configuring SmartPort Macros

Switch# show parser macro name cisco-desktop
Macro name: cisco-desktop
Macro type: customizable

# Basic interface - Enable data VLAN only
# Recommended value for access vlan (AVID) should not be 1
switchport access vlan $AVID [access_vlan_id]
switchport mode access
# Enable port security limiting port to a single
# MAC address -- that of desktop
switchport port-security
# Ensure port-security age is greater than one minute
# and use inactivity timer
# "Port-security maximum 1" is the default and will not
# Show up in the config
switchport port-security violation restrict
switchport port-security aging time 2
switchport port-security aging type inactivity
# Configure port as an edge network port
spanning-tree portfast
spanning-tree bpduguard enable

</tr>
<tr>
<td>show parser macro brief</td>
<td>Displays the configured macro names.</td>
</tr>
<tr>
<td>show parser macro description [interface interface-id]</td>
<td>Displays the macro description for all interfaces or for a specified interface.</td>
</tr>
</tbody>
</table>
Configuring STP and MST

This chapter describes how to configure the Spanning Tree Protocol (STP) on a Catalyst 4500 series switch. This chapter also describes how to configure the IEEE 802.1s Multiple Spanning Tree (MST) protocol on the Catalyst 4500 series switch. MST is a new IEEE standard derived from Cisco's proprietary Multi-Instance Spanning-Tree Protocol (MISTP) implementation. With MST, you can map a single spanning-tree instance to several VLANs.

This chapter provides guidelines, procedures, and configuration examples. It includes the following major sections:

- Overview of STP, page 16-1
- Default STP Configuration, page 16-6
- Configuring STP, page 16-7
- Overview of MST, page 16-21
- MST Configuration Restrictions and Guidelines, page 16-29
- Configuring MST, page 16-29

For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

Overview of STP

STP is a Layer 2 link management protocol that provides path redundancy while preventing undesirable loops in the network. For a Layer 2 Ethernet network to function properly, only one active path can exist between any two stations. A loop-free subset of a network topology is called a spanning tree. The operation of a spanning tree is transparent to end stations, which cannot detect whether they are connected to a single LAN segment or a switched LAN of multiple segments.
A Catalyst 4500 series switch use STP (the IEEE 802.1D bridge protocol) on all VLANs. By default, a single spanning tree runs on each configured VLAN (provided you do not manually disable the spanning tree). You can enable and disable a spanning tree on a per-VLAN basis.

When you create fault-tolerant internetworks, you must have a loop-free path between all nodes in a network. The spanning tree algorithm calculates the best loop-free path throughout a switched Layer 2 network. Switches send and receive spanning tree frames at regular intervals. The switches do not forward these frames, but use the frames to construct a loop-free path.

Multiple active paths between end stations cause loops in the network. If a loop exists in the network, end stations might receive duplicate messages and switches might learn end station MAC addresses on multiple Layer 2 interfaces. These conditions result in an unstable network.

A spanning tree defines a tree with a root switch and a loop-free path from the root to all switches in the Layer 2 network. A spanning tree forces redundant data paths into a standby (blocked) state. If a network segment in the spanning tree fails and a redundant path exists, the spanning tree algorithm recalculates the spanning tree topology and activates the standby path.

When two ports on a switch are part of a loop, the spanning tree port priority and port path cost setting determine which port is put in the forwarding state and which port is put in the blocking state. The spanning tree port priority value represents the location of an interface in the network topology and how well located it is to pass traffic. The spanning tree port path cost value represents media speed.

### Understanding the Bridge ID

Each VLAN on each network device has a unique 64-bit bridge ID consisting of a bridge priority value, an extended system ID, and an STP MAC address allocation.

#### Bridge Priority Value

The bridge priority value determines whether a given redundant link receives priority and is considered part of a given span in a spanning tree. Preference is given to lower values, and if you want to manually configure a preference, assign a lower bridge priority value to a link than to its redundant possibility. With Cisco IOS releases prior to 12.1(12c)EW, the bridge priority is a 16-bit value (see Table 16-1). With Cisco IOS Release 12.1(12c)EW and later releases, the bridge priority is a 4-bit value when the extended system ID is enabled (see Table 16-2). See the “Configuring the Bridge Priority of a VLAN” section on page 16-16.

#### Extended System ID

Extended system IDs are VLAN IDs between 1025 and 4096. Cisco IOS Releases 12.1(12c)EW and later releases support a 12-bit extended system ID field as part of the bridge ID (see Table 16-2). Chassis that support only 64 MAC addresses always use the 12-bit extended system ID. On chassis that support 1024 MAC addresses, you can enable use of the extended system ID. STP uses the VLAN ID as the extended system ID. See the “Enabling the Extended System ID” section on page 16-8.

</tr>
</tbody>
</table>
Chapter 16  Configuring STP and MST

Overview of STP

STP MAC Address Allocation

A Catalyst 4500 series switch chassis has either 64 or 1024 MAC addresses available to support software features like STP. Enter the `show module` command to view the MAC address range on your chassis.

Cisco IOS Release 12.1(12c)EW and later releases support chassis with 64 or 1024 MAC addresses. For chassis with 64 MAC addresses, STP uses the extended system ID plus a MAC address to make the bridge ID unique for each VLAN.

Earlier releases support chassis with 1024 MAC addresses. With earlier releases, STP uses one MAC address per VLAN to make the bridge ID unique for each VLAN.

Bridge Protocol Data Units

The following elements determine the stable active spanning tree topology of a switched network:

- The unique bridge ID (bridge priority and MAC address) associated with each VLAN on each switch
- The spanning tree path cost (or bridge priority value) to the root bridge
- The port identifier (port priority and MAC address) associated with each Layer 2 interface

Bridge protocol data units (BPDUs) contain information about the transmitting bridge and its ports, including the bridge and MAC addresses, bridge priority, port priority, and path cost. The system computes the spanning tree topology by transmitting BPDUs among connecting switches, and in one direction from the root switch. Each configuration BPDU contains at least the following:

- The unique bridge ID of the switch that the transmitting switch believes to be the root switch
- The spanning tree path cost to the root
- The bridge ID of the transmitting bridge
- The age of the message
- The identifier of the transmitting port
- Values for the `hello`, `forward delay`, and `max-age` protocol timers

When a switch transmits a BPDU frame, all switches connected to the LAN on which the frame is transmitted receive the BPDU. When a switch receives a BPDU, it does not forward the frame but instead uses the information in the frame to calculate a BPDU and, if the topology changes, initiate a BPDU transmission.

A BPDU exchange results in the following:

- One switch is elected as the root bridge.
- The shortest distance to the root bridge is calculated for each switch based on the path cost.
- A designated bridge for each LAN segment is selected. This is the switch closest to the root bridge through which frames are forwarded to the root.
- A root port is selected. This is the port providing the best path from the bridge to the root bridge.

Software Configuration Guide—Release IOS-XE 3.1.0 SG
Overview of STP

- Ports included in the spanning tree are selected.

Election of the Root Bridge

For each VLAN, the switch with the highest bridge priority (the lowest numerical priority value) is elected as the root bridge. If all switches are configured with the default priority value (32,768), the switch with the lowest MAC address in the VLAN becomes the root bridge.

The spanning tree root bridge is the logical center of the spanning tree topology in a switched network. All paths that are not required to reach the root bridge from anywhere in the switched network are placed in spanning tree blocking mode.

A spanning tree uses the information provided by BPDUs to elect the root bridge and root port for the switched network, as well as the root port and designated port for each switched segment.

STP Timers

Table 16-3 describes the STP timers that affect the performance of the entire spanning tree.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hello_time</td>
<td>Determines how often the switch broadcasts hello messages to other switches.</td>
</tr>
<tr>
<td>forward_time</td>
<td>Determines how long each of the listening and learning states lasts before the port begins forwarding.</td>
</tr>
<tr>
<td>max_age</td>
<td>Determines the amount of time that protocol information received on a port is stored by the switch.</td>
</tr>
</tbody>
</table>

Creating the STP Topology

The goal of the spanning tree algorithm is to make the most direct link the root port. When the spanning tree topology is calculated based on default parameters, the path between source and destination end stations in a switched network might not be optimal according to link speed. For instance, connecting higher-speed links to a port that has a higher number than the current root port can cause a root-port change.

In Figure 16-1, Switch A is elected as the root bridge. (This could happen if the bridge priority of all the switches is set to the default value [32,768] and Switch A has the lowest MAC address.) However, due to traffic patterns, the number of forwarding ports, or link types, Switch A might not be the ideal root bridge. By increasing the STP port priority (lowering the numerical value) of the ideal switch so that it becomes the root bridge, you force a spanning tree recalculation to form a new spanning tree topology with the ideal switch as the root.
Chapter 16 Configuring STP and MST

Overview of STP

Figure 16-1 Spanning Tree Topology

RP = Root Port
DP = Designated Port

For example, assume that one port on Switch B is a fiber-optic link, and another port on Switch B (an unshielded twisted-pair [UTP] link) is the root port. Network traffic might be more efficient over the high-speed fiber-optic link. By changing the spanning tree port priority on the fiber-optic port to a higher priority (lower numerical value) than the priority set for the root port, the fiber-optic port becomes the new root port.

STP Port States

Propagation delays can occur when protocol information passes through a switched LAN. As a result, topology changes can take place at different times and at different places in a switched network. When a Layer 2 interface transitions directly from nonparticipation in the spanning tree topology to the forwarding state, it can create temporary data loops. Ports must wait for new topology information to propagate through the switched LAN before starting to forward frames. They must allow the frame lifetime to expire for frames that have been forwarded under the old topology.

Each Layer 2 interface on a switch that uses spanning tree exists in one of the following five states:

- Blocking—In this state, the Layer 2 interface does not participate in frame forwarding.
- Listening—This state is the first transitional state after the blocking state when spanning tree determines that the Layer 2 interface should participate in frame forwarding.
- Learning—In this state, the Layer 2 interface prepares to participate in frame forwarding.
- Forwarding—In this state, the Layer 2 interface forwards frames.
- Disabled—In this state, the Layer 2 interface does not participate in spanning tree and does not forward frames.

MAC Address Allocation

The supervisor engine has a pool of 1024 MAC addresses that are used as the bridge IDs for the VLAN spanning trees. Use the `show module` command to view the MAC address range (allocation range for the supervisor) that the spanning tree uses for the algorithm.

MAC addresses for the Catalyst 4506 switch are allocated sequentially, with the first MAC address in the range assigned to VLAN 1, the second MAC address in the range assigned to VLAN 2, and so forth. For example, if the MAC address range is 00-e0-1e-9b-2e-00 to 00-e0-1e-9b-31-ff, the VLAN 1 bridge ID is 00-e0-1e-9b-2e-00, the VLAN 2 bridge ID is 00-e0-1e-9b-2e-01, the VLAN 3 bridge ID is 00-e0-1e-9b-2e-02, and so on. On other Catalyst 4500 series platforms, all VLANS map to the same MAC address rather than mapping to separate MAC addresses.
STP and IEEE 802.1Q Trunks

802.1Q VLAN trunks impose some limitations on the spanning tree strategy for a network. In a network of Cisco switches connected through 802.1Q trunks, the switches maintain one instance of spanning tree for each VLAN allowed on the trunks. However, non-Cisco 802.1Q switches maintain only one instance of spanning tree for all VLANs allowed on the trunks.

When you connect a Cisco switch to a non-Cisco device (that supports 802.1Q) through an 802.1Q trunk, the Cisco switch combines the spanning tree instance of the 802.1Q native VLAN of the trunk with the spanning tree instance of the non-Cisco 802.1Q switch. However, all per-VLAN spanning tree information is maintained by Cisco switches separated by a network of non-Cisco 802.1Q switches. The non-Cisco 802.1Q network separating the Cisco switches is treated as a single trunk link between the switches.

**Note**
For more information on 802.1Q trunks, see Chapter 14, “Configuring Layer 2 Ethernet Interfaces.”

Per-VLAN Rapid Spanning Tree

Per-VLAN Rapid Spanning Tree (PVRST+) is the same as PVST+, although PVRST+ utilizes a rapid STP based on IEEE 802.1w rather than 802.1D to provide faster convergence. PVRST+ uses roughly the same configuration as PVST+ and needs only minimal configuration. In PVRST+, dynamic CAM entries are flushed immediately on a per-port basis when any topology change is made. UplinkFast and BackboneFast are enabled but not active in this mode, because the functionality is built into the Rapid STP. PVRST+ provides for rapid recovery of connectivity following the failure of a bridge, bridge port, or LAN.

**Note**
When you interconnect PVST and Rapid-PVST bridges, if the PVST bridge has a higher priority than the Rapid PVST bridge, then the Rapid PVST bridge transitions directly to the forwarding state, bypassing the intermediate transition states.

Like Per Vlan Spanning Tree (PVST+), Per Vlan Rapid Spanning Tree (PVRST+) instances are equal to the number of vlans configured on the switch and can go up to a maximum of 4094 instances.

For enabling information, see “Enabling Per-VLAN Rapid Spanning Tree” on page 20.

Default STP Configuration

Table 16-4 shows the default spanning tree configuration.

<table>
<thead>

**Note**

The spanning tree commands described in this chapter can be configured on any interface except those configured with the `no switchport` command.

### Enabling STP

**Note**

By default, spanning tree is enabled on all the VLANs.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Value</th>
</tr>
</thead>
</table>
| Spanning tree port cost (configurable on a per-interface basis—used on interfaces configured as Layer 2 access ports) | • 10-Gigabit Ethernet: 2  
• Gigabit Ethernet: 4  
• Fast Ethernet: 19 |
| Spanning tree VLAN port priority value (configurable on a per-VLAN basis—used on interfaces configured as Layer 2 trunk ports) | 128 |
| Spanning tree VLAN port cost (configurable on a per-VLAN basis—used on interfaces configured as Layer 2 trunk ports) | • 10-Gigabit Ethernet: 2  
• Gigabit Ethernet: 4  
• Fast Ethernet: 19 |
| Hello time | 2 sec |
| Forward delay time | 15 sec |
| Maximum aging time | 20 sec |
You can enable a spanning tree on a per-VLAN basis. The switch maintains a separate instance of spanning tree for each VLAN (except on VLANs on which you have disabled a spanning tree).

To enable a spanning tree on a per-VLAN basis, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# spanning-tree vlan vlan_ID</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch# show spanning-tree vlan vlan_ID</td>
</tr>
</tbody>
</table>

This example shows how to enable a spanning tree on VLAN 200:

Switch# configure terminal
Switch(config)# spanning-tree vlan 200
Switch(config)# end
Switch#

Note Because spanning tree is enabled by default, issuing a show running command to view the resulting configuration does not display the command you entered to enable spanning tree.

This example shows how to verify that spanning tree is enabled on VLAN 200:

Switch# show spanning-tree vlan 200

VLAN200 is executing the ieee compatible Spanning Tree protocol
Bridge Identifier has priority 32768, address 0050.3e8d.6401
Configured hello time 2, max age 20, forward delay 15
Current root has priority 16384, address 0060.704c.7000
Root port is 264 (FastEthernet5/8), cost of root path is 38
Topology change flag not set, detected flag not set
Number of topology changes 0 last change occurred 01:53:48 ago
Times:  hold 1, topology change 24, notification 2
        hello 2, max age 14, forward delay 10
        Timers: hello 0, topology change 0, notification 0

Port 264 (FastEthemet5/8) of VLAN200 is forwarding
Port path cost 19, Port priority 128, Port Identifier 128.9.
Designated root has priority 16384, address 0060.704c.7000
Designated bridge has priority 32768, address 00e0.4fac.b000
Designated port id is 128.2, designated path cost 19
Timers: message age 3, forward delay 0, hold 0
Number of transitions to forwarding state: 1
BPDU: sent 3, received 3417

Switch#

Enabling the Extended System ID

Note The extended system ID is enabled permanently on chassis that support 64 MAC addresses.
Use the `spanning-tree extend system-id` command to enable the extended system ID on chassis that support 1024 MAC addresses. See the “Understanding the Bridge ID” section on page 16-2.

To enable the extended system ID, perform this task:

```plaintext
Step 1
Switch(config)# spanning-tree extend system-id
Enables the extended system ID.
Disables the extended system ID.

Note
You cannot disable the extended system ID on chassis that support 64 MAC addresses or when you have configured extended range VLANs (see “Table 16-4 Spanning Tree Default Configuration Values” section on page 16-6).

Step 2
Switch(config)# end
Exits configuration mode.

Step 3
Switch# show spanning-tree vlan vlan_ID
Verifies the configuration.
```

This example shows how to enable the extended system ID:

```plaintext
Switch# configure terminal
Switch(config)# spanning-tree extend system-id
Switch(config)# end
Switch#
```

This example shows how to verify the configuration:

```plaintext
Switch# show spanning-tree summary | include extended
Extended system ID is enabled.
```

### Configuring the Root Bridge

A Catalyst 4000 family switch maintains an instance of spanning tree for each active VLAN configured on the switch. A bridge ID, consisting of the bridge priority and the bridge MAC address, is associated with each instance. For each VLAN, the switch with the lowest bridge ID becomes the root bridge for that VLAN. Whenever the bridge priority changes, the bridge ID also changes. This results in the recomputation of the root bridge for the VLAN.

To configure a switch to become the root bridge for the specified VLAN, use the `spanning-tree vlan vlan-ID root` command to modify the bridge priority from the default value (32,768) to a significantly lower value. The bridge priority for the specified VLAN is set to 8192 if this value causes the switch to become the root for the VLAN. If any bridge for the VLAN has a priority lower than 8192, the switch sets the priority to 1 less than the lowest bridge priority.

For example, assume that all the switches in the network have the bridge priority for VLAN 100 set to the default value of 32,768. Entering the `spanning-tree vlan 100 root primary` command on a switch sets the bridge priority for VLAN 100 to 8192, causing this switch to become the root bridge for VLAN 100.
Configure STP

Note

The root switch for each instance of spanning tree should be a backbone or distribution switch. Do not configure an access switch as the spanning tree primary root.

Use the **diameter** keyword to specify the Layer 2 network diameter (the maximum number of bridge hops between any two end stations in the network). When you specify the network diameter, a switch automatically picks an optimal hello time, forward delay time, and maximum age time for a network of that diameter. This behavior can significantly reduce the spanning tree convergence time.

Use the **hello-time** keyword to override the automatically calculated hello time.

Note

We recommend that you avoid manually configuring the hello time, forward delay time, and maximum age time after configuring the switch as the root bridge.

To configure a switch as the root switch, perform this task:

**Command**

**Step 1**

Switch(config)# [no] spanning-tree vlan **vlan_ID** root primary [diameter **hops** [hello-time **seconds**]]

Configures a switch as the root switch.

Purpose

Use the **no** keyword to restore the defaults.

**Step 2**

Switch(config)# end

Exits configuration mode.

This example shows how to configure a switch as the root bridge for VLAN 10, with a network diameter of 4:

Switch# configure terminal
Switch(config)# spanning-tree vlan 10 root primary diameter 4
Switch(config)# end
Switch#

This example shows how the configuration changes when a switch becomes a spanning tree root. This is the configuration before the switch becomes the root for VLAN 1:

Switch# show spanning-tree vlan 1

VLAN1 is executing the ieee compatible Spanning Tree protocol
Bridge Identifier has priority 32768, address 0030.94fc.0a00
Configured hello time 2, max age 20, forward delay 15
Current root has priority 32768, address 0001.6445.4400
Root port is 323 (FastEthernet6/3), cost of root path is 19
Topology change flag not set, detected flag not set
Number of topology changes 2 last change occurred 00:02:19 ago
from FastEthernet6/1
Times: hold 1, topology change 35, notification 2
  hello 2, max age 20, forward delay 15
Timers:hello 0, topology change 0, notification 0, aging 300

Port 323 (FastEthernet6/3) of VLAN1 is forwarding
Port path cost 19, Port priority 128, Port Identifier 129.67.
Designated root has priority 32768, address 0001.6445.4400
Designated bridge has priority 32768, address 0001.6445.4400
Designated port id is 129.67, designated path cost 0
Timers:message age 2, forward delay 0, hold 0
Number of transitions to forwarding state:1
BPDU:sent 3, received 91
Port 324 (FastEthernet6/4) of VLAN1 is blocking
Port path cost 19, Port priority 128, Port Identifier 129.68.
Designated root has priority 32768, address 0001.6445.4400
Designated bridge has priority 32768, address 0001.6445.4400
Designated port id is 129.68, designated path cost 0
Timers:message age 2, forward delay 0, hold 0
Number of transitions to forwarding state:0
BPDU: sent 1, received 89

Now, you can set the switch as the root:

Switch# configure terminal
Switch(config)# spanning-tree vlan 1 root primary
Switch(config)# spanning-tree vlan 1 root primary
VLAN 1 bridge priority set to 8192
VLAN 1 bridge max aging time unchanged at 20
VLAN 1 bridge hello time unchanged at 2
VLAN 1 bridge forward delay unchanged at 15
Switch(config)# end

This is the configuration after the switch becomes the root:

Switch# show spanning-tree vlan 1
VLAN1 is executing the ieee compatible Spanning Tree protocol
Bridge Identifier has priority 8192, address 0030.94fc.0a00
Configured hello time 2, max age 20, forward delay 15
We are the root of the spanning tree
Topology change flag set, detected flag set
Number of topology changes 3 last change occurred 00:00:09 ago
Times: hold 1, topology change 35, notification 2
hello 2, max age 20, forward delay 15
Timers: hello 0, topology change 25, notification 0, aging 15

Port 323 (FastEthernet6/3) of VLAN1 is forwarding
Port path cost 19, Port priority 128, Port Identifier 129.67.
Designated root has priority 8192, address 0030.94fc.0a00
Designated bridge has priority 8192, address 0030.94fc.0a00
Designated port id is 129.67, designated path cost 0
Timers:message age 0, forward delay 0, hold 0
Number of transitions to forwarding state:1
BPDU: sent 9, received 105

Port 324 (FastEthernet6/4) of VLAN1 is listening
Port path cost 19, Port priority 128, Port Identifier 129.68.
Designated root has priority 8192, address 0030.94fc.0a00
Designated bridge has priority 8192, address 0030.94fc.0a00
Designated port id is 129.68, designated path cost 0
Timers:message age 0, forward delay 5, hold 0
Number of transitions to forwarding state:0
BPDU: sent 6, received 102

Switch#

Note Because the bridge priority is now set at 8192, this switch becomes the root of the spanning tree.
Configuring a Secondary Root Switch

When you configure a switch as the secondary root, the spanning tree bridge priority is modified from the default value (32,768) to 16,384. This action means that the switch is likely to become the root bridge for the specified VLANs if the primary root bridge fails (assuming the other switches in the network use the default bridge priority of 32,768).

You can run this command on more than one switch to configure multiple backup root switches. Use the same network diameter and hello time values that you used when configuring the primary root switch.

**Note**  
We recommend that you avoid manually configuring the hello time, forward delay time, and maximum age time after configuring the switch as the root bridge.

To configure a switch as the secondary root switch, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>Switch(config)# [no] spanning-tree vlan vlan_ID root secondary [diameter hops [hello-time seconds]]</td>
<td>Configures a switch as the secondary root switch. Use the no keyword to restore the defaults.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td>Switch(config)# end</td>
<td>Exits configuration mode.</td>
</tr>
</tbody>
</table>

This example shows how to configure the switch as the secondary root switch for VLAN 10, with a network diameter of 4:

```bash
Switch# configure terminal
Switch(config)# spanning-tree vlan 10 root secondary diameter 4
VLAN 10 bridge priority set to 16384
VLAN 10 bridge max aging time set to 14
VLAN 10 bridge hello time unchanged at 2
VLAN 10 bridge forward delay set to 10
Switch(config)# end
Switch# sh spanning-tree vlan 1

VLAN0001

Switch#
```
Configuring STP Port Priority

In the event of a loop, a spanning tree considers port priority when selecting an interface to put into the forwarding state. You can assign higher priority values to interfaces that you want a spanning tree to select first and lower priority values to interfaces that you want a spanning tree to select last. If all interfaces have the same priority value, a spanning tree puts the interface with the lowest interface number in the forwarding state and blocks other interfaces. The possible priority range is 0 through 240, configurable in increments of 16 (the default is 128).

Note

The Cisco IOS software uses the port priority value when the interface is configured as an access port and uses VLAN port priority values when the interface is configured as a trunk port.

To configure the spanning tree port priority of an interface, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch(config)# interface {{(fastethernet</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config-if)# [no] spanning-tree port-priority port_priority Configures the port priority for an interface. The <em>port_priority</em> value can be from 0 to 240, in increments of 16. Use the <em>no</em> keyword to restore the defaults.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config-if)# [no] spanning-tree vlan vlan_ID port-priority port_priority Configures the VLAN port priority for an interface. The <em>port_priority</em> value can be from 0 to 240, in increments of 16. Use the <em>no</em> keyword to restore the defaults.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config-if)# end Exits configuration mode.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch# show spanning-tree interface {{(fastethernet</td>
</tr>
</tbody>
</table>

This example shows how to configure the spanning tree port priority of a Fast Ethernet interface:

Switch# configure terminal
Switch(config)# interface fastethernet 5/8
Switch(config-if)# spanning-tree port-priority 100
Switch(config-if)# end
Switch#

This example shows how to verify the configuration of a Fast Ethernet interface when it is configured as an access port:

Switch# show spanning-tree interface fastethernet 3/1

<table>
<thead>
<tr>
<th>Vlan</th>
<th>Role</th>
<th>Sts</th>
<th>Cost</th>
<th>Prio.Nbr</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>

Number of transitions to forwarding state:1
Link type is point-to-point by default
BPDU:sent 187, received 1

Port 129 (FastEthernet3/1) of VLAN1002 is forwarding
Port path cost 19, Port priority 128, Port Identifier 128.129.
Designated root has priority 32768, address 0003.6b10.ebe9
Designated bridge has priority 32768, address 0003.6b10.ebe9
Designated port id is 128.129, designated path cost 0
Timers:message age 0, forward delay 0, hold 0
Number of transitions to forwarding state:1
Link type is point-to-point by default
BPDU:sent 94, received 2

Port 129 (FastEthernet3/1) of VLAN1003 is forwarding
Port path cost 19, Port priority 128, Port Identifier 128.129.
Designated root has priority 32768, address 0003.6b10.ebea
Designated bridge has priority 32768, address 0003.6b10.ebea
Designated port id is 128.129, designated path cost 0
Timers:message age 0, forward delay 0, hold 0
Number of transitions to forwarding state:1
Link type is point-to-point by default
BPDU:sent 94, received 2

Port 129 (FastEthernet3/1) of VLAN1004 is forwarding
Port path cost 19, Port priority 128, Port Identifier 128.129.
Designated root has priority 32768, address 0003.6b10.ebeb
Designated bridge has priority 32768, address 0003.6b10.ebeb
Designated port id is 128.129, designated path cost 0
Timers:message age 0, forward delay 0, hold 0
Number of transitions to forwarding state:1
Link type is point-to-point by default
BPDU:sent 95, received 2

Port 129 (FastEthernet3/1) of VLAN1005 is forwarding
Port path cost 19, Port priority 128, Port Identifier 128.129.
Designated root has priority 32768, address 0003.6b10.ebec
Designated bridge has priority 32768, address 0003.6b10.ebec
Designated port id is 128.129, designated path cost 0
Timers:message age 0, forward delay 0, hold 0
Number of transitions to forwarding state:1
Link type is point-to-point by default
BPDU:sent 95, received 2

Switch#

Note
The `show spanning-tree port-priority` command displays only information for ports with an active link. If there is no port with an active link, enter a `show running-config interface` command to verify the configuration.
This example shows how to configure the spanning tree VLAN port priority of a Fast Ethernet interface:

```plaintext
Switch# configure terminal
Switch(config)# interface fastethernet 5/8
Switch(config-if)# spanning-tree vlan 200 port-priority 64
Switch(config-if)# end

Switch# show spanning-tree vlan 200
<...output truncated...>
Port 264 (FastEthernet5/8) of VLAN200 is forwarding
Port path cost 19, Port priority 64, Port Identifier 129.8.
  Designated root has priority 32768, address 0010.0d40.34c7
  Designated bridge has priority 32768, address 0010.0d40.34c7
  Designated port id is 128.1, designated path cost 0
  Timers: message age 2, forward delay 0, hold 0
  Number of transitions to forwarding state: 1
  BPDU: sent 0, received 13513
<...output truncated...>
Switch#
```

### Configuring STP Port Cost

The default value for spanning tree port path cost is derived from the interface media speed. In the event of a loop, spanning tree considers port cost when selecting an interface to put into the forwarding state. You can assign lower cost values to interfaces that you want spanning tree to select first, and higher cost values to interfaces that you want spanning tree to select last. If all interfaces have the same cost value, spanning tree puts the interface with the lowest interface number in the forwarding state and blocks other interfaces. The possible cost range is 1 through 200,000,000 (the default is media-specific).

Spanning tree uses the port cost value when the interface is configured as an access port and uses VLAN port cost values when the interface is configured as a trunk port.

To configure the spanning tree port cost of an interface, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch(config)# interface {{fastethernet</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config-if)# [no] spanning-tree cost port_cost</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config-if)# [no] spanning-tree vlan vlan_ID cost port_cost</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config-if)# end</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch# show spanning-tree interface {{fastethernet</td>
</tr>
</tbody>
</table>
This example shows how to change the spanning tree port cost of a Fast Ethernet interface:

Switch# configure terminal
Switch(config)# interface fastethernet 5/8
Switch(config-if)# spanning-tree cost 18
Switch(config-if)# end
Switch#

This example shows how to verify the configuration of the interface when it is configured as an access port:

Switch# show spanning-tree interface fastethernet 5/8
Port 264 (FastEthernet5/8) of VLAN200 is forwarding
Port path cost 18, Port priority 100, Port Identifier 129.8.
Designated root has priority 32768, address 0010.0d40.34c7
Designated bridge has priority 32768, address 0010.0d40.34c7
Designated port id is 128.1, designated path cost 0
Timers: message age 2, forward delay 0, hold 0
Number of transitions to forwarding state: 1
BPDU: sent 0, received 13513
Switch#

This example shows how to configure the spanning tree VLAN port cost of a Fast Ethernet interface:

Switch# configure terminal
Switch(config)# interface fastethernet 5/8
Switch(config-if)# spanning-tree vlan 200 cost 17
Switch(config-if)# end
Switch#

This example shows how to verify the configuration of VLAN 200 on the interface when it is configured as a trunk port:

Switch# show spanning-tree vlan 200
<...output truncated...>
Port 264 (FastEthernet5/8) of VLAN200 is forwarding
Port path cost 17, Port priority 64, Port Identifier 129.8.
Designated root has priority 32768, address 0010.0d40.34c7
Designated bridge has priority 32768, address 0010.0d40.34c7
Designated port id is 128.1, designated path cost 0
Timers: message age 2, forward delay 0, hold 0
Number of transitions to forwarding state: 1
BPDU: sent 0, received 13513
<...output truncated...>
Switch#

The show spanning-tree command displays only information for ports with an active link (green light is on). If there is no port with an active link, you can issue a show running-config command to confirm the configuration.

### Configuring the Bridge Priority of a VLAN

Exercise care when configuring the bridge priority of a VLAN. In most cases, we recommend that you enter the spanning-tree vlan vlan_ID root primary and the spanning-tree vlan vlan_ID root secondary commands to modify the bridge priority.
To configure the spanning tree bridge priority of a VLAN, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 Switch(config)# [no] spanning-tree vlan vlan_ID priority bridge_priority</td>
<td>Configures the bridge priority of a VLAN. The <code>bridge_priority</code> value can be from 1 to 65,534. Use the <code>no</code> keyword to restore the defaults.</td>
</tr>
<tr>
<td>Step 2 Switch(config)# end</td>
<td>Exits configuration mode.</td>
</tr>
<tr>
<td>Step 3 Switch# show spanning-tree vlan vlan_ID bridge [brief]</td>
<td>Verifies the configuration.</td>
</tr>
</tbody>
</table>

This example shows how to configure the bridge priority of VLAN 200 to 33,792:

```plaintext
Switch# configure terminal
Switch(config)# spanning-tree vlan 200 priority 33792
Switch(config)# end
```

This example shows how to verify the configuration:

```plaintext
Switch# show spanning-tree vlan 200 bridge brief
```

<table>
<thead>
<tr>
<th>Vlan</th>
<th>Bridge ID</th>
<th>Time</th>
<th>Age</th>
<th>Delay</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>VLAN200</td>
<td>33792 0050.3e8d.64c8</td>
<td>2</td>
<td>20</td>
<td>15</td>
<td>ieee</td>
</tr>
</tbody>
</table>

**Configuring the Hello Time**

- **Note**: Exercise care when configuring the hello time. In most cases, we recommend that you use the `spanning-tree vlan vlan_ID root primary` and the `spanning-tree vlan vlan_ID root secondary` commands to modify the hello time.

To configure the spanning tree hello time of a VLAN, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 Switch(config)# [no] spanning-tree vlan vlan_ID hello-time hello_time</td>
<td>Configures the hello time of a VLAN. The <code>hello_time</code> value can be from 1 to 10 seconds. Use the <code>no</code> keyword to restore the defaults.</td>
</tr>
<tr>
<td>Step 2 Switch(config)# end</td>
<td>Exits configuration mode.</td>
</tr>
<tr>
<td>Step 3 Switch# show spanning-tree vlan vlan_ID bridge [brief]</td>
<td>Verifies the configuration.</td>
</tr>
</tbody>
</table>

This example shows how to configure the hello time for VLAN 200 to 7 seconds:

```plaintext
Switch# configure terminal
Switch(config)# spanning-tree vlan 200 hello-time 7
Switch(config)# end
```
Chapter 16      Configuring STP and MST

Configuring STP

This example shows how to verify the configuration:

Switch# show spanning-tree vlan 200 bridge brief

<table>
<thead>
<tr>
<th>Vlan</th>
<th>Bridge ID</th>
<th>Hello</th>

Switch#

Configuring the Maximum Aging Time for a VLAN

*Note* Exercise care when configuring aging time. In most cases, we recommend that you use the `spanning-tree vlan vlan_ID root primary` and the `spanning-tree vlan vlan_ID root secondary` commands to modify the maximum aging time.

To configure the spanning tree maximum aging time for a VLAN, perform this task:

1. **Step 1**
   - **Switch(config)# [no] spanning-tree vlan vlan_ID max-age max_age**
   - Configures the maximum aging time of a VLAN. The `max_age` value can be from 6 to 40 seconds. Use the `no` keyword to restore the defaults.

2. **Step 2**
   - **Switch(config)# end**
   - Exits configuration mode.

3. **Step 3**
   - **Switch# show spanning-tree vlan vlan_ID bridge [brief]**
   - Verifies the configuration.

This example shows how to configure the maximum aging time for VLAN 200 to 36 seconds:

Switch# configure terminal
Switch(config)# spanning-tree vlan 200 max-age 36
Switch(config)# end
Switch#

This example shows how to verify the configuration:

Switch# show spanning-tree vlan 200 bridge brief

<table>
<thead>
<tr>
<th>Vlan</th>
<th>Bridge ID</th>
<th>Hello</th>
<th>Max</th>
<th>Fwd</th>
</tr>
</thead>
<tbody>
<tr>
<td>VLAN200</td>
<td>49152 0050.3e8d.64c8</td>
<td>2</td>
<td>36</td>
<td>15</td>
</tr>
</tbody>
</table>

Switch#

Configuring the Forward-Delay Time for a VLAN

*Note* Exercise care when configuring forward-delay time. In most cases, we recommend that you use the `spanning-tree vlan vlan_ID root primary` and the `spanning-tree vlan vlan_ID root secondary` commands to modify the forward delay time.
To configure the spanning tree forward delay time for a VLAN, perform this task:

**Command**

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# <code>no spanning-tree vlan vlan_ID</code> forward-time forward_time</td>
<td>Configures the forward time of a VLAN. The <code>forward_time</code> value can be from 4 to 30 seconds. Use the <code>no</code> keyword to restore the defaults.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 2</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# <code>end</code></td>
<td>Exits configuration mode.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 3</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# <code>show spanning-tree vlan vlan_ID bridge [brief]</code></td>
<td>Verifies the configuration.</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to configure the forward delay time for VLAN 200 to 21 seconds:

Switch# `configure terminal`
Switch(config)# `spanning-tree vlan 200 forward-time 21`
Switch(config)# `end`
Switch#

This example shows how to verify the configuration:

Switch# `show spanning-tree vlan 200 bridge brief`

<table>
<thead>
<tr>
<th>Vlan</th>
<th>Bridge ID</th>
<th>Hello Time</th>
<th>Max Age</th>
<th>Dly</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>VLAN200</td>
<td>49152 0050.3e8d.64c8</td>
<td>2</td>
<td>20</td>
<td>21</td>
<td>ieee</td>
</tr>
</tbody>
</table>

Switch#

This example shows how to display spanning tree information for the bridge:

Switch# `show spanning-tree bridge`

<table>
<thead>
<tr>
<th>Vlan</th>
<th>Bridge ID</th>
<th>Hello Time</th>
<th>Max Age</th>
<th>Dly</th>
<th>Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>VLAN200</td>
<td>49152 0050.3e8d.64c8</td>
<td>2</td>
<td>20</td>
<td>15</td>
<td>ieee</td>
</tr>
<tr>
<td>VLAN202</td>
<td>49152 0050.3e8d.64c9</td>

<td>15</td>
<td>ieee</td>
</tr>
<tr>
<td>VLAN206</td>
<td>49152 0050.3e8d.64cd</td>
<td>2</td>
<td>20</td>
<td>15</td>
<td>ieee</td>
</tr>
</tbody>
</table>

Switch#

**Disabling Spanning Tree Protocol**

To disable spanning tree on a per-VLAN basis, perform this task:

**Command**

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# <code>no spanning-tree vlan vlan_ID</code></td>
<td>Disables spanning tree on a per-VLAN basis.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 2</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# <code>end</code></td>
<td>Exits configuration mode.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Step 3</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# <code>show spanning-tree vlan vlan_ID</code></td>
<td>Verifies that spanning tree is disabled.</td>
<td></td>
</tr>
</tbody>
</table>
This example shows how to disable spanning tree on VLAN 200:

```
Switch# configure terminal
Switch(config)# no spanning-tree vlan 200
Switch(config)# end
Switch#
```

This example shows how to verify the configuration:

```
Switch# show spanning-tree vlan 200
Spanning tree instance for VLAN 200 does not exist.
Switch#
```

### Enabling Per-VLAN Rapid Spanning Tree

Per-VLAN Rapid Spanning Tree (PVRST+) uses the existing PVST+ framework for configuration purposes and for interaction with other features. It also supports some of the PVST+ extensions.

To configure PVRST+, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch(config)# [no] spantree mode rapid-pvst</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# interface interface/port</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config)# spanning-tree link-type point-to-point</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config-if)# exit</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch(config)# exit</td>
</tr>
<tr>
<td>Step 6</td>
<td>Switch(config-if)# clear spantree detected-protocols mod/port</td>
</tr>
<tr>
<td>Step 7</td>
<td>Switch# show spanning-tree summary totals</td>
</tr>
</tbody>
</table>

The following example shows how to configure Rapid-PVST+:

```
Switch# config t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# spanning-tree mode rapid-pvst
Switch(config)# int fa 6/4
Switch(config-if)# spanning-tree link-type point-to-point
Switch(config-if)# end
Switch(config)# end
Switch#
23:55:32:*SYS-5-CONFIG_I:Configured from console by console
Switch# clear spanning-tree detected-protocols
```

The following example shows how to verify the configuration:

```
Switch# show spanning-tree summary totals
Switch is in rapid-pvst mode
Root bridge for:VLAN0001
Extended system ID is disabled
Portfast Default is disabled
PortFast BPDGU Guard Default is disabled
Portfast BPDU filter Default is disabled
Loopguard Default is disabled
```
EtherChannel misconfig guard is enabled
UplinkFast is disabled
BackboneFast is disabled
Pathcost method used is short

<table>
<thead>
<tr>
<th>Name</th>
<th>Blocking</th>
<th>Listening</th>
<th>Learning</th>
<th>Forwarding</th>
<th>STP Active</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 vlan</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>2</td>
<td>2</td>
</tr>
</tbody>
</table>

Specifying the Link Type

Rapid connectivity is established only on point-to-point links. Spanning tree views a point-to-point link as a segment connecting only two switches running the spanning tree algorithm. Because the switch assumes that all full-duplex links are point-to-point links and that half-duplex links are shared links, you can avoid explicitly configuring the link type. To configure a specific link type, use the `spanning-tree linktype` command.

Restarting Protocol Migration

A switch running both MSTP and RSTP supports a built-in protocol migration process that enables the switch to interoperate with legacy 802.1D switches. If this switch receives a legacy 802.1D configuration BPDU (a BPDU with the protocol version set to 0), it sends only 802.1D BPDUs on that port. Furthermore, when an MSTP switch receives a legacy BPDU, it can also detect the following:

- that a port is at the boundary of a region
- an MST BPDU (version 3) associated with a different region, or
- an RST BPDU (version 2).

The switch, however, does not automatically revert to the MSTP mode if it no longer receives 802.1D BPDUs because it cannot determine whether or not the legacy switch has been removed from the link unless the legacy switch is the designated switch. A switch also might continue to assign a boundary role to a port when the switch to which it is connected has joined the region.

To restart the protocol migration process on the entire switch (that is, to force renegotiation with neighboring switches), use the `clear spanning-tree detected-protocols` commands in privileged EXEC mode. To restart the protocol migration process on a specific interface, enter the `clear spanning-tree detected-protocols interface` command in interface-id privileged EXEC mode.

Overview of MST

The following sections describe how MST works on a Catalyst 4000 family switch:

- IEEE 802.1s MST, page 16-22
- IEEE 802.1w RSTP, page 16-23
- MST-to-SST Interoperability, page 16-24
- Common Spanning Tree, page 16-25
- MST Instances, page 16-26
IEEE 802.1s MST

MST extends the IEEE 802.1w rapid spanning tree (RST) algorithm to multiple spanning trees. This extension provides both rapid convergence and load balancing in a VLAN environment. MST converges faster than Per VLAN Spanning Tree Plus (PVST+) and is backward compatible with 802.1D STP, 802.1w (Rapid Spanning Tree Protocol [RSTP]), and the Cisco PVST+ architecture.

MST allows you to build multiple spanning trees over trunks. You can group and associate VLANs to spanning tree instances. Each instance can have a topology independent of other spanning tree instances. This architecture provides multiple forwarding paths for data traffic and enables load balancing.

Network fault tolerance is improved because a failure in one instance (forwarding path) does not affect other instances.

In large networks, you can more easily administer the network and use redundant paths by locating different VLAN and spanning tree instance assignments in different parts of the network. A spanning tree instance can exist only on bridges that have compatible VLAN instance assignments. You must configure a set of bridges with the same MST configuration information, which allows them to participate in a specific set of spanning tree instances. Interconnected bridges that have the same MST configuration are referred to as an MST region.

MST uses the modified RSTP, MSTP. MST has the following characteristics:

- MST runs a variant of spanning tree called Internal Spanning Tree (IST). IST augments Common Spanning Tree (CST) information with internal information about the MST region. The MST region appears as a single bridge to adjacent single spanning tree (SST) and MST regions.

- A bridge running MST provides interoperability with SST bridges as follows:
  - MST bridges run IST, which augments CST information with internal information about the MST region.
  - IST connects all the MST bridges in the region and appears as a subtree in the CST that includes the whole bridged domain. The MST region appears as a virtual bridge to adjacent SST bridges and MST regions.
  - The Common and Internal Spanning Tree (CIST) is the collection of the following: ISTs in each MST region, the CST that interconnects the MST regions, and the SST bridges. CIST is identical to an IST inside an MST region and identical to a CST outside an MST region. The STP, RSTP, and MSTP together elect a single bridge as the root of the CIST.

- MST establishes and maintains additional spanning trees within each MST region. These spanning trees are termed MST instances (MSTIs). The IST is numbered 0, and the MSTIs are numbered 1, 2, 3, and so on. Any MSTI is local to the MST region and is independent of MSTIs in another region, even if the MST regions are interconnected.

MST instances combine with the IST at the boundary of MST regions to become the CST as follows:

- Spanning tree information for an MSTI is contained in an MSTP record (M-record).
  - M-records are always encapsulated within MST bridge protocol data units (BPDUs). The original spanning trees computed by MSTP are called M-trees, which are active only within the MST region. M-trees merge with the IST at the boundary of the MST region and form the CST.
MST provides interoperability with PVST+ by generating PVST+ BPDUs for the non-CST VLANs.

MST supports some of the PVST+ extensions in MSTP as follows:

- UplinkFast and BackboneFast are not available in MST mode; they are part of RSTP.
- PortFast is supported.
- BPDU filter and BPDU guard are supported in MST mode.
- Loop guard and root guard are supported in MST. MST preserves the VLAN 1 disabled functionality except that BPDUs are still transmitted in VLAN 1.
- MST switches operate as if MAC reduction is enabled.
- For private VLANs (PVLANs), you must map a secondary VLAN to the same instance as the primary.

### IEEE 802.1w RSTP

RSTP, specified in 802.1w, supersedes STP specified in 802.1D, but remains compatible with STP. You configure RSTP when you configure the MST feature. For more information, see the “Configuring MST” section on page 16-29.

RSTP provides the structure on which the MST operates, significantly reducing the time to reconfigure the active topology of a network when its physical topology or configuration parameters change. RSTP selects one switch as the root of a spanning-tree-connected active topology and assigns port roles to individual ports of the switch, depending on whether that port is part of the active topology.

RSTP provides rapid connectivity following the failure of a switch, switch port, or a LAN. A new root port and the designated port on the other side of the bridge transition to the forwarding state through an explicit handshake between them. RSTP allows switch port configuration so the ports can transition to forwarding directly when the switch reinitializes.

RSTP provides backward compatibility with 802.1D bridges as follows:

- RSTP selectively sends 802.1D-configured BPDUs and Topology Change Notification (TCN) BPDUs on a per-port basis.
- When a port initializes, the migration delay timer starts and RSTP BPDUs are transmitted. While the migration delay timer is active, the bridge processes all BPDUs received on that port.
- If the bridge receives an 802.1D BPDU after a port’s migration delay timer expires, the bridge assumes it is connected to an 802.1D bridge and starts using only 802.1D BPDUs.
- When RSTP uses 802.1D BPDUs on a port and receives an RSTP BPDU after the migration delay expires, RSTP restarts the migration delay timer and begins using RSTP BPDUs on that port.

### RSTP Port Roles

In RSTP, the port roles are defined as follows:

- **Root**—A forwarding port elected for the spanning tree topology.
- **Designated**—A forwarding port elected for every switched LAN segment.
- **Alternate**—An alternate path to the root bridge to that provided by the current root port.
- **Backup**—A backup for the path provided by a designated port toward the leaves of the spanning tree. Backup ports can exist only where two ports are connected together in a loopback mode or bridge with two or more connections to a shared LAN segment.
Overview of MST

- Disabled—A port that has no role within the operation of spanning tree.

The system assigns port roles as follows:
- A root port or designated port role includes the port in the active topology.
- An alternate port or backup port role excludes the port from the active topology.

RSTP Port States

The port state controls the forwarding and learning processes and provides the values of discarding, learning, and forwarding. Table 16-5 shows the STP port states and RSTP port states.

<table>
<thead>
<tr>
<th>Operational Status</th>
<th>STP Port State</th>
<th>RSTP Port State</th>
<th>Port Included in Active Topology</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enabled</td>
<td>Blocking(^1)</td>
<td>Discarding(^2)</td>
<td>No</td>
</tr>
<tr>
<td>Enabled</td>
<td>Listening</td>
<td>Discarding</td>
<td>No</td>
</tr>
<tr>
<td>Enabled</td>
<td>Learning</td>
<td>Learning</td>
<td>Yes</td>
</tr>
<tr>
<td>Enabled</td>
<td>Forwarding</td>
<td>Forwarding</td>
<td>Yes</td>
</tr>
<tr>
<td>Disabled</td>
<td>Disabled</td>
<td>Discarding</td>
<td>No</td>
</tr>
</tbody>
</table>

1. IEEE 802.1D port state designation.
2. IEEE 802.1w port state designation. Discarding is the same as blocking in MST.

In a stable topology, RSTP ensures that every root port and designated port transitions to the forwarding state while all alternate ports and backup ports are always in the discarding state.

MST-to-SST Interoperability

A virtual bridged LAN may contain interconnected regions of SST and MST bridges. Figure 16-2 shows this relationship.
To STP running in the SST region, an MST region appears as a single SST or pseudobridge, which operates as follows:

- Although the values for root identifiers and root path costs match for all BPDUs in all pseudobridges, a pseudobridge differs from a single SST bridge as follows:
  - The pseudobridge BPDUs have different bridge identifiers. This difference does not affect STP operation in the neighboring SST regions because the root identifier and root cost are the same.
  - BPDUs sent from the pseudobridge ports may have significantly different message ages. Because the message age increases by one second for each hop, the difference in the message age is measured in seconds.
- Data traffic from one port of a pseudobridge (a port at the edge of a region) to another port follows a path entirely contained within the pseudobridge or MST region. Data traffic belonging to different VLANs might follow different paths within the MST regions established by MST.
- The system prevents looping by doing either of the following:
  - Blocking the appropriate pseudobridge ports by allowing one forwarding port on the boundary and blocking all other ports.
  - Setting the CST partitions to block the ports of the SST regions.

Common Spanning Tree

CST (802.1Q) is a single spanning tree for all the VLANs. In a Catalyst 4500 series switch running PVST+, the VLAN 1 spanning tree corresponds to CST. In a Catalyst 4500 series switch running MST, IST (instance 0) corresponds to CST.
MST Instances

We support 65 instances including instance 0. Each spanning tree instance is identified by an instance ID that ranges from 0 to 4094. Instance 0 is mandatory and is always present. Rest of the instances are optional.

MST Configuration Parameters

MST configuration has three parts, as follows:

- **Name**—A 32-character string (null padded) that identifies the MST region.
- **Revision number**—An unsigned 16-bit number that identifies the revision of the current MST configuration.

**Note** You must set the revision number when required as part of the MST configuration. The revision number is not incremented automatically each time you commit the MST configuration.

- **MST configuration table**—An array of 4096 bytes. Each byte, interpreted as an unsigned integer, corresponds to a VLAN. The value is the instance number to which the VLAN is mapped. The first byte that corresponds to VLAN 0 and the 4096th byte that corresponds to VLAN 4095 are unused and always set to zero.

You must configure each byte manually. Use SNMP or the CLI to perform the configuration.

MST BPDU contains the MST configuration ID and the checksum. An MST bridge accepts an MST BPDU only if the MST BPDU configuration ID and the checksum match its own MST region configuration ID and checksum. If either value is different, the MST BPDU is considered to be an SST BPDU.

MST Regions

These sections describe MST regions:

- **MST Region Overview, page 16-26**
- **Boundary Ports, page 16-27**
- **IST Master, page 16-27**
- **Edge Ports, page 16-27**
- **Link Type, page 16-28**

MST Region Overview

Interconnected bridges that have the same MST configuration are referred to as an MST region. There is no limit on the number of MST regions in the network.

To form an MST region, bridges can be either of the following:

- An MST bridge that is the only member of the MST region.
• An MST bridge interconnected by a LAN. A LAN’s designated bridge has the same MST configuration as an MST bridge. All the bridges on the LAN can process MST BPDUs.

If you connect two MST regions with different MST configurations, the MST regions do the following:
• Load balance across redundant paths in the network. If two MST regions are redundantly connected, all traffic flows on a single connection with the MST regions in a network.
• Provide an RSTP handshake to enable rapid connectivity between regions. However, the handshaking is not as fast as between two bridges. To prevent loops, all the bridges inside the region must agree upon the connections to other regions. This situation introduces a delay. We do not recommend partitioning the network into a large number of regions.

**Boundary Ports**

A boundary port is a port that connects to a LAN, the designated bridge of which is either an SST bridge or a bridge with a different MST configuration. A designated port knows that it is on the boundary if it detects an STP bridge or receives an agreement message from an RST or MST bridge with a different configuration.

At the boundary, the role of MST ports do not matter; their state is forced to be the same as the IST port state. If the boundary flag is set for the port, the MSTP Port Role selection mechanism assigns a port role to the boundary and the same state as that of the IST port. The IST port at the boundary can take up any port role except a backup port role.

**IST Master**

The IST master of an MST region is the bridge with the lowest bridge identifier and the least path cost to the CST root. If an MST bridge is the root bridge for CST, then it is the IST master of that MST region. If the CST root is outside the MST region, then one of the MST bridges at the boundary is selected as the IST master. Other bridges on the boundary that belong to the same region eventually block the boundary ports that lead to the root.

If two or more bridges at the boundary of a region have an identical path to the root, you can set a slightly lower bridge priority to make a specific bridge the IST master.

The root path cost and message age inside a region stay constant, but the IST path cost is incremented and the IST remaining hops are decremented at each hop. Enter the `show spanning-tree mst` command to display the information about the IST master, path cost, and remaining hops for the bridge.

**Edge Ports**

A port that is connected to a nonbridging device (for example, a host or a switch) is an edge port. A port that connects to a hub is also an edge port if the hub or any LAN that is connected to it does not have a bridge. An edge port can start forwarding as soon as the link is up.

MST requires that you configure each port connected to a host. To establish rapid connectivity after a failure, you need to block the non-edge designated ports of an intermediate bridge. If the port connects to another bridge that can send back an agreement, then the port starts forwarding immediately. Otherwise, the port needs twice the forward delay time to start forwarding again. You must explicitly configure the ports that are connected to the hosts and switches as edge ports while using MST.

To prevent a misconfiguration, the PortFast operation is turned off if the port receives a BPDU. You can display the configured and operational status of PortFast by using the `show spanning-tree mst interface` command.
Chapter 16     Configuring STP and MST

Overview of MST

Rapid connectivity is established only on point-to-point links. You must configure ports explicitly to a host or switch. However, cabling in most networks meets this requirement, and you can avoid explicit configuration by treating all full-duplex links as point-to-point links by entering the spanning-tree linktype command.

Message Age and Hop Count

IST and MST instances do not use the message age and maximum age timer settings in the BPDU. IST and MST use a separate hop count mechanism that is very similar to the IP time-to-live (TTL) mechanism. You can configure each MST bridge with a maximum hop count. The root bridge of the instance sends a BPDU (or M-record) with the remaining hop count that is equal to the maximum hop count. When a bridge receives a BPDU (or M-record), it decrements the received remaining hop count by one. The bridge discards the BPDU (M-record) and ages out the information held for the port if the count reaches zero after decrementing. The nonroot bridges propagate the decremented count as the remaining hop count in the BPDU (M-records) they generate.

The message age and maximum age timer settings in the RST portion of the BPDU remain the same throughout the region, and the same values are propagated by the region’s designated ports at the boundary.

MST-to-PVST+ Interoperability

Keep these guidelines in mind when you configure MST switches (in the same region) to interact with PVST+ switches:

- Configure the root for all VLANs inside the MST region as shown in this example:

  Switch# show spanning-tree mst interface gigabitethernet 1/1

  GigabitEthernet1/1 of MST00 is root forwarding
  Edge port: no (trunk)  port guard : none (default)
  Link type: point-to-point (auto)  bpdu filter: disable (default)
  Boundary : boundary (PVST)  bpdu guard : disable (default)
  Bpdu's sent 10, received 310
  Instance Role Sts Cost  Prio.Nbr Vlans mapped
  -------- ---- --- --------- -------- -------------------------------
  0  Root FWD 20000 128.1 1-2,4-2999,4000-4094
  3  Boun FWD 20000 128.1 3,3000-3999

  The ports that belong to the MST switch at the boundary simulate PVST+ and send PVST+ BPDU for all the VLANs.

  If you enable loop guard on the PVST+ switches, the ports might change to a loop-inconsistent state when the MST switches change their configuration. To correct the loop-inconsistent state, you must disable and renewable loop guard on that PVST+ switch.

  - Do not locate the root for some or all of the VLANs inside the PVST+ side of the MST switch because when the MST switch at the boundary receives PVST+ BPDU for all or some of the VLANs on its designated ports, root guard sets the port to the blocking state.
When you connect a PVST+ switch to two different MST regions, the topology change from the PVST+ switch does not pass beyond the first MST region. In such a case, the topology changes are propagated only in the instance to which the VLAN is mapped. The topology change stays local to the first MST region, and the Cisco Access Manager (CAM) entries in the other region are not flushed. To make the topology change visible throughout other MST regions, you can map that VLAN to IST or connect the PVST+ switch to the two regions through access links.

### MST Configuration Restrictions and Guidelines

Follow these restrictions and guidelines to avoid configuration problems:

- Do not disable spanning tree on any VLAN in any of the PVST bridges.
- Do no use PVST bridges as the root of CST.
- Do not connect switches with access links, because access links may partition a VLAN.
- Ensure that all PVST root bridges have lower (numerically higher) priority than the CST root bridge.
- Ensure that trunks carry all of the VLANs mapped to an instance or do not carry any VLANs at all for this instance.
- Complete any MST configuration that incorporates a large number of either existing or new logical VLAN ports during a maintenance window because the complete MST database gets reinitialized for any incremental change (such as adding new VLANs to instances or moving VLANs across instances).

### Configuring MST

The following sections describe how to configure MST:

- **Enabling MST**, page 16-29
- **Configuring MST Instance Parameters**, page 16-31
- **Configuring MST Instance Port Parameters**, page 16-32
- **Restarting Protocol Migration**, page 16-33
- **Displaying MST Configurations**, page 16-33

### Enabling MST

To enable and configure MST on a Catalyst 4500, perform this task:

<table>
<thead>
<tr>
<th>Step</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch(config)# spanning-tree mode mst</td>
<td>Enters MST mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# spanning-tree mst configuration</td>
<td>Enters MST configuration submode. Use the <code>no</code> keyword to clear the MST configuration.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config-mst)# show current</td>
<td>Displays the current MST configuration.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config-mst)# name name</td>
<td>Sets the MST region name.</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch(config-mst)# revision revision_number</td>
<td>Sets the MST configuration revision number.</td>
</tr>
</tbody>
</table>
### Chapter 16 Configuring STP and MST

#### Configuring MST

This example shows how to enable MST:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# spanning-tree mode mst
```

```
Switch(config)# spanning-tree mst configuration
```

```
Switch(config-mst)# instance instance_number vlan vlan_range
Maps the VLANs to an MST instance.
If you do not specify the `vlan` keyword, use the `no` keyword to unmap all the VLANs that were mapped to an MST instance.
If you specify the `vlan` keyword, use the `no` keyword to unmap a specified VLAN from an MST instance.
```

```
Switch(config-mst)# show pending
Displays the new MST configuration to be applied.
```

```
Switch(config-mst)# end
Applies the configuration and exit MST configuration submode.
```

```
Switch# show spanning-tree mst configuration
Displays the current MST configuration.
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 6</td>
<td><code>Switch(config-mst)# instance instance_number vlan vlan_range</code></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>Step 7</td>
<td><code>Switch(config-mst)# show pending</code></td>
</tr>
<tr>
<td>Step 8</td>
<td><code>Switch(config-mst)# end</code></td>
</tr>
<tr>
<td>Step 9</td>
<td><code>Switch# show spanning-tree mst configuration</code></td>
</tr>
</tbody>
</table>

This example shows how to enable MST:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# spanning-tree mode mst
```

```
Switch(config)# spanning-tree mst configuration
```

```
Switch(config-mst)# instance instance_number vlan vlan_range
Maps the VLANs to an MST instance.
If you do not specify the `vlan` keyword, use the `no` keyword to unmap all the VLANs that were mapped to an MST instance.
If you specify the `vlan` keyword, use the `no` keyword to unmap a specified VLAN from an MST instance.
```

```
Switch(config-mst)# show pending
Displays the new MST configuration to be applied.
```

```
Switch(config-mst)# end
Applies the configuration and exit MST configuration submode.
```

```
Switch# show spanning-tree mst configuration
Displays the current MST configuration.
```

<table>

Switch#
Restarting Protocol Migration

RSTP and MST have built-in compatibility mechanisms that allow them to interact properly with other regions or other versions of IEEE spanning-tree. For example, an RSTP bridge connected to a legacy bridge can send 802.1D BPDUs on one of its ports. Similarly, when an MST bridge receives a legacy BPDU or an MST BPDU associated with a different region, it is also to detect that a port is at the boundary of a region.

Unfortunately, these mechanisms cannot always revert to the most efficient mode. For example, an RSTP bridge designated for a legacy 802.1D stays in 802.1D mode even after the legacy bridge has been removed from the link. Similarly, an MST port still assumes that it is a boundary port when the bridge(s) to which it is connected have joined the same region. To force a Catalyst 4500 series switch to renegotiate with the neighbors (that is, to restart protocol migration), you must enter the `clear spanning-tree detected-protocols` command, as follows:

```
Switch# clear spanning-tree detected-protocols fastethernet 4/4
Switch#
```

Displaying MST Configurations

To display MST configurations, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><code>Switch# show spanning-tree mst configuration</code></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><code>Switch# show spanning-tree mst [detail]</code></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><code>Switch# show spanning-tree mst instance-id [detail]</code></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><code>Switch# show spanning-tree mst interface interface [detail]</code></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><code>Switch# show spanning-tree mst instance-id interface interface [detail]</code></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td><code>Switch# show spanning-tree vlan vlan_ID</code></td>
</tr>
</tbody>
</table>

The following examples show how to display spanning tree VLAN configurations in MST mode:

```

Configuring Optional STP Features

This chapter describes the Spanning Tree Protocol (STP) features supported on the Catalyst 4500 series switch. It also provides guidelines, procedures, and configuration examples.

This chapter includes the following major sections:

- About Root Guard, page 18-2
- Enabling Root Guard, page 18-2
- About Loop Guard, page 18-3
- Enabling Loop Guard, page 18-5
- About EtherChannel Guard, page 18-6
- Enabling EtherChannel Guard (Optional), page 18-6
- About PortFast, page 18-7
- Enabling PortFast, page 18-7
- About BPDU Guard, page 18-8
- Enabling BackboneFast, page 18-16
- About PortFast BPDU Filtering, page 18-9
- Enabling BackboneFast, page 18-16
- About UplinkFast, page 18-11
- Enabling UplinkFast, page 18-12
- About BackboneFast, page 18-14
- Enabling BackboneFast, page 18-16

For information on configuring STP, see Chapter 16, “Configuring STP and MST.”
About Root Guard

Spanning Tree root guard forces an interface to become a designated port, to protect the current root status and prevent surrounding switches from becoming the root switch.

When you enable root guard on a per-port basis, it is automatically applied to all of the active VLANs to which that port belongs. When you disable root guard, it is disabled for the specified port and the port automatically goes into the listening state.

When a switch that has ports with root guard enabled detects a new root, the ports goes into root-inconsistent state. Then, when the switch no longer detects a new root, its ports automatically go into the listening state.

Enabling Root Guard

To enable root guard on a Layer 2 access port (to force it to become a designated port), perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch(config)# interface {{fastethernet</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config-if)# [no] spanning-tree guard root Enables root guard. Use the no keyword to disable Root Guard.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config-if)# end Exits configuration mode.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch# show spanning-tree Verifies the configuration.</td>
</tr>
</tbody>
</table>

This example shows how to enable root guard on Fast Ethernet interface 5/8:

Switch(config)# interface fastethernet 5/8
Switch(config-if)# spanning-tree guard root
Switch(config-if)# end
Switch#

This example shows how to verify the configuration:

Switch# show running-config interface fastethernet 5/8
Building configuration...
Current configuration: 67 bytes
!
interface FastEthernet5/8
   switchport mode access
   spanning-tree guard root
end

Switch#

This example shows how to determine whether any ports are in root inconsistent state:

Switch# show spanning-tree inconsistentports

<table>
<thead>
<tr>
<th>Name</th>
<th>Interface</th>
<th>Inconsistency</th>
</tr>
</thead>
<tbody>
<tr>
<td>VLAN0001</td>
<td>FastEthernet3/1</td>

<td>Root Inconsistent</td>
</tr>
<tr>
<td>VLAN1005</td>
<td>FastEthernet3/1</td>
<td>Root Inconsistent</td>
</tr>
<tr>
<td>VLAN1005</td>
<td>FastEthernet3/2</td>
<td>Root Inconsistent</td>
</tr>
</tbody>
</table>

Number of inconsistent ports (segments) in the system :10

### About Loop Guard

Loop guard helps prevent bridging loops that could occur because of a unidirectional link failure on a point-to-point link. When enabled globally, loop guard applies to all point-to-point ports on the system. Loop guard detects root ports and blocked ports and ensures that they keep receiving BPDUs from their designated port on the segment. If a loop-guard-enabled root or blocked port stop receiving BPDUs from its designated port, it transitions to the blocking state, assuming there is a physical link error on this port. The port recovers from this state as soon as it receives a BPDU.

You can enable loop guard on a per-port basis. When you enable loop guard, it is automatically applied to all of the active instances or VLANs to which that port belongs. When you disable loop guard, it is disabled for the specified ports. Disabling loop guard moves all loop-inconsistent ports to the listening state.

If you enable loop guard on a channel and the first link becomes unidirectional, loop guard blocks the entire channel until the affected port is removed from the channel. Figure 18-1 shows loop guard in a triangular switch configuration.
About Loop Guard

Figure 18-1  Triangular Switch Configuration with Loop Guard

- Switches A and B are distribution switches.
- Switch C is an access switch.
- Loop guard is enabled on ports 3/1 and 3/2 on Switches A, B, and C.

Enabling loop guard on a root switch has no effect but provides protection when a root switch becomes a nonroot switch.

Follow these guidelines when using loop guard:
- Do not enable loop guard on PortFast-enabled or dynamic VLAN ports.
- Do not enable loop guard if root guard is enabled.

Loop guard interacts with other features as follows:
- Loop guard does not affect the functionality of UplinkFast or BackboneFast.
- Enabling loop guard on ports that are not connected to a point-to-point link does not work.
- Root guard forces a port to always be the root port. Loop guard is effective only if the port is a root port or an alternate port. You cannot enable loop guard and root guard on a port at the same time.
- Loop guard uses the ports known to spanning tree. Loop guard can take advantage of logical ports provided by the Port Aggregation Protocol (PAgP). However, to form a channel, all the physical ports grouped in the channel must have compatible configurations. PAgP enforces uniform configurations of root guard or loop guard on all the physical ports to form a channel.

These caveats apply to loop guard:
- Spanning tree always chooses the first operational port in the channel to send the BPDUs. If that link becomes unidirectional, loop guard blocks the channel, even if other links in the channel are functioning properly.
- If a set of ports that are already blocked by loop guard are grouped together to form a channel, spanning tree loses all the state information for those ports and the new channel port may obtain the forwarding state with a designated role.
Enabling Loop Guard

You can enable loop guard globally or per port.

To enable loop guard globally on the switch, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch(config)# spanning-tree loopguard default</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch# show spanning tree interface 4/4 detail</td>
</tr>
</tbody>
</table>

This example shows how to enable loop guard globally:

Switch(config)# spanning-tree loopguard default
Switch(config)# Ctrl-Z

This example shows how to verify the previous configuration of port 4/4:

Switch# show spanning-tree interface fastethernet 4/4 detail
Port 196 (FastEthernet4/4) of VLAN0010 is forwarding
Port path cost 1000, Port priority 160, Port Identifier 160.196.
Designated root has priority 32768, address 00d0.00b8.140a
Designated bridge has priority 32768, address 00d0.00b8.140a
Designated port id is 160.196, designated path cost 0
Timers:message age 0, forward delay 0, hold 0
Number of transitions to forwarding state:1
The port is in the portfast mode by portfast trunk configuration
Link type is point-to-point by default
Bpdu filter is enabled
Loop guard is enabled by default on the port
BPDU: sent 0, received 0

To enable loop guard on an interface, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch(config)# interface (type slot/port)</td>
</tr>
<tr>
<td></td>
<td>(port-channel port_channel_number)</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config-if)# spanning-tree guard loop</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch# show spanning tree interface 4/4 detail</td>
</tr>
</tbody>
</table>
Chapter 18      Configuring Optional STP Features

About EtherChannel Guard

EtherChannel guard allows you to detect an EtherChannel misconfiguration between the switch and a connected device. A misconfiguration can occur if the interfaces of a switch are manually configured in an EtherChannel, and one or more interfaces on the other device are not. For EtherChannel configuration guidelines, see the “EtherChannel Configuration Guidelines and Restrictions” section on page 19-5.

Note

EtherChannel guard applies only to EtherChannels in forced mode (that is, “manually configured”) rather than through PAgP or LACP.

If the switch detects a misconfiguration on the other device, EtherChannel guard error-disables all interfaces in the EtherChannel bundle, and displays an error message.

You can enable this feature with the `spanning-tree etherchannel guard misconfig` global configuration command.

Enabling EtherChannel Guard (Optional)

You can enable EtherChannel guard to detect an EtherChannel misconfiguration if your switch is running PVST+, rapid PVST+, or MSTP.

To enable EtherChannel guard, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 Switch(config)# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 2 Switch(config)# spanning-tree</td>
<td>Enables EtherChannel guard.</td>
</tr>
<tr>
<td>etherchannel guard misconfig</td>
<td></td>
</tr>
<tr>
<td>Step 3 Switch(config)# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
</tbody>
</table>
To disable the EtherChannel guard feature, use the `no spanning-tree etherchannel guard misconfig` global configuration command.

Use the `show interfaces status err-disabled` privileged EXEC command to show which switch ports are disabled because of an EtherChannel misconfiguration. On the remote device, you can enter the `show etherchannel summary` privileged EXEC command to verify the EtherChannel configuration.

After the configuration is corrected, enter the `shutdown` and `no shutdown` interface configuration commands on the port-channel interfaces that were misconfigured.

### About PortFast

Spanning Tree PortFast causes an interface configured as a Layer 2 access port to enter the forwarding state immediately, bypassing the listening and learning states. Use PortFast on Layer 2 access ports connected to a single workstation or server to allow those devices to connect to the network immediately, rather than waiting for spanning tree to converge. Even if the interface receives a bridge protocol data unit (BPDU), spanning tree does not place the port into the blocking state. Instead, it sets the port’s operating state to `non-port fast` even if the configured state remains `port fast` and starts participating in the topology change.

**Note**  
Because the purpose of PortFast is to minimize the time that access ports must wait for spanning tree to converge, it is most effective when used on access ports. If you enable PortFast on a port connecting to another switch, you risk creating a spanning tree loop.

### Enabling PortFast

**Caution**  
Use PortFast only when connecting a single end station to a Layer 2 access port. Otherwise, you might create a network loop.

To enable PortFast on a Layer 2 access port to force it to enter the forwarding state immediately, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**

Chapter 18      Configuring Optional STP Features

About BPDU Guard

Spanning Tree BPDU guard shuts down PortFast-configured interfaces that receive BPDUs, rather than putting them into the spanning tree blocking state. In a valid configuration, PortFast-configured interfaces do not receive BPDUs. Reception of a BPU by a PortFast-configured interface signals an invalid configuration, such as connection of an unauthorized device. BPDU guard provides a secure response to invalid configurations, because the administrator must manually put the interface back in service.

Note

When the BPDU guard feature is enabled, spanning tree applies the BPDU guard feature to all PortFast-configured interfaces.

To prevent the port from shutting down, use errdisable detect cause bpdu-guard shutdown vlan global configuration command to shut down just the offending VLAN on the port where the violation occurred.
Enabling BPDU Guard

To enable BPDU guard to shut down PortFast-configured interfaces that receive BPDUs, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>Switch(config)# [no] spanning-tree portfast bpduguard</strong></td>
</tr>
<tr>
<td></td>
<td>Enables BPDU guard on all the switch’s PortFast-configured interfaces.</td>
</tr>
<tr>
<td></td>
<td>Use the no keyword to disable BPDU guard.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><strong>Switch(config)# end</strong></td>
</tr>
<tr>
<td></td>
<td>Exits configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><strong>Switch# show spanning-tree summary totals</strong></td>
</tr>
<tr>
<td></td>
<td>Verifies the BPDU configuration.</td>
</tr>
</tbody>
</table>

This example shows how to enable BPDU guard:

```
Switch(config)# spanning-tree portfast bpduguard
Switch(config)# end
Switch#
```

This example shows how to verify the BPDU configuration:

```
Switch# show spanning-tree summary totals
```

Root bridge for: none.
PortFast BPDU Guard is enabled
Etherchannel misconfiguration guard is enabled
UplinkFast is disabled
BackboneFast is disabled
Default pathcost method used is short

</table>

Switch#

About PortFast BPDU Filtering

Cisco IOS Release 12.2(25)EW and later support PortFast BPDU filtering, which allows the administrator to prevent the system from sending or even receiving BPDUs on specified ports.

When configured globally, PortFast BPDU filtering applies to all operational PortFast ports. Ports in an operational PortFast state should be connected to hosts that typically drop BPDUs. If an operational PortFast port receives a BPU, it immediately loses its operational PortFast status. In that case, PortFast BPDU filtering is disabled on this port and STP resumes sending BPDUs on this port.

PortFast BPDU filtering can also be configured on a per-port basis. When PortFast BPDU filtering is explicitly configured on a port, it does not send any BPDUs and drops all BPDUs it receives.

⚠️ Caution

Explicitly configuring PortFast BPDU filtering on a port that is not connected to a host can result in bridging loops, because the port ignores any BPDU it receives and goes to the forwarding state.
When you enable PortFast BPDU filtering globally and set the port configuration as the default for PortFast BPDU filtering (see the “Enabling BackboneFast” section on page 18-16), PortFast enables or disables PortFast BPDU filtering.

If the port configuration is not set to default, then the PortFast configuration does not affect PortFast BPDU filtering. Table 18-1 lists all the possible PortFast BPDU filtering combinations. PortFast BPDU filtering allows access ports to move directly to the forwarding state as soon as the end hosts are connected.

Table 18-1 PortFast BPDU Filtering Port Configurations

<table>
<thead>
<tr>
<th>Per-Port Configuration</th>
<th>Global Configuration</th>

</tr>
</tbody>
</table>

1. The port transmits at least 10 BPDUs. If this port receives any BPDUs, then PortFast and PortFast BPDU filtering are disabled.

Enabling PortFast BPDU Filtering

To enable PortFast BPDU filtering globally, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch(config)# spanning-tree portfast bpdufilter default</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch# show spanning-tree summary totals</td>
</tr>
</tbody>
</table>

This example shows how to enable PortFast BPDU filtering on a port:

Switch(config)# spanning-tree portfast bpdufilter default
Switch(config)# Ctrl-Z

This example shows how to verify the BPDU configuration in PVST+ mode:

Switch# show spanning-tree summary totals
Root bridge for:VLAN0010
EtherChannel misconfiguration guard is enabled
Extended system ID is disabled
Portfast is enabled by default
PortFast BPDU Guard is disabled by default
Portfast BPDU Filter is enabled by default
Loopguard is disabled by default
UplinkFast is disabled
BackboneFast is disabled
Pathcost method used is long
Chapter 18      Configuring Optional STP Features

About UplinkFast

Note

UplinkFast is most useful in wiring-closet switches. This feature might not be useful for other types of applications.

Spanning Tree UplinkFast provides fast convergence after a direct link failure and uses uplink groups to achieve load balancing between redundant Layer 2 links. Convergence is the speed and ability of a group of internetworking devices running a specific routing protocol to agree on the topology of an
Enabling UplinkFast

UplinkFast increases the bridge priority to 49,152 and adds 3000 to the spanning tree port cost of all interfaces on the switch, making it unlikely that the switch becomes the root switch. The `max_update_rate` value represents the number of multicast packets transmitted per second (the default is 150 packets per second [pps]).
UplinkFast cannot be enabled on VLANs that have been configured for bridge priority. To enable UplinkFast on a VLAN with bridge priority configured, restore the bridge priority on the VLAN to the default value by entering a `no spanning-tree vlan vlan_ID priority` command in global configuration mode.

**Note**

When you enable UplinkFast, it affects all VLANs on the switch. You cannot configure UplinkFast on an individual VLAN.

To enable UplinkFast, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 Switch(config)# [no] spanning-tree uplinkfast [max-update-rate max_update_rate]</td>
<td>Enables UplinkFast. Use the <code>no</code> keyword to disable UplinkFast and restore the default rate, use the command</td>
</tr>
<tr>
<td>Step 2 Switch(config)# end</td>
<td>Exits configuration mode.</td>
</tr>
<tr>
<td>Step 3 Switch# show spanning-tree vlan vlan_ID</td>
<td>Verifies that UplinkFast is enabled on that VLAN.</td>
</tr>
</tbody>
</table>

This example shows how to enable UplinkFast with a maximum update rate of 400 pps:

```
Switch(config)# spanning-tree uplinkfast max-update-rate 400
Switch(config)# exit
Switch#
```

This example shows how to verify which VLANs have UplinkFast enabled:

```
Switch# show spanning-tree uplinkfast
UplinkFast is enabled
Station update rate set to 150 packets/sec.
UplinkFast statistics

Switch#
About BackboneFast

BackboneFast is a complementary technology to UplinkFast. Whereas UplinkFast is designed to quickly respond to failures on links directly connected to leaf-node switches, it does not help with indirect failures in the backbone core. BackboneFast optimizes based on the Max Age setting. It allows you to reduce the default convergence time for indirect failures from 50 seconds to 30 seconds. However, it never eliminates forward delays and offers no assistance for direct failures.

**Note**
Enable BackboneFast on every switch in your network.

Sometimes a switch receives a BPDU from a designated switch that identifies the root bridge and the designated bridge as the same switch. Because this shouldn’t happen, the BPDU is considered inferior. BPDUs are considered inferior when a link from the designated switch has lost its link to the root bridge. The designated switch transmits the BPDUs with the information that it is now the root bridge as well as the designated bridge. The receiving switch ignores the inferior BPDU for the time defined by the Max Age setting.

After receiving inferior BPDUs, the receiving switch tries to determine if there is an alternate path to the root bridge.

- If the port that the inferior BPDUs are received on is already in blocking mode, then the root port and other blocked ports on the switch become alternate paths to the root bridge.
- If the inferior BPDUs are received on a root port, then all presently blocking ports become the alternate paths to the root bridge. Also, if the inferior BPDUs are received on a root port and there are no other blocking ports on the switch, the receiving switch assumes that the link to the root bridge is down and the time defined by the Max Age setting expires, which turns the switch into the root switch.

If the switch finds an alternate path to the root bridge, it uses this new alternate path. This new path, and any other alternate paths, are used to send a Root Link Query (RLQ) BPDU. When BackboneFast is enabled, the RLQ BPDUs are sent out as soon as an inferior BPDU is received. This process can enable faster convergence in the event of a backbone link failure.

*Figure 18-4 shows an example of a topology with no link failures. Switch A, the root switch, connects directly to Switch B over link L1 and to Switch C over link L2. In this example, because switch B has a lower priority than A but higher than C, switch B becomes the designated bridge for L3. Consequently, the Layer 2 interface on Switch C that connects directly to Switch B must be in the blocking state.*
Next, assume that L1 fails. Switch A and Switch B, the switches directly connected to this segment, instantly know that the link is down. The blocking interface on Switch C must enter the forwarding state for the network to recover by itself. However, because L1 is not directly connected to Switch C, Switch C does not start sending any BPDUs on L3 under the normal rules of STP until the time defined by the Max Age setting has expired.

In an STP environment without BackboneFast, if L1 should fail, Switch C cannot detect this failure because it is not connected directly to link L1. However, because Switch B is directly connected to the root switch over L1, Switch B detects the failure and elects itself the root. Then Switch B begins sending configuration BPDUs to Switch C, listing itself as the root.

Here are additional actions that occur when you use BackboneFast to eliminate the time defined by the Max Age setting (20-second) delay:

1. When Switch C receives the inferior configuration BPDUs from Switch B, Switch C infers that an indirect failure has occurred.
2. Switch C then sends out an RLQ.
3. Switch A receives the RLQ. Because Switch A is the root bridge, it replies with an RLQ response, listing itself as the root bridge.
4. When Switch C receives the RLQ response on its existing root port, it knows that it still has a stable connection to the root bridge. Because Switch C originated the RLQ request, it does not need to forward the RLQ response on to other switches.
5. BackboneFast allows the blocked port on Switch C to move immediately to the listening state without waiting for the time defined by the Max Age setting for the port to expire.
6. BackboneFast transitions the Layer 2 interface on Switch C to the forwarding state, providing a path from Switch B to Switch A.

This switchover takes approximately 30 seconds, twice the Forward Delay time if the default forward delay time of 15 seconds is set.

Figure 18-5 shows how BackboneFast reconfigures the topology to account for the failure of link L1.

![Figure 18-5 BackboneFast after Indirect Link Failure](image)

If a new switch is introduced into a shared-medium topology as shown in Figure 18-6, BackboneFast is not activated, because the inferior BPDUs did not come from the recognized designated bridge (Switch B). The new switch begins sending inferior BPDUs that say it is the root switch. However, the other switches ignore these inferior BPDUs, and the new switch learns that Switch B is the designated bridge to Switch A, the root switch.
Enabling BackboneFast

**Note**
For BackboneFast to work, you must enable it on all switches in the network. BackboneFast is supported for use with third-party switches but it is not supported on Token Ring VLANs.

To enable BackboneFast, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch(config)# [no] spanning-tree backbonefast</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch# show spanning-tree backbonefast</td>
</tr>
</tbody>
</table>

This example shows how to enable BackboneFast:

```
Switch(config)# spanning-tree backbonefast
Switch(config)# end
Switch#
```

This example shows how to verify that BackboneFast is enabled:

```
Switch# show spanning-tree backbonefast
BackboneFast is enabled
BackboneFast statistics
-----------------------
Number of transition via backboneFast (all VLANs) : 0
Number of inferior BPDUs received (all VLANs) : 0
Number of RLQ request PDU received (all VLANs) : 0

Switch#
Configuring EtherChannel

This chapter describes how to use the command-line interface (CLI) to configure EtherChannel on the Catalyst 4500 series switch Layer 2 or Layer 3 interfaces. It also provides guidelines, procedures, and configuration examples.

This chapter includes the following major sections:

- EtherChannel Overview, page 19-1
- EtherChannel Configuration Guidelines and Restrictions, page 19-5
- Configuring EtherChannel, page 19-6
- Displaying EtherChannel to a Virtual Switch System, page 19-14

Note
The commands in the following sections can be used on all Ethernet interfaces on a Catalyst 4500 series switch, including the uplink ports on the supervisor engine.

Note
For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

EtherChannel Overview

EtherChannel bundles up to eight individual Ethernet links into a single logical link that provides an aggregate bandwidth of up to 800 Mbps (Fast EtherChannel), 8 Gbps (Gigabit EtherChannel), or 80 Gbps (10 Gigabit EtherChannel) between a Catalyst 4500 or 4500X series switch and another switch or host.
EtherChannel Overview

**Note**
Because some linecards have a maximum bandwidth capacity toward the backplane, they can limit the aggregate bandwidth of an Etherchannel when all the Etherchannel members belong to the same linecard.

A Catalyst 4500 series switch supports a maximum of 64 EtherChannels. You can form an EtherChannel with up to eight compatibly configured Ethernet interfaces across modules in a Catalyst 4500 series switch. All interfaces in each EtherChannel must be the same speed and must be configured as either Layer 2 or Layer 3 interfaces.

**Note**
The network device to which a Catalyst 4500 series switch is connected may impose its own limits on the number of interfaces in an EtherChannel.

If a segment within an EtherChannel fails, traffic previously carried over the failed link switches to the remaining segments within the EtherChannel. When the segment fails, an SNMP trap is sent, identifying the switch, the EtherChannel, and the failed link. Inbound broadcast and multicast packets on one segment in an EtherChannel are blocked from returning on any other segment of the EtherChannel.

**Note**
The port channel link failure switchover for the Catalyst 4500 series switch was measured at 50 ms, giving you SONET-like link failure switchover time.

These subsections describe how EtherChannel works:

- Port-Channel Interfaces, page 19-2
- How EtherChannels Are Configured, page 19-2
- Load Balancing, page 19-5

**Port-Channel Interfaces**

Each EtherChannel has a numbered port-channel interface. A configuration applied to the port-channel interface affects all physical interfaces assigned to that interface.

**Note**
QoS does not propagate to members. The defaults, QoS cos = 0 and QoS dscp = 0, apply on the portchannel. Input or output policies applied on individual interfaces are ignored.

After you configure an EtherChannel, the configuration that you apply to the port-channel interface affects the EtherChannel; the configuration that you apply to the physical interfaces affects only the interface where you apply the configuration. To change the parameters of all ports in an EtherChannel, apply configuration commands to the port-channel interface (such commands can be STP commands or commands to configure a Layer 2 EtherChannel as a trunk).

**How EtherChannels Are Configured**

These subsections describe how EtherChannels are configured:

- EtherChannel Configuration Overview, page 19-3
- Manual EtherChannel Configuration, page 19-3
EtherChannel Configuration Overview

You can configure EtherChannels manually, use the Port Aggregation Control Protocol (PAgP) or, with Cisco IOS Release 12.2(25)EWA and later, the Link Aggregation Control Protocol (LACP) to form EtherChannels. The EtherChannel protocols allow ports with similar characteristics to form an EtherChannel through dynamic negotiation with connected network devices. PAgP is a Cisco-proprietary protocol and LACP is defined in IEEE 802.3ad.

PAgP and LACP do not interoperate. Ports configured to use PAgP cannot form EtherChannels with ports configured to use LACP and vice versa.

Table 19-1 lists the user-configurable EtherChannel modes.

Table 19-1 EtherChannel Modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>on</td>
<td>Mode that forces the LAN port to channel unconditionally. In the on mode, a usable EtherChannel exists only when a LAN port group in the on mode is connected to another LAN port group in the on mode. Because ports configured in the on mode do not negotiate, there is no negotiation traffic between the ports.</td>
</tr>
<tr>
<td>auto</td>
<td>PAgP mode that places a LAN port into a passive negotiating state in which the port responds to PAgP packets it receives but does not initiate PAgP negotiation.</td>
</tr>
<tr>
<td>desirable</td>
<td>PAgP mode that places a LAN port into an active negotiating state in which the port initiates negotiations with other LAN ports by sending PAgP packets.</td>
</tr>
<tr>
<td>passive</td>
<td>LACP mode that places a port into a passive negotiating state in which the port responds to LACP packets it receives but does not initiate LACP negotiation.</td>
</tr>
<tr>
<td>active</td>
<td>LACP mode that places a port into an active negotiating state in which the port initiates negotiations with other ports by sending LACP packets.</td>
</tr>
</tbody>
</table>

Manual EtherChannel Configuration

Manually configured EtherChannel ports do not exchange EtherChannel protocol packets. A manually configured EtherChannel forms only when you configure all ports in the EtherChannel compatibly.

PAgP EtherChannel Configuration

PAgP supports the automatic creation of EtherChannels by exchanging PAgP packets between LAN ports. PAgP packets are exchanged only between ports in auto and desirable modes.

The protocol learns the capabilities of LAN port groups dynamically and informs the other LAN ports. Once PAgP identifies correctly matched Ethernet links, it facilitates grouping the links into an EtherChannel. The EtherChannel is then added to the spanning tree as a single bridge port.

Both the auto and desirable modes allow PAgP to negotiate between LAN ports to determine if they can form an EtherChannel, based on criteria such as port speed and trunking state. Layer 2 EtherChannels also use VLAN numbers.

LAN ports can form an EtherChannel when they are in different PAgP modes if the modes are compatible. For example:
### EtherChannel Overview

- A LAN port in **desirable** mode can form an EtherChannel successfully with another LAN port that is in **desirable** mode.
- A LAN port in **desirable** mode can form an EtherChannel with another LAN port in **auto** mode.
- A LAN port in **auto** mode cannot form an EtherChannel with another LAN port that is also in **auto** mode because neither port initiates negotiation.

### IEEE 802.3ad LACP EtherChannel Configuration

Cisco IOS Release 12.2(25)EWA and later releases support IEEE 802.3ad LACP EtherChannels. LACP supports the automatic creation of EtherChannels by exchanging LACP packets between LAN ports. LACP packets are exchanged only between ports in **passive** and **active** modes.

The protocol learns the capabilities of LAN port groups dynamically and informs the other LAN ports. Once LACP identifies correctly matched Ethernet links, it facilitates grouping the links into an EtherChannel. The EtherChannel is then added to the spanning tree as a single bridge port.

Both the **passive** and **active** modes allow LACP to negotiate between LAN ports to determine if they can form an EtherChannel, based on criteria such as port speed and trunking state. Layer 2 EtherChannels also use VLAN numbers.

LAN ports can form an EtherChannel when they are in different LACP modes as long as the modes are compatible. For example:

- A LAN port in **active** mode can form an EtherChannel successfully with another LAN port that is in **active** mode.
- A LAN port in **active** mode can form an EtherChannel with another LAN port in **passive** mode.
- A LAN port in **passive** mode cannot form an EtherChannel with another LAN port that is also in **passive** mode, because neither port initiates negotiation.

LACP uses the following parameters:

- **LACP system priority**—You may configure an LACP system priority on each switch running LACP. The system priority can be configured automatically or through the CLI. See the “Configuring the LACP System Priority and System ID” section on page 19-11. LACP uses the system priority with the switch MAC address to form the system ID and also during negotiation with other systems.

  **Note**  
  The LACP system ID is the combination of the LACP system priority value and the MAC address of the switch.

- **LACP port priority**—You must configure an LACP port priority on each port configured to use LACP. The port priority can be configured automatically or through the CLI. See the “Configuring Layer 2 EtherChannels” section on page 19-9. LACP uses the port priority with the port number to form the port identifier.

- **LACP administrative key**—LACP automatically configures an administrative key value equal to the channel group identification number on each port configured to use LACP. The administrative key defines the ability of a port to aggregate with other ports. A port’s ability to aggregate with other ports is determined by these factors:
  - Port physical characteristics, such as data rate, duplex capability, and point-to-point or shared medium
  - Configuration restrictions that you establish
LACP tries to configure the maximum number of compatible ports in an EtherChannel up to the maximum allowed by the hardware (eight ports). If a port cannot be actively included in a channel, it is not included automatically if a channelled port fails.

**Note** Standby and “sub-channeling” are not supported in LACP and PAgP.

### Load Balancing

EtherChannel can balance the traffic load across the links in the channel by reducing part of the binary pattern formed from the addresses or ports in the frame to a numerical value that selects one of the links in the channel. To balance the load, EtherChannel uses MAC addresses, IP addresses, or Layer 4 port numbers, and either the message source or message destination, or both.

Use the option that provides the greatest variety in your configuration. For example, if the traffic on a channel is going only to a single MAC address, using the destination MAC address always chooses the same link in the channel; using source addresses or IP addresses might result in better load balancing.

**Note** Load balancing can only be configured globally. As a result, all channels (manually configured, PAgP, or LACP) use the same load balancing method.

For additional information on load balancing, see the “Configuring EtherChannel Load Balancing” section on page 19-12.

### EtherChannel Configuration Guidelines and Restrictions

If improperly configured, some EtherChannel interfaces are disabled automatically to avoid network loops and other problems. Follow these guidelines and restrictions to avoid configuration problems:

- All Ethernet interfaces on all modules support EtherChannel (maximum of eight interfaces) with no requirement that interfaces be physically contiguous or on the same module.
- Configure all interfaces in an EtherChannel to operate at the same speed and duplex mode.
- Enable all interfaces in an EtherChannel. Putting down an interface in an Ether Channel is treated as a link failure, and its traffic is transferred to one of the remaining interfaces in the EtherChannel.
- An EtherChannel does not form if one of the interfaces is a Switched Port Analyzer (SPAN) destination port.
- For Layer 3 EtherChannels:
  - Assign Layer 3 addresses to the port-channel logical interface, not to the physical interfaces in the channel.
- For Layer 2 EtherChannels:
  - Assign all interfaces in the EtherChannel to the same VLAN, or configure them as trunks.
  - If you configure an EtherChannel from trunk interfaces, verify that the trunking mode and the native VLAN is the same on all the trunks. Interfaces in an EtherChannel with different trunk modes or different native VLANs can have unexpected results.
Chapter 19    Configuring EtherChannel

**Configuring EtherChannel**

These sections describe how to configure EtherChannel:

- Configuring Layer 3 EtherChannels, page 19-6
- Configuring Layer 2 EtherChannels, page 19-9
- Configuring the LACP System Priority and System ID, page 19-11
- Configuring EtherChannel Load Balancing, page 19-12
- Removing an Interface from an EtherChannel, page 19-13
- Removing an EtherChannel, page 19-14

**Note**

Ensure that the interfaces are configured correctly. (See the “EtherChannel Configuration Guidelines and Restrictions” section on page 19-5.)

**Configuring Layer 3 EtherChannels**

To configure Layer 3 EtherChannels, create the port-channel logical interface and then put the Ethernet interfaces into the portchannel.

These sections describe Layer 3 EtherChannel configuration:

- Creating Port-Channel Logical Interfaces, page 19-7
- Configuring Physical Interfaces as Layer 3 EtherChannels, page 19-7

- An EtherChannel supports the same allowed range of VLANs on all the interfaces in a trunking Layer 2 EtherChannel. If the allowed ranges differ for selected interface differ, they do not form an EtherChannel.

- Interfaces with different Spanning Tree Protocol (STP) port path costs can form an EtherChannel as long they are otherwise compatibly configured. Setting different STP port path costs does not, by itself, make interfaces incompatible for the formation of an EtherChannel.

- After you configure an EtherChannel, any configuration that you apply to the port-channel interface affects the EtherChannel; any configuration that you apply to the physical interfaces affects only the interface you configure.

  Storm Control is an exception to this rule. For example, you cannot configure Storm Control on some of the members of an EtherChannel; Storm Control must be configured on all or none of the ports. If you configure Storm Control on only some of the ports, those ports are dropped from the EtherChannel interface (put in suspended state). Therefore, you should configure Storm Control at the port-channel interface level, and not at the physical interface level.

- A physical interface with port security enabled can join a Layer 2 EtherChannel only if port security is also enabled on the EtherChannel; otherwise the command is rejected by the CLI.

- You cannot configure a 802.1X port in an EtherChannel.

Storm Control is an exception to this rule. For example, you cannot configure Storm Control on some of the members of an EtherChannel; Storm Control must be configured on all or none of the ports. If you configure Storm Control on only some of the ports, those ports are dropped from the EtherChannel interface (put in suspended state). Therefore, you should configure Storm Control at the port-channel interface level, and not at the physical interface level.

- A physical interface with port security enabled can join a Layer 2 EtherChannel only if port security is also enabled on the EtherChannel; otherwise the command is rejected by the CLI.

- You cannot configure a 802.1X port in an EtherChannel.
Creating Port-Channel Logical Interfaces

To move an IP address from a physical interface to an EtherChannel, you must delete the IP address from the physical interface before configuring it on the port-channel interface.

To create a port-channel interface for a Layer 3 EtherChannel, perform this task:

### Command Purpose

<table>
<thead>
<tr>
<th>Step</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch(config)# interface port-channel</td>
<td>Creates the port-channel interface. The value for port_channel_number can range from 1 to 64.</td>
</tr>
<tr>
<td></td>
<td>port_channel_number</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config-if)# ip address ip_address</td>
<td>Assigns an IP address and subnet mask to the EtherChannel.</td>
</tr>
<tr>
<td></td>
<td>mask</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config-if)# end</td>
<td>Exits configuration mode.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch# show running-config interface</td>
<td>Verifies the configuration.</td>
</tr>
<tr>
<td></td>
<td>port-channel port_channel_number</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to create port-channel interface 1:

```
Switch# configure terminal
Switch(config)# interface port-channel 1
Switch(config-if)# ip address 172.32.52.10 255.255.255.0
Switch(config-if)# end
```

This example shows how to verify the configuration of port-channel interface 1:

```
Switch# show running-config interface port-channel 1
Building configuration...

Current configuration:
!
interface Port-channel1
 ip address 172.32.52.10 255.255.255.0
 no ip directed-broadcast
 end
```

Configuring Physical Interfaces as Layer 3 EtherChannels

To configure physical interfaces as Layer 3 EtherChannels, perform this task for each interface:

### Command Purpose

<table>
<thead>
<tr>
<th>Step</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch(config)# interface (fastethernet</td>
<td>Selects a physical interface to configure.</td>
</tr>
<tr>
<td></td>
<td>gigabitethernet</td>
<td>tengigabitethernet) slot/port</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config-if)# no switchport</td>
<td>Makes this a Layer 3 routed port.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config-if)# no ip address</td>
<td>Ensures that no IP address is assigned to the physical interface.</td>
</tr>
</tbody>
</table>
Chapter 19      Configuring EtherChannel

Configuring EtherChannel

This example shows how to configure Fast Ethernet interfaces 5/4 and 5/5 into port-channel 1 with PAgP mode desirable:

Switch# configure terminal
Switch(config)# interface range fastethernet 5/4 - 5 (Note: Space is mandatory.)
Switch(config-if)# no switchport
Switch(config-if)# no ip address
Switch(config-if)# channel-group 1 mode desirable
Switch(config-if)# end

See the “Configuring a Range of Interfaces” section on page 7-4 for information about the range keyword.

The following two examples show how to verify the configuration of Fast Ethernet interface 5/4:

Switch# show running-config interface fastethernet 5/4
Building configuration...

Current configuration:
!
interface FastEthernet5/4
  no ip address
  no switchport
  no ip directed-broadcast
  channel-group 1 mode desirable
end

Switch# show interfaces fastethernet 5/4 etherchannel
Port state = EC-Enbld Up In-Bndl Usr-Config
Channel group = 1 Mode = Desirable Gcchange = 0
Port-channel = Po1 GC = 0x00010001 Pseudo-port-channel = Po1
Port indx = 0 Load = 0x55

Flags:  S - Device is sending Slow hello.  C - Device is in Consistent state.
        A - Device is in Auto mode.  P - Device learns on physical port.
        H - Hello timer is running.  Q - Quit timer is running.
        S - Switching timer is running.  I - Interface timer is running.
Local information:

<table>
<thead>

Switch#

**Configuring Layer 2 EtherChannels**

To configure Layer 2 EtherChannels, configure the Ethernet interfaces with the `channel-group` command. This creates the port-channel logical interface.

**Note**

Cisco IOS software creates port-channel interfaces for Layer 2 EtherChannels when you configure Layer 2 Ethernet interfaces with the `channel-group` command.
To configure Layer 2 Ethernet interfaces as Layer 2 EtherChannels, perform this task for each interface:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1: [Switch(\text{config})# interface (fastethernet</td>
<td>gigabitethernet</td>
</tr>
<tr>
<td>Step 2: [Switch(\text{config-if})# channel-group port_channel_number mode (active</td>
<td>on</td>
</tr>
<tr>
<td>Step 3: [Switch(\text{config-if})# end]</td>
<td>Exits configuration mode.</td>
</tr>
<tr>
<td>Step 4: [Switch# show running-config interface {fastethernet</td>
<td>gigabitethernet} slot/port]</td>
</tr>
<tr>
<td>[Switch# show interface {fastethernet</td>
<td>gigabitethernet</td>
</tr>
</tbody>
</table>

This example shows how to configure Fast Ethernet interfaces 5/6 and 5/7 into port-channel 2 with PAgP mode desirable:

Switch\# configure terminal  
Switch\(\text{config}\)# interface range fastethernet 5/6 - 7 (Note: Space is mandatory.)  
Switch\(\text{config-if-range}\)# channel-group 2 mode desirable  
Switch\(\text{config-if-range}\)# end  
Switch\# end

Note: See the “Configuring a Range of Interfaces” section on page 7-4 for information about the range keyword.

This example shows how to verify the configuration of port-channel interface 2:

Switch\# show running-config interface port-channel 2  
Building configuration...

Current configuration:  
!  
interface Port-channel2  
  switchport access vlan 10  
  switchport mode access  
end

Switch#

The following two examples show how to verify the configuration of Fast Ethernet interface 5/6:

Switch\# show running-config interface fastethernet 5/6  
Building configuration...

Current configuration:  
!  
interface FastEthernet5/6  
  switchport access vlan 10  
  switchport mode access  
  channel-group 2 mode desirable  
end
Switch# show interfaces fastethernet 5/6 etherchannel
Port state = EC-Enbld Up In-Bndl Usr-Config
Channel group = 1 Mode = Desirable Gcchange = 0
Port-channel = Po1 GC = 0xFF00010001
Port indx = 0 Load = 0x55

Flags:  S - Device is sending Slow hello.  C - Device is in Consistent state.
       A - Device is in Auto mode.  P - Device learns on physical port.
       d - PAgP is down.
Timers:  H - Hello timer is running.  Q - Quit timer is running.
       S - Switching timer is running.  I - Interface timer is running.

Age of the port in the current state: 00h:10m:57s

This example shows how to verify the configuration of port-channel interface 2 after the interfaces have been configured:

Switch# show etherchannel 2 port-channel
Port-channels in the group: 
----------------------
| Port-channel: Po2 |

Port-channel: Po2

Age of the Port-channel = 00h:23m:33s
Logical slot/port = 10/2
Number of ports in agport = 2
GC = 0x00020001
HotStandBy port = null
Port state = Port-channel Ag-Inuse

Ports in the Port-channel:

<table>
<thead>
<tr>
<th>Index</th>
<th>Load</th>
<th>Port</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>00</td>
<td>Fa5/6</td>
</tr>
<tr>
<td>0</td>
<td>00</td>
<td>Fa5/7</td>
</tr>
</tbody>
</table>

Time since last port bundled: 00h:23m:33s Fa5/6

Switch#

Configuring the LACP System Priority and System ID

The LACP system ID is the LACP system priority value combined with the MAC address of the switch.
### Configuring EtherChannel

To configure the LACP system priority and system ID, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch(config)# lACP system-priority priority_value</td>
</tr>
<tr>
<td></td>
<td>Switch(config)# no system port-priority</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch# show lacp sys-id</td>
</tr>
</tbody>
</table>

This example shows how to configure the LACP system priority:

```
Switch# configure terminal
Switch(config)# lACP system-priority 23456
Switch(config)# end
Switch# show module
```

```
Mod | Ports | Card Type | Model | Serial No.
---+-------+-----------+-------+-----------
1   | 2     | 1000BaseX (GBIC) Supervisor(active) | WS-X4014 | JAB063808YZ
2   | 48    | 10/100BaseTX (RJ45) | WS-X4148-RJ | JAB0447072W
3   | 48    | 10/100BaseTX (RJ45)V | WS-X4148-RJ45V | JAE061704J6
4   | 48    | 10/100BaseTX (RJ45)V | WS-X4148-RJ45V | JAE061704ML
```

```
M MAC addresses | Hw | Fw | Sw | Status
---+-------+-----+-----+-------
1 0005.9a39.7a80 to 0005.9a39.7a81 | 2.1 | 12.1(12r)EW | 12.1(13)EW(0.26) | Ok
2 0002.fd80.f530 to 0002.fd80.f55f | 0.1 | Ok
3 0009.7c45.67c0 to 0009.7c45.67ef | 1.6 | Ok
4 0009.7c45.4a80 to 0009.7c45.4aaf | 1.6 | Ok
```

This example shows how to verify the configuration:

```
Switch# show lacp sys-id
23456,0050.3e8d.6400
Switch#
```

The system priority is displayed first, followed by the MAC address of the switch.

### Configuring EtherChannel Load Balancing

**Load balancing can only be configured globally. As a result, all channels (manually configured, PagP, or LACP) use the same load balancing method.**
To configure EtherChannel load balancing, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch(config)# [no] port-channel load-balance {src-mac</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch# show etherchannel load-balance</td>
</tr>
</tbody>
</table>

The load-balancing keywords are:
- `src-mac`—Source MAC addresses
- `dst-mac`—Destination MAC addresses
- `src-dst-mac`—Source and destination MAC addresses
- `src-ip`—Source IP addresses
- `dst-ip`—Destination IP addresses
- `src-dst-ip`—Source and destination IP addresses (Default)
- `src-port`—Source Layer 4 port
- `dst-port`—Destination Layer 4 port
- `src-dst-port`—Source and destination Layer 4 port

This example shows how to configure EtherChannel to use source and destination IP addresses:

```
Switch# configure terminal
Switch(config)# port-channel load-balance src-dst-ip
Switch(config)# end
Switch#
```

This example shows how to verify the configuration:

```
Switch# show etherchannel load-balance
EtherChannel Load-Balancing Configuration:
  src-dst-ip
```

EtherChannel Load-Balancing Addresses Used Per-Protocol:
- Non-IP: Source XOR Destination MAC address
- IPv4: Source XOR Destination IP address
- IPv6: Source XOR Destination IP address

### Removing an Interface from an EtherChannel

To remove an Ethernet interface from an EtherChannel, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch(config)# interface {fastethernet</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config-if)# no channel-group</td>
</tr>
</tbody>
</table>
Chapter 19  Configuring EtherChannel

Displaying EtherChannel to a Virtual Switch System

This example shows how to remove Fast Ethernet interfaces 5/4 and 5/5 from port-channel 1:

Switch# configure terminal
Switch(config)# interface range fastethernet 5/4 - 5 (Note: Space is mandatory.)
Switch(config-if)# no channel-group 1
Switch(config-if)# end

Removing an EtherChannel

If you remove an EtherChannel, the member ports are shut down and removed from the channel group.

If you want to change an EtherChannel from Layer 2 to Layer 3, or Layer 3 to Layer 2, you must remove the EtherChannel and recreate it in the desired configuration.

To remove an EtherChannel, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch(config)# no interface port-channel port_channel_number</td>
</tr>
<tr>
<td></td>
<td>Removes the port-channel interface.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td></td>
<td>Exits configuration mode.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch# show etherchannel summary</td>
</tr>
<tr>
<td></td>
<td>Verifies the configuration.</td>
</tr>
</tbody>
</table>

This example shows how to remove port-channel 1:

Switch# configure terminal
Switch(config)# no interface port-channel 1
Switch(config)# end

Displaying EtherChannel to a Virtual Switch System

Catalyst 4500 series switches support enhanced PAgP. If a Catalyst 4500 series switch is connected to a Catalyst 6500 series Virtual Switch System (VSS) via a PAgP EtherChannel, the Catalyst 4500 series switch automatically serve as a VSS client, using enhanced PAgP on this EtherChannel for dual-active detection. This VSS client feature has no impact on the performance of Catalyst 4500 series switches and does not require any user configuration.

Topics include:

- Understanding VSS Client, page 19-15
- Displaying EtherChannel Links to VSS, page 19-17
Understanding VSS Client

Topics covered include:
- Virtual Switch System, page 19-15
- Dual-Active Scenarios, page 19-15
- Dual-Active Detection Using Enhance PAgP, page 19-15

Virtual Switch System

The Cisco Catalyst 6500 Series VSS 1440 allows for the combination of two Cisco Catalyst 6500 Series switches into a single, logical network entity from the network control-plane and management perspectives. Within the Cisco VSS, one chassis is designated as the active virtual switch, acting as the single management point of the entire system, and the other is designated as the standby virtual switch. There two chassis are bound together by a special link, called Virtual Switch Link (VSL), which carries the internal signaling and control information between them.

Dual-Active Scenarios

One of the failure scenarios in a VSS is called dual-active, which occurs when the VSL fails completely. In this case, neither virtual switch knows of the other's status. From the perspective of the active virtual switch, the standby chassis is lost. The standby virtual switch also views the active chassis as failed and transitions to active state via an SSO switchover. So, two active virtual switches exist in the network with identical configurations, causing duplicate IP addresses and bridge identifiers. This scenario has adverse effects on the network topology and traffic if it persists.

Dual-Active Detection Using Enhance PAgP

One mechanism for detecting a dual-active scenario is based on enhanced PAgP (PAgP+). Specifically, the VSS sends regularly scheduled PAgP messages with Type-Length-Values (TLVs) containing the ID of the current active virtual switch (Figure 19-1). When the VSL fails completely, the standby virtual switch immediately sends asynchronous PAgP messages with TLVs containing its own ID on all port channels enabled for enhanced PAgP dual-active detection (Figure 19-2). The remote switch (the VSS client) connected to both VSS components via EtherChannel links, compares every received active ID with its stored active ID. If they match, the remote switch simply sends TLVs containing its stored active ID back to the VSS in its regularly scheduled PAgP messages. If they do not match, the remote switch stores the new active ID and immediately transmits asynchronous PAgP messages with TLVs containing the new active ID. Upon receiving the new active ID from the remote switch, the original active virtual switch detects the dual-active scenario and takes appropriate actions.
As a remote switch, the Catalyst 4500 series switch supports stateful VSS client. In particular, the ID of the current active virtual switch is synchronized from the active supervisor engine to the redundant supervisor engine of the Catalyst 4500 series switch. This ensures that dual-active detection is not disrupted even when the active supervisor engine switches over to the redundant supervisor engine.
Displaying EtherChannel Links to VSS

To display the dual-active detection capability of the configured PAgP portchannel, use the 
\texttt{show pagp port\_channel\_number dual-active} command.

It indicates whether:

- A switch uses enhanced PAgP for dual-active detection.
  
  You should always see “Yes” after “PAgP dual-active detection enabled” on a Catalyst 4500 switch.

- The configured PAgP EtherChannel is connected to a Catalyst 6500 switch VSS.
  
  You see “N/A” below “Partner Version” if this EtherChannel is \textit{not} connected to a VSS. Otherwise, user sees the version of enhanced PAgP dual-active detection implemented in the VSS.

- This switch is capable of detecting dual-active scenarios in the connected VSS.
  
  You see “Yes” below “Dual-Active Detect Capable” if and only if the configured EtherChannel is connected to a Catalyst 6500 series VSS that uses the same version of enhanced PAgP dual-active detection.

\textbf{Note}

You can also see the name of the neighboring switch (Partner Name) and the ports to which this EtherChannel is connected (Partner Port).

If a Catalyst 4500 switch is connected to a Catalyst 6500 series VSS with the same version of enhanced PAgP dual-active detection, the switch \textit{can} detect a dual-active scenario:

\begin{verbatim}
Switch# show pagp 1 dual-active
PAgP dual-active detection enabled: Yes
PAgP dual-active version: 1.1

Channel group 1
  Dual-Active   Partner     Partner     Partner
  Port   Detect Capable Name     Port       Version
G16/5   Yes           VSS        Gi1/8/1     1.1
G16/6   Yes           VSS        Gi2/8/1     1.1
\end{verbatim}

If a Catalyst 4500 switch is not connected to a Catalyst 6500 series VSS, the switch \textit{cannot} detect a dual-active scenario:

\begin{verbatim}
Switch# show pagp 1 dual-active
PAgP dual-active detection enabled: Yes
PAgP dual-active version: 1.1

Channel group 1
  Dual-Active   Partner     Partner     Partner
  Port   Detect Capable Name     Port       Version
G16/5   No            Switch      Pa6/5      N/A
G16/6   No            Switch      Pa6/6      N/A
\end{verbatim}
Configuring CDP

This chapter describes how to configure Cisco Discovery Protocol (CDP) on the Catalyst 4500 series switch. It also provides guidelines, procedures, and configuration examples.

This chapter includes the following major sections:

- About CDP, page 20-1
- Configuring CDP, page 20-2

**Note**

For complete syntax and usage information for the commands used in this chapter, refer to the Cisco IOS Configuration Fundamentals Configuration Guide, Release 12.4:

and the Cisco IOS Configuration Fundamentals Command Reference, Release 12.2:

**Note**

For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

About CDP

CDP is a protocol that runs over Layer 2 (the data link layer) on all Cisco routers, bridges, access servers, and switches. CDP allows network management applications to discover Cisco devices that are neighbors of already known devices, in particular, neighbors running lower-layer, transparent protocols. With CDP, network management applications can learn the device type and the SNMP agent address of neighboring devices. CDP enables applications to send SNMP queries to neighboring devices.
CDP runs on all LAN and WAN media that support Subnetwork Access Protocol (SNAP).

Each CDP-configured device sends periodic messages to a multicast address. Each device advertises at least one address at which it can receive SNMP messages. The advertisements also contain the time-to-live, or holdtime information, which indicates the length of time a receiving device should hold CDP information before discarding it.

### Configuring CDP

The following sections describe how to configure CDP:

- Enabling CDP Globally, page 20-2
- Displaying the CDP Global Configuration, page 20-2
- Enabling CDP on an Interface, page 20-3
- Displaying the CDP Interface Configuration, page 20-3
- Monitoring and Maintaining CDP, page 20-3

### Enabling CDP Globally

To enable CDP globally, perform this task:

```
Switch(config)# cdp run
```

This example shows how to enable CDP globally:

```
Switch(config)# cdp run
```

### Displaying the CDP Global Configuration

To display the CDP configuration, perform this task:

```
Switch# show cdp
```

This example shows how to display the CDP configuration:

```
Switch# show cdp
Global CDP information:
    Sending CDP packets every 120 seconds
    Sending a holdtime value of 180 seconds
    Sending CDPv2 advertisements is enabled
Switch#
```

For additional CDP `show` commands, see the “Monitoring and Maintaining CDP” section on page 20-3.
Enabling CDP on an Interface

To enable CDP on an interface, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config-if)# cdp enable</td>
<td>Enables CDP on an interface. Use the <code>no</code> keyword to disable CDP on an interface.</td>
</tr>
</tbody>
</table>

This example shows how to enable CDP on Fast Ethernet interface 5/1:

```
Switch(config)# interface fastethernet 5/1
Switch(config-if)# cdp enable
```

This example shows how to disable CDP on Fast Ethernet interface 5/1:

```
Switch(config)# interface fastethernet 5/1
Switch(config-if)# no cdp enable
```

Displaying the CDP Interface Configuration

To display the CDP configuration for an interface, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# show cdp interface [type/number]</td>
<td>Displays information about interfaces where CDP is enabled.</td>
</tr>
</tbody>
</table>

This example shows how to display the CDP configuration of Fast Ethernet interface 5/1:

```
Switch# show cdp interface fastethernet 5/1
FastEthernet5/1 is up, line protocol is up
Encapsulation ARPA
   Sending CDP packets every 120 seconds
   Holdtime is 180 seconds
Switch#
```

Monitoring and Maintaining CDP

To monitor and maintain CDP on your device, perform one or more of these tasks:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# clear cdp counters</td>
<td>Resets the traffic counters to zero.</td>
</tr>
<tr>
<td>Switch# clear cdp table</td>
<td>Deletes the CDP table of information about neighbors.</td>
</tr>
<tr>
<td>Switch# show cdp</td>
<td>Displays global information such as frequency of transmissions and the holdtime for packets being transmitted.</td>
</tr>
<tr>
<td>Switch# show cdp entry entry_name [protocol</td>
<td>version]</td>
</tr>
</tbody>
</table>
This example shows how to clear the CDP counter configuration on your switch:

```
Switch# clear cdp counters
```

This example shows how to display information about the neighboring equipment:

```
Switch# show cdp neighbors [type/number] [detail]
```

<table>
<thead>
<tr>
<th>Device ID</th>
<th>Local Intrfce</th>
<th>Holdtme</th>
<th>Capability</th>
<th>Platform</th>
<th>Port ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>JAB023807H1</td>

Command Purpose

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# show cdp interface [type/number]</td>
<td>Displays information about interfaces on which CDP is enabled.</td>
</tr>
<tr>
<td>Switch# show cdp neighbors [type/number] [detail]</td>
<td>Displays information about neighboring equipment. You can limit the display to neighbors on a specific interface and expand to provide more detailed information.</td>
</tr>
<tr>
<td>Switch# show cdp traffic</td>
<td>Displays CDP counters, including the number of packets sent and received and checksum errors.</td>
</tr>
<tr>
<td>Switch# show debugging</td>
<td>Displays information about the types of debugging that are enabled for your switch.</td>
</tr>
</tbody>
</table>
CHAPTER 21

Configuring IGMP Snooping and Filtering

This chapter describes how to configure Internet Group Management Protocol (IGMP) snooping on the Catalyst 4500 series switch. It provides guidelines, procedures, and configuration examples.

This chapter consists of the following major sections:

- Overview of IGMP Snooping, page 21-1
- Configuring IGMP Snooping, page 21-5
- Displaying IGMP Snooping Information, page 21-14
- Configuring IGMP Filtering, page 21-20
- Displaying IGMP Filtering Configuration, page 21-24

Note
To support Cisco Group Management Protocol (CGMP) client devices, configure the switch as a CGMP server. For more information, see the chapters “IP Multicast” and “Configuring IP Multicast Routing” in the Cisco IOS IP and IP Routing Configuration Guide, Cisco IOS Release 12.1 at this location:

Note
For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

Overview of IGMP Snooping

This section includes the following subsections:

- Immediate-Leave Processing, page 21-3
- IGMP Configurable-Leave Timer, page 21-4
Overview of IGMP Snooping

- IGMP Snooping Querier, page 21-4
- Explicit Host Tracking, page 21-4

**Note**
Quality of service does not apply to IGMP packets.

IGMP snooping allows a switch to snoop or capture information from IGMP packets transmitted between hosts and a router. Based on this information, a switch adds or deletes multicast addresses from its address table, thereby enabling (or disabling) multicast traffic from flowing to individual host ports. IGMP snooping supports all versions of IGMP: IGMPv1, IGMPv2, and IGMPv3.

In contrast to IGMPv1 and IGMPv2, IGMPv3 snooping provides immediate-leave processing by default. It provides Explicit Host Tracking (EHT) and allows network administrators to deploy SSM functionality on Layer 2 devices that truly support IGMPv3. (See the “Explicit Host Tracking” section on page 21-4.)

In subnets where IGMP is configured, IGMP snooping manages multicast traffic at Layer 2. You can configure interfaces to dynamically forward multicast traffic only to those interfaces that are interested in receiving it by using the `switchport` keyword.

IGMP snooping restricts traffic in MAC multicast groups 0100.5e00.0001 to 01-00-5e-ff-ff-ff. IGMP snooping does not restrict Layer 2 multicast packets generated by routing protocols.

**Note**
For more information on IP multicast and IGMP, refer to RFC 1112, RFC 2236, RFC 3376 (for IGMPv3).

IGMP (configured on a router) periodically sends out IGMP general queries. A host responds to these queries with IGMP membership reports for groups that it is interested in. When IGMP snooping is enabled, the switch creates one entry per VLAN in the Layer 2 forwarding table for each Layer 2 multicast group from which it receives an IGMP join request. All hosts interested in this multicast traffic send IGMP membership reports and are added to the forwarding table entry.

Layer 2 multicast groups learned through IGMP snooping are dynamic. However, you can statically configure Layer 2 multicast groups using the `ip igmp snooping static` command. If you specify group membership statically, your setting supersedes any automatic manipulation by IGMP snooping. Multicast group membership lists can contain both user-defined and IGMP snooping settings.

Groups with IP addresses in the range 224.0.0.0 to 224.0.0.255, which map to the multicast MAC address range 0100.5E00.0001 to 0100.5E00.00FF, are reserved for routing control packets. These groups are flooded to all forwarding ports of the VLAN with the exception of 224.0.0.22, which is used for IGMPv3 membership reports.

**Note**
If a VLAN experiences a spanning-tree topology change, IP multicast traffic floods on all VLAN ports where PortFast is not enabled, as well as on ports with the `no igmp snooping tcn flood` command configured for a period of TCN query count.

For a Layer 2 IGMPv2 host interface to join an IP multicast group, a host sends an IGMP membership report for the IP multicast group. For a host to leave a multicast group, it can either ignore the periodic IGMP general queries or it can send an IGMP leave message. When the switch receives an IGMP leave message from a host, it sends out an IGMP group-specific query to determine whether any devices connected to that interface are interested in traffic for the specific multicast group. The switch then updates the table entry for that Layer 2 multicast group so that only those hosts interested in receiving multicast traffic for the group are listed.
In contrast, IGMPv3 hosts send IGMPv3 membership reports (with the allow group record mode) to join a specific multicast group. When IGMPv3 hosts send membership reports (with the block group record) to reject traffic from all sources in the previous source list, the last host on the port is removed by immediate-leave if EHT is enabled.

### Immediate-Leave Processing

IGMP snooping immediate-leave processing allows the switch to remove an interface from the forwarding-table entry without first sending out IGMP group-specific queries to the interface. The VLAN interface is pruned from the multicast tree for the multicast group specified in the original IGMP leave message. Immediate-leave processing ensures optimal bandwidth management for all hosts on a switched network, even when multiple multicast groups are being used simultaneously.

When a switch with IGMP snooping enabled receives an IGMPv2 or IGMPv3 leave message, it sends an IGMP group-specific query from the interface where the leave message was received to determine when there are other hosts attached to that interface that are interested in joining the MAC multicast group. If the switch does not receive an IGMP join message within the query response interval, the interface is removed from the port list of the (MAC-group, VLAN) entry in the Layer 2 forwarding table.

---

**Note**

By default all IGMP joins are forwarded to all multicast router ports.

With immediate-leave processing enabled on the VLAN, an interface can be removed immediately from the port list of the Layer 2 entry when the IGMP leave message is received, unless a multicast router was learned on the port.

**Note**

When using IGMPv2 snooping, use immediate-leave processing only on VLANs where just one host is connected to each interface. If immediate-leave processing is enabled on VLANs where multiple hosts are connected to an interface, some hosts might be dropped inadvertently. When using IGMPv3, immediate-leave processing is enabled by default, and due to Explicit Host Tracking (see below), the switch can detect when a port has single or multiple hosts maintained by the switch for IGMPv3 hosts. As a result, the switch can perform immediate-leave processing when it detects a single host behind a given port.

**Note**

IGMPv3 is interoperable with older versions of IGMP.

Use the `show ip igmp snooping querier vlan` command to display the IGMP version on a particular VLAN.

Use the `show ip igmp snooping vlan` command to display whether the switch supports IGMPv3 snooping.

Use the `ip igmp snooping immediate-leave` command to enable immediate-leave for IGMPv2.

**Note**

Immediate-leave processing is enabled by default for IGMPv3.
Overview of IGMP Snooping

IGMP Configurable-Leave Timer

Immediate-leave processing cannot be used on VLANs where multiple hosts may be connected to a single interface. To reduce leave latency in such a scenario, IGMPv3 provides a configurable leave timer.

In Cisco IOS Release 12.2(25)SG and earlier, the IGMP snooping leave time was based on query response time. If membership reports were not received by the switch before the query response time of the query expired, a port was removed from the multicast group membership.

In Cisco IOS Release 12.2(31)SG and later, you can configure the length of time that the switch waits after sending a group-specific query to determine if hosts are still interested in a specific multicast group. The IGMP leave response time can be configured from 100 to 5000 milliseconds. The timer can be set either globally or per VLAN. The VLAN configuration of the leave time overrides the global configuration.

For configuration steps, see the “Configuring the IGMP Leave Timer” section on page 21-9.

IGMP Snooping Querier

IGMP Snooping Querier support was introduced in Cisco IOS Release 12.2(50)SG. This is a Layer 2 feature required to support IGMP snooping in a VLAN where PIM and IGMP are not configured because the multicast traffic does not require routing.

In a network where IP multicast routing is configured, the IP multicast router acts as the IGMP querier by sending general queries. If the IP-multicast traffic in a VLAN only needs to be Layer 2-switched, an IP-multicast router is not required. Without an IP-multicast router on the VLAN, you must configure another switch as the IGMP querier so that it can send queries.

When enabled, the IGMP snooping querier sends out periodic IGMPv2 queries that trigger IGMP report messages from the switch that requests IP multicast traffic. IGMP snooping listens to these IGMP reports to establish appropriate forwarding.

On switches that use IGMP to report interest in IP multicast traffic, configure at least one switch as the IGMP snooping querier in each supported VLAN.

You can configure a switch to generate IGMP queries on a VLAN regardless of whether IP multicast routing is enabled.

Explicit Host Tracking

Explicit Host Tracking (EHT) monitors group membership by tracking hosts that are sending IGMPv3 membership reports. This tracking enables a switch to detect host information associated with the groups of each port. Furthermore, EHT enables the user to track the membership and various statistics.

EHT enables a switch to track membership on a per-port basis. Consequently, a switch is aware of the hosts residing on each port and can perform immediate-leave processing when there is only one host behind a port.

To determine whether EHT is enabled on a VLAN, use the `show ip igmp snoop vlan` command.
Configuring IGMP Snooping

When configuring IGMP, configure the VLAN in the VLAN database mode. (See Chapter 12, “Configuring VLANs, VTP, and VMPS”.)

IGMP snooping allows switches to examine IGMP packets and make forwarding decisions based on their content.

These sections describe how to configure IGMP snooping:

- Default IGMP Snooping Configuration, page 21-5
- Enabling IGMP Snooping Globally, page 21-6
- Enabling IGMP Snooping on a VLAN, page 21-6
- Configuring Learning Methods, page 21-7
- Configuring a Static Connection to a Multicast Router, page 21-8
- Enabling IGMP Immediate-Leave Processing, page 21-8
- Configuring the IGMP Leave Timer, page 21-9
- Configuring IGMP Snooping Querier, page 21-10
- Configuring Explicit Host Tracking, page 21-11
- Configuring a Host Statically, page 21-11
- Suppressing Multicast Flooding, page 21-12

Default IGMP Snooping Configuration

Table 21-1 shows the IGMP snooping default configuration values.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>IGMP snooping</td>
<td>Enabled</td>
</tr>
<tr>
<td>Multicast routers</td>
<td>None configured</td>
</tr>
<tr>
<td>Explicit Host Tracking</td>
<td>Enabled for IGMPv3; Not available for IGMPv2</td>
</tr>
<tr>
<td>Immediate-leave processing</td>
<td>Enabled for IGMPv3; Disabled for IGMPv2</td>
</tr>
<tr>
<td>Report Suppression</td>
<td>Enabled</td>
</tr>
<tr>
<td>IGMP snooping learning method</td>
<td>PIM/DVMRP(^1)</td>
</tr>
</tbody>
</table>

1. PIM/DVMRP = Protocol Independent Multicast/Distance Vector Multicast Routing Protocol
### Enabling IGMP Snooping Globally

To enable IGMP snooping globally, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# [no] ip igmp snooping</td>
</tr>
<tr>
<td></td>
<td>Enables IGMP snooping. Use the no keyword to disable IGMP snooping.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td></td>
<td>Exits configuration mode.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch# show ip igmp snooping</td>
</tr>
<tr>
<td></td>
<td>Verifies the configuration.</td>
</tr>
</tbody>
</table>

This example shows how to enable IGMP snooping globally and verify the configuration:

```
Switch# configure terminal
Switch(config)# ip igmp snooping
Switch(config)# end
Switch(config)# show ip igmp snooping
```

Global IGMP Snooping configuration:

```
IGMP snooping             : Enabled
IGMPv3 snooping           : Enabled
Report suppression        : Enabled
TCN solicit query         : Disabled
TCN flood query count     : 2
Vlan 1: 
--------
IGMP snooping                : Enabled
IGMPv2 immediate leave       : Disabled
Explicit host tracking       : Enabled
Multicast router learning mode : pim-dvmrp
CGMP interoperability mode   : IGMP_ONLY

Vlan 2: 
--------
IGMP snooping                : Enabled
IGMPv2 immediate leave       : Disabled
Explicit host tracking       : Enabled
Multicast router learning mode : pim-dvmrp
CGMP interoperability mode   : IGMP_ONLY
```

### Enabling IGMP Snooping on a VLAN

To enable IGMP snooping on a VLAN, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch(config)# [no] ip igmp snooping vlan vlan_ID</td>
</tr>
<tr>
<td></td>
<td>Enables IGMP snooping. Use the no keyword to disable IGMP snooping.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td></td>
<td>Exits configuration mode.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch# show ip igmp snooping vlan vlan_ID</td>
</tr>
<tr>
<td></td>
<td>Verifies the configuration.</td>
</tr>
</tbody>
</table>
Chapter 21 Configuring IGMP Snooping and Filtering

Configuring IGMP Snooping

This example shows how to enable IGMP snooping on VLAN 2 and verify the configuration:

Switch# configure terminal
Switch(config)# ip igmp snooping vlan 2
Switch(config)# end
Switch# show ip igmp snooping vlan 2
Global IGMP Snooping configuration:
-----------------------------------
IGMP snooping             : Enabled
IGMPv3 snooping           : Enabled
Report suppression        : Enabled
TCN solicit query         : Disabled
TCN flood query count     : 2
Vlan 2:-------------------
IGMP snooping             : Enabled
IGMPv2 immediate leave    : Disabled
Explicit host tracking    : Enabled
Multicast router learning mode : pim-dvmrp
CGMP interoperability mode : IGMP_ONLY

Configuring Learning Methods

The following sections describe IGMP snooping learning methods:

- Configuring PIM/DVMRP Learning, page 21-7
- Configuring CGMP Learning, page 21-7

Configuring PIM/DVMRP Learning

To configure IGMP snooping to learn from PIM/DVMRP packets, perform this task:

Command | Purpose
---|---
Switch(config)# ip igmp snooping vlan vlan_ID mrouter learn pim-dvmrp | Specifies the learning method for the VLAN.

This example shows how to configure IP IGMP snooping to learn from PIM/DVMRP packets:

Switch# configure terminal
Switch(config)# ip igmp snooping vlan 1 mrouter learn pim-dvmrp
Switch(config)# end
Switch#

Configuring CGMP Learning

To configure IGMP snooping to learn from CGMP self-join packets, perform this task:

Command | Purpose
---|---
Switch(config)# ip igmp snooping vlan vlan_ID mrouter learn cgmp | Specifies the learning method for the VLAN.
This example shows how to configure IP IGMP snooping to learn from CGMP self-join packets:

```
Switch# configure terminal
Switch(config)# ip igmp snooping vlan 1 mrouter learn cgmp
Switch(config)# end
Switch#
```

## Configuring a Static Connection to a Multicast Router

To configure a static connection to a multicast router, enter the `ip igmp snooping vlan mrouter interface` command on the switch.

To configure a static connection to a multicast router, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# ip igmp snooping vlan vlan_ID mrouter interface interface_num</td>
</tr>
<tr>
<td></td>
<td>Specifies a static connection to a multicast router for the VLAN.</td>
</tr>
<tr>
<td></td>
<td>Note The interface to the router must be in the VLAN where you are entering the command. The router and the line protocol must be up.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td></td>
<td>Exits configuration mode.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch# show ip igmp snooping mrouter vlan vlan_ID</td>
</tr>
<tr>
<td></td>
<td>Verifies the configuration.</td>
</tr>
</tbody>
</table>

This example shows how to configure a static connection to a multicast router:

```
Switch# configure terminal
Switch(config)# ip igmp snooping vlan 200 mrouter interface fastethernet 2/10
Switch# show ip igmp snooping mrouter vlan 200
        vlan   ports
        -----+----------------------------------------
       200   Fa2/10
Switch#
```

## Enabling IGMP Immediate-Leave Processing

When you enable IGMP immediate-leave processing on a VLAN, a switch removes an interface from the multicast group when it detects an IGMPv2 leave message on that interface.

**Note** For IGMPv3, immediate-leave processing is enabled by default with EHT.

To enable immediate-leave processing on an IGMPv2 interface, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Switch(config)# ip igmp snooping vlan vlan_ID immediate-leave</td>
</tr>
<tr>
<td></td>
<td>Enables immediate-leave processing in the VLAN.</td>
</tr>
<tr>
<td></td>
<td>Note This command applies only to IGMPv2 hosts.</td>
</tr>
</tbody>
</table>
This example shows how to enable IGMP immediate-leave processing on interface VLAN 200 and to verify the configuration:

```
Switch# configure terminal
Switch(config)# ip igmp snooping vlan 200 immediate-leave
Configuring immediate leave on vlan 200
Switch(config)# end
Switch# show ip igmp interface vlan 200 | include immediate leave
Immediate leave          : Disabled
Switch(config)#
```

### Configuring the IGMP Leave Timer

Follows these guidelines when configuring the IGMP leave timer:

- You can configure the leave time globally or per VLAN.
- Configuring the leave time on a VLAN overrides the global setting.
- The default leave time is 1000 milliseconds.
- The IGMP configurable leave time is only supported on hosts running IGMP Version 2.
- The actual leave latency in the network is usually the configured leave time. However, the leave time might vary around the configured time, depending on real-time CPU load conditions, network delays and the amount of traffic sent through the interface.

To enable the IGMP configurable-leave timer, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# ip igmp snooping last-member-query-interval time</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config)# ip igmp snooping vlan vlan_ID last-member-query-interval time</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch# show ip igmp snooping</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Switch# copy running-config startup-config</td>
</tr>
</tbody>
</table>

This example shows how to enable the IGMP configurable-leave timer and to verify the configuration:

```
Switch# configure terminal
Switch(config)# ip igmp snooping last-member-query-interval 200
Switch(config)# ip igmp snooping vlan 10 last-member-query-interval 500
Switch(config)# end
```
Switch# show ip igmp snooping show ip igmp snooping
Global IGMP Snooping configuration:
-----------------------------------
IGMP snooping              : Enabled
IGMPv3 snooping            : Enabled
Report suppression         : Enabled
TCN solicit query          : Disabled
TCN flood query count      : 2
Last Member Query Interval : 200

Vlan 1:
--------
IGMP snooping                       : Enabled
IGMPv2 immediate leave              : Disabled
Explicit host tracking              : Enabled
Multicast router learning mode      : pim-dvmrp
Last Member Query Interval          : 200
CGMP interoperability mode          : IGMP_ONLY

Vlan 10:
--------
IGMP snooping                       : Enabled
IGMPv2 immediate leave              : Disabled
Explicit host tracking              : Enabled
Multicast router learning mode      : pim-dvmrp
Last Member Query Interval          : 500
CGMP interoperability mode          : IGMP_ONLY

Switch#

Configuring IGMP Snooping Querier

The IGMP Snooping Querier feature can be enabled either globally (i.e. they affect every VLAN) or on a per-vlan basis.

Note

The IGMP snooping querier is disabled by default.

To configure IGMP Snooping Querier, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1  | Switch# configure terminal
|         | Enters global configuration mode. |
| Step 2  | Switch(config)# [no] ip igmp snooping [vlan vlan_id] querier
|         | Enables IGMP Snooping Querier. |
| Step 3  | Switch(config)# [no] ip igmp snooping [vlan vlan_id] querier address abcd
|         | Configures the IGMP Snooping Querier source IP address. |
| Step 4  | Switch(config)# [no] ip igmp snooping [vlan vlan_id] querier version [1 | 2]
|         | Configures IGMP Snooping Querier IGMP version. |
| Step 5  | Switch(config)# ip igmp snooping [vlan vlan_id] querier query-interval interval
|         | Configures IGMP Snooping Querier query interval. |
| Step 6  | Switch(config)# ip igmp snooping [vlan vlan_id] querier max-response-time value
|         | Configures IGMP Snooping Querier query maximum response time. |
Configuring IGMP Snooping

For an example of how to display Querier information, refer to the “Displaying IGMP Snooping Querier Information” section on page 21-19.

Configuring Explicit Host Tracking

For IGMPv3, EHT is enabled by default and can be disabled on a per-VLAN basis.

To disable EHT processing on a VLAN, perform this task:

```
Step 7
Switch(config)# ip igmp snooping [vlan vlan_id] querier timer expiry value
```

Step 8
```
Switch(config)# ip igmp snooping [vlan vlan_id] querier tcn query count value
```

Step 9
```
Switch(config)# ip igmp snooping [vlan vlan_id] querier tcn query interval value
```

Step 10
```
Switch(config)# end
```

For an example of how to display Querier information, refer to the “Displaying IGMP Snooping Querier Information” section on page 21-19.

```
Command Purpose
Step 7 Switch(config)# ip igmp snooping [vlan vlan_id] querier timer expiry value Configures IGMP Snooping Querier expiry time out.
Step 8 Switch(config)# ip igmp snooping [vlan vlan_id] querier tcn query count value Configures IGMP Snooping Querier tcn query count.
Step 9 Switch(config)# ip igmp snooping [vlan vlan_id] querier tcn query interval value Configures IGMP Snooping Querier tcn query interval.
Step 10 Switch(config)# end Returns to privileged EXEC mode.
```

This example shows how to disable IGMP EHT on VLAN 200 and to verify the configuration:

```
Switch# configure terminal
Switch(config)# no ip igmp snooping vlan 200 explicit-tracking
Switch(config)# end
Switch# show ip igmp snooping vlan 200 | include Explicit host tracking
Explicit host tracking : Disabled
```

Configuring a Host Statically

Hosts normally join multicast groups dynamically, but you can also configure a host statically on an interface.

To configure a host statically on an interface, perform this task:

```
Command Purpose
Step 7 Switch(config)# [no] ip igmp snooping vlan vlan_ID explicit-tracking Enables EHT on a VLAN.
The no keyword disables EHT.
Step 8 Switch(config)# ip igmp snooping vlan vlan_ID static mac_address interface interface_num Configures a host statically in the VLAN.
```

```
Command Purpose
Step 8 Switch(config-if)# ip igmp snooping vlan vlan_ID static mac_address interface interface_num Configures a host statically in the VLAN.
```

Note This command cannot be configured to receive traffic for specific source IP addresses.
Chapter 21  Configuring IGMP Snooping and Filtering

Configuring IGMP Snooping

This example shows how to configure a host statically in VLAN 200 on interface FastEthernet 2/11:

```
Switch# configure terminal
Switch(config)# ip igmp snooping vlan 200 static 0100.5e02.0203 interface fastethernet 2/11
Configuring port FastEthernet2/11 on group 0100.5e02.0203 vlan 200
Switch(config)# end
```

Suppressing Multicast Flooding

An IGMP snooping-enabled switch floods multicast traffic to all ports in a VLAN when a spanning-tree Topology Change Notification (TCN) is received. Multicast flooding suppression enables a switch to stop sending such traffic. To support flooding suppression, the following interface and global commands were introduced in Cisco IOS Release 12.1(11b)EW.

The interface command is as follows:

```
[no | default] ip igmp snooping tcn flood
```

The global commands are as follows:

```
[no | default] ip igmp snooping tcn flood query count [1 - 10]
[no | default] ip igmp snooping tcn query solicit
```

Prior to Cisco IOS Release 12.1(11b)EW, when a spanning tree topology change notification (TCN) was received by a switch, the multicast traffic was flooded to all the ports in a VLAN for a period of three IGMP query intervals. This was necessary for redundant configurations. In Cisco IOS Release 12.1(11b)EW, the default time period the switch waits before multicast flooding stops was changed to two IGMP query intervals.

This flooding behavior is undesirable if the switch that does the flooding has many ports that are subscribed to different groups. The traffic could exceed the capacity of the link between the switch and the end host, resulting in packet loss.

With the `no ip igmp snooping tcn flood` command, you can disable multicast flooding on a switch interface following a topology change. Only the multicast groups that have been joined by a port are sent to that port, even during a topology change.

With the `ip igmp snooping tcn flood query count` command, you can enable multicast flooding on a switch interface for a short period of time following a topology change by configuring an IGMP query threshold.

Typically, if a topology change occurs, the spanning tree root switch issues a global IGMP leave message (referred to as a “query solicitation”) with the group multicast address 0.0.0.0. When a switch receives this solicitation, it floods this solicitation on all ports in the VLAN where the spanning tree change occurred. When the upstream router receives this solicitation, it immediately issues an IGMP general query.

With the `ip igmp snooping tcn query solicit` command, you can now direct a non-spanning tree root switch to issue the same query solicitation.

The following sections provide additional details on the new commands and illustrate how to use them.

IGMP Snooping Interface Configuration

A topology change in a VLAN may invalidate previously learned IGMP snooping information. A host that was on one port before the topology change may move to another port after the topology change. When the topology changes, the Catalyst 4500 series switch takes special actions to ensure that multicast traffic is delivered to all multicast receivers in that VLAN.
When the spanning tree protocol is running in a VLAN, a spanning tree topology change notification (TCN) is issued by the root switch in the VLAN. A Catalyst 4500 series switch that receives a TCN in a VLAN for which IGMP snooping has been enabled immediately enters into “multicast flooding mode” for a period of time until the topology restabilizes and the new locations of all multicast receivers are learned.

While in “multicast flooding mode,” IP multicast traffic is delivered to all ports in the VLAN, and not restricted to those ports on which multicast group members have been detected.

Starting with Cisco IOS Release 12.1(11b)EW, you can manually prevent IP multicast traffic from being flooded to a switchport by using the `no ip igmp snooping tcn flood` command on that port.

For trunk ports, the configuration applies to all VLANs.

By default, multicast flooding is enabled. Use the `no` keyword to disable flooding, and use `default` to restore the default behavior (flooding is enabled).

To disable multicast flooding on an interface, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>**Switch(config)# interface (fastethernet</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><strong>Switch(config-if)# no ip igmp snooping tcn flood</strong></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><strong>Switch(config)# end</strong></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>**Switch# show running interface (fastethernet</td>
</tr>
</tbody>
</table>

This example shows how to disable multicast flooding on interface FastEthernet 2/11:

```
Switch(config)# interface fastethernet 2/11
Switch(config-if)# no ip igmp snooping tcn flood
Switch(config-if)# end
Switch#
```

**IGMP Snooping Switch Configuration**

By default, “flooding mode” persists until the switch receives two IGMP general queries. You can change this period of time by using the `ip igmp snooping tcn flood query count` command, where `n` is a number between 1 and 10.

This command operates at the global configuration level.

The default number of queries is 2. The `no` and `default` keywords restore the default.
To establish an IGMP query threshold, perform this task:

**Command**

```
Step 1  Switch(config)#
ip igmp snooping tcn flood query count <n>
```

**Purpose**

Modifies the number of IGMP queries the switch waits for before it stops flooding multicast traffic.

To return the switch to the default number of IGMP queries, enter this command:
```
default ip igmp snooping tcn flood query count .
```

```
Step 2  Switch(config)# end
```

Exits configuration mode.

This example shows how to modify the switch to stop flooding multicast traffic after four queries:
```
Switch(config)# ip igmp snooping tcn flood query count 4
Switch(config)# end
Switch#
```

When a spanning tree root switch receives a topology change in an IGMP snooping-enabled VLAN, the switch issues a query solicitation that causes an IOS router to send out one or more general queries. The new command `ip igmp snooping tcn query solicit` causes the switch to send the query solicitation whenever it notices a topology change, even if that switch is not the spanning tree root.

This command operates at the global configuration level.

By default, query solicitation is disabled unless the switch is the spanning tree root. The `default` keyword restores the default behavior.

To direct a switch to send a query solicitation, perform this task:

**Command**

```
Step 1  Switch(config)# ip igmp snooping tcn query solicit
```

**Purpose**

Configures the switch to send a query solicitation when a TCN is detected.

To stop the switch from sending a query solicitation (if it’s not a spanning tree root switch), enter this command:
```
no ip igmp snooping tcn query solicit
```

```
Step 2  Switch(config)# end
```

Exits configuration mode.

This example shows how to configure the switch to send a query solicitation upon detecting a TCN:
```
Switch(config)# ip igmp snooping tcn query solicit
Switch(config)# end
Switch#
```

**Displaying IGMP Snooping Information**

The following sections show how to display IGMP snooping information:

- Displaying Querier Information, page 21-15
- Displaying IGMP Host Membership Information, page 21-15
- Displaying Group Information, page 21-16
- Displaying Multicast Router Interfaces, page 21-17
Displaying Querier Information

To display querier information, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# show ip igmp snooping querier [vlan vlan_ID]</td>
<td>Displays multicast router interfaces.</td>
</tr>
</tbody>
</table>

This example shows how to display the IGMP snooping querier information for all VLANs on the switch:

Switch# show ip igmp snooping querier
Vlan | IP Address | IGMP Version | Port |
---|---|---|---|
2 | 10.10.10.1 | v2 | Router |
3 | 172.20.50.22 | v3 | Fa3/15 |

This example shows how to display the IGMP snooping querier information for VLAN 3:

Switch# show ip igmp snooping querier vlan 3
Vlan | IP Address | IGMP Version | Port |
---|---|---|---|
3 | 172.20.50.22 | v3 | Fa3/15 |

Displaying IGMP Host Membership Information

Note

By default, EHT maintains a maximum of 1000 entries in the EHT database. Once this limit is reached, no additional entries are created. To create additional entries, clear the database with the clear ip igmp snooping membership vlan command.

To display host membership information, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# show ip igmp snooping membership [interface interface_num][vlan vlan_ID] [reporter a.b.c.d] [source a.b.c.d group a.b.c.d]</td>
<td>Displays Explicit Host Tracking information. Note This command is valid only if EHT is enabled on the switch.</td>
</tr>
</tbody>
</table>

This example shows how to display host membership information for VLAN 20 and to delete the EHT database:

Switch# show ip igmp snooping membership vlan 20
#channels: 5
#hosts : 1
Source/Group Interface Reporter Uptime Last-Join Last-Leave
Chapter 21      Configuring IGMP Snooping and Filtering

Displaying IGMP Snooping Information

This example shows how to display host membership for interface gi4/1:

Switch# clear ip igmp snooping membership vlan 20

This example shows how to display host membership for VLAN 20 and group 224.10.10.10:

Switch# show ip igmp snooping membership vlan 20 source 40.40.40.2 group 224.10.10.10

Displaying Group Information

To display detailed IGMPv3 information associated with a group, perform one of the following tasks:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Switch# show ip igmp snooping groups [vlan vlan_ID] | Displays groups, the type of reports that were received for the group (Host Type), and the list of ports on which reports were received.
The report list includes neither the multicast router ports nor the complete forwarding port set for the group. Rather, it lists the ports on which the reports have been received.
To display the complete forwarding port set for the group, display the CLI output for the MAC address that maps to this group by using the show mac-address-table multicast command. |
| Switch# show ip igmp snooping groups [vlan vlan_ID a.b.c.d] [summary|sources|hosts] | Displays information specific to a group address, providing details about the current state of the group with respect to sources and hosts.  
**Note** This command applies only to full IGMPv3 snooping support and can be used for IGMPv1, IGMPv2, or IGMPv3 groups. |
| Switch# show ip igmp snooping groups [vlan vlan_ID] [count] | Displays the total number of group addresses learned by the system on a global or per-VLAN basis. |
Chapter 21 Configuring IGMP Snooping and Filtering

Displaying IGMP Snooping Information

This example shows how to display the host types and ports of a group in VLAN 1:

```
Switch# show ip igmp snooping groups vlan 10 226.6.6.7
Vlan    Group     Version    Ports
-----------------------------
10   226.6.6.7   v3   Fa7/13, Fa7/14
Switch>
```

This example shows how to display the current state of a group with respect to a source IP address:

```
Switch# show ip igmp snooping groups vlan 10 226.6.6.7 sources
Source information for group 226.6.6.7:
Timers: Expired sources are deleted on next IGMP General Query

SourceIP   Expires   Uptime   Inc Hosts Exc Hosts
----------------------------------------------
2.0.0.1     00:03:04  00:03:48  2         0
2.0.0.2     00:03:04  00:02:07  2         0
Switch>
```

This example shows how to display the current state of a group with respect to a host MAC address:

```
Switch# show ip igmp snooping groups vlan 10 226.6.6.7 hosts
IGMPv3 host information for group 226.6.6.7
Timers: Expired hosts are deleted on next IGMP General Query

Host (MAC/IP)   Filter mode    Expires   Uptime   # Sources
-----------------------------
175.1.0.29     INCLUDE        stopped   00:00:51       2
175.2.0.30     INCLUDE        stopped   00:04:14       2
```

This example shows how to display summary information for an IGMPv3 group:

```
Switch# show ip igmp snooping groups vlan 10 226.6.6.7 summary
Group Address (Vlan 10) : 226.6.6.7
Host type : v3
Member Ports : Fa7/13, Fa7/14
Expires : stopped
Filter mode : INCLUDE
Sources : 2
Reporters (Include/Exclude) : 2/0
```

This example shows how to display the total number of group addresses learned by the system globally:

```
Switch# show ip igmp snooping groups count
Total number of groups: 54
```

This example shows how to display the total number of group addresses learned on VLAN 5:

```
Switch# show ip igmp snooping groups vlan 5 count
Total number of groups: 30
```

**Displaying Multicast Router Interfaces**

When you enable IGMP snooping, the switch automatically learns to which interface the multicast routers are connected.
To display multicast router interfaces, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# show ip igmp snooping mrouter vlan vlan_ID</td>
<td>Displays multicast router interfaces.</td>
</tr>
</tbody>
</table>

This example shows how to display the multicast router interfaces in VLAN 1:

```
Switch# show ip igmp snooping mrouter vlan 1
  vlan   ports
         ---------------------------
     1  Gi1/1,Gi2/1,Fa3/48,Router
Switch#
```

**Displaying MAC Address Multicast Entries**

To display MAC address multicast entries for a VLAN, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# show mac-address-table multicast vlan vlan_ID [count]</td>
<td>Displays MAC address multicast entries for a VLAN.</td>
</tr>
</tbody>
</table>

This example shows how to display MAC address multicast entries for VLAN 1:

```
Switch# show mac-address-table multicast vlan 1
  Multicast Entries
  vlan  mac address    type   ports
         ---------------------------
     1  0100.5e01.0101    igmp Switch,Gi6/1
     1  0100.5e01.0102    igmp Switch,Gi6/1
     1  0100.5e01.0103    igmp Switch,Gi6/1
     1  0100.5e01.0104    igmp Switch,Gi6/1
     1  0100.5e01.0105    igmp Switch,Gi6/1
     1  0100.5e01.0106    igmp Switch,Gi6/1
Switch#
```

This example shows how to display a total count of MAC address entries for VLAN 1:

```
Switch# show mac-address-table multicast vlan 1 count
  Multicast MAC Entries for vlan 1:  4
Switch#
```

**Displaying IGMP Snooping Information on a VLAN Interface**

To display IGMP snooping information on a VLAN, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# show ip igmp snooping vlan vlan_ID</td>
<td>Displays IGMP snooping information on a VLAN interface.</td>
</tr>
</tbody>
</table>
Chapter 21 Configuring IGMP Snooping and Filtering

Displaying IGMP Snooping Information

This example shows how to display IGMP snooping information on VLAN 5:

Switch# show ip igmp snooping vlan 5
Global IGMP Snooping configuration:
-----------------------------------
IGMP snooping : Enabled
IGMPV3 snooping support : Full
Report suppression : Enabled
TCN solicit query : Disabled
TCN flood query count : 2
Vlan 5:
--------
IGMP snooping : Enabled
Immediate leave : Disabled
Explicit Host Tracking : Disabled
Multicast router learning mode : pim-dvmrp
CGMP interoperability mode : IGMP_ONLY

Displaying IGMP Snooping Querier Information

To display IGMP Snooping Querier information, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# show ip igmp snooping querier [vlan vlan_ID] [detail]</td>
<td>Displays the IGMP Snooping Querier state.</td>
</tr>
</tbody>
</table>

This example shows how to display Querier information:

switch# show ip igmp snooping querier vlan 2 detail
IP address : 1.2.3.4
IGMP version : v2
Port : Router/Switch
Max response time : 12s

Global IGMP switch querier status
-----------------------------------
admin state : Enabled
admin version : 2
source IP address : 1.2.3.4
query-interval (sec) : 130
max-response-time (sec) : 10
querier-timeout (sec) : 100
tcn query count : 2
tcn query interval (sec) : 10

Vlan 2: IGMP switch querier status
-----------------------------------
admin state : Enabled
admin version : 2
source IP address : 1.2.3.4
query-interval (sec) : 55
max-response-time (sec) : 12
querier-timeout (sec) : 70
tcn query count : 10
Configuring IGMP Filtering

This section includes the following subsections:

- Default IGMP Filtering Configuration, page 21-20
- Configuring IGMP Profiles, page 21-21
- Applying IGMP Profiles, page 21-22
- Setting the Maximum Number of IGMP Groups, page 21-23

Note

The IGMP filtering feature works for IGMPv1 and IGMPv2 only.

In some environments, for example metropolitan or multiple-dwelling unit (MDU) installations, an administrator might want to control the multicast groups to which a user on a switch port can belong. This allows the administrator to control the distribution of multicast services, such as IP/TV, based on some type of subscription or service plan.

With the IGMP filtering feature, an administrator can exert this type of control. With this feature, you can filter multicast joins on a per-port basis by configuring IP multicast profiles and associating them with individual switch ports. An IGMP profile can contain one or more multicast groups and specifies whether access to the group is permitted or denied. If an IGMP profile denying access to a multicast group is applied to a switch port, the IGMP join report requesting the stream of IP multicast traffic is dropped, and the port is not allowed to receive IP multicast traffic from that group. If the filtering action permits access to the multicast group, the IGMP report from the port is forwarded for normal processing.

IGMP filtering controls only IGMP membership join reports and has no relationship to the function that directs the forwarding of IP multicast traffic.

You can also set the maximum number of IGMP groups that a Layer 2 interface can join with the `ip igmp max-groups <n>` command.

Default IGMP Filtering Configuration

Table 21-2 shows the default IGMP filtering configuration.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>IGMP filters</td>
<td>No filtering</td>
</tr>
<tr>
<td>IGMP maximum number of IGMP groups</td>
<td>No limit</td>
</tr>
<tr>
<td>IGMP profiles</td>
<td>None defined</td>
</tr>
</tbody>
</table>
Configuring IGMP Profiles

To configure an IGMP profile and to enter IGMP profile configuration mode, use the `ip igmp profile` global configuration command. From the IGMP profile configuration mode, you can specify the parameters of the IGMP profile to be used for filtering IGMP join requests from a port. When you are in IGMP profile configuration mode, you can create the profile using these commands:

- **deny**: Specifies that matching addresses are denied; this is the default condition.
- **exit**: Exits from igmp-profile configuration mode.
- **no**: Negates a command or sets its defaults.
- **permit**: Specifies that matching addresses are permitted.
- **range**: Specifies a range of IP addresses for the profile. You can enter a single IP address or a range with starting and ending addresses.

By default, no IGMP profiles are configured. When a profile is configured with neither the `permit` nor the `deny` keyword, the default is to deny access to the range of IP addresses.

To create an IGMP profile for a port, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong> Switch(config)# ip igmp profile profile number</td>
<td>Enters IGMP profile configuration mode, and assigns a number to the profile you are configuring. The range is from 1 to 4,294,967,295.</td>
</tr>
<tr>
<td><strong>Step 3</strong> Switch(config-igmp-profile)# permit</td>
<td>(Optional) Sets the action to permit or deny access to the IP multicast address. If no action is configured, the default for the profile is to deny access.</td>
</tr>
<tr>
<td><strong>Step 4</strong> Switch(config-igmp-profile)# range ip multicast address</td>
<td>Enters the IP multicast address or range of IP multicast addresses to which access is being controlled. If entering a range, enter the low IP multicast address, a space, and the high IP multicast address. Use the <code>range</code> command multiple times to enter multiple addresses or ranges of addresses.</td>
</tr>
<tr>
<td><strong>Step 5</strong> Switch(config-igmp-profile)# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 6</strong> Switch# show ip igmp profile profile number</td>
<td>Verifies the profile configuration.</td>
</tr>
<tr>
<td><strong>Step 7</strong> Switch# copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

To delete a profile, use the `no ip igmp profile profile number` global configuration command.

To delete an IP multicast address or range of IP multicast addresses, use the `no range ip multicast address` IGMP profile configuration command.

This example shows how to create IGMP profile 4 (allowing access to the single IP multicast address) and how to verify the configuration. If the action were to deny (the default), it would not appear in the `show ip igmp profile command` output.

```plaintext
Switch# configure terminal
Switch(config)# ip igmp profile 4
Switch(config-igmp-profile)# permit
Switch(config-igmp-profile)# range 229.9.9.0
Switch(config-igmp-profile)# end
```
Switch# show ip igmp profile 4
IGMP Profile 4
permit
range 229.9.9.0 229.9.9.0

### Applying IGMP Profiles

To control access as defined in an IGMP profile, use the `ip igmp filter` interface configuration command to apply the profile to the appropriate interfaces. You can apply a profile to multiple interfaces, but each interface can only have one profile applied to it.

**Note**

You can apply IGMP profiles to Layer 2 ports only. You cannot apply IGMP profiles to routed ports (or SVIs) or to ports that belong to an EtherChannel port group.

To apply an IGMP profile to a switch port, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# interface interface-id</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config-if)# ip igmp filter profile number</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config-if)# end</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch# show running configuration interface interface-id</td>
</tr>
<tr>
<td>Step 6</td>
<td>Switch# copy running-config startup-config</td>
</tr>
</tbody>
</table>

To remove a profile from an interface, use the `no ip igmp filter` command.

This example shows how to apply IGMP profile 4 to an interface and to verify the configuration:

```
Switch# configure terminal
Switch(config)# interface fastethernet2/12
Switch(config-if)# ip igmp filter 4
Switch(config-if)# end
Switch# show running-config interface fastethernet2/12
Building configuration...
Current configuration : 123 bytes
!
interface FastEthernet2/12
   no ip address
   shutdown
   snmp trap link-status
   ip igmp max-groups 25
   ip igmp filter 4
end
```
Setting the Maximum Number of IGMP Groups

You can set the maximum number of IGMP groups that a Layer 2 interface can join by using the `ip igmp max-groups` interface configuration command. Use the `no` form of this command to set the maximum back to the default, which is no limit.

**Note**

This restriction applies to Layer 2 ports only. You cannot set a maximum number of IGMP groups on routed ports (or SVIs) or on ports that belong to an EtherChannel port group.

To apply an IGMP profile on a switch port, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# interface interface-id</td>
</tr>
<tr>
<td></td>
<td>Enters interface configuration mode, and enter the physical interface to configure, for example gigabitethernet1/1. The interface must be a Layer 2 port that does not belong to an EtherChannel group.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config-if)# ip igmp max-groups number</td>
</tr>
<tr>
<td></td>
<td>Sets the maximum number of IGMP groups that the interface can join. The range is from 0 to 4,294,967,294. By default, no maximum is set.</td>
</tr>
<tr>
<td></td>
<td>To remove the maximum group limitation and return to the default of no maximum, use the <code>no ip igmp max-groups</code> command.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config-if)# end</td>
</tr>
<tr>
<td></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch# show running-configuration interface interface-id</td>
</tr>
<tr>
<td></td>
<td>Verifies the configuration.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Switch# copy running-config startup-config</td>
</tr>
<tr>
<td></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

This example shows how to limit the number of IGMP groups that an interface can join to 25:

```
Switch# configure terminal
Switch(config)# interface fastethernet2/12
Switch(config-if)# ip igmp max-groups 25
Switch(config-if)# end
Switch# show running-configuration interface fastethernet2/12
Building configuration...

Current configuration : 123 bytes
!
interface FastEthernet2/12
   no ip address
   shutdown
   snmp trap link-status
   ip igmp max-groups 25
   ip igmp filter 4
end
```
Displaying IGMP Filtering Configuration

You can display IGMP profile and maximum group configuration for all interfaces on the switch or for a specified interface.

To display IGMP profiles, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# show ip igmp profile [profile number]</td>
<td>Displays the specified IGMP profile or all IGMP profiles defined on the switch.</td>
</tr>
</tbody>
</table>

To display interface configuration, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# show running-configuration [interface interface-id]</td>
<td>Displays the configuration of the specified interface or all interfaces on the switch, including (if configured) the maximum number of IGMP groups to which an interface can belong and the IGMP profile applied to the interface.</td>
</tr>
</tbody>
</table>

This is an example of the `show ip igmp profile` privileged EXEC command when no profile number is entered. All profiles defined on the switch are displayed.

Switch# show ip igmp profile
IGMP Profile 3
range 230.9.9.0 230.9.9.0
IGMP Profile 4
permit
range 229.9.9.0 229.255.255.255

This is an example of the `show running-config` privileged EXEC command when an interface is specified with IGMP maximum groups configured and IGMP profile 4 has been applied to the interface:

Switch# show running-config interface fastethernet2/12
Building configuration...
Current configuration : 123 bytes
  interface FastEthernet2/12
    no ip address
    shutdown
    snmp trap link-status
    ip igmp max-groups 25
    ip igmp filter 4
    end
Configuring IPv6 MLD Snooping

Multicast Listener Discovery (MLD) snooping allows you to enable efficient distribution of IP version 6 (IPv6) multicast data to clients and routers in a switched network on the Catalyst 4500 series switch.

This chapter includes these sections:

- About MLD Snooping, page 22-1
- Configuring IPv6 MLD Snooping, page 22-5
- Displaying MLD Snooping Information, page 22-11

For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

About MLD Snooping

In IP version 4 (IPv4), Layer 2 switches can use Internet Group Management Protocol (IGMP) snooping to limit the flooding of multicast traffic by dynamically configuring Layer 2 interfaces so that multicast traffic is forwarded to only those interfaces associated with IP multicast devices. In IPv6, MLD snooping performs a similar function. With MLD snooping, IPv6 multicast data is selectively forwarded to a list of ports that want to receive the data, instead of being flooded to all ports in a VLAN. This list is constructed by snooping IPv6 multicast control packets.
MLD is a protocol used by IPv6 multicast routers to discover the presence of multicast listeners (nodes wishing to receive IPv6 multicast packets) on its directly attached links and to discover which multicast packets are of interest to neighboring nodes. MLD is derived from IGMP; MLD version 1 (MLDv1) is equivalent to IGMPv2 and MLD version 2 (MLDv2) is equivalent to IGMPv3. MLD is a subprotocol of Internet Control Message Protocol version 6 (ICMPv6), and MLD messages are a subset of ICMPv6 messages, identified in IPv6 packets by a preceding Next Header value of 58.

The switch supports two versions of MLD snooping:
- MLDv1 snooping detects MLDv1 control packets and sets up traffic bridging based on IPv6 destination multicast addresses.
- MLDv2 basic snooping (MBSS) uses MLDv2 control packets to set up traffic forwarding based on IPv6 destination multicast addresses.

The switch can snoop on both MLDv1 and MLDv2 protocol packets and bridge IPv6 multicast data based on destination IPv6 multicast addresses.

MLD snooping can be enabled or disabled globally or per VLAN. When MLD snooping is enabled, a per-VLAN IPv6 multicast MAC address table is constructed in software and a per-VLAN IPv6 multicast address table is constructed in software and hardware. The switch then performs IPv6 multicast-address based bridging in hardware.

These sections describe some parameters of IPv6 MLD snooping:
- MLD Messages, page 22-2
- MLD Queries, page 22-3
- Multicast Client Aging Robustness, page 22-3
- Multicast Router Discovery, page 22-3
- MLD Reports, page 22-4
- MLD Done Messages and Immediate-Leave, page 22-4
- Topology Change Notification Processing, page 22-4

**MLD Messages**

MLDv1 supports three types of messages:
- Listener Queries are the equivalent of IGMPv2 queries and are either General Queries or Multicast-Address-Specific Queries (MASQs).
- Multicast Listener Reports are the equivalent of IGMPv2 reports
- Multicast Listener Done messages are the equivalent of IGMPv2 leave messages.

MLDv2 supports MLDv2 queries and reports, as well as MLDv1 Report and Done messages.

Message timers and state transitions resulting from messages being sent or received are the same as those of IGMPv2 messages. MLD messages that do not have valid link-local IPv6 source addresses are ignored by MLD routers and switches.
**MLD Queries**

The switch sends out MLD queries, constructs an IPv6 multicast address database, and generates MLD group-specific and MLD group-and-source-specific queries in response to MLD Done messages. The switch also supports report suppression, report proxying, Immediate-Leave functionality, and static IPv6 multicast MAC-address configuration.

When MLD snooping is disabled, all MLD queries are flooded in the ingress VLAN.

When MLD snooping is enabled, received MLD queries are flooded in the ingress VLAN, and a copy of the query is sent to the CPU for processing. From the received query, MLD snooping builds the IPv6 multicast address database. It detects multicast router ports, maintains timers, sets report response time, learns the querier IP source address for the VLAN, learns the querier port in the VLAN, and maintains multicast-address aging.

When a group exists in the MLD snooping database, the switch responds to a group-specific query by sending an MLDv1 report. When the group is unknown, the group-specific query is flooded to the ingress VLAN.

When a host wants to leave a multicast group, it can send out an MLD Done message (equivalent to IGMP Leave message). When the switch receives an MLDv1 Done message, if Immediate-Leave is not enabled, the switch sends an MASQ to the port from which the message was received to determine if other devices connected to the port should remain in the multicast group.

**Multicast Client Aging Robustness**

You can configure port membership removal from addresses based on the number of queries. A port is removed from membership to an address only when there are no reports to the address on the port for the configured number of queries. The default number is 2.

**Multicast Router Discovery**

Like IGMP snooping, MLD snooping performs multicast router discovery, with these characteristics:

- Ports configured by a user never age out.
- Dynamic port learning results from MLDv1 snooping queries and IPv6 PIMv2 packets.
- If there are multiple routers on the same Layer 2 interface, MLD snooping tracks a single multicast router on the port (the router that most recently sent a router control packet).
- Dynamic multicast router port aging is based on a default timer of 5 minutes; the multicast router is deleted from the router port list if no control packet is received on the port for 5 minutes.
- IPv6 multicast router discovery only takes place when MLD snooping is enabled on the switch.
- Received IPv6 multicast router control packets are always flooded to the ingress VLAN, whether MLD snooping is enabled on the switch.
- After the discovery of the first IPv6 multicast router port, unknown IPv6 multicast data is forwarded only to the discovered router ports (before that time, all IPv6 multicast data is flooded to the ingress VLAN).
Chapter 22      Configuring IPv6 MLD Snooping

MLD Reports

The processing of MLDv1 join messages is essentially the same as with IGMPv2. When no IPv6 multicast routers are detected in a VLAN, reports are not processed or forwarded from the switch. When IPv6 multicast routers are detected and an MLDv1 report is received, an IPv6 multicast group address and an IPv6 multicast MAC address are entered in the VLAN MLD database. Then all IPv6 multicast traffic to the group within the VLAN is forwarded using this address. When MLD snooping is disabled, reports are flooded in the ingress VLAN.

When MLD snooping is enabled, MLD report suppression, called listener message suppression, is automatically enabled. With report suppression, the switch forwards the first MLDv1 report received by a group to IPv6 multicast routers; subsequent reports for the group are not sent to the routers. When MLD snooping is disabled, report suppression is disabled, and all MLDv1 reports are flooded to the ingress VLAN.

The switch also supports MLDv1 proxy reporting. When an MLDv1 MASQ is received, the switch responds with MLDv1 reports for the address on which the query arrived if the group exists in the switch on another port and if the port on which the query arrived is not the last member port for the address.

MLD Done Messages and Immediate-Leave

When the Immediate-Leave feature is enabled and a host sends an MLDv1 Done message (equivalent to an IGMP leave message), the port on which the Done message was received is immediately deleted from the group. You enable Immediate-Leave on VLANs and (as with IGMP snooping), you should only use the feature on VLANs where a single host is connected to the port. If the port was the last member of a group, the group is also deleted, and the leave information is forwarded to the detected IPv6 multicast routers.

When Immediate Leave is not enabled in a VLAN (which would be the case when there are multiple clients for a group on the same port) and a Done message is received on a port, an MASQ is generated on that port. The user can control when a port membership is removed for an existing address in terms of the number of MASQs. A port is removed from membership to an address when there are no MLDv1 reports to the address on the port for the configured number of queries.

The number of MASQs generated is configured by using the `ipv6 mld snooping last-listener-query count` global configuration command. The default number is 2.

The MASQ is sent to the IPv6 multicast address for which the Done message was sent. If there are no reports sent to the IPv6 multicast address specified in the MASQ during the switch maximum response time, the port on which the MASQ was sent is deleted from the IPv6 multicast address database. The maximum response time is the time configured by using the `ipv6 mld snooping last-listener-query-interval` global configuration command. If the deleted port is the last member of the multicast address, the multicast address is also deleted, and the switch sends the address leave information to all detected multicast routers.

Topology Change Notification Processing

When topology change notification (TCN) solicitation is enabled by using the `ipv6 mld snooping tcn query solicit` global configuration command, MLDv1 snooping sets the VLAN to flood all IPv6 multicast traffic with a configured number of MLDv1 queries before it begins sending multicast data only to selected ports. You set this value by using the `ipv6 mld snooping tcn flood query count` global
configuration command. The default is to send two queries. The switch also generates MLDv1 global
Done messages with valid link-local IPv6 source addresses when the switch becomes the STP root in the
VLAN or when it is configured by the user. This is same as done in IGMP snooping.

**Configuring IPv6 MLD Snooping**

These sections describe how to configure IPv6 MLD snooping:
- Default MLD Snooping Configuration, page 22-5
- MLD Snooping Configuration Guidelines, page 22-6
- Enabling or Disabling MLD Snooping, page 22-6
- Configuring a Static Multicast Group, page 22-7
- Configuring a Multicast Router Port, page 22-7
- Enabling MLD Immediate Leave, page 22-8
- Configuring MLD Snooping Queries, page 22-9
- Disabling MLD Listener Message Suppression, page 22-10

**Default MLD Snooping Configuration**

Table 22-1 shows the default MLD snooping configuration.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>MLD snooping (Global)</td>
<td>Disabled.</td>
</tr>
<tr>
<td>MLD snooping (per VLAN)</td>
<td>Enabled. MLD snooping must be globally enabled for VLAN MLD snooping to take place.</td>
</tr>
<tr>
<td>IPv6 Multicast addresses</td>
<td>None configured.</td>
</tr>
<tr>
<td>IPv6 Multicast router ports</td>
<td>None configured.</td>
</tr>
<tr>
<td>MLD snooping Immediate Leave</td>
<td>Disabled.</td>
</tr>
</tbody>
</table>
| MLD snooping robustness variable | Global: 2; Per VLAN: 0.  
  **Note** The VLAN value overrides the global setting. When the VLAN value is 0, the VLAN uses the global count. |
MLD Snooping Configuration Guidelines

When configuring MLD snooping, consider these guidelines:

- You can configure MLD snooping characteristics at any time, but you must globally enable MLD snooping by using the `ipv6 mld snooping` global configuration command for the configuration to take effect.

- MLD snooping and IGMP snooping act independently of each other. You can enable both features at the same time on the switch. The total number of IPv4 and IPv6 multicast groups entries that can coexist on the Catalyst 4500 series switch is limited to 16384.

- The Supervisor Engine 7-E with 512MB of memory supports about 11000 MLD Snooping multicast groups whereas a Supervisor Engine 6-E with 1GB memory supports 16384 MLD Snooping multicast groups.

Enabling or Disabling MLD Snooping

By default, IPv6 MLD snooping is globally disabled on the switch and enabled on all VLANs. When MLD snooping is globally disabled, it is also disabled on all VLANs. When you globally enable MLD snooping, the VLAN configuration overrides the global configuration. That is, MLD snooping is enabled only on VLAN interfaces in the default state (enabled).

You can enable and disable MLD snooping on a per-VLAN basis, but if you globally disable MLD snooping, it is disabled in all VLANs. If global snooping is enabled, you can enable or disable VLAN snooping.

To globally enable MLD snooping on the switch, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Switch(config)# ipv6 mld snooping</td>
<td>Globally enables MLD snooping on the switch.</td>
</tr>
<tr>
<td>Switch(config)# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Switch# copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

To globally disable MLD snooping on the switch, use the `no ipv6 mld snooping` global configuration command.

To enable MLD snooping on a VLAN, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Switch(config)# ipv6 mld snooping</td>
<td>Globally enables MLD snooping on the switch.</td>
</tr>
<tr>
<td>Switch(config)# ipv6 mld snooping vlan vlan-id</td>
<td>Enables MLD snooping on the VLAN.The VLAN ID range is 1 to 1001 and 1006 to 4094.</td>
</tr>
<tr>
<td>Note</td>
<td>MLD snooping must be globally enabled for VLAN snooping to be enabled.</td>
</tr>
</tbody>
</table>
To disable MLD snooping on a VLAN interface, use the `no ipv6 mld snooping vlan vlan-id` global configuration command for the specified VLAN number.

### Configuring a Static Multicast Group

Hosts or Layer 2 ports normally join multicast groups dynamically, but you can also statically configure an IPv6 multicast address and member ports for a VLAN.

To add a Layer 2 port as a member of a multicast group, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 Switch(config)# <code>configure terminal</code></td>
<td>Enters global configuration mode</td>
</tr>
<tr>
<td>Step 2 Switch(config)# <code>ipv6 mld snooping vlan vlan-id static ipv6_multicast_address interface interface-id</code></td>
<td>Statically configures a multicast group with a Layer 2 port as a member of a multicast group:</td>
</tr>
<tr>
<td></td>
<td>• <code>vlan-id</code> is the multicast group VLAN ID. The VLAN ID range is 1 to 1001 and 1006 to 4094.</td>
</tr>
<tr>
<td></td>
<td>• <code>ipv6_multicast_address</code> is the 128-bit group IPv6 address. The address must be in the form specified in RFC 2373.</td>
</tr>
<tr>
<td></td>
<td>• <code>interface-id</code> is the member port. It can be a physical interface or a port channel (1 to 64).</td>
</tr>
<tr>
<td>Step 3 Switch(config)# <code>end</code></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Step 4 Switch# <code>show mac-address-table multicast mld-snooping</code></td>
<td>Verifies the static member port and the IPv6 address.</td>
</tr>
<tr>
<td>Step 5 Switch# <code>copy running-config startup-config</code></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

To remove a Layer 2 port from the multicast group, use the `no ipv6 mld snooping vlan vlan-id static mac-address interface interface-id` global configuration command. If all member ports are removed from a group, the group is deleted.

This example shows how to statically configure an IPv6 MAC address:

```
Switch# `configure terminal`
Switch(config)# `ipv6 mld snooping vlan 2 static 3333.0000.0003 interface gigabitethernet1/1`
Switch(config)# `end`
```

### Configuring a Multicast Router Port

Although MLD snooping learns about router ports through MLD queries and PIMv6 queries, you can also use the command-line interface (CLI) to add a multicast router port to a VLAN. To add a multicast router port (add a static connection to a multicast router), use the `ipv6 mld snooping vlan mrouter` global configuration command on the switch.
Chapter 22      Configuring IPv6 MLD Snooping

Configuring IPv6 MLD Snooping

Note
Static connections to multicast routers are supported only on switch ports.

To add a multicast router port to a VLAN, follow these steps:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# ipv6 mld snooping vlan vlan-id mrouter interface interface-id</td>
</tr>
<tr>
<td></td>
<td>Specifies the multicast router VLAN ID, and specify the interface to the multicast router.</td>
</tr>
<tr>
<td></td>
<td>- The VLAN ID range is 1 to 1001 and 1006 to 4094.</td>
</tr>
<tr>
<td></td>
<td>- The interface can be a physical interface or a port channel.</td>
</tr>
<tr>
<td></td>
<td>The port-channel range is 1 to 64.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch# show ipv6 mld snooping mrouter [vlan vlan-id]</td>
</tr>
<tr>
<td></td>
<td>Verifies that IPv6 MLD snooping is enabled on the VLAN interface.</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch# copy running-config startup-config</td>
</tr>
<tr>
<td></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

To remove a multicast router port from the VLAN, use the no ipv6 mld snooping vlan vlan-id mrouter interface interface-id global configuration command.

This example shows how to add a multicast router port to VLAN 200:

```
Switch# configure terminal
Switch(config)# ipv6 mld snooping vlan 200 mrouter interface gigabitethernet1/0/2
Switch(config)# exit
```

Enabling MLD Immediate Leave

When you enable MLDv1 Immediate Leave, the switch immediately removes a port from a multicast group when it detects an MLD Done message on that port. You should only use the Immediate-Leave feature when there is a single receiver present on every port in the VLAN. When there are multiple clients for a multicast group on the same port, you should not enable Immediate-Leave in a VLAN.

To enable MLDv1 Immediate Leave, follow these steps:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# ipv6 mld snooping vlan vlan-id immediate-leave</td>
</tr>
<tr>
<td></td>
<td>Enables MLD Immediate Leave on the VLAN interface.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch# show ipv6 mld snooping vlan vlan-id</td>
</tr>
<tr>
<td></td>
<td>Verifies that Immediate Leave is enabled on the VLAN interface.</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch# copy running-config startup-config</td>
</tr>
<tr>
<td></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>
Chapter 22  Configuring IPv6 MLD Snooping

To disable MLD Immediate Leave on a VLAN, use the \texttt{no ipv6 mld snooping vlan vlan-id immediate-leave} global configuration command.

This example shows how to enable MLD Immediate Leave on VLAN 130:

\begin{verbatim}
Switch# configure terminal
Switch(config)# ipv6 mld snooping vlan 130 immediate-leave
Switch(config)# exit
\end{verbatim}

### Configuring MLD Snooping Queries

When Immediate Leave is not enabled and a port receives an MLD Done message, the switch generates MASQs on the port and sends them to the IPv6 multicast address for which the Done message was sent. You can optionally configure the number of MASQs that are sent and the length of time the switch waits for a response before deleting the port from the multicast group.

To configure MLD snooping query characteristics for the switch or for a VLAN, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# ipv6 mld snooping robustness-variable value</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config)# ipv6 mld snooping vlan vlan-id robustness-variable value</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config)# ipv6 mld snooping last-listener-query-count count</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch(config)# ipv6 mld snooping vlan vlan-id last-listener-query-count count</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Switch(config)# ipv6 mld snooping last-listener-query-interval interval</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>Switch(config)# ipv6 mld snooping vlan vlan-id last-listener-query-interval interval</td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>Switch(config)# ipv6 mld snooping tcn query solicit</td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>Switch(config)# ipv6 mld snooping tcn flood query count count</td>
</tr>
</tbody>
</table>
### Configuring IPv6 MLD Snooping

This example shows how to set the MLD snooping global robustness variable to 3:

```markdown
Switch# configure terminal
Switch(config)# ipv6 mld snooping robustness-variable 3
Switch(config)# exit
```

This example shows how to set the MLD snooping last-listener query count for a VLAN to 3:

```markdown
Switch# configure terminal
Switch(config)# ipv6 mld snooping vlan 200 last-listener-query-count 3
Switch(config)# exit
```

This example shows how to set the MLD snooping last-listener query interval (maximum response time) to 2000 (2 seconds):

```markdown
Switch# configure terminal
Switch(config)# ipv6 mld snooping last-listener-query-interval 2000
Switch(config)# exit
```

### Disabling MLD Listener Message Suppression

MLD snooping listener message suppression is enabled by default. When it is enabled, the switch forwards only one MLD report per multicast router query. When message suppression is disabled, multiple MLD reports could be forwarded to the multicast routers.

To disable MLD listener message suppression, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# no ipv6 mld snooping listener-message-suppression</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch# show ipv6 mld snooping</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch# copy running-config startup-config</td>
</tr>
</tbody>
</table>

To re-enable MLD message suppression, use the `ipv6 mld snooping listener-message-suppression` global configuration command.
Displaying MLD Snooping Information

You can display MLD snooping information for dynamically learned and statically configured router ports and VLAN interfaces. You can also display MAC address multicast entries for a VLAN configured for MLD snooping.

To display MLD snooping information, use one or more of the privileged EXEC commands in Table 22-2.

Table 22-2 Commands for Displaying MLD Snooping Information

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show ipv6 mld snooping [vlan vlan-id]</code></td>
<td>Displays the MLD snooping configuration information for all VLANs on the switch or for a specified VLAN. (Optional) Enter <code>vlan vlan-id</code> to display information for a single VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094.</td>
</tr>
<tr>
<td><code>show ipv6 mld snooping mrouter [vlan vlan-id]</code></td>
<td>Displays information on dynamically learned and manually configured multicast router interfaces. When you enable MLD snooping, the switch automatically learns the interface to which a multicast router is connected. These are dynamically learned interfaces. (Optional) Enter <code>vlan vlan-id</code> to display information for a single VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094.</td>
</tr>
<tr>
<td><code>show ipv6 mld snooping querier [vlan vlan-id]</code></td>
<td>Displays information about the IPv6 address and incoming port for the most-recently received MLD query messages in the VLAN. (Optional) Enter <code>vlan vlan-id</code> to display information for a single VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094.</td>
</tr>
</tbody>
</table>
Configuring LLDP, and LLDP-MED

This chapter describes how to configure the Link Layer Discovery Protocol (LLDP) and LLDP Media Endpoint Discovery (LLDP-MED) on the Catalyst 4500 series switch.

Note
For complete syntax and usage information for the commands used in this chapter, see the command reference for this release and the “System Management Commands” section in the Cisco IOS Configuration Fundamentals Command Reference, Release 12.2.

This chapter consists of these sections:
- About LLDP and LLDP-MED, page 23-1
- Configuring LLDP and LLDP-MED, page 23-3
- Cisco IOS Carries Ethernet Features in Cisco IOS XE 3.1.0 SG, page 23-10

About LLDP and LLDP-MED

This section contains this conceptual information:
- Understanding LLDP, page 23-1
- Understanding LLDP-MED, page 23-2

Understanding LLDP

The Cisco Discovery Protocol (CDP) is a device discovery protocol that runs over Layer 2 (the data link layer) on all Cisco-manufactured devices (routers, bridges, access servers, and switches). CDP allows network management applications to automatically discover and learn about other Cisco devices connected to the network.

To support non-Cisco devices and to allow for interoperability between other devices, the switch supports the IEEE 802.1AB LLDP. LLDP is a neighbor discovery protocol that is used for network devices to advertise information about themselves to other devices on the network. This protocol runs over the data-link layer, which allows two systems running different network layer protocols to learn about each other.
LLDP supports a set of attributes that it uses to discover neighbor devices. These attributes contain type, length, and value descriptions and are referred to as TLVs. LLDP supported devices can use TLVs to receive and send information to their neighbors. Details such as configuration information, device capabilities, and device identity can be advertised using this protocol.

The switch supports the following basic management TLVs, which are optional:

- Port description TLV
- System name TLV
- System description TLV
- System capabilities TLV
- Management address TLV
- Power Management TLV

These organizationally specific LLDP TLVs are also advertised to support LLDP-MED.

- Port VLAN ID TLV ((IEEE 802.1 organizationally specific TLVs)
- MAC/PHY configuration/status TLV(IEEE 802.3 organizationally specific TLVs)

### Understanding LLDP-MED

LLDP for Media Endpoint Devices (LLDP-MED) is an extension to LLDP that operates between endpoint devices such as IP phones and network devices such as switches. It specifically provides support for voice over IP (VoIP) applications and provides additional TLVs for capabilities discovery, network policy, Power over Ethernet, inventory management, and location information. By default, all LLDP-MED TLVs are enabled.

LLDP-MED supports these TLVs:

- **LLDP-MED capabilities TLV**
  Allows LLDP-MED endpoints to determine the capabilities that the connected device supports and what capabilities the device has enabled.

- **Network policy TLV**
  Allows both network connectivity devices and endpoints to advertise VLAN configurations and associated Layer 2 and Layer 3 attributes for the specific application on that port. For example, the switch can notify a phone of the VLAN number that it should use. The phone can connect into any switch, obtain its VLAN number, and then start communicating with the call control.

- **Power management TLV**
  Enables advanced power management between LLDP-MED endpoint and network connectivity devices. Allows switches and phones to convey power information, such as how the device is powered, power priority, and how much power the device needs.

  **Note**
  Power Management TLV only exchanges power information; it does not perform power negotiation, which is handled by CDP.

- **Inventory management TLV**
  Allows an endpoint to send detailed inventory information about itself to the switch, including information hardware revision, firmware version, software version, serial number, manufacturer name, model name, and asset ID TLV.
• Location TLV

  Provides location information from the switch to the endpoint device. The location TLV can send this information:
  
  - Civic location information
    
    Provides the civic address information and postal information. Examples of civic location information are street address, road name, and postal community name information.
  
  - ELIN location information
    
    Provides the location information for a caller. The location is determined by the Emergency location identifier number (ELIN), which is a phone number that routes an emergency call to the local public safety answering point (PSAP) and which the PSAP can use to call back the emergency caller.

  Note

  A switch cannot send LLDP and LLDP-MED simultaneously to an end-point device. By default, a network device sends only LLDP packets until it receives LLDP-MED packets from an end-point device. The network device then sends LLDP-MED packets until it receives only LLDP packets.

---

### Configuring LLDP and LLDP-MED

This section contains this configuration information:

- Default LLDP Configuration, page 23-3
- Configuring LLDP Characteristics, page 23-4
- Disabling and Enabling LLDP Globally, page 23-5
- Disabling and Enabling LLDP on an Interface, page 23-6
- Configuring LLDP-MED TLVs, page 23-7
- Configuring LLDP Power Negotiation, page 23-8
- Configuring LLDP and Location TLV, page 23-9
- Monitoring and Maintaining LLDP and LLDP-MED, page 23-10

### Default LLDP Configuration

**Table 23-1** shows the default LLDP configuration. To change the default settings, use the LLDP global configuration and LLDP interface configuration commands.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>LLDP global state</td>
<td>Disabled</td>
</tr>
<tr>
<td>LLDP holdtime (before discarding)</td>
<td>120 seconds</td>
</tr>
<tr>
<td>LLDP timer (packet update frequency)</td>
<td>30 seconds</td>
</tr>
<tr>
<td>LLDP reinitialization delay</td>
<td>2 seconds</td>
</tr>
<tr>
<td>LLDP tlv-select</td>
<td>Enabled to send and receive all TLVs.</td>
</tr>
</tbody>
</table>
Configuring LLDP Characteristics

You can configure the frequency of LLDP updates, the amount of time to hold the information before discarding it, the initialization delay time. You can also select the LLDP and LLDP-MED TLVs for sending and receiving. The location service feature is available only when the switch is running the cryptographic (encrypted) software image.

To configure these characteristics, perform this task:

<table>
<thead>
<tr>
<th>Step</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>2</td>
<td>Switch(config)# lldp holdtime</td>
<td>(Optional) Specifies the amount of time a receiving device should hold</td>
</tr>
<tr>
<td></td>
<td>seconds</td>
<td>the information sent by your device before discarding it.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The range is 0 to 65535 seconds; the default is 120 seconds.</td>
</tr>
<tr>
<td>3</td>
<td>Switch(config)# lldp reinit</td>
<td>(Optional) Specific the delay time in seconds for LLDP to initialize on</td>
</tr>
<tr>
<td></td>
<td></td>
<td>any interface.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The range is 2 to 5 seconds; the default is 2 seconds.</td>
</tr>
<tr>
<td>4</td>
<td>Switch(config)# lldp timer</td>
<td>(Optional) Sets the transmission frequency of LLDP updates in seconds.</td>
</tr>
<tr>
<td></td>
<td>seconds</td>
<td>The range is 5 to 65534 seconds; the default is 30 seconds.</td>
</tr>
<tr>
<td>5</td>
<td>Switch(config)# lldp tlv-select</td>
<td>(Optional) Specifies the LLDP TLVs to send or receive.</td>
</tr>
<tr>
<td>6</td>
<td>Switch(config)# copy running-config startup-config</td>
<td>Saves your entries in the configuration file.</td>
</tr>
<tr>
<td>7</td>
<td>Switch(config)# lldp med-tlv-select</td>
<td>(Optional) Specifies the LLDP-MED TLVs to send or receive.</td>
</tr>
</tbody>
</table>

**Note**
Steps 2 through 5 can be performed in any order.

Use the no form of each of the LLDP commands to return to the default setting.

This example shows how to configure a holdtime of 120 second, a delay time of 2 seconds and an update frequency of 30:

```
Switch# configure terminal
Switch(config)# lldp holdtime 120
Switch(config)# lldp reinit 2
Switch(config)# lldp timer 30
Switch(config)# end
```
This example shows how to transmit only LLDP packets:

```
switch# configure terminal
switch(config)# no lldp receive
switch(config)# end
```

If you want to receive LLDP packets again, do the following:

```
switch# configure terminal
switch(config)# lldp receive
switch(config)# end
```

For additional LLDP `show` commands, see the “Monitoring and Maintaining LLDP and LLDP-MED” section on page 23-10.

### Disabling and Enabling LLDP Globally

**Note**

LLDP is disabled by default.

To disable LLDP globally, do the following:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong> Switch(config)# no lldp run</td>
<td>Disables LLDP.</td>
</tr>
<tr>
<td><strong>Step 3</strong> Switch(config)# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
</tbody>
</table>

To enable LLDP once it has been disabled, do the following:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong> Switch(config)# lldp run</td>
<td>Enables LLDP.</td>
</tr>
<tr>
<td><strong>Step 3</strong> Switch(config)# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
</tbody>
</table>

This example shows how to globally disable LLDP.

```
Switch# configure terminal
Switch(config)# no lldp run
Switch(config)# end
```

This example shows how to globally enable LLDP.

```
Switch# configure terminal
Switch(config)# lldp run
Switch(config)# end
```
Disabling and Enabling LLDP on an Interface

LLDP is disabled globally on all supported interfaces. You must enable LLDP globally to allow a device to send LLDP packets. However, no changes are required at the interface level.

You can configure the interface to selectively not to send and receive LLDP packets with the **no lldp transmit** and **no lldp receive** commands.

**Note**

If the interface is configured as a tunnel port, LLDP is automatically disabled.

To disable LLDP on an interface, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# interface interface-id</td>
</tr>
<tr>
<td></td>
<td>Specifies the interface on which you are disabling LLDP, and enter interface configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config)# no lldp transmit</td>
</tr>
<tr>
<td></td>
<td>Disallows sending LLDP packets on the interface.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config)# no lldp receive</td>
</tr>
<tr>
<td></td>
<td>Disallows receiving LLDP packets on the interface.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Switch(config)# copy running-config startup-config</td>
</tr>
<tr>
<td></td>
<td>Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

To enable LLDP on an interface once it has been disabled, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# interface interface-id</td>
</tr>
<tr>
<td></td>
<td>Specifies the interface on which you are enabling LLDP, and enter interface configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config)# lldp transmit</td>
</tr>
<tr>
<td></td>
<td>Sends LLDP packets on the interface.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config)# lldp receive</td>
</tr>
<tr>
<td></td>
<td>Receives LLDP packets on the interface.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Switch# copy running-config startup-config</td>
</tr>
<tr>
<td></td>
<td>Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

This example shows how to enable LLDP on an interface.

Switch# configure terminal
Switch(config)# interface GigabitEthernet 1/1
Switch(config-if)# lldp transmit
Switch(config-if)# lldp receive
Switch(config-if)# end
Configuring LLDP-MED TLVs

By default, the switch only sends LLDP packets until it receives LLDP-MED packets from the end device. The switch continues to send LLDP-MED packets until it only receives LLDP packets.

By using the `lldp` interface configuration command, you can configure the interface not to send the TLVs listed in Table 23-2.

**Table 23-2   LLDP-MED TLVs**

<table>
<thead>
<tr>
<th>LLDP-MED TLV</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inventory-management</td>
<td>LLDP-MED inventory management TLV</td>
</tr>
<tr>
<td>location</td>
<td>LLDP-MED location TLV</td>
</tr>
<tr>
<td>network-policy</td>
<td>LLDP-MED network policy TLV</td>
</tr>
<tr>
<td>power-management</td>
<td>LLDP-MED power management TLV</td>
</tr>
</tbody>
</table>

To disable a TLV on an interface, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong>   Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong>   Switch(config)# interface interface-id</td>
<td>Specifies the interface on which you are configuring a LLDP-MED TLV, and enter interface configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong>   Switch(config-if)# no lldp med-tlv-select tlv</td>
<td>Specifies the TLV to disable.</td>
</tr>
<tr>
<td><strong>Step 4</strong>   Switch(config-if)# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 5</strong>   Switch# copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

To enable a TLV on an interface, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong>   Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong>   Switch(config)# interface interface-id</td>
<td>Specifies the interface on which you are configuring an LLDP-MED TLV, and enter interface configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong>   Switch(config-if)# lldp med-tlv-select tlv</td>
<td>Specifies the TLV to enable.</td>
</tr>
<tr>
<td><strong>Step 4</strong>   Switch(config-if)# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 5</strong>   Switch# copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

This example shows how to enable a TLV on an interface when it has been disabled.

```
Switch# configure terminal
Switch(config)# interface GigabitEthernet0/1
Switch(config-if)# lldp med-tlv-select inventory management
Switch(config-if)# end
```
Configuring LLDP Power Negotiation

Starting with Cisco IOS Release 12.2(54)SG, Catalyst 4500 series switches can perform inline power negotiation using LLDP as specified in the IEEE 802.3at standard. (The LLDP TLV used is DTE Power-via-MDI TLV.) With this feature, inline powered devices based on the IEEE standard can be powered in the PoE+ power range (12.95W to 25.5W at the device end) by the switch on PoE+ supported modules.

Note
To verify inline power utilization negotiated by using LLDP using the LLDP-MED TLV, use the show lldp neighbors detail command. To verify inline power utilization negotiated by using the IEEE 802.3at TLV, use the show power inline interface detail command. The show power inline interface detail command does not display power negotiated with LLDP.

Note
When an inline powered device that performs power negotiation using multiple protocols (CDP/LLDP 802.3at/LLDP-MED) is connected to a switch, the switch "locks" to the first protocol packet (CDP or LLDP) that contains the power negotiation TLV. The LLDP 802.3at power negotiation TLV overrides the LLDP-MED power negotiation TLV if both are received by the switch. If the administrator needs to use any single protocol for power negotiation each time, he needs to administratively disable the other power negotiation protocols on the switch interface or the end device.

To enable LLDP power negotiation, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong> Switch(config)# interface interface-id</td>
<td>Specifies the interface on which you are configuring LLDP power negotiation.</td>
</tr>
<tr>
<td><strong>Step 3</strong> Switch(config-if)# lldp tlv-select power-management</td>
<td>Enables LLDP power negotiation.</td>
</tr>
<tr>
<td><strong>Step 4</strong> Switch(config-if)# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 5</strong> Switch# copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

This example shows how to enable LLDP power negotiation on interface Gigabit Ethernet 3/1:

Switch# config t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# int gi 3/1
Switch(config-if)# lldp tlv-select power-management
# Configuring LLDP and Location TLV

To configure location information for an end-point and to apply it to an interface, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# location {admin-tag string</td>
</tr>
<tr>
<td></td>
<td>• admin-tag—Specify an administrative tag or site information.</td>
</tr>
<tr>
<td></td>
<td>• civic-location—Specify civic location information.</td>
</tr>
<tr>
<td></td>
<td>Note The civic location identifier in the LLDP-MED TLV is limited to 250 bytes or less. To avoid receiving error messages regarding available buffer space during switch configuration, never allow the total length of all civic location information specified for each civic-location identifier to exceed 250 bytes.</td>
</tr>
<tr>
<td></td>
<td>• elin-location—Specify emergency location information (ELIN).</td>
</tr>
<tr>
<td></td>
<td>• identifier id—Specify the ID for the civic location.</td>
</tr>
<tr>
<td></td>
<td>• string—specify the site or location information in alphanumeric format.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config-civic)# exit</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config)# interface interface-id</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch(config-if)# location {additional-location-information word</td>
</tr>
<tr>
<td></td>
<td>• additional-location-information—Specifies additional information for a location or place.</td>
</tr>
<tr>
<td></td>
<td>• civic-location-id—Specifies global civic location information for an interface.</td>
</tr>
<tr>
<td></td>
<td>• elin-location-id—Specifies emergency location information for an interface.</td>
</tr>
<tr>
<td></td>
<td>• id—Specifies the ID for the civic location or the ELIN location. The ID range is 1 to 4095.</td>
</tr>
<tr>
<td></td>
<td>• word—Specifies a word or phrase that provides additional location information.</td>
</tr>
<tr>
<td>Step 6</td>
<td>Switch(config-if)# end</td>
</tr>
<tr>
<td>Step 7</td>
<td>Switch# show location</td>
</tr>
<tr>
<td>Step 8</td>
<td>Switch# copy running-config startup-config</td>
</tr>
</tbody>
</table>

Use the no form of each command to return to the default setting.

This example shows how to configure civic location information on the switch:

```
Switch# configure terminal
Switch(config)# location civic-location identifier 1
Switch(config-civic)# number 3550
Switch(config-civic)# primary-road-name "Cisco Way"
```
Switch(config-civic)# city "San Jose"
Switch(config-civic)# state CA
Switch(config-civic)# building 19
Switch(config-civic)# room C6
Switch(config-civic)# county "Santa Clara"
Switch(config-civic)# country US
Switch(config-civic)# end

Monitoring and Maintaining LLDP and LLDP-MED

To monitor and maintain LLDP and LLDP-MED on your device, perform one or more of the following commands in privileged EXEC mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>clear lldp counters</td>
<td>Resets the traffic and error counters to zero.</td>
</tr>
<tr>
<td>clear lldp table</td>
<td>Deletes the LLDP table of information about neighbors.</td>
</tr>
<tr>
<td>show lldp</td>
<td>Displays global information, such as frequency of transmissions, the holdtime for packets being sent, and the delay time for LLDP to initialize on an interface.</td>
</tr>
<tr>
<td>show lldp entry entry-name</td>
<td>Displays information about a specific neighbor. You can enter an asterisk (*) to display all neighbors, or you can enter the name of the neighbor about which you want information.</td>
</tr>
<tr>
<td>show lldp errors</td>
<td>Displays LLDP computational errors and overflows.</td>
</tr>
<tr>
<td>show lldp interface [interface-id]</td>
<td>Displays information about interfaces where LLDP is enabled.</td>
</tr>
<tr>
<td>show lldp neighbors [interface-id] [detail]</td>
<td>Displays information about neighbors, including device type, interface type and number, holdtime settings, capabilities, and port ID. You can limit the display to neighbors of a specific interface or expand the display to provide more detailed information.</td>
</tr>
<tr>
<td>show lldp traffic</td>
<td>Displays LLDP counters, including the number of packets sent and received, number of packets discarded, and number of unrecognized TLVs.</td>
</tr>
<tr>
<td>show location</td>
<td>Displays the location information for an endpoint.</td>
</tr>
<tr>
<td>show power inline interface [detail]</td>
<td>Displays detailed information on the PoE status for the interface</td>
</tr>
<tr>
<td>show power inline module mod [detail]</td>
<td>Displays detailed information on the PoE consumption for the specified module.</td>
</tr>
</tbody>
</table>

Cisco IOS Carries Ethernet Features in Cisco IOS XE 3.1.0 SG

This section provides a list of High Availability software features that are supported in Cisco IOS XE 3.1.0SG. Links to the feature documentation are included.

Feature guides may contain information about more than one feature. To find information about a specific feature within a feature guide, see the Feature Information table at the end of the guide.
Feature guides document features that are supported on many different software releases and platforms. Your Cisco software release or platform may not support all the features documented in a feature guide. See the Feature Information table at the end of the feature guide for information about which features in that guide are supported in your software release. Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

ANSI TIA-1057 LLDP-MED Support and IEEE 802.1ab LLDP (Link Layer Discovery Protocol)

Configuring UDLD

This chapter describes how to configure the UniDirectional Link Detection (UDLD) and Unidirectional Ethernet on the Catalyst 4500 series switch. It also provides guidelines, procedures, and configuration examples.

This chapter includes the following major sections:

- About UDLD, page 24-1
- Default UDLD Configuration, page 24-2
- Configuring UDLD on the Switch, page 24-3

Note

For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

About UDLD

UDLD is a layer 2 protocol that enables devices connected through fiber-optic or twisted-pair Ethernet cables. It monitors a physical connection (such as wrong cabling) to detect unidirectional links to avoid spanning-tree topology loops or silent drop traffic.

All connected devices must support UDLD for the protocol to successfully identify the unidirectional links. When UDLD detects a unidirectional link, it can administratively shut down the affected port and send you a warning message.

Modes of Operation

UDLD supports two operation modes: normal and aggressive.
A UDLD-capable port A periodically sends a UDLD probe to port B. If port B is not UDLD capable, no unidirectional link detection occurs. If both devices are UDLD capable and bi-directional connectivity exists, probe messages travel in both directions at a rate of 1 every few seconds (through the UDLD message time interval global configuration command). Upon receiving the probe, the UDLD protocol attempts to synchronize the devices by sending echo messages to the peer port and waiting for an answer during the detection window. If the unidirectional traffic is detected when the port link is still up (port B no longer sends traffic to port A), port B enters errdisable mode. Port A is marked Undetermined but does not enter errdisable mode. It continues to operate under its current STP status because this mode is informational only; it is potentially less disruptive although it does not prevent STP loops.

**aggressive** If port A loses its neighbor connectivity, it actively tries to re-establish the relationship by sending a probe to port B. If port B does not respond, it is considered unidirectional and port A enters errdisable state to avoid silent drop traffic.

UDLD aggressive mode can interoperate with UDLD normal mode. When the unidirectional condition is detected, only the aggressive mode link shuts down.

By default,

- UDLD is locally disabled on copper LAN ports to avoid sending unnecessary control traffic (BPDU control packets) on this type of media; this protocol is most often used for access ports.
- UDLD is enabled on a fiber port if global UDLD is activated.

Figure 24-1 illustrates a unidirectional link condition. Each switch can send packets to a neighbor switch but cannot receive packets from the switch it is sending packets to. UDLD detects and disables these one-way connections.

**Default UDLD Configuration**

Table 24-1 shows the UDLD default configuration.
Table 24-1  UDLD Default Configuration

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>UDLD global enable state</td>
<td>Globally disabled</td>
</tr>
<tr>
<td>UDLD per-interface enable state for fiber-optic media</td>
<td>Enabled on all Ethernet fiber-optic interfaces</td>
</tr>
<tr>
<td>UDLD per-interface enable state for twisted-pair (copper) media</td>
<td>Disabled on all Ethernet 10/100 and 1000BaseTX interfaces</td>
</tr>
</tbody>
</table>

Configuring UDLD on the Switch

The following sections describe how to configure UDLD:

- Enabling UDLD Globally, page 24-4
- Enabling UDLD on Individual Interfaces, page 24-4
- Disabling UDLD on Non-Fiber-Optic Interfaces, page 24-5
- Configuring the UDLD Probe Message Interval, page 24-5
- Resetting Disabled LAN Interfaces, page 24-5
## Enabling UDLD Globally

To enable UDLD in the aggressive or normal mode and to set the configurable message timer on all fiber-optic interfaces on the switch, follow these steps:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# udld (\text{aggressive</td>
</tr>
<tr>
<td></td>
<td>Specifies the UDLD mode of operation:</td>
</tr>
<tr>
<td></td>
<td>* <strong>aggressive</strong> Enables UDLD in aggressive mode on all fiber-optic interfaces.</td>
</tr>
<tr>
<td></td>
<td>* <strong>enable</strong> Enables UDLD in normal mode on all fiber-optic interfaces on the switch. UDLD is disabled by default.</td>
</tr>
<tr>
<td></td>
<td>An individual interface configuration overrides the setting of the <strong>udld enable</strong> global configuration command.</td>
</tr>
<tr>
<td></td>
<td>For more information about aggressive and normal modes, see the <strong>Modes of Operation</strong>, page 24-1 section.</td>
</tr>
<tr>
<td></td>
<td>* <strong>message time message-timer-interval</strong>-Configures the period of time between UDLD probe messages on ports that are in the advertisement phase and are determined to be bidirectional. The range is from 1 to 90 seconds.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch# show udld</td>
</tr>
</tbody>
</table>

### Enabling UDLD on Individual Interfaces

To enable UDLD on individual interfaces, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch(config-if)# udld enable</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch# show udld interface</td>
</tr>
<tr>
<td></td>
<td>Enables UDLD on a specific interface. On a fiber-optic interface, this command overrides the <strong>udld enable</strong> global configuration command setting.</td>
</tr>
<tr>
<td></td>
<td>Verifies the configuration.</td>
</tr>
</tbody>
</table>
Disabling UDLD on Non-Fiber-Optic Interfaces

To disable UDLD on individual non-fiber-optic interfaces, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td><code>Switch(config-if)# no udld enable</code></td>
<td>Disables UDLD on a non-fiber-optic interface.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>On fiber-optic interfaces, the <code>no udld enable</code> command reverts the interface configuration to the <code>udld enable</code> global configuration command setting.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td><code>Switch# show udld interface</code></td>
<td>Verifies the configuration.</td>
</tr>
</tbody>
</table>

Configuring the UDLD Probe Message Interval

To configure the time between UDLD probe messages on ports that are in advertisement mode and are currently determined to be bidirectional, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td><code>Switch(config)# udld message time interval</code></td>
<td>Configures the time between UDLD probe messages on ports that are in advertisement mode and are currently determined to be bidirectional; valid values are from 1 to 90 seconds.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>Prior to Cisco IOS Release 12.2(31)SGA, the time interval is 7-90 seconds. With Cisco IOS Release 12.2(31)SGA, the time interval is 1-90 second. The <code>no udld message</code> command returns to the default value (60 seconds).</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td><code>Switch# show udld type-slot/interface</code></td>
<td>Verifies the configuration.</td>
</tr>
</tbody>
</table>

Resetting Disabled LAN Interfaces

To reset all LAN ports that have been shut down by UDLD, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Switch(config)# udld reset</code></td>
<td>Resets all LAN ports that have been shut down by UDLD.</td>
</tr>
</tbody>
</table>
Configuring Unidirectional Ethernet

Note

This feature is not supported on Supervisor Engine 7-E uplinks.

This chapter describes how to configure Unidirectional Ethernet on the Catalyst 4000 family switch and contains these sections:

- About Unidirectional Ethernet, page 25-1
- Configuring Unidirectional Ethernet, page 25-2

Note

For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

About Unidirectional Ethernet

You can set stubless Gigabit Ethernet ports to unidirectionally transmit or receive traffic. Unidirectional Ethernet uses only one strand of fiber for either transmitting or receiving one-way traffic for the GigaPort, instead of two strands of fiber for a full-duplex GigaPort Ethernet. Configuring your GigaPorts either to transmit or receive traffic effectively doubles the amount of traffic capabilities for applications, such as video streaming, where most traffic is sent as unacknowledged unidirectional video broadcast streams.
# Configuring Unidirectional Ethernet

**Note**

You must configure Unidirectional Ethernet on the non-blocking GigaPort, which automatically disables UDLD on the port.

To enable Unidirectional Ethernet, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong>&lt;br&gt;`Switch(config)# interface {vlan vlan_ID</td>
<td>(fastethernet</td>
</tr>
<tr>
<td><strong>Step 2</strong>&lt;br&gt;`Switch(config-if)# [no] unidirectional {send-only</td>
<td>receive-only}`&lt;br&gt;Enables Unidirectional Ethernet.</td>
</tr>
<tr>
<td><strong>Step 3</strong>&lt;br&gt;<code>Switch(config-if)# end</code>&lt;br&gt;Exits configuration mode.</td>
<td>Use the no keyword to disable Unidirectional Ethernet.</td>
</tr>
<tr>
<td><strong>Step 4</strong>&lt;br&gt;`Switch# show interface {vlan vlan_ID</td>
<td>(fastethernet</td>
</tr>
</tbody>
</table>

This example shows how to set Gigabit Ethernet interface 1/1 to unidirectionally send traffic:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface gigabitethernet 1/1
Switch(config-if)# unidirectional send-only
Switch(config-if)# end
```

Warning!

Enable L2 port unidirectional mode will automatically disable port udld. You must manually ensure that the unidirectional link does not create a spanning tree loop in the network.

Enable L3 port unidirectional mode will automatically disable ip routing on the port. You must manually configure static ip route and arp entry in order to route ip traffic.

This example shows how to set Gigabit Ethernet interface 1/1 to receive traffic unidirectionally:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface gigabitethernet 1/1
Switch(config-if)# unidirectional receive-only
Switch(config-if)# end
```

Warning!

Enable L2 port unidirectional mode will automatically disable port udld. You must manually ensure that the unidirectional link does not create a spanning tree loop in the network.

Enable L3 port unidirectional mode will automatically disable ip routing on the port. You must manually configure static ip route and arp entry in order to route ip traffic.
This example shows how to verify the configuration

Switch> show interface gigabitethernet 1/1 unidirectional
  show interface gigabitethernet 1/1 unidirectional
  Unidirectional configuration mode: send only
  CDP neighbor unidirectional configuration mode: receive only

This example shows how to disable Unidirectional Ethernet on Gigabit Ethernet interface 1/1:

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface gigabitethernet 1/1
Switch(config-if)# no unidirectional
Switch(config-if)# end

This example shows the result of issuing the show interface command for a port that does not support Unidirectional Ethernet:

Switch#show interface f6/1 unidirectional
Unidirectional Ethernet is not supported on FastEthernet6/1
Configuring Layer 3 Interfaces

This chapter describes the Layer 3 interfaces on a Catalyst 4500 series switch. It also provides guidelines, procedures, and configuration examples.

This chapter includes the following major sections:

- **Overview of Layer 3 Interfaces**, page 26-1
- **Configuration Guidelines**, page 26-4
- **Configuring Logical Layer 3 VLAN Interfaces**, page 26-5
- **Configuring VLANs as Layer 3 Interfaces**, page 26-6
- **Configuring Physical Layer 3 Interfaces**, page 26-10
- **Configuring EIGRP Stub Routing**, page 26-11

*Note*

For complete syntax and usage information for the switch commands used in this chapter, look at the *Cisco Catalyst 4500 Series Switch Command Reference* and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the *Catalyst 4500 Series Switch Cisco IOS Command Reference* and related publications at this location:

**Overview of Layer 3 Interfaces**

This section contains the following subsections:

- **Logical Layer 3 VLAN Interfaces**, page 26-2
- **Physical Layer 3 Interfaces**, page 26-2
- **Understanding SVI Autostate Exclude**, page 26-3
- **Understanding Layer 3 Interface Counters**, page 26-3

The Catalyst 4500 family switch supports Layer 3 interfaces with the Cisco IOS IP and IP routing protocols. Layer 3, the *network* layer, is primarily responsible for the routing of data in packets across logical internetwork paths.
Layer 2, the data link layer, contains the protocols that control the physical layer (Layer 1) and how data is framed before being transmitted on the medium. The Layer 2 function of filtering and forwarding data in frames between two segments on a LAN is known as bridging.

The Catalyst 4500 series switch supports two types of Layer 3 interfaces. The logical Layer 3 VLAN interfaces integrate the functions of routing and bridging. The physical Layer 3 interfaces allow the Catalyst 4500 series switch to be configured like a traditional router.

**Logical Layer 3 VLAN Interfaces**

The logical Layer 3 VLAN interfaces provide logical routing interfaces to VLANs on Layer 2 switches. A traditional network requires a physical interface from a router to a switch to perform inter-VLAN routing. The Catalyst 4500 series switch supports inter-VLAN routing by integrating the routing and bridging functions on a single Catalyst 4500 series switch.

Figure 26-1 shows how the routing and bridging functions in the three physical devices of the traditional network are performed logically on one Catalyst 4500 series switch.

**Physical Layer 3 Interfaces**

The physical Layer 3 interfaces support capabilities equivalent to a traditional router. These Layer 3 interfaces provide hosts with physical routing interfaces to a Catalyst 4500 series switch.

Figure 26-2 shows how the Catalyst 4500 series switch functions as a traditional router.
Understanding SVI Autostate Exclude

To be “up/up,” a router VLAN interface must fulfill the following general conditions:

- The VLAN exists and is “active” on the VLAN database of the switch.
- The VLAN interface exists on the router and is not administratively down.
- At least one Layer 2 (access port or trunk) port exists, has a link “up” on this VLAN and is in spanning-tree forwarding state on the VLAN.

**Note**

The protocol line state for the VLAN interfaces comes up when the first switchport belonging to the corresponding VLAN link comes up and is in spanning-tree forwarding state.

Ordinarily, when a VLAN interface has multiple ports in the VLAN, the SVI goes down when all the ports in the VLAN goes down. The SVI Autostate exclude feature provides a knob to mark a port so that it is not counted in the SVI “up and down” calculation and applies to all VLANs that are enabled on that port.

A VLAN interface is brought up after the Layer 2 port has had time to converge (that is, transition from listening-learning to forwarding). This prevents routing protocols and other features from using the VLAN interface as if it were fully operational. This also prevents other problems from occurring, such as routing black holes.

Understanding Layer 3 Interface Counters

**Note**

Supervisor Engine 7-E does not support Layer 2 Interface Counters. However, it does support Layer 3 (SVI) Interface Counters.

With Supervisor Engine 6-E, IPv4 and v6 packets are routed in hardware by the forwarding engine. This engine supports statistics for counting routed packets for up to 4095 interfaces. These statistics include:

- Input unicast
- Input multicast
Chapter 26 Configuring Layer 3 Interfaces

Configuration Guidelines

- Output unicast
- Output multicast

For each type of counter, both the number of packets and the total number of bytes received or transmitted are counted.

Because the total number of counters supported is lower than the total number of Layer 3 interfaces supported, it is not always possible for all Layer 3 interfaces to have counters. For this reason, the user assigns counters to Layer 3 interfaces, and the default configuration for a Layer 3 interface has no counters.

To enable Layer 3 Interface Counters, you need to issue the **counter** command in interface mode. Refer to the “Configuring Layer 3 Interface Counters” section on page 26-9 for instructions on how to configure Layer 3 Interface Counters.

These hardware counters are displayed in the output of the **show interface** command. For example:

```
Switch# show interface vlan 1
Vlan1 is up, line protocol is up
  Hardware is Ethernet SVI, address is 0005.9a38.6cff (bia 0005.9a38.6cff)
  Internet address is 10.0.0.1/8
  MTU 1500 bytes, BW 1000000 Kbit, DLY 10 usec,
    reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Keepalive not supported
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input never, output never, output hang never
  Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/40 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
  L3 in Switched: ucast: 0 pkt, 0 bytes - mcast: 0 pkt, 0 bytes
  L3 out Switched: ucast: 0 pkt, 0 bytes - mcast: 0 pkt, 0 bytes
  0 packets input, 0 bytes, 0 no buffer
  Received 0 broadcasts (0 IP multicasts)
  0 runts, 0 giants, 0 throttles
  0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
  1 packets output, 46 bytes, 0 underruns
  0 output errors, 0 interface resets
  0 output buffer failures, 0 output buffers swapped out
```

**Configuration Guidelines**

The Catalyst 4500 series switch supports AppleTalk routing and IPX routing. For AppleTalk routing and IPX routing information, refer to “Configuring AppleTalk” and “Configuring Novell IPX” in the *Cisco IOS AppleTalk and Novell IPX Configuration guides* at the following URLs:

Supervisor Engine 7-E does not support AppleTalk and IPX routing.
A Catalyst 4500 series switch does not support subinterfaces or the `encapsulation` keyword on Layer 3 Fast Ethernet, Gigabit Ethernet, TenGigabitEthernet interfaces.

**Note**

As with any Layer 3 interface running Cisco IOS software, the IP address and network assigned to an SVI cannot overlap those assigned to any other Layer 3 interface on the switch.

### Configuring Logical Layer 3 VLAN Interfaces

**Note**

Before you can configure logical Layer 3 VLAN interfaces, you must create and configure the VLANs on the switch, assign VLAN membership to the Layer 2 interfaces, enable IP routing if IP routing is disabled, and specify an IP routing protocol.

To configure logical Layer 3 VLAN interfaces, perform this task:

<table>
<thead>
<tr>
<th>Step</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Switch(config)# vlan vlan_ID</td>
<td>Creates the VLAN.</td>
</tr>
<tr>
<td>2</td>
<td>Switch(config)# interface vlan vlan_ID</td>
<td>Selects an interface to configure.</td>
</tr>
<tr>
<td>3</td>
<td>Switch(config-if)# ip address ip_address subnet_mask</td>
<td>Configures the IP address and IP subnet.</td>
</tr>
<tr>
<td>4</td>
<td>Switch(config-if)# no shutdown</td>
<td>Enables the interface.</td>
</tr>
<tr>
<td>5</td>
<td>Switch(config-if)# end</td>
<td>Exits configuration mode.</td>
</tr>
<tr>
<td>6</td>
<td>Switch# copy running-config startup-config</td>
<td>Saves your configuration changes to NVRAM.</td>
</tr>
<tr>
<td>7</td>
<td>Switch# show interfaces [type slot/interface]</td>
<td>Verifies the configuration.</td>
</tr>
<tr>
<td></td>
<td>Switch# show ip interfaces [type slot/interface]</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Switch# show running-config interfaces [type slot/interface]</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Switch# show running-config interfaces vlan vlan_ID</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to configure the logical Layer 3 VLAN interface vlan 2 and assign an IP address:

```
Switch> enable
Switch# config term
Enter configuration commands, one per line.  End with CNTL/Z.
Switch(config)# vlan 2
Switch(config)# interface vlan 2
Switch(config-if)# ip address 10.1.1.1 255.255.255.248
Switch(config-if)# no shutdown
Switch(config-if)# end
```

This example uses the `show interfaces` command to display the interface IP address configuration and status of Layer 3 VLAN interface vlan 2:

```
Switch# show interfaces vlan 2
Vlan2 is up, line protocol is down
Hardware is Ethernet SVI, address is 00D.588F.B604 (bia 00D.588F.B604)
Internet address is 172.20.52.106/29
MTU 1500 bytes, BW 100000 Kbit, DLY 10 usec,
    reliability 255/255, txload 1/255, rxload 1/255
Encapsulation ARPA, loopback not set
```
Configuring VLANs as Layer 3 Interfaces

This section consists of the following subsections:

- Configuring SVI Autostate Exclude, page 26-6
- Configuring IP MTU Sizes, page 26-8
- Configuring Layer 3 Interface Counters, page 26-9

Configuring SVI Autostate Exclude

The SVI Autostate exclude feature is enabled by default and is synchronized with the STP state.

The SVI Autostate exclude feature shuts down (or brings up) the Layer 3 interfaces of a switch when the following port configuration changes occur:

- When the last port on a VLAN goes down, the Layer 3 interface on that VLAN is shut down (SVI- autostated).
• When the first port on the VLAN is brought back up, the Layer 3 interface on the VLAN that was previously shut down is brought up.

SVI Autostate exclude enables you to exclude the access ports/trunks in defining the status of the SVI (up or down) even if it belongs to the same VLAN. Moreover, even if the excluded access port/trunk is in up state and other ports are in down state in the VLAN, the SVI state is changed to down.

At least one port in the VLAN should be up and not excluded to make the SVI state up. This helps to exclude the monitoring port status when you are determining the status of the SVI.

To apply SVI Autostate exclude, perform this task:

```
Step 1
Switch# configure terminal
Enters global configuration mode.

Step 2
Switch(config)# interface interface-id
Enters interface configuration mode.

Step 3
Switch(config-if)# switchport autostate exclude
Exclude the access ports/trunks in defining the status of an SVI (up or down).

Step 4
Switch(config)# end
Exits configuration mode.

Step 5
Switch# show run int g3/4
Displays the running configuration.

Step 6
Switch# show int g3/4 switchport
Verifies the configuration.
```

The following example shows how to apply SVI Autostate Exclude on interface g3/1:

```
Switch# conf terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface g3/1
Switch(config-if)# switchport autostate exclude
Switch(config-if)# end
Switch# show run int g3/4
Building configuration...

Current configuration : 162 bytes
!
interface GigabitEthernet3/4
  switchport trunk encapsulation dot1q
  switchport trunk allowed vlan 2,3
  switchport autostate exclude
  switchport mode trunk
end

Switch# show int g3/4 switchport
Name: Gi3/4
Switchport: Enabled
Administrative Mode: trunk
Operational Mode: trunk
Administrative Trunking Encapsulation: dot1q Operational Trunking Encapsulation: dot1q
Autostate mode exclude
```

Unknown unicast blocked: disabled
Unknown multicast blocked: disabled
Appliance trust: none
Switch#

## Configuring IP MTU Sizes

You can set the protocol-specific maximum transmission unit (MTU) size of IPv4 or IPv6 packets sent on an interface.

For information on MTU limitations, refer to Maximum Transmission Units, page 7-17.

### Note

To set the nonprotocol-specific MTU value for an interface, use the `mtu` interface configuration command. Changing the MTU value (with the `mtu` interface configuration command) can affect the IP MTU value. If the current IP MTU value matches the MTU value, and you change the MTU value, the IP MTU value is modified automatically to match the new MTU. However, the reverse is not true; changing the IP MTU value has no effect on the value for the `mtu` command.

For information on how to configure MTU size, refer to Configuring MTU Sizes, page 7-19.

To set the protocol-specific maximum transmission unit (MTU) size of IPv4 or IPv6 packets sent on an interface, perform this task:

### Command

<table>
<thead>
<tr>
<th>Step</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>2</td>
<td>Switch(config)# interface interface-id</td>
<td>Enters interface configuration mode.</td>
</tr>
<tr>
<td>3</td>
<td>Switch(config-if)# [no] ip mtu mtu_size</td>
<td>Configures the IPv4 MTU size</td>
</tr>
<tr>
<td></td>
<td>or</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Switch(config-if)# [no] ipv6 mtu mtu_size</td>
<td>Configures the IPv6 MTU size.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The no form of the command reverts to the default MTU size (1500 bytes).</td>
</tr>
<tr>
<td>4</td>
<td>Switch(config-if)# exit</td>
<td>Exits configuration interface mode.</td>
</tr>
<tr>
<td>5</td>
<td>Switch(config)# end</td>
<td>Exits configuration mode.</td>
</tr>
<tr>
<td>6</td>
<td>Switch# show run interface interface-id</td>
<td>Displays the running configuration.</td>
</tr>
</tbody>
</table>

The following example shows how to configure IPv4 MTU on an interface:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)#  interface vlan 1
Switch(config-if)#  ip mtu 68
Switch(config-if)#  exit
Switch(config)#  end
Switch# show ip interface vlan 1
Vlan1 is up, line protocol is up
  Internet address is 10.10.10.1/24
  Broadcast address is 255.255.255.255
  Address determined by setup command
  MTU is 68 bytes
  Helper address is not set
```
The following example shows how to configure ipv6 mtu on an interface

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface vlan 1
Switch(config-if)# ipv6 mtu 1280
Switch(config)# end
Switch# show ipv6 interface vlan 1
Vlan1 is up, line protocol is up
IPv6 is enabled, link-local address is FE80::214:6AFF:FEBC:DEEA
Global unicast address(es):
    1001::1, subnet is 1001::/64
Joined group address(es):
    FF02::1
    FF02::1:FF00:1
    FF02::1:FFBC:DEEA
MTU is 1280 bytes
```

Note: When ipv6 is enabled on an interface via any CLI, it is possible to see the following message:

```
% Hardware MTU table exhausted
```

In such a scenario, the ipv6 MTU value programmed in hardware differs from the ipv6 interface MTU value. This happens if there is no room in the hardware MTU table to store additional values. You must free up some space in the table by unconfiguring some unused MTU values and subsequently disable/re-enable ipv6 on the interface or reapply the MTU configuration.

### Configuring Layer 3 Interface Counters

**Note:** When a linecard is removed, the Layer 3 counters previously enabled on ports of that line card are unconfigured. This means that to re-enable Layer 3 counters upon re-insertion of the linecard, you need to reconfigure the counter CLI for Layer 3 ports of that line card.

To configure Layer 3 Interface Counters (assign counters to a Layer 3 interface), perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td>Switch(config)# interface interface-id</td>
<td>Enters interface configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td></td>
</tr>
<tr>
<td>Switch(config-if)# counter</td>
<td>Enables counters.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td></td>
</tr>
<tr>
<td>Switch(config-if)# end</td>
<td>Exits configuration mode.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td></td>
</tr>
<tr>
<td>Switch# show run interface interface-id</td>
<td>Displays the running configuration.</td>
</tr>
</tbody>
</table>

The following example shows how to enable counters on interface VLAN 1

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface vlan 1
Switch(config-if)# counter
Switch(config-if)# end
Switch#
```
Configuring Physical Layer 3 Interfaces

Note: Before you can configure physical Layer 3 interfaces, you must enable IP routing if IP routing is disabled, and specify an IP routing protocol.

To configure physical Layer 3 interfaces, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch(config)#ip routing</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# interface (fastethernet</td>
</tr>
<tr>
<td></td>
<td>gigabitethernet</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config-if)#no switchport</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config-if)# ip address ip_address subnet_mask</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch(config-if)# no shutdown</td>
</tr>
<tr>
<td>Step 6</td>
<td>Switch(config-if)# end</td>
</tr>
</tbody>
</table>
This example shows how to configure an IP address on Fast Ethernet interface 2/1:

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# ip routing
Switch(config)# interface fastethernet 2/1
Switch(config-if)# no switchport
Switch(config-if)# ip address 10.1.1.1 255.255.255.248
Switch(config-if)# no shutdown
Switch(config-if)# end
Switch#

This example uses the show running-config command to display the interface IP address configuration of Fast Ethernet interface 2/1:

Switch# show running-config
Building configuration...
!
interface FastEthernet2/1
  no switchport
  ip address 10.1.1.1 255.255.255.248
  
  ip classless
  no ip http server
  
  line con 0
  line aux 0
  line vty 0 4
  
end

Configuring EIGRP Stub Routing

This section consists of the following subsections:

- Overview, page 26-11
- How to Configure EIGRP Stub Routing, page 26-12
- Monitoring and Maintaining EIGRP, page 26-17
- EIGRP Configuration Examples, page 26-18

Overview

The EIGRP stub routing feature, available in all images, reduces resource utilization by moving routed traffic closer to the end user.
The IP base image contains only EIGRP stub routing. The IP services image contains complete EIGRP routing.

In a network using EIGRP stub routing, the only route for IP traffic to follow to the user is through a switch that is configured with EIGRP stub routing. The switch sends the routed traffic to interfaces that are configured as user interfaces or are connected to other devices.

When using EIGRP stub routing, you need to configure the distribution and remote switches to use EIGRP, and to configure only the switch as a stub. Only specified routes are propagated from the switch. The switch responds to all queries for summaries, connected routes, and routing updates.

Any neighbor that receives a packet informing it of the stub status does not query the stub switch for any routes, and a switch that has a stub peer does not query that peer. The stub switch depends on the distribution switch to send the proper updates to all peers.

In Figure 26-3, switch B is configured as an EIGRP stub switch. Switches A and C are connected to the rest of the WAN. Switch B advertises connected, static, redistribution, and summary routes from switch A and C to Hosts A, B, and C. Switch B does not advertise any routes learned from switch A (and the reverse).

**How to Configure EIGRP Stub Routing**

The EIGRP Stub Routing feature improves network stability, reduces resource utilization, and simplifies stub switch configuration.

Stub routing is commonly used in a hub-and-spoke network topology. In a hub-and-spoke network, one or more end (stub) networks are connected to a remote switch (the spoke) that is connected to one or more distribution switches (the hub). The remote switch is adjacent only to one or more distribution switches. The only route for IP traffic to follow into the remote switch is through a distribution switch. This type of configuration is commonly used in WAN topologies where the distribution switch is directly connected to a WAN. The distribution switch can be connected to many more remote switches. Often, the distribution switch is connected to 100 or more remote routers. In a hub-and-spoke topology,
the remote router must forward all nonlocal traffic to a distribution router, so it becomes unnecessary for the remote router to hold a complete routing table. Generally, the distribution router need not send anything more than a default route to the remote router.

When using the EIGRP Stub Routing feature, you need to configure the distribution and remote routers to use EIGRP, and to configure only the remote router as a stub. Only specified routes are propagated from the remote (stub) router. The stub router responds to all queries for summaries, connected routes, redistributed static routes, external routes, and internal routes with the message “inaccessible.” A router that is configured as a stub sends a special peer information packet to all neighboring routers to report its status as a stub router.

Any neighbor that receives a packet informing it of the stub status does not query the stub router for any routes, and a router that has a stub peer does not query that peer. The stub router depends on the distribution router to send the proper updates to all peers.

Figure 26-4 shows a simple hub-and-spoke configuration.

The stub routing feature by itself does not prevent routes from being advertised to the remote router. In the example in Figure 26-4, the remote router can access the corporate network and the Internet through the distribution router only. Having a full route table on the remote router, in this example, would serve no functional purpose because the path to the corporate network and the Internet would always be through the distribution router. The larger route table would only reduce the amount of memory required by the remote router. Bandwidth and memory can be conserved by summarizing and filtering routes in the distribution router. The remote router need not receive routes that have been learned from other networks because the remote router must send all nonlocal traffic, regardless of destination, to the distribution router. If a true stub network is desired, the distribution router should be configured to send only a default route to the remote router. The EIGRP Stub Routing feature does not automatically enable summarization on the distribution router. In most cases, the network administrator must configure summarization on the distribution routers.

**Note**

When configuring the distribution router to send only a default route to the remote router, you must use the `ip classless` command on the remote router. By default, the `ip classless` command is enabled in all Cisco IOS images that support the EIGRP Stub Routing feature.
Without the stub feature, even after the routes that are sent from the distribution router to the remote router have been filtered or summarized, a problem might occur. If a route is lost somewhere in the corporate network, EIGRP could send a query to the distribution router, which in turn sends a query to the remote router even if routes are being summarized. If there is a problem communicating over the WAN link between the distribution router and the remote router, an EIGRP stuck in active (SIA) condition could occur and cause instability elsewhere in the network. The EIGRP Stub Routing feature allows a network administrator to prevent queries from being sent to the remote router.

**Dual-Homed Remote Topology**

In addition to a simple hub-and-spoke network where a remote router is connected to a single distribution router, the remote router can be dual-homed to two or more distribution routers. This configuration adds redundancy and introduces unique issues, and the stub feature helps to address some of these issues.

A dual-homed remote router has two or more distribution (hub) routers. However, the principles of stub routing are the same as they are with a hub-and-spoke topology. Figure 26-5 shows a common dual-homed remote topology with one remote router, but 100 or more routers could be connected on the same interfaces on distribution router 1 and distribution router 2. The remote router uses the best route to reach its destination. If distribution router 1 experiences a failure, the remote router can still use distribution router 2 to reach the corporate network.

Figure 26-5 shows a simple dual-homed remote with one remote router and two distribution routers. Both distribution routers maintain routes to the corporate network and stub network 10.1.1.0/24.

Dual-homed routing can introduce instability into an EIGRP network. In Figure 26-6, distribution router 1 is directly connected to network 10.3.1.0/24. If summarization or filtering is applied on distribution router 1, the router advertises network 10.3.1.0/24 to all of its directly connected EIGRP neighbors (distribution router 2 and the remote router).
Figure 26-6 shows a simple dual-homed remote router where distribution router 1 is connected to both network 10.3.1.0/24 and network 10.2.1.0/24.

If the 10.2.1.0/24 link between distribution router 1 and distribution router 2 has failed, the lowest cost path to network 10.3.1.0/24 from distribution router 2 is through the remote router (see Figure 26-7). This route is not desirable because the traffic that was previously traveling across the corporate network 10.2.1.0/24 is now sent across a much lower bandwidth connection. The over utilization of the lower bandwidth WAN connection can cause a number of problems that might affect the entire corporate network. The use of the lower bandwidth route that passes through the remote router might cause WAN EIGRP distribution routers to be dropped. Serial lines on distribution and remote routers could also be dropped, and EIGRP SIA errors on the distribution and core routers could occur.
Chapter 26      Configuring Layer 3 Interfaces

Configuring EIGRP Stub Routing

It is not desirable for traffic from distribution router 2 to travel through any remote router in order to reach network 10.3.1.0/24. If the links are sized to handle the load, it would be acceptable to use one of the backup routes. However, most networks of this type have remote routers located at remote offices with relatively slow links. This problem can be prevented if proper summarization is configured on the distribution router and remote router.

It is typically undesirable for traffic from a distribution router to use a remote router as a transit path. A typical connection from a distribution router to a remote router would have much less bandwidth than a connection at the network core. Attempting to use a remote router with a limited bandwidth connection as a transit path would generally produce excessive congestion to the remote router. The EIGRP Stub Routing feature can prevent this problem by preventing the remote router from advertising core routes back to distribution routers. Routes learned by the remote router from distribution router 1 is not advertised to distribution router 2. Because the remote router does not advertise core routes to distribution router 2, the distribution router does not use the remote router as a transit for traffic destined for the network core.

The EIGRP Stub Routing feature can help to provide greater network stability. In the event of network instability, this feature prevents EIGRP queries from being sent over limited bandwidth links to nontransit routers. Instead, distribution routers to which the stub router is connected answer the query on behalf of the stub router. This feature greatly reduces the chance of further network instability due to congested or problematic WAN links. The EIGRP Stub Routing feature also simplifies the configuration and maintenance of hub-and-spoke networks. When stub routing is enabled in dual-homed remote configurations, it is no longer necessary to configure filtering on remote routers to prevent those remote routers from appearing as transit paths to the hub routers.

Caution

EIGRP Stub Routing should only be used on stub routers. A stub router is defined as a router connected to the network core or distribution layer through which core transit traffic should not flow. A stub router should not have any EIGRP neighbors other than distribution routers. Ignoring this restriction causes undesirable behavior.

Note

Multi-access interfaces, such as ATM, Ethernet, Frame Relay, ISDN PRI, and X.25, are supported by the EIGRP Stub Routing feature only when all routers on that interface, except the hub, are configured as stub routers.

EIGRP Stub Routing Configuration Task List

To configure EIGRP Stub Routing, perform the tasks described in the following sections. The tasks in the first section are required; the task in the last section is optional.

- Configuring EIGRP Stub Routing (required)
- Verifying EIGRP Stub Routing (optional)
Configuring EIGRP Stub Routing

To configure a remote or spoke router for EIGRP stub routing, use the following commands beginning in router configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch(config)# router eigrp 1</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config-router)# network network-number</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config-router)# eigrp stub [receive-only</td>
</tr>
<tr>
<td></td>
<td>connected</td>
</tr>
</tbody>
</table>

Verifying EIGRP Stub Routing

To verify that a remote router has been configured as a stub router with EIGRP, use the `show ip eigrp neighbor detail` command from the distribution router in privileged EXEC mode. The last line of the output shows the stub status of the remote or spoke router. The following example shows output is from the `show ip eigrp neighbor detail` command:

```
router# show ip eigrp neighbor detail
IP-EIGRP neighbors for process 1
H   Address            Interface   Hold Uptime   SRTT   RTO  Q  Seq Type
      (sec)         (ms)       Cnt Num
0   10.1.1.2           Se3/1         11 00:00:59    1  4500  0  7
Version 12.1/1.2, Retrans: 2, Retries: 0
Stub Peer Advertising ( CONNECTED SUMMARY ) Routes
```

Monitoring and Maintaining EIGRP

To delete neighbors from the neighbor table, use the following command:

```
Command | Purpose |
---------|---------|
Switch# clear ip eigrp neighbors [ip-address | Deletes neighbors from the neighbor table. |
interface]
```

To display various routing statistics, use the following commands:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Switch# show ip eigrp interfaces [interface] [as-number]</strong></td>
<td>Displays information about interfaces configured for EIGRP.</td>
</tr>
<tr>
<td>**Switch# show ip eigrp neighbors [type</td>
<td>number</td>
</tr>
<tr>
<td>**Switch# show ip eigrp topology [autonomous-system-number</td>
<td>Displays the EIGRP topology table for a given process.</td>
</tr>
<tr>
<td>[[ip-address] mask]]]</td>
<td></td>
</tr>
<tr>
<td><strong>Switch# show ip eigrp traffic [autonomous-system-number]</strong></td>
<td>Displays the number of packets sent and received for all or a specified EIGRP process.</td>
</tr>
</tbody>
</table>
Chapter 26  Configuring Layer 3 Interfaces

EIGRP Configuration Examples

This section contains the following examples:

- **Route Summarization Example**
- **Route Authentication Example**
- **Stub Routing Example**

### Route Summarization Example

The following example configures route summarization on the interface and also configures the autosummary feature. This configuration causes EIGRP to summarize network 10.0.0.0 out Ethernet interface 0 only. In addition, this example disables autosummarization.

```plaintext
interface Ethernet 0
  ip summary-address eigrp 1 10.0.0.0 255.0.0.0

router eigrp 1
  network 172.16.0.0
  no auto-summary
```

**Note**

You should not use the `ip summary-address eigrp` summarization command to generate the default route (0.0.0.0) from an interface. This causes the creation of an EIGRP summary default route to the null 0 interface with an administrative distance of 5. The low administrative distance of this default route can cause this route to displace default routes learned from other neighbors from the routing table. If the default route learned from the neighbors is displaced by the summary default route, or if the summary route is the only default route present, all traffic destined for the default route does not leave the router, instead, this traffic is sent to the null 0 interface where it is dropped.

The recommended way to send only the default route out a given interface is to use a `distribute-list` command. You can configure this command to filter all outbound route advertisements sent out the interface with the exception of the default (0.0.0.0).

### Route Authentication Example

The following example enables MD5 authentication on EIGRP packets in autonomous system 1.

**Router A**

```plaintext
interface ethernet 1
  ip authentication mode eigrp 1 md5
  ip authentication key-chain eigrp 1 holly
```
Router B

```plaintext
interface ethernet 1
  ip authentication mode eigrp 1 md5
  ip authentication key-chain eigrp 1 mikel
  key chain mikel
    key 1
      key-string 0987654321
      accept-lifetime 04:00:00 Dec 4 1996 infinite
      send-lifetime 04:00:00 Dec 4 1996 infinite
    exit
    key 2
      key-string 1234567890
      accept-lifetime 04:00:00 Dec 4 1996 infinite
      send-lifetime 04:45:00 Dec 4 1996 infinite
```

Router A accepts and attempts to verify the MD5 digest of any EIGRP packet with a key equal to 1. It also accepts a packet with a key equal to 2. All other MD5 packets are dropped. Router A sends all EIGRP packets with key 2.

Router B accepts key 1 or key 2, and sends key 1. In this scenario, MD5 authenticates.

**Stub Routing Example**

A router that is configured as a stub with the `eigrp stub` command shares connected and summary routing information with all neighbor routers by default. Four optional keywords can be used with the `eigrp stub` command to modify this behavior:

- receive-only
- connected
- static
- summary

This section provides configuration examples for all forms of the `eigrp stub` command. The `eigrp stub` command can be modified with several options, and these options can be used in any combination except for the `receive-only` keyword. The `receive-only` keyword restricts the router from sharing any of its routes with any other router in that EIGRP autonomous system, and the `receive-only` keyword does not permit any other option to be specified because it prevents any type of route from being sent. The three other optional keywords (`connected`, `static`, and `summary`) can be used in any combination but cannot be used with the `receive-only` keyword. If any of these three keywords is used individually with the `eigrp stub` command, connected and summary routes are not sent automatically.

The `connected` keyword permits the EIGRP Stub Routing feature to send connected routes. If the connected routes are not covered by a network statement, it may be necessary to redistribute connected routes with the `redistribute connected` command under the EIGRP process. This option is enabled by default.

The `static` keyword permits the EIGRP Stub Routing feature to send static routes. Without this option, EIGRP does not send any static routes, including internal static routes that normally would be automatically redistributed. It is still necessary to redistribute static routes with the `redistribute static` command.

The `summary` keyword permits the EIGRP Stub Routing feature to send summary routes. Summary routes can be created manually with the `summary address` command or automatically at a major network border router with the `auto-summary` command enabled. This option is enabled by default.

In the following example, the `eigrp stub` command is used to configure the router as a stub that advertises connected and summary routes:
In the following example, the `eigrp stub connected static` command is used to configure the router as a stub that advertises connected and static routes (sending summary routes is not permitted):

```
router eigrp 1
network 10.0.0.0
eigrp stub
```

In the following example, the `eigrp stub receive-only` command is used to configure the router as a stub, and connected, summary, or static routes is not sent:

```
router eigrp 1
network 10.0.0.0 eigrp
stub receive-only
```
CHAPTER 27

Configuring Cisco Express Forwarding

This chapter describes Cisco Express Forwarding (CEF) on the Catalyst 4000 family switch. It also provides guidelines, procedures, and examples to configure this feature.

This chapter includes the following major sections:

- About CEF, page 27-1
- Catalyst 4500 Series Switch Implementation of CEF, page 27-3
- CEF Configuration Restrictions, page 27-6
- Configuring CEF, page 27-6
- Monitoring and Maintaining CEF, page 27-8

Note

For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

About CEF

This section contains information on the two primary components that comprise the CEF operation:

- Benefits of CEF, page 27-2
- Forwarding Information Base, page 27-2
- Adjacency Tables, page 27-2
Benefits of CEF

CEF is advanced Layer 3 IP switching technology that optimizes performance and scalability for large networks with dynamic traffic patterns or networks with intensive web-based applications and interactive sessions.

CEF provides the following benefits:

- Improves performance over the caching schemes of multilayer switches, which often flush the entire cache when information changes in the routing tables.
- Provides load balancing that distributes packets across multiple links based on Layer 3 routing information. If a network device discovers multiple paths to a destination, the routing table is updated with multiple entries for that destination. Traffic to that destination is then distributed among the various paths.

CEF stores information in several data structures rather than the route cache of multilayer switches. The data structures optimize lookup for efficient packet forwarding.

Forwarding Information Base

The Forwarding Information Base (FIB) is a table that contains a copy of the forwarding information in the IP routing table. When routing or topology changes occur in the network, the route processor updates the IP routing table and CEF updates the FIB. Because there is a one-to-one correlation between FIB entries and routing table entries, the FIB contains all known routes and eliminates the need for route cache maintenance that is associated with switching paths, such as fast switching and optimum switching. CEF uses the FIB to make IP destination-based switching decisions and maintain next-hop address information based on the information in the IP routing table.

On the Catalyst 4500 series switches, CEF loads the FIB into the Integrated Switching Engine hardware to increase the performance of forwarding. The Integrated Switching Engine has a finite number of forwarding slots for storing routing information. If this limit is exceeded, CEF is automatically disabled and all packets are forwarded in software. In this situation, you should reduce the number of routes on the switch and then reenable hardware switching with the `ip cef` command.

Adjacency Tables

In addition to the FIB, CEF uses adjacency tables to prepend Layer 2 addressing information. Nodes in the network are said to be adjacent if they are within a single hop from each other. The adjacency table maintains Layer 2 next-hop addresses for all FIB entries.

Adjacency Discovery

The adjacency table is populated as new adjacent nodes are discovered. Each time an adjacency entry is created (such as through the Address Resolution Protocol (ARP), a link-layer header for that adjacent node is stored in the adjacency table. Once a route is determined, the link-layer header points to a next hop and corresponding adjacency entry. The link-layer header is subsequently used for encapsulation during CEF switching of packets.
Chapter 27  Configuring Cisco Express Forwarding

Adjacency Resolution

A route might have several paths to a destination prefix, such as when a router is configured for simultaneous load balancing and redundancy. For each resolved path, a pointer is added for the adjacency corresponding to the next-hop interface for that path. This mechanism is used for load balancing across several paths.

Adjacency Types That Require Special Handling

In addition to adjacencies for next-hop interfaces (host-route adjacencies), other types of adjacencies are used to expedite switching when certain exception conditions exist. When the prefix is defined, prefixes requiring exception processing are cached with one of the special adjacencies listed in Table 27-1.

Table 27-1  Adjacency Types for Exception Processing

<table>
<thead>
<tr>
<th>This adjacency type...</th>
<th>Receives this processing...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Null adjacency</td>
<td>Packets destined for a Null0 interface are dropped. A Null0 interface can be used as an effective form of access filtering.</td>
</tr>
<tr>
<td>Glean adjacency</td>
<td>When a router is connected directly to several hosts, the FIB table on the router maintains a prefix for the subnet rather than for each individual host. The subnet prefix points to a glean adjacency. When packets must be forwarded to a specific host, the adjacency database is gleaned for the specific prefix.</td>
</tr>
<tr>
<td>Punt adjacency</td>
<td>Features that require special handling or features that are not yet supported by CEF switching are sent (punted) to the next higher switching level.</td>
</tr>
<tr>
<td>Discard adjacency</td>
<td>Packets are discarded.</td>
</tr>
<tr>
<td>Drop adjacency</td>
<td>Packets are dropped.</td>
</tr>
</tbody>
</table>

Unresolved Adjacency

When a link-layer header is prepended to packets, FIB requires the prepend to point to an adjacency corresponding to the next hop. If an adjacency was created by FIB and was not discovered through a mechanism such as ARP, the Layer 2 addressing information is not known and the adjacency is considered incomplete. When the Layer 2 information is known, the packet is forwarded to the route processor, and the adjacency is determined through ARP.

Catalyst 4500 Series Switch Implementation of CEF

This section contains the following subsections:

- Hardware and Software Switching, page 27-4
- Load Balancing, page 27-6
- Software Interfaces, page 27-6
Catalyst 4000 Family switches support an ASIC-based Integrated Switching Engine that provides these features:

- Ethernet bridging at Layer 2
- IP routing at Layer 3

Because the ASIC is specifically designed to forward packets, the Integrated Switching Engine hardware can run this process much faster than CPU subsystem software.

Figure 27-1 shows a high-level view of the ASIC-based Layer 2 and Layer 3 switching process on the Integrated Switching Engine.

**Figure 27-1 Logical L2 and L3 Switch Components**

The Integrated Switching Engine performs inter-VLAN routing on logical Layer 3 interfaces with the ASIC hardware. The ASIC hardware also supports a physical Layer 3 interface that can be configured to connect with a host, a switch, or a router.

**Hardware and Software Switching**

For the majority of packets, the Integrated Switching Engine performs the packet forwarding function in hardware. These packets are hardware-switched at very high rates. Exception packets are forwarded by the CPU subsystem software. Statistic reports should show that the Integrated Switching Engine is forwarding the vast majority of packets in hardware. Software forwarding is significantly slower than hardware forwarding, but packets forwarded by the CPU subsystem do not reduce hardware forwarding speed.

Figure 27-2 shows a logical view of the Integrated Switching Engine and the CPU subsystem switching components.
Figure 27-2 Hardware and Software Switching Components

The Integrated Switching Engine performs inter-VLAN routing in hardware. The CPU subsystem software supports Layer 3 interfaces to VLANs that use Subnetwork Access Protocol (SNAP) encapsulation. The CPU subsystem software also supports generic routing encapsulation (GRE) tunnel.

**Hardware Switching**

Hardware switching is the normal operation for the Catalyst 4500 series switch.

**Software Switching**

Software switching occurs when traffic cannot be processed in hardware. The following types of exception packets are processed in software at a much slower rate:

- Packets that use IP header options

**Note** Packets that use TCP header options are switched in hardware because they do not affect the forwarding decision.

- Packets that have an expiring IP time-to-live (TTL) counter
- Packets that are forwarded to a tunnel interface
- Packets that arrive with non-supported encapsulation types
- Packets that are routed to an interface with non-supported encapsulation types
- Packets that exceed the MTU of an output interface and must be fragmented
- Packets that require an IGMP redirect to be routed
Load Balancing

The Catalyst 4000 family switch supports load balancing for routing packets in the Integrated Switching Engine hardware. Load balancing is always enabled. It works when multiple routes for the same network with different next-hop addresses are configured. These routes can be configured either statically or through a routing protocol such as OSPF or EIGRP.

The hardware makes a forwarding decision by using a hardware load sharing hash function to compute a value, based on the source and destination IP addresses and the source and destination TCP port numbers (if available). This load sharing hash value is then used to select which route to use to forward the packet. All hardware switching within a particular flow (such as a TCP connection) is routed to the same next hop, thereby reducing the chance that packet reordering occurs. Up to eight different routes for a particular network are supported.

Software Interfaces

Cisco IOS for the Catalyst 4000 family switch supports GRE and IP tunnel interfaces that are not part of the hardware forwarding engine. All packets that flow to or from these interfaces must be processed in software and has a significantly lower forwarding rate than that of hardware-switched interfaces. Also, Layer 2 features are not supported on these interfaces.

CEF Configuration Restrictions

The Integrated Switching Engine supports only ARPA and ISL/802.1q encapsulation types for Layer 3 switching in hardware. The CPU subsystem supports a number of encapsulations such as SNAP for Layer 2 switching that you can use for Layer 3 switching in software.

Configuring CEF

These sections describe how to configure CEF:

- **Enabling CEF, page 27-6**
- **Configuring Load Balancing for CEF, page 27-7**

Enabling CEF

By default, CEF is enabled globally on the Catalyst 4000 family switch. No configuration is required. To reenable CEF, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Switch(config)# ip cef distributed</code></td>
<td>Enables standard CEF operation.</td>
</tr>
</tbody>
</table>
Configuring Load Balancing for CEF

CEF load balancing is based on a combination of source and destination packet information; it allows you to optimize resources by distributing traffic over multiple paths for transferring data to a destination. You can configure load balancing on a per-destination basis. Load-balancing decisions are made on the outbound interface. You can configure per-destination load balancing for CEF on outbound interfaces.

The following topics are discussed:
- Configuring Per-Destination Load Balancing, page 27-7
- Configuring Load Sharing Hash Function, page 27-7
- Viewing CEF Information, page 27-8

Configuring Per-Destination Load Balancing

Per-destination load balancing is enabled by default when you enable CEF. To use per-destination load balancing, you do not perform any additional tasks once you enable CEF.

Per-destination load balancing allows the router to use multiple paths to achieve load sharing. Packets for a given source-destination host pair are guaranteed to take the same path, even if multiple paths are available. Traffic destined for different pairs tend to take different paths. Per-destination load balancing is enabled by default when you enable CEF; it is the load balancing method of choice in most situations.

Because per-destination load balancing depends on the statistical distribution of traffic, load sharing becomes more effective as the number of source-destination pairs increases.

You can use per-destination load balancing to ensure that packets for a given host pair arrive in order. All packets for a certain host pair are routed over the same link or links.

Configuring Load Sharing Hash Function

When multiple unicast routes exist to a particular destination IP prefix, the hardware sends packets matching that prefix across all possible routes, thereby sharing the load across all next hop routers. By default, the route used is chosen by computing a hash of the source and destination IP addresses and using the resulting value to select the route. This preserves packet ordering for packets within a flow by ensuring that all packets within a single IP source/destination flow are sent on the same route, but it provides a near-random distribution of flows to routes.

The load-sharing hash function can be changed, so that in addition to the source and destination IP addresses, the source TCP/UDP port, the destination TCP/UDP port, or both can also be included in the hash.

To configure load sharing hash function to use the source and/or destination ports, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch (config)# [no] ip cef load-sharing algorithm include-ports source destination</td>
<td>Enables load sharing hash function to use source and destination ports. Use the no keyword to set the switch to use the default Cisco IOS load-sharing algorithm.</td>
</tr>
</tbody>
</table>
Note

The \texttt{include-ports} option does not apply to software-switched traffic on the Catalyst 4500 series switches.

Viewing CEF Information

You can view the collected CEF information. To view CEF information, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# \texttt{show ip cef}</td>
<td>Displays the collected CEF information.</td>
</tr>
</tbody>
</table>

Monitoring and Maintaining CEF

To display information about IP traffic, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# \texttt{show interface type slot/interface \begin{array}{c} \texttt{begin L3} \end{array}}</td>
<td>Displays a summary of IP unicast traffic.</td>
</tr>
</tbody>
</table>

This example shows how to display information about IP unicast traffic on interface Fast Ethernet 3/3:

\begin{verbatim}
Switch# \texttt{show interface fastethernet 3/3 | begin L3}
L3 in Switched: ucast: 0 pkt, 0 bytes - mcast: 12 pkt, 778 bytes mcast
L3 out Switched: ucast: 0 pkt, 0 bytes - mcast: 0 pkt, 0 bytes
4046399 packets input, 349370039 bytes, 0 no buffer
Received 3795255 broadcasts, 2 runts, 0 giants, 0 throttles
<...output truncated...>
Switch#
\end{verbatim}

Note

The IP unicast packet count is updated approximately every five seconds.

Displaying IP Statistics

IP unicast statistics are gathered on a per-interface basis. To display IP statistics, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# \texttt{show interface type number counters detail}</td>
<td>Displays IP statistics.</td>
</tr>
</tbody>
</table>
This example shows how to display IP unicast statistics for Part 3/1:

Switch# `show interface fastethernet 3/1 counters detail`

<table>
<thead>
<tr>
<th>Port</th>
<th>InBytes</th>
<th>InUcastPkts</th>
<th>InMcastPkts</th>
<th>InBcastPkts</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fa3/1</td>
<td>7263539133</td>
<td>5998222</td>
<td>6412307</td>
<td>156</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Port</th>
<th>OutBytes</th>
<th>OutUcastPkts</th>
<th>OutMcastPkts</th>
<th>OutBcastPkts</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fa3/1</td>
<td>7560137031</td>
<td>5079852</td>
<td>12140475</td>
<td>38</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Port</th>
<th>InPkts 64</th>
<th>OutPkts 64</th>
<th>InPkts 65-127</th>
<th>OutPkts 65-127</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fa3/1</td>
<td>11274</td>
<td>168536</td>
<td>7650482</td>
<td>12395769</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Fa3/1</td>
<td>31191</td>
<td>55269</td>
<td>26923</td>
<td>65017</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Port</th>
<th>InPkts 512-1023</th>
<th>OutPkts 512-1023</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fa3/1</td>
<td>133807</td>
<td>151582</td>
</tr>
</tbody>
</table>

To display CEF (software switched) and hardware IP unicast adjacency table information, perform this task:

Switch# `show adjacency gigabitethernet 3/5 detail`

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Interface</th>
<th>Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP</td>
<td>GigabitEthernet9/5</td>
<td>172.20.53.206(11)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>504 packets, 6110 bytes</td>
</tr>
<tr>
<td></td>
<td></td>
<td>03605C865BB82</td>
</tr>
<tr>
<td></td>
<td></td>
<td>00164F83FA50800</td>
</tr>
<tr>
<td></td>
<td></td>
<td>03:49:31</td>
</tr>
</tbody>
</table>

This example shows how to display adjacency statistics:

Switch# `show adjacency gigabitethernet 3/5 detail`

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Interface</th>
<th>Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP</td>
<td>GigabitEthernet9/5</td>
<td>172.20.53.206(11)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>504 packets, 6110 bytes</td>
</tr>
<tr>
<td></td>
<td></td>
<td>03605C865BB82</td>
</tr>
<tr>
<td></td>
<td></td>
<td>00164F83FA50800</td>
</tr>
<tr>
<td></td>
<td></td>
<td>03:49:31</td>
</tr>
</tbody>
</table>

Note: Adjacency statistics are updated approximately every 10 seconds.
Configuring Unicast Reverse Path Forwarding

This chapter describes the Unicast Reverse Path Forwarding (Unicast RPF) feature. The Unicast RPF feature helps to mitigate problems that are caused by malformed or forged IP source addresses that are passing through a switch.

For a complete description of the Unicast RPF commands in this chapter, refer to the chapter “Unicast Reverse Path Forwarding Commands” of the Cisco IOS Security Command Reference. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature or refer to the software release notes for a specific release. For more information, see the “Identifying Supported Platforms” section in the chapter “Using Cisco IOS Software.”

For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

In This Chapter

This chapter has the following sections:

- About Unicast Reverse Path Forwarding
- Unicast RPF Configuration Task List
- Monitoring and Maintaining Unicast RPF
- Monitoring and Maintaining Unicast RPF
- Unicast RPF Configuration Example: Inbound and Outbound Filters
About Unicast Reverse Path Forwarding

The Unicast RPF feature helps to mitigate problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network by discarding IP packets that lack a verifiable IP source address. For example, a number of common types of denial-of-service (DoS) attacks, including Smurf and Tribal Flood Network (TFN), can take advantage of forged or rapidly changing source IP addresses to allow attackers to thwart efforts to locate or filter the attacks. For Internet service providers (ISPs) that provide public access, Unicast RPF deflects such attacks by forwarding only packets that have source addresses that are valid and consistent with the IP routing table. This action protects the network of the ISP, its customer, and the rest of the Internet.

This section covers the following information:

- How Unicast RPF Works
- Implementing Unicast RPF
- Restrictions
- Related Features and Technologies
- Prerequisites to Configuring Unicast RPF

How Unicast RPF Works

When Unicast RPF is enabled on an interface, the switch examines all packets received as input on that interface to make sure that the source address and source interface appear in the routing table and match the interface on which the packet was received. This “look backwards” ability is available only when Cisco express forwarding (CEF) is enabled on the switch, because the lookup relies on the presence of the Forwarding Information Base (FIB). CEF generates the FIB as part of its operation.

Note

Unicast RPF is an input function and is applied only on the input interface of a switch at the upstream end of a connection.

Unicast RPF checks to see if any packet received at a switch interface arrives on the best return path (return route) to the source of the packet. Unicast RPF does this by doing a reverse lookup in the CEF table. If the packet was received from one of the best reverse path routes, the packet is forwarded as normal. If there is no reverse path route on the same interface from which the packet was received, it might mean that the source address was modified. If Unicast RPF does not find a reverse path for the packet, the packet is dropped.

Note

With Unicast RPF, all equal-cost “best” return paths are considered valid. This means that Unicast RPF works in cases where multiple return paths exist, provided that each path is equal to the others in terms of the routing cost (number of hops, weights, and so on) and as long as the route is in the FIB. Unicast RPF also functions where EIGRP variants are being used and unequal candidate paths back to the source IP address exist.

When a packet is received at the interface where Unicast RPF and ACLs have been configured, the following actions occur:

Step 1

Input ACLs configured on the inbound interface are checked.
Step 2  Unicast RPF checks to see if the packet has arrived on the best return path to the source, which it does by doing a reverse lookup in the FIB table.

Step 3  CEF table (FIB) lookup is carried out for packet forwarding.

Step 4  Output ACLs are checked on the outbound interface.

Step 5  The packet is forwarded.

This section provides information about Unicast RPF enhancements:

- Access Control Lists and Logging
- Per-Interface Statistics

Figure 28-1 illustrates how Unicast RPF and CEF work together to validate IP source addresses by verifying packet return paths. In this example, a customer has sent a packet having a source address of 192.168.1.1 from interface Gigabit Ethernet 1/1. Unicast RPF checks the FIB to see if 192.168.1.1 has a path to Gigabit Ethernet 1/1. If there is a matching path, the packet is forwarded. If there is no matching path, the packet is dropped.

Figure 28-1  Unicast RPF Validating IP Source Addresses

Figure 28-2 illustrates how Unicast RPF drops packets that fail validation. In this example, a customer has sent a packet having a source address of 209.165.200.225, which is received at interface Gigabit Ethernet 1/1. Unicast RPF checks the FIB to see if 209.165.200.225 has a return path to Gigabit Ethernet
1/1. If there is a matching path, the packet is forwarded. In this case, there is no reverse entry in the routing table that routes the customer packet back to source address 209.165.200.225 on interface Gigabit Ethernet 1/1, and so the packet is dropped.

**Figure 28-2 Unicast RPF Dropping Packets That Fail Verification**

Implementing Unicast RPF

Unicast RPF has several key implementation principles:

- The packet must be received at an interface that has the best return path (route) to the packet source (a process called symmetric routing). There must be a route in the FIB matching the route to the receiving interface. Adding a route in the FIB can be done via static route, network statement, or dynamic routing. (ACLs permit Unicast RPF to be used when packets are known to be arriving by specific, less optimal asymmetric input paths.)
- IP source addresses at the receiving interface must match the routing entry for the interface.
- Unicast RPF is an input function and is applied only on the input interface of a switch at the upstream end of a connection.

Given these implementation principles, Unicast RPF becomes a tool that network administrators can use not only for their customers but also for their downstream network or ISP, even if the downstream network or ISP has other connections to the Internet.
Chapter 28      Configuring Unicast Reverse Path Forwarding

About Unicast Reverse Path Forwarding

Caution

Using optional BGP attributes such as weight and local preference, the best path back to the source address can be modified. Modification would affect the operation of Unicast RPF.

This section provides information about the implementation of Unicast RPF:

- Security Policy and Unicast RPF
- Where to Use Unicast RPF
- Routing Table Requirements
- Where Not to Use Unicast RPF
- Unicast RPF with BOOTP and DHCP

Security Policy and Unicast RPF

Consider the following points in determining your policy for deploying Unicast RPF:

- Unicast RPF must be applied at the interface downstream from the larger portion of the network, preferably at the edges of your network.
- The further downstream you apply Unicast RPF, the finer the granularity you have in mitigating address spoofing and in identifying the sources of spoofed addresses. For example, applying Unicast RPF on an aggregation switch helps mitigate attacks from many downstream networks or clients and is simple to administer, but it does not help identify the source of the attack. Applying Unicast RPF at the network access server helps limit the scope of the attack and trace the source of the attack; however, deploying Unicast RPF across many sites does add to the administration cost of operating the network.
- The more entities that deploy Unicast RPF across Internet, intranet, and extranet resources, the better the chances of mitigating large-scale network disruptions throughout the Internet community, and the better the chances of tracing the source of an attack.
- Unicast RPF does not inspect IP packets encapsulated in tunnels, such as GRE, LT2P, or PPTP. Unicast RPF must be configured at a home gateway so that Unicast RPF processes network traffic only after the tunneling and encryption layers have been stripped off the packets.

Where to Use Unicast RPF

Unicast RPF can be used in any “single-homed” environment where there is essentially only one access point out of the network; that is, one upstream connection. Networks having one access point offer the best example of symmetric routing, which means that the interface where a packet enters the network is also the best return path to the source of the IP packet. Unicast RPF is best used at the network perimeter for Internet, intranet, or extranet environments, or in ISP environments for customer network terminations.

Enterprise Networks with a Single Connection to an ISP

In enterprise networks, one objective of using Unicast RPF for filtering traffic at the input interface (a process called ingress filtering) is for protection from malformed packets arriving from the Internet. Traditionally, local networks that have one connection to the Internet would use ACLs at the receiving interface to prevent spoofed packets from the Internet from entering their local network.
Chapter 28      Configuring Unicast Reverse Path Forwarding

About Unicast Reverse Path Forwarding

ACLs work well for many single-homed customers; however, there are trade-offs when ACLs are used as ingress filters, including two commonly referenced limitations:

- Packet per second (PPS) performance at very high packet rates

Note: This restriction applies only to software packet forwarding. Hardware packet forwarding is the same on both ACL and uRPF.

- Maintenance of the ACL (whenever there are new addresses added to the network)

Unicast RPF is one tool that addresses both of these limitations. With Unicast RPF, ingress filtering is done at CEF PPS rates. This processing speed makes a difference when the link is more than 1 Mbps. Additionally, because Unicast RPF uses the FIB, no ACL maintenance is necessary, and thus the administration overhead of traditional ACLs is reduced. The following figure and example demonstrate how Unicast RPF is configured for ingress filtering.

Figure 28-3 illustrates an enterprise network that has a single link to an upstream ISP. In this example, Unicast RPF is applied at interface Gigabit Ethernet 1/1 on the Enterprise switch for protection from malformed packets arriving from the Internet. Unicast RPF is also applied at interface Gigabit Ethernet 2/1 on the ISP switch for protection from malformed packets arriving from the enterprise network.

Using the topography in Figure 28-3, a typical configuration (assuming that CEF is turned on) on the ISP switch would be as follows:

```plaintext
interface Gigabit Ethernet 2/1
  description Link to Enterprise Network
  ip address 192.168.3.1 255.255.255.255
  no switchport
  ip address 10.1.1.2 255.255.255.0
  ip verify unicast source reachable-via rx allow-default
```

The gateway switch configuration of the enterprise network (assuming that CEF is turned on) would look similar to the following:

```plaintext
interface Gigabit Ethernet 1/2
  description ExampleCorp LAN
  ip address 192.168.10.1 255.255.252.0
  no ip redirects
  no ip directed-broadcast
  no ip proxy-arp

interface Gigabit Ethernet 1/1
  description Link to Internet
  no switchport
  ip address 10.1.1.1 255.255.255.0
  ip verify unicast source reachable-via allow-default
  no ip proxy-arp
  no ip redirects
  no ip directed-broadcast
```
Notice that Unicast RPF works with a single default route. There are no additional routes or routing protocols. Network 192.168.10.0/22 is a connected network. Hence, packets coming from the Internet with a source address in the range 192.168.10.0/22 is dropped by Unicast RPF.

Routing Table Requirements

To work correctly, Unicast RPF needs proper information in the CEF tables. This requirement does not mean that the switch must have the entire Internet routing table. The amount of routing information needed in the CEF tables depends on where Unicast RPF is configured and what functions the switch performs in the network. For example, in an ISP environment, a switch that is a leased-line aggregation switch for customers needs only the information based on the static routes redistributed into the IGP or IBGP (depending on which technique is used in the network). Unicast RPF would be configured on the customer interfaces—hence the requirement for minimal routing information. In another scenario, a single-homed ISP could place Unicast RPF on the gateway link to the Internet. The full Internet routing table would be required. Requiring the full routing table would help protect the ISP from external DoS attacks that use addresses that are not in the Internet routing table.

Where Not to Use Unicast RPF

Unicast RPF should not be used on interfaces that are internal to the network. Internal interfaces are likely to have routing asymmetry (see Figure 28-4), meaning multiple routes to the source of a packet. Unicast RPF should be applied only where there is natural or configured symmetry. As long as administrators carefully plan which interfaces they activate Unicast RPF on, routing asymmetry is not a serious problem.

For example, switches at the edge of the network of an ISP are more likely to have symmetrical reverse paths than switches that are in the core of the ISP network. Switches that are in the core of the ISP network have no guarantee that the best forwarding path out of the switch is the path selected for packets returning to the switch. Hence, it is not recommended that you apply Unicast RPF where there is a chance of asymmetric routing, unless you use ACLs to allow the switch to accept incoming packets. ACLs permit Unicast RPF to be used when packets are known to be arriving by specific, less optimal asymmetric input paths. However, it is simplest to place Unicast RPF only at the edge of a network or, for an ISP, at the customer edge of the network.

Figure 28-4 illustrates how Unicast RPF can block legitimate traffic in an asymmetrical routing environment.
### Unicast RPF with BOOTP and DHCP

Unicast RPF allows packets with 0.0.0.0 source and 255.255.255.255 destination to pass so that Bootstrap Protocol (BOOTP) and Dynamic Host Configuration Protocol (DHCP) functions work properly.

### Restrictions

There are some basic restrictions to applying Unicast RPF to multihomed clients:
- Clients should not be multihomed to the same switch because multihoming defeats the purpose of building a redundant service for the client.
- Customers must ensure that the packets flowing up the link (out to the Internet) match the route advertised out the link. Otherwise, Unicast RPF filters those packets as malformed packets.

### Limitations

There are some basic limitations associated with applying Unicast RPF:
- Unicast loose mode is not supported.

### Related Features and Technologies

For more information about Unicast RPF-related features and technologies, review the following:
- Unicast RPF requires Cisco express forwarding (CEF) to function properly on the switch. For more information about CEF, refer to the *Cisco IOS Switching Services Configuration Guide*.
• Unicast RPF can be more effective at mitigating spoofing attacks when combined with a policy of ingress and egress filtering using Cisco IOS access control lists (ACLs).
  - Ingress filtering applies filters to traffic received at a network interface from either internal or external networks. With ingress filtering, packets that arrive from other networks or the Internet and that have a source address that matches a local network, private, or broadcast address are dropped. In ISP environments, for example, ingress filtering can apply to traffic received at the switch from either the client (customer) or the Internet.
  - Egress filtering applies filters to traffic exiting a network interface (the sending interface). By filtering packets on switches that connect your network to the Internet or to other networks, you can permit only packets with valid source IP addresses to leave your network.

For more information on network filtering, refer to RFC 2267 and to the Cisco IOS IP Configuration Guide.

Prerequisites to Configuring Unicast RPF

Prior to configuring Unicast RPF, configure ACLs:
• Configure standard or extended ACLs to mitigate transmission of invalid IP addresses (perform egress filtering). Permit only valid source addresses to leave your network and get onto the Internet. Prevent all other source addresses from leaving your network for the Internet.
• Configure standard or extended ACLs entries to drop (deny) packets that have invalid source IP addresses (perform ingress filtering). Invalid source IP addresses include the following types:
  - Reserved addresses
  - Loopback addresses
  - Private addresses (RFC 1918, Address Allocation for Private Internets)
  - Broadcast addresses (including multicast addresses)
  - Source addresses that fall outside the range of valid addresses associated with the protected network

Unicast RPF Configuration Task List

The following sections describe the configuration tasks for Unicast RPF. Each task in the list is identified as either optional or required.
• Configuring Unicast RPF (Required)
• Verifying Unicast RPF (Optional)

See the section “Unicast RPF Configuration Example: Inbound and Outbound Filters” at the end of this chapter.

Configuring Unicast RPF

Unicast RPF is an input-side function that is enabled on an interface operates on IP packets received by the switch.
To configure Unicast RPF, perform the following task:

### Command Purpose

**Step 1**

Switch(config-if)# interface type

Selects the input interface on which you want to apply Unicast RPF. This is the receiving interface, which allows Unicast RPF to verify the best return path before forwarding the packet on to the next destination.

The interface type is specific to your switch and the types of interface cards installed on the switch. To display a list of available interface types, enter the **interface ?** command.

**Step 2**

Switch(config-if)# ip verify unicast source reachable-via rx allow-default

Enables Unicast RPF on the interface.

**Step 3**

Switch(config-if)# exit

Exits interface configuration mode. Repeat Steps 2 and 3 for each interface on which you want to apply Unicast RPF.

---

### Verifying Unicast RPF

To verify that Unicast RPF is operational, use the **show cef interface** command. The following example shows that Unicast RPF is enabled at interface Gigabit Ethernet 3/1.

Switch# show cef interface gigabitEthernet 3/1
GigabitEthernet3/1 is up (if_number 79)
Corresponding hwidb fast_if_number 79
Corresponding hwidb firstsw->if_number 79
Internet address is 10.1.1.1/24
ICMP redirects are always sent
IP unicast RPF check is enabled <======
Input features: uRPF <=====
Inbound access list is not set
Outbound access list is not set
IP policy routing is disabled
BGP based policy accounting on input is disabled
BGP based policy accounting on output is disabled
Hardware idb is GigabitEthernet3/1
Fast switching type 1, interface type 155
IP CEF switching enabled
IP Null turbo vector
IP prefix lookup IPv4 mtrie 8-8-8-8 optimized
Input fast flags 0x4000, Output fast flags 0x0
ifindex 78(78)
Slot 3 Slot unit 1 VC -1
Transmit limit accumulator 0x0 (0x0)
IP MTU 1500
Monitoring and Maintaining Unicast RPF

This section describes commands used to monitor and maintain Unicast RPF.

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# show ip traffic</td>
<td>Displays global switch statistics about Unicast RPF drops and suppressed drops.</td>
</tr>
<tr>
<td>Switch(config-if)# no ip verify unicast</td>
<td>Disables Unicast RPF at the interface.</td>
</tr>
</tbody>
</table>

Unicast RPF counts the number of packets dropped or suppressed because of malformed or forged source addresses. Unicast RPF counts dropped or forwarded packets that include the following global and per-interface information:

- Global Unicast RPF drops
- Per-interface Unicast RPF drops
- Per-interface Unicast RPF suppressed drops

The show ip traffic command shows the total number (global count) of dropped or suppressed packets for all interfaces on the switch. The Unicast RPF drop count is included in the IP statistics section.

Switch# show ip traffic

IP statistics:

Rcvd: 1471590 total, 887368 local destination
0 format errors, 0 checksum errors, 301274 bad hop count
0 security failures, 0 bad options, 0 with options

Opts: 0 end, 0 nop, 0 basic security, 0 loose source route
0 timestamp, 0 extended security, 0 record route
0 stream ID, 0 strict source route, 0 alert, 0 other

Frags: 0 reassembled, 0 timeouts, 0 couldn't reassemble
0 fragmented, 0 couldn't fragment

Bcast: 205233 received, 0 sent
Mcast: 463292 received, 462118 sent
Sent: 990158 generated, 282938 forwarded

! The second line below ("0 unicast RPF") displays Unicast RPF packet dropping information.

Drop: 3 encapsulation failed, 0 unresolved, 0 no adjacency
0 no route, 0 unicast RPF, 0 forced drop

A nonzero value for the count of dropped or suppressed packets can mean one of two things:

- Unicast RPF is dropping or suppressing packets that have a bad source address (normal operation).
- Unicast RPF is dropping or suppressing legitimate packets because the route is misconfigured to use Unicast RPF in environments where asymmetric routing exists; that is, where multiple paths can exist as the best return path for a source address.

The show ip interface command shows the total of dropped or suppressed packets at a specific interface. If Unicast RPF is configured to use a specific ACL, that ACL information is displayed along with the drop statistics.

Switch> show ip interface fast 2/1

Unicast RPF ACL 197
1 unicast RPF drop
1 unicast RPF suppressed drop
The show access-lists command displays the number of matches found for a specific entry in a specific access list.

Switch> show access-lists

Extended IP access list 197
   deny ip 192.168.201.0 0.0.0.63 any log-input (1 match)
   permit ip 192.168.201.64 0.0.0.63 any log-input (1 match)
   deny ip 192.168.201.128 0.0.0.63 any log-input
   permit ip 192.168.201.192 0.0.0.63 any log-input

Unicast RPF Configuration Example: Inbound and Outbound Filters

The following example uses a very simple single-homed ISP to demonstrate the concepts of ingress and egress filters used in conjunction with Unicast RPF. The example illustrates an ISP-allocated classless interdomain routing (CIDR) block 209.165.202.128/28 that has both inbound and outbound filters on the upstream interface. Be aware that ISPs are usually not single-homed. Hence, provisions for asymmetrical flows (when outbound traffic goes out one link and returns via a different link) need to be designed into the filters on the border switches of the ISP.

ip cef distributed
!
interface Serial 5/0/0
   description Connection to Upstream ISP
   ip address 209.165.200.225 255.255.255.252
   no ip redirects
   no ip directed-broadcast
   no ip proxy-arp
   ip verify unicast reverse-path rx allow-default
   ip access-group 111 in
   ip access-group 110 out
!
   access-list 110 permit ip 209.165.202.128 0.0.0.31 any
   access-list 110 deny ip any any log
   access-list 111 deny ip host 0.0.0.0 any log
   access-list 111 deny ip 127.0.0.0 0.255.255.255 any log
   access-list 111 deny ip 10.0.0.0 0.255.255.255 any log
   access-list 111 deny ip 172.16.0.0 0.15.255.255 any log
   access-list 111 deny ip 192.168.0.0 0.0.255.255 any log
   access-list 111 deny ip 209.165.202.128 0.0.0.31 any log
   access-list 111 permit ip any any
CHAPTER 29

Configuring IP Multicast

This chapter describes IP multicast routing on the Catalyst 4500 series switch. It also provides procedures and examples to configure IP multicast routing.

Note

For more detailed information on IP Multicast, refer to this URL

Note

For complete syntax and usage information for the switch commands used in this chapter, first look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it will be found in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

This chapter includes the following major sections:

- Overview of IP Multicast, page 29-1
- Configuring IP Multicast Routing, page 29-12
- Monitoring and Maintaining IP Multicast Routing, page 29-21
- Configuration Examples, page 29-26

Overview of IP Multicast

This section includes these subsections:

- IP Multicast Protocols, page 29-2
- IP Multicast on the Catalyst 4500 Series Switch, page 29-5
- Unsupported Feature, page 29-12
At one end of the IP communication spectrum is IP unicast, where a source IP host sends packets to a specific destination IP host. In IP unicast, the destination address in the IP packet is the address of a single, unique host in the IP network. These IP packets are forwarded across the network from the source to the destination host by routers. At each point on the path between source and destination, a router uses a unicast routing table to make unicast forwarding decisions, based on the IP destination address in the packet.

At the other end of the IP communication spectrum is an IP broadcast, where a source host sends packets to all hosts on a network segment. The destination address of an IP broadcast packet has the host portion of the destination IP address set to all ones and the network portion set to the address of the subnet. IP hosts, including routers, understand that packets, which contain an IP broadcast address as the destination address, are addressed to all IP hosts on the subnet. Unless specifically configured otherwise, routers do not forward IP broadcast packets, so IP broadcast communication is normally limited to a local subnet.

IP multicasting falls between IP unicast and IP broadcast communication. IP multicast communication enables a host to send IP packets to a group of hosts anywhere within the IP network. To send information to a specific group, IP multicast communication uses a special form of IP destination address called an IP multicast group address. The IP multicast group address is specified in the IP destination address field of the packet.

To multicast IP information, Layer 3 switches and routers must forward an incoming IP packet to all output interfaces that lead to members of the IP multicast group. In the multicasting process on the Catalyst 4500 Series switch, a packet is replicated in the Integrated Switching Engine, forwarded to the appropriate output interfaces, and sent to each member of the multicast group.

It is not uncommon for people to think of IP multicasting and video conferencing as almost the same thing. Although the first application in a network to use IP multicast is often video conferencing, video is only one of many IP multicast applications that can add value to a company’s business model. Other IP multicast applications that have potential for improving productivity include multimedia conferencing, data replication, real-time data multicasts, and simulation applications.

This section contains the following subsections:

- **IP Multicast Protocols**, page 29-2
- **IP Multicast on the Catalyst 4500 Series Switch**, page 29-5
- **Unsupported Feature**, page 29-12

### IP Multicast Protocols

The Catalyst 4500 Series switch primarily uses these protocols to implement IP multicast routing:

- Internet Group Management Protocol (IGMP)
- Protocol Independent Multicast (PIM)
- Cisco Group Management Protocol (CGMP)

Figure 29-1 shows where these protocols operate within the IP multicast environment.
Internet Group Management Protocol

IGMP messages are used by IP multicast hosts to send their local Layer 3 switch or router a request to join a specific multicast group and begin receiving multicast traffic. With some extensions in IGMPv2, IP hosts can also send a request to a Layer 3 switch or router to leave an IP multicast group and not receive the multicast group traffic.

Using the information obtained via IGMP, a Layer 3 switch or router maintains a list of multicast group memberships on a per-interface basis. A multicast group membership is active on an interface if at least one host on the interface sends an IGMP request to receive multicast group traffic.

Protocol-Independent Multicast

PIM is protocol independent because it can leverage whichever unicast routing protocol is used to populate the unicast routing table, including EIGRP, OSPF, BGP, or static route, to support IP multicast. PIM also uses a unicast routing table to perform the reverse path forwarding (RPF) check function instead of building a completely independent multicast routing table. PIM does not send and receive multicast routing updates between routers like other routing protocols do.

PIM Dense Mode

PIM Dense Mode (PIM-DM) uses a push model to flood multicast traffic to every corner of the network. PIM-DM is intended for networks in which most LANs need to receive the multicast, such as LAN TV and corporate or financial information broadcasts. It can be an efficient delivery mechanism if there are active receivers on every subnet in the network.

Note

Supervisor Engine 7-E does not increment counters for (*, G) in PIM Dense Mode. (*, G) counters are incremented only when running Bidirectional PIM Mode.

For more detailed information on PIM Dense Mode, refer to this URL:

### PIM Sparse Mode

PIM Sparse Mode (PIM-SM) uses a pull model to deliver multicast traffic. Only networks with active receivers that have explicitly requested the data will be forwarded the traffic. PIM-SM is intended for networks with several different multicasts, such as desktop video conferencing and collaborative computing, that go to a small number of receivers and are typically in progress simultaneously.

**Note**  
Supervisor Engine 7-E does not increment counters for (*) G in PIM Dense Mode. (*) G counters are incremented only when running Bidirectional PIM Mode.

### Bidirectional PIM Mode

In bidirectional PIM (Bidir-PIM) mode, traffic is routed only along a bidirectional shared tree that is rooted at the rendezvous point (RP) for the group. The IP address of the RP functions as a key enabling all routers to establish a loop-free spanning tree topology rooted in that IP address.

Bidir-PIM is intended for many-to-many applications within individual PIM domains. Multicast groups in bidirectional mode can scale to an arbitrary number of sources without incurring overhead due to the number of sources.

**Note**  
Supervisor Engine 7-E does not increment counters for (*) G in PIM Dense or Sparse Mode. (*) G counters are incremented only when running Bidirectional PIM Mode.

For more detailed information on Bidirectional Mode, refer to this URL:

### Rendezvous Point (RP)

If you configure PIM to operate in sparse mode, you must also choose one or more routers to be rendezvous points (RPs). Senders to a multicast group use RPs to announce their presence. Receivers of multicast packets use RPs to learn about new senders. You can configure Cisco IOS software so that packets for a single multicast group can use one or more RPs.

The RP address is used by first hop routers to send PIM register messages on behalf of a host sending a packet to the group. The RP address is also used by last hop routers to send PIM join and prune messages to the RP to inform it about group membership. You must configure the RP address on all routers (including the RP router).

A PIM router can be an RP for more than one group. Only one RP address can be used at a time within a PIM domain for the same group. The conditions specified by the access list determine for which groups the router is an RP (as different groups can have different RPs).

### IGMP Snooping

IGMP snooping is used for multicasting in a Layer 2 switching environment. With IGMP snooping, a Layer 3 switch or router examines Layer 3 information in the IGMP packets in transit between hosts and a router. When the switch receives the IGMP Host Report from a host for a particular multicast group, the switch adds the host’s port number to the associated multicast table entry. When the switch receives the IGMP Leave Group message from a host, it removes the host’s port from the table entry.
IP Multicast on the Catalyst 4500 Series Switch

The Catalyst 4500 Series switch supports an ASIC-based Integrated Switching Engine that provides Ethernet bridging at Layer 2 and IP routing at Layer 3. Because the ASIC is specifically designed to forward packets, the Integrated Switching Engine hardware provides very high performance with ACLs and QoS enabled. At wire-speed, forwarding in hardware is significantly faster than the CPU subsystem software, which is designed to handle exception packets.

The Integrated Switching Engine hardware supports interfaces for inter-VLAN routing and switchports for Layer 2 bridging. It also provides a physical Layer 3 interface that can be configured to connect with a host, a switch, or a router.

Figure 29-2 shows a logical view of Layer 2 and Layer 3 forwarding in the Integrated Switching Engine hardware.

This section contains the following subsections:
- CEF, MFIB, and Layer 2 Forwarding, page 29-5
- IP Multicast Tables, page 29-7
- Hardware and Software Forwarding, page 29-8
- Non-Reverse Path Forwarding Traffic, page 29-9
- Multicast Fast Drop, page 29-10
- Multicast Forwarding Information Base, page 29-11
- S/M, 224/4, page 29-12

CEF, MFIB, and Layer 2 Forwarding

The implementation of IP multicast on the Catalyst 4500 Series switch is an extension of centralized Cisco Express Forwarding (CEF). CEF extracts information from the unicast routing table, which is created by unicast routing protocols, such as BGP, OSPF, and EIGR and loads it into the hardware Forwarding Information Base (FIB). With the unicast routes in the FIB, when a route is changed in the
upper-layer routing table, only one route needs to be changed in the hardware routing state. To forward unicast packets in hardware, the Integrated Switching Engine looks up source and destination routes in ternary content addressable memory (TCAM), takes the adjacency index from the hardware FIB, and gets the Layer 2 rewrite information and next-hop address from the hardware adjacency table.

The new Multicast Forwarding Information Base (MFIB) subsystem is the multicast analog of the unicast CEF. The MFIB subsystem extracts the multicast routes that PIM and IGMP create and refines them into a protocol-independent format for forwarding in hardware. The MFIB subsystem removes the protocol-specific information and leaves only the essential forwarding information. Each entry in the MFIB table consists of an (S,G) or (*,G) route, an input RPF VLAN, and a list of Layer 3 output interfaces. The MFIB subsystem, together with platform-dependent management software, loads this multicast routing information into the hardware FIB and hardware replica expansion table (RET).

The Catalyst 4500 Series switch performs Layer 3 routing and Layer 2 bridging at the same time. There can be multiple Layer 2 switchports on any VLAN interface. To determine the set of output switchports on which to forward a multicast packet, the supervisor engine combines Layer 3 MFIB information with Layer 2 forwarding information and stores it in the hardware RET for packet replication. Figure 29-3 shows a functional overview of how the Catalyst 4500 Series switch combines unicast routing, multicast routing, and Layer 2 bridging information to forward in hardware.

Figure 29-3 Combining CEF, MFIB, and Layer 2 Forwarding Information in Hardware

Like the CEF unicast routes, the MFIB routes are Layer 3 and must be merged with the appropriate Layer 2 information. The following example shows an MFIB route:

(*,224.1.2.3)
RPF interface is Vlan3
Output Interfaces are:
Vlan 1
Vlan 2

The route (*,224.1.2.3) is loaded in the hardware FIB table and the list of output interfaces is loaded into the RET. A pointer to the list of output interfaces, the RET index, and the RPF interface are also loaded in the hardware FIB with the (*,224.1.2.3) route. With this information loaded in hardware, merging of the Layer 2 information can begin. For the output interfaces on VLAN1, the Integrated Switching Engine
must send the packet to all switchports in VLAN1 that are in the spanning tree forwarding state. The same process applies to VLAN 2. To determine the set of switchports in VLAN 2, the Layer 2 Forwarding Table is used.

When the hardware routes a packet, in addition to sending it to all of the switchports on all output interfaces, the hardware also sends the packet to all switchports (other than the one it arrived on) in the input VLAN. For example, assume that VLAN 3 has two switchports in it, Gig 3/1 and Gig 3/2. If a host on Gig 3/1 sends a multicast packet, the host on Gig 3/2 might also need to receive the packet. To send a multicast packet to the host on Gig 3/2, all of the switchports in the ingress VLAN must be added to the portset that is loaded in the RET.

If VLAN 1 contains 1/1 and 1/2, VLAN 2 contains 2/1 and 2/2, and VLAN 3 contains 3/1 and 3/2, the RET chain for this route would contain these switchports: (1/1, 1/2, 2/1, 2/2, 3/1, and 3/2).

If IGMP snooping is on, the packet should not be forwarded to all output switchports on VLAN 2. The packet should be forwarded only to switchports where IGMP snooping has determined that there is either a group member or router. For example, if VLAN 1 had IGMP snooping enabled, and IGMP snooping determined that only port 1/2 had a group member on it, then the RET chain would contain these switchports: (1/1, 1/2, 2/1, 2/2, 3/1, and 3/2).

**IP Multicast Tables**

Figure 29-4 shows some key data structures that the Catalyst 4500 Series switch uses to forward IP multicast packets in hardware.

Overview of IP Multicast

The Integrated Switching Engine maintains the hardware FIB table to identify individual IP multicast routes. Each entry consists of a destination group IP address and an optional source IP address. Multicast traffic flows on primarily two types of routes: \((S,G)\) and \((*,G)\). The \((S,G)\) routes flow from a source to a group based on the IP address of the multicast source and the IP address of the multicast group destination. Traffic on a \((*,G)\) route flows from the PIM RP to all receivers of group G. Only sparse-mode groups use \((*,G)\) routes. The Integrated Switching Engine hardware contains space for a total of 128,000 routes, which are shared by unicast routes, multicast routes, and multicast fast-drop entries.

For RET, we can have up to 102K entries (32K used for floodsets, 70,000 used for multicast entries). The RET resources are shared by both Layer 3 multicast routes and by Layer 2 multicast entries. The actual number of output interface lists available in hardware depends on the specific configuration. If the total number of multicast routes exceed 32,000, multicast packets might not be switched by the Integrated Switching Engine. They would be forwarded by the CPU subsystem at much slower speeds.

**Note**

For RET, a maximum of 102K entries is supported (32K used for floodsets, 70K used for multicast entries).

**Note**

Partial multicast routing is not supported on Supervisor Engine 7-E; only hardware and software routing are supported.

Hardware and Software Forwarding

The Integrated Switching Engine forwards the majority of packets in hardware at very high rates of speed. The CPU subsystem forwards exception packets in software. Statistical reports should show that the Integrated Switching Engine is forwarding the vast majority of packets in hardware.

Replication is a particular type of forwarding where, instead of sending out one copy of the packet, the packet is replicated and multiple copies of the packet are sent out. At Layer 3, replication occurs only for multicast packets; unicast packets are never replicated to multiple Layer 3 interfaces. In IP multicasting, for each incoming IP multicast packet that is received, many replicas of the packet are sent out.

IP multicast packets can be transmitted on the following types of routes:

- Hardware routes
- Software routes
- Partial routes

Hardware routes occur when the Integrated Switching Engine hardware forwards all replicas of a packet. Software routes occur when the CPU subsystem software forwards all replicas of a packet. Partial routes occur when the Integrated Switching Engine forwards some of the replicas in hardware and the CPU subsystem forwards some of the replicas in software.

**Partial Routes**

**Note**

The conditions listed below cause the replicas to be forwarded by the CPU subsystem software, but the performance of the replicas that are forwarded in hardware is not affected.
The following conditions cause some replicas of a packet for a route to be forwarded by the CPU subsystem:

- The switch is configured with the `ip igmp join-group` command as a member of the IP multicast group on the RPF interface of the multicast source.
- The switch is the first-hop to the source in PIM sparse mode. In this case, the switch must send PIM-register messages to the RP.

### Software Routes

If any one of the following conditions is configured on the RPF interface or the output interface, all replication of the output is performed in software.

The following conditions cause all replicas of a packet for a route to be forwarded by the CPU subsystem software:

- The interface is configured with multicast helper.
- The interface is a generic routing encapsulation (GRE) or Distance Vector Multicast Routing Protocol (DVMRP) tunnel.
- The interface uses non-Advanced Research Products Agency (ARPA) encapsulation.

The following packets are always forwarded in software:

- Packets sent to multicast groups that fall into the range 224.0.0.* (where * is in the range from 0 to 255). This range is used by routing protocols. Layer 3 switching supports all other multicast group addresses.
- Packets with IP options.

### Non-Reverse Path Forwarding Traffic

Traffic that fails an Reverse Path Forwarding (RPF) check is called non-RPF traffic. Non-RPF traffic is forwarded by the Integrated Switching Engine by filtering (persistently dropping) or rate limiting the non-RPF traffic.

In a redundant configuration where multiple Layer 3 switches or routers connect to the same LAN segment, only one device forwards the multicast traffic from the source to the receivers on the outgoing interfaces. Figure 29-5 shows how Non-RPF traffic can occur in a common network configuration.
Overview of IP Multicast

Figure 29-5 Redundant Multicast Router Configuration in a Stub Network

In this kind of topology, only Router A, the PIM designated router (PIM DR), forwards data to the common VLAN. Router B receives the forwarded multicast traffic, but must drop this traffic because it has arrived on the wrong interface and fails the RPF check. Traffic that fails the RPF check is called non-RPF traffic.

Multicast Fast Drop

In IP multicast protocols, such as PIM-SM and PIM-DM, every (S,G) or (*,G) route has an incoming interface associated with it. This interface is referred to as the reverse path forwarding interface. In some cases, when a packet arrives on an interface other than the expected RPF interface, the packet must be forwarded to the CPU subsystem software to allow PIM to perform special protocol processing on the packet. One example of this special protocol processing that PIM performs is the PIM Assert protocol.

By default, the Integrated Switching Engine hardware sends all packets that arrive on a non-RPF interface to the CPU subsystem software. However, processing in software is not necessary in many cases, because these non-RPF packets are often not needed by the multicast routing protocols. The problem is that if no action is taken, the non-RPF packets that are sent to the software can overwhelm the CPU.

To prevent this from happening, the CPU subsystem software loads fast-drop entries in the hardware when it receives an RPF failed packet that is not needed by the PIM protocols running on the switch. A fast-drop entry is keyed by (S,G, incoming interface). Any packet matching a fast-drop entry is bridged in the ingress VLAN, but is not sent to the software, so the CPU subsystem software is not overloaded by processing these RPF failures unnecessarily.

Protocol events, such as a link going down or a change in the unicast routing table, can impact the set of packets that can safely be fast dropped. A packet that was correctly fast dropped before might, after a topology change, need to be forwarded to the CPU subsystem software so that PIM can process it. The CPU subsystem software handles flushing fast-drop entries in response to protocol events so that the PIM code in IOS can process all the necessary RPF failures.

The use of fast-drop entries in the hardware is critical in some common topologies because it is possible to have persistent RPF failures. Without the fast-drop entries, the CPU would be exhausted by RPF failed packets that it did not need to process.
Chapter 29  Configuring IP Multicast

Overview of IP Multicast

The Multicast Forwarding Information Base (MFIB) subsystem supports IP multicast routing in the Integrated Switching Engine hardware on the Catalyst 4500 Series switch. The MFIB logically resides between the IP multicast routing protocols in the CPU subsystem software (PIM, IGMP, MSDP, MBGP, and DVMRP) and the platform-specific code that manages IP multicast routing in hardware. The MFIB translates the routing table information created by the multicast routing protocols into a simplified format that can be efficiently processed and used for forwarding by the Integrated Switching Engine hardware.

To display the information in the multicast routing table, use the `show ip mroute` command. To display the MFIB table information, use the `show ip mfib` command.

The MFIB table contains a set of IP multicast routes. There are several types of IP multicast routes, including (S,G) and (*,G) routes. Each route in the MFIB table can have one or more optional flags associated with it. The route flags indicate how a packet that matches a route should be forwarded. For example, the Internal Copy (IC) flag on an MFIB route indicates that a process on the switch needs to receive a copy of the packet. The following flags can be associated with MFIB routes:

- **Internal Copy (IC) flag**—set on a route when a process on the router needs to receive a copy of all packets matching the specified route
- **Signalling (S) flag**—set on a route when a process needs to be notified when a packet matching the route is received; the expected behavior is that the protocol code updates the MFIB state in response to receiving a packet on a signalling interface
- **Connected (C) flag**—when set on an MFIB route, has the same meaning as the Signalling (S) flag, except that the C flag indicates that only packets sent by directly connected hosts to the route should be signalled to a protocol process

A route can also have a set of optional flags associated with one or more interfaces. For example, an (S,G) route with the flags on VLAN 1 indicates how packets arriving on VLAN 1 should be treated, and they also indicate whether packets matching the route should be forwarded onto VLAN 1. The per-interface flags supported in the MFIB include the following:

- **Accepting (A)**—set on the interface that is known in multicast routing as the RPF interface. A packet that arrives on an interface that is marked as Accepting (A) is forwarded to all Forwarding (F) interfaces.
- **Forwarding (F)**—used in conjunction with the Accepting (A) flag as described above. The set of Forwarding interfaces that form what is often referred to as the multicast “olist” or output interface list.
- **Signalling (S)**—set on an interface when some multicast routing protocol process in IOS needs to be notified of packets arriving on that interface.

When PIM-SM routing is in use, the MFIB route might include an interface like in this example: PimTunnel [1.2.3.4]. This is a virtual interface that the MFIB subsystem creates to indicate that packets are being tunnelled to the specified destination address. A PimTunnel interface cannot be displayed with the normal `show interface` command.
S/M, 224/4

An (S/M, 224/4) entry is created in the MFIB for every multicast-enabled interface. This entry ensures that all packets sent by directly connected neighbors can be Register-encapsulated to the PIM-SM RP. Typically, only a small number of packets would be forwarded using the (S/M,224/4) route, until the (S,G) route is established by PIM-SM.

For example, on an interface with IP address 10.0.0.1 and netmask 255.0.0.0, a route would be created matching all IP multicast packets in which the source address is anything in the class A network 10. This route can be written in conventional subnet/masklength notation as (10/8,224/4). If an interface has multiple assigned IP addresses, then one route is created for each such IP address.

Restrictions on using Bidirectional PIM

Restrictions include the following:
- IPv4 Bidirectional (Bidir) PIM is supported on Supervisor Engine 7-E. IPv6 Bidir PIM is not supported.
- The Catalyst 4500 switch enables you to forward Bidir PIM traffic in hardware up to a maximum of seven RPs. If you configure more than seven Bidir RPs, only the first seven RPs can forward traffic in hardware. The traffic directed to the remaining RPs is forwarded in software.

Unsupported Feature

The following IP multicast feature is not supported in this release:
- Controlling the transmission rate to a multicast group

Configuring IP Multicast Routing

The following sections describe IP multicast routing configuration tasks:
- Default Configuration in IP Multicast Routing, page 29-12
- Enabling IP Multicast Routing, page 29-13
- Enabling PIM on an Interface, page 29-13
- Enabling Bidirectional Mode, page 29-15
- Enabling PIM-SSM Mapping, page 29-16
- Configuring a Rendezvous Point, page 29-16
- Configuring a Single Static RP, page 29-19

For more detailed information on IP multicast routing, such as Auto-RP, PIM Version 2, and IP multicast static routes, refer to the Cisco IOS IP and IP Routing Configuration Guide, Cisco IOS Release 12.3.

Default Configuration in IP Multicast Routing

Table 29-1 shows the IP multicast default configuration.
Chapter 29      Configuring IP Multicast

Configuring IP Multicast Routing

Note

Source-specific multicast and IGMP v3 are supported.

For more information about source-specific multicast with IGMPv3 and IGMP, see the following URL:

Table 29-1  Default IP Multicast Configuration

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rate limiting of RPF</td>
<td>Enabled globally</td>
</tr>
<tr>
<td>IP multicast routing</td>
<td>Disabled globally</td>
</tr>
</tbody>
</table>

Note  When IP multicast routing is disabled, IP multicast traffic data packets are not forwarded by the Catalyst 4500 Series switch. However, IP multicast control traffic will continue to be processed and forwarded. Therefore, IP multicast routes can remain in the routing table even if IP multicast routing is disabled.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>PIM</td>
<td>Disabled on all interfaces</td>
</tr>
<tr>
<td>IGMP snooping</td>
<td>Enabled on all VLAN interfaces</td>
</tr>
</tbody>
</table>

Note  If you disable IGMP snooping on an interface, all output ports are forwarded by the Integrated Switching Engine. When IGMP snooping is disabled on an input VLAN interface, multicast packets related to that interface are sent to all forwarding switchports in the VLAN.

Enabling IP Multicast Routing

Enabling IP multicast routing allows the Catalyst 4500 Series switch to forward multicast packets. To enable IP multicast routing on the router, perform this task in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# ip multicast-routing</td>
<td>Enables IP multicast routing.</td>
</tr>
</tbody>
</table>

Enabling PIM on an Interface

Enabling PIM on an interface also enables IGMP operation on that interface. An interface can be configured to be in dense mode, sparse mode, or sparse-dense mode. The mode determines how the Layer 3 switch or router populates its multicast routing table and how the Layer 3 switch or router forwards multicast packets it receives from its directly connected LANs. You must enable PIM in one of these modes for an interface to perform IP multicast routing.

When the switch populates the multicast routing table, dense-mode interfaces are always added to the table. Sparse-mode interfaces are added to the table only when periodic join messages are received from downstream routers, or when there is a directly connected member on the interface. When forwarding from a LAN, sparse-mode operation occurs if there is an RP known for the group. If so, the packets are...
Configuring IP Multicast Routing

Configuring IP Multicast

Encapsulated and sent toward the RP. When no RP is known, the packet is flooded in a dense-mode fashion. If the multicast traffic from a specific source is sufficient, the receiver’s first-hop router can send join messages toward the source to build a source-based distribution tree.

There is no default mode setting. By default, multicast routing is disabled on an interface.

Enabling Dense Mode

To configure PIM on an interface to be in dense mode, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config-if)# ip pim dense-mode</td>
<td>Enables dense-mode PIM on the interface.</td>
</tr>
</tbody>
</table>

See the “PIM Dense Mode: Example” section at the end of this chapter for an example of how to configure a PIM interface in dense mode.

Enabling Sparse Mode

To configure PIM on an interface to be in sparse mode, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config-if)# ip pim sparse-mode</td>
<td>Enables sparse-mode PIM on the interface.</td>
</tr>
</tbody>
</table>

See the “PIM Sparse Mode: Example” section at the end of this chapter for an example of how to configure a PIM interface in sparse mode.

Enabling Sparse-Dense Mode

When you enter either the ip pim sparse-mode or ip pim dense-mode command, sparseness or denseness is applied to the interface as a whole. However, some environments might require PIM to run in a single region in sparse mode for some groups and in dense mode for other groups.

An alternative to enabling only dense mode or only sparse mode is to enable sparse-dense mode. In this case, the interface is treated as dense mode if the group is in dense mode; the interface is treated in sparse mode if the group is in sparse mode. If you want to treat the group as a sparse group, and the interface is in sparse-dense mode, you must have an RP.

If you configure sparse-dense mode, the idea of sparseness or denseness is applied to the group on the switch, and the network manager should apply the same concept throughout the network.

Another benefit of sparse-dense mode is that Auto-RP information can be distributed in a dense-mode manner; yet, multicast groups for user groups can be used in a sparse-mode manner. Thus, there is no need to configure a default RP at the leaf routers.

When an interface is treated in dense mode, it is populated in a multicast routing table’s outgoing interface list when either of the following is true:

- When there are members or DVMRP neighbors on the interface
- When there are PIM neighbors and the group has not been pruned
When an interface is treated in sparse mode, it is populated in a multicast routing table's outgoing interface list when either of the following is true:

- When there are members or DVMRP neighbors on the interface
- When an explicit join has been received by a PIM neighbor on the interface

To enable PIM to operate in the same mode as the group, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config-if)# ip pim sparse-dense-mode</td>
<td>Enables PIM to operate in sparse or dense mode, depending on the group.</td>
</tr>
</tbody>
</table>

### Enabling Bidirectional Mode

Most of the configuration requirements for Bidir-PIM are the same as those for configuring PIM-SM. You need not enable or disable an interface for carrying traffic for multicast groups in bidirectional mode. Instead, you configure which multicast groups you want to operate in bidirectional mode. Similar to PIM-SM, you can perform this configuration with Auto-RP, static RP configurations, or the PIM Version 2 bootstrap router (PIMv2 BSR) mechanism.

To enable bidir-PIM, use the following command in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# ip pim bidir-enable</td>
<td>Enables bidir-PIM on a switch.</td>
</tr>
</tbody>
</table>

To configure Bidir-PIM, use the following commands in global configuration mode, depending on which method you use to distribute group-to-RP mappings:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# ip pim rp-address rp-address [access-list] [override] bidir</td>
<td>Configures the address of a PIM RP for a particular group, and specifies bidirectional mode. Use this command when you are not distributing group-to-RP mappings using either Auto-RP or the PIMv2 BSR mechanism.</td>
</tr>
<tr>
<td>Switch(config)# ip pim rp-candidate type number [group-list access-list] bidir</td>
<td>Configures the router to advertise itself as a PIM Version 2 candidate RP to the BSR, and specifies bidirectional mode. Use this command when you are using the PIMv2 BSR mechanism to distribute group-to-RP mappings.</td>
</tr>
<tr>
<td>Switch(config)# ip pim send-rp-address type number scope ttl-value [group-list access-list] [interval seconds] bidir</td>
<td>Configures the router to use Auto-RP to configure for which groups the router is willing to act as RP, and specifies bidirectional mode. Use this command when you are using Auto-RP to distribute group-to-RP mappings.</td>
</tr>
</tbody>
</table>

For an example of how to configure bidir-PIM, see the Bidirectional PIM Mode: Example, page 29-27 section.
Enabling PIM-SSM Mapping

The Catalyst 4500 series switch supports SSM mapping, enabling an SSM transition in cases either where neither URD nor IGMP v3-lite is available, or when supporting SSM on the end system is impossible or unwanted due to administrative or technical reasons. With SSM mapping, you can leverage SSM for video delivery to legacy set-top boxes (STBs) that do not support IGMPv3 or for applications that do not take advantage of the IGMPv3 host stack.

For more details, refer to this URL:

Configuring a Rendezvous Point

A rendezvous point (RP) is required in networks running Protocol Independent Multicast sparse mode (PIM-SM). In PIM-SM, traffic will be forwarded only to network segments with active receivers that have explicitly requested multicast data.

There are different ways to configure a Rendezvous Point. The most commonly used, described here, are the usage of Static RP and the usage of the Auto-RP protocol. Another way, not described here, are the use of the Bootstrap Router (BSR) protocol.

Configuring Auto-RP

Auto-rendezvous point (Auto-RP) automates the distribution of group-to-rendezvous point (RP) mappings in a PIM network. To make Auto-RP work, a router must be designated as an RP mapping agent, which receives the RP announcement messages from the RPs and arbitrates conflicts. The RP mapping agent then sends the consistent group-to-RP mappings to all other routers by way of dense mode flooding.

Thus, all routers automatically discover which RP to use for the groups they support. The Internet Assigned Numbers Authority (IANA) has assigned two group addresses, 224.0.1.39 and 224.0.1.40, for Auto-RP.

The mapping agent receives announcements of intention to become the RP from Candidate-RPs. The mapping agent then announces the winner of the RP election. This announcement is made independently of the decisions by the other mapping agents.

To configure Auto-RP, perform this task:

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch&gt; enable</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config)# ip multicast-routing</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config)# interface [FastEthernet</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch(config-if)# ip pim [sparse-mode</td>
</tr>
<tr>
<td>Step 6</td>
<td>Switch(config-if)# exit</td>
</tr>
</tbody>
</table>
### Chapter 29  Configuring IP Multicast

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>Repeat Steps 4 and 5 on all PIM interfaces.</td>
<td>—</td>
</tr>
</tbody>
</table>
| 8    | `Switch(config)# ip pim autorp listener` | Causes IP multicast traffic for the two Auto-RP groups 224.0.1.39 and 224.0.1.40 to be PIM dense mode flooded across interfaces operating in PIM sparse mode.  
   - Skip this step if you are configuring sparse-dense mode in Step 8. |
| 9    | `Switch(config)# ip pim send-rp-announce`  
   - (interface-type interface-number | ip-address)  
   - scope tti-value [group-list access-list]  
   - [interval seconds] [bidir] | Sends RP announcements out all PIM-enabled interfaces.  
   - Perform this step on the RP router only.  
   - Use the `interface-type` and `interface-number` arguments to define which IP address is to be used as the RP address.  
   - Use the `ip-address` argument to specify a directly connected IP address as the RP address.   
   **Note**  
   If the `ip-address` argument is configured for this command, the RP-announce message will be sourced by the interface to which this IP address is connected (that is, the source address in the IP header of the RP-announce message is the IP address of that interface).  
   - This example shows that the interface is enabled with a maximum of 31 hops. The IP address by which the router wants to be identified as RP is the IP address associated with loopback interface 0. Access list 5 describes the groups for which this router serves as RP. |
### Configuring IP Multicast

#### Chapter 29: Configuring IP Multicast

#### Configuring IP Multicast Routing

</tbody>
</table>
This example illustrates how to configure Auto-RP:

Switch> enable
Switch# configure terminal
Switch(config)# ip multicast-routing
Switch(config)# interface ethernet 1
Switch(config-if)# ip pim sparse-mode
Switch(config-if)# end
Switch(config)# ip pim autorp listener
Switch(config)# ip pim send-rp-announce loopback0 scope 31 group-list 5
Switch(config)# ip pim send-rp-discovery loopback 1 scope 31
Switch(config)# ip pim rp-announce-filter rp-list 1 group-list 2
Switch(config)# interface ethernet 1
Switch(config-if)# ip multicast boundary 10 filter-autorp
Switch(config-if)# end
Switch# show ip pim autorp
Switch# show ip pim rp mapping
Switch# show ip igmp groups
Switch# show ip mroute cbone-audio

### Configuring a Single Static RP

If you are configuring PIM sparse mode, you must configure a PIM RP for a multicast group. An RP can either be configured statically in each device, or learned through a dynamic mechanism. This task explains how to statically configure an RP, as opposed to the router learning the RP through a dynamic mechanism such as Auto-RP.

PIM designated routers (DRs) forward data from directly connected multicast sources to the RP for distribution down the shared tree. Data is forwarded to the RP in one of two ways. It is encapsulated in register packets and unicast directly to the RP, or, if the RP has itself joined the source tree, it is multicast forwarded per the RPF forwarding algorithm. Last hop routers directly connected to receivers may, at their discretion, join themselves to the source tree and prune themselves from the shared tree.

A single RP can be configured for multiple groups that are defined by an access list. If no RP is configured for a group, the router treats the group as dense using the PIM dense mode techniques. (You can prevent this occurrence by configuring the no ip pim dm-fallback command.)

If a conflict exists between the RP configured with the ip pim rp-address command and one learned by Auto-RP, the Auto-RP information is used, unless the override keyword is configured.
To configure a single static RP, perform this step:

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**  
Switch> enable                                                          | Enables privileged EXEC mode.                                           |
| **Step 2**  
Switch# configure terminal                                                    | Enters global configuration mode.                                       |
| **Step 3**  
Switch(config)# ip multicast-routing                                          | Enables IP multicast routing.                                           |
| **Step 4**  
Switch(config)# interface type number                                          | Selects an interface that is connected to hosts on which PIM can be enabled. |
| **Step 5**  
Switch(config-if)# ip pim [sparse-mode | sparse-dense-mode]                                                           | Enables PIM on an interface. You must use sparse mode.                 |
| **Step 6**  
Repeat Steps 4 and 5 on every interface that uses IP multicast.                | —                                                                      |
| **Step 7**  
Switch(config-if)# exit                                                        | Returns to global configuration mode.                                   |
| **Step 8**  
Switch(config)# ip pim rp-address rp-address [access-list] [override]         | Configures the address of a PIM RP for a particular group.              |
|                                                                                   | - Perform this step on any router.                                      |
|                                                                                   | - The access-list argument specifies the number or name of an access list that defines for which multicast groups the RP should be used. |
|                                                                                   | - The override keyword specifies that if there is a conflict between the RP configured with this command and one learned by Auto-RP, the RP configured with this command prevails. |
| **Step 9**  
Switch(config)# end                                                        | Ends the current configuration session and returns to EXEC mode.        |
| **Step 10**  
Switch# show ip pim rp [mapping] [rp-address]                                   | (Optional) Displays RPs known in the network and shows how the router learned about each RP. |
| **Step 11**  
Switch# show ip igmp groups [group-name | group-address | interface-type interface-number] [detail]                                   | (Optional) Displays the multicast groups having receivers that are directly connected to the router and that were learned through IGMP. |
|                                                                                   | - A receiver must be active on the network at the time that this command is issued in order for receiver information to be present on the resulting display. |
| **Step 12**  
Switch# show ip mroute [group-address | group-name] [source-address | source-name] [interface-type interface-number] [summary] [count] [active kbps] | (Optional) Displays the contents of the IP multicast routing (mroute) table. |
This example shows how to configure a single-static RP:

Switch> enable
Switch# configure terminal
Switch(config)# ip multicast-routing
Switch(config)# interface ethernet 1
Switch(config-if)# ip pim sparse-mode
Switch(config-if)# exit
Switch(config)# ip pim rp-address 192.168.0.0
Switch(config)# end
Switch#

**Monitoring and Maintaining IP Multicast Routing**

You can remove all contents of a particular cache, table, or database. You also can display specific statistics. The following sections describe how to monitor and maintain IP multicast:

- Displaying System and Network Statistics, page 29-21
- Displaying the Multicast Routing Table, page 29-22
- Displaying IP MFIB, page 29-24
- Displaying Bidirectional PIM Information, page 29-25
- Displaying PIM Statistics, page 29-25
- Clearing Tables and Databases, page 29-26

**Displaying System and Network Statistics**

You can display specific statistics, such as the contents of IP routing tables and databases. Information provided can be used to determine resource utilization and solve network problems. You can also display information about node reachability and discover the routing path your device’s packets are taking through the network.

To display various routing statistics, you can perform any of these tasks:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# ping [group-name</td>
<td>group-address]</td>
</tr>
<tr>
<td>Switch# show ip mroute [hostname</td>
<td>group_number]</td>
</tr>
<tr>
<td>Switch# show ip pim interface [type number] [count]</td>
<td>Displays information about interfaces configured for PIM.</td>
</tr>
<tr>
<td>Switch# show ip interface</td>
<td>Displays PIM information for all interfaces.</td>
</tr>
</tbody>
</table>
Chapter 29      Configuring IP Multicast

Displaying the Multicast Routing Table

The following is sample output from the `show ip mroute` command for a router operating in dense mode.
This command displays the contents of the IP multicast FIB table for the multicast group named cbone-audio.

Switch# `show ip mroute cbone-audio`

IP Multicast Routing Table
Flags: D - Dense, S - Sparse, C - Connected, L - Local, P - Pruned
R - RP-bit set, F - Register flag, T - SPT-bit set
Timers: Uptime/Expires
Interface state: Interface, Next-Hop, State/Mode

(*, 224.0.255.1), uptime 0:57:31, expires 0:02:59, RP is 0.0.0.0, flags: DC
  Incoming interface: Null, RPF neighbor 0.0.0.0, Dvmrp
  Outgoing interface list:
    Ethernet0, Forward/Dense, 0:57:31/0:02:52
    Tunnel0, Forward/Dense, 0:56:55/0:01:28

(198.92.37.100/32, 224.0.255.1), uptime 20:20:00, expires 0:02:55, flags: C
  Incoming interface: Tunnel0, RPF neighbor 10.20.37.33, Dvmrp
  Outgoing interface list:
    Ethernet0, Forward/Dense, 20:20:00/0:02:52

The following is sample output from the `show ip mroute` command for a router operating in sparse mode:

Switch# `show ip mroute`

IP Multicast Routing Table
Flags: D - Dense, S - Sparse, C - Connected, L - Local, P - Pruned
R - RP-bit set, F - Register flag, T - SPT-bit set
Timers: Uptime/Expires
Interface state: Interface, Next-Hop, State/Mode

(*, 224.0.255.3), uptime 5:29:15, RP is 198.92.37.2, flags: SC
  Incoming interface: Tunnel0, RPF neighbor 10.3.35.33, Dvmrp
  Outgoing interface list:
    Ethernet0, Forward/Sparse, 5:29:15/0:02:57

(198.92.46.0/24, 224.0.255.3), uptime 5:29:15, expires 0:02:59, flags: C
  Incoming interface: Tunnel0, RPF neighbor 10.3.35.1
  Outgoing interface list:
    Ethernet0, Forward/Sparse, 5:29:15/0:02:57

Note: Interface timers are not updated for hardware-forwarded packets. Entry timers are updated approximately every five seconds.

The following is sample output from the `show ip mroute` command with the `summary` keyword:

Switch# `show ip mroute summary`

IP Multicast Routing Table
Flags: D - Dense, S - Sparse, C - Connected, L - Local, P - Pruned
R - RP-bit set, F - Register flag, T - SPT-bit set, J - Join SPT
Timers: Uptime/Expires
Interface state: Interface, Next-Hop, State/Mode

(*, 224.255.255.255), 2d16h/00:02:30, RP 171.69.10.13, flags: SJPC
The following is sample output from the `show ip mroute` command with the `active` keyword:

```
Switch# show ip mroute active
Active IP Multicast Sources - sending >= 4 kbps
Group: 224.2.127.254, (sdr.cisco.com)
  Source: 146.137.28.69 (mbone.ipd.anl.gov)
  Rate: 1 pps/4 kbps(lsec), 4 kbps(last 1 secs), 4 kbps(life avg)
Group: 224.2.201.241, ACM 97
  Source: 130.129.52.160 (webcast3-el.acm97.interop.net)
  Rate: 9 pps/93 kbps(lsec), 145 kbps(last 20 secs), 85 kbps(life avg)
Group: 224.2.207.215, ACM 97
  Source: 130.129.52.160 (webcast3-el.acm97.interop.net)
  Rate: 3 pps/31 kbps(lsec), 63 kbps(last 19 secs), 65 kbps(life avg)
```

The following is sample output from the `show ip mroute` command with the `count` keyword:

```
Switch# show ip mroute count
IP Multicast Statistics - Group count: 8, Average sources per group: 9.87
Counts: Pkt Count/Pkts per second/Avg Pkt Size/Kilobits per second
Group: 224.255.255.255, Source count: 0, Group pkt count: 0
  RP-tree: 0/0/0/0
Group: 224.2.127.254, Source count: 0, Group pkt count: 0
  RP-tree: 0/0/0/0
Group: 224.1.127.255, Source count: 0, Group pkt count: 0
  RP-tree: 0/0/0/0
Group: 224.2.127.254, Source count: 9, Group pkt count: 14
  RP-tree: 0/0/0/0
  Source: 128.2.6.9/32, 2/0/796/0
  Source: 128.32.131.87/32, 1/0/616/0
  Source: 128.125.51.58/32, 1/0/412/0
  Source: 130.207.8.33/32, 1/0/936/0
  Source: 131.243.2.62/32, 1/0/750/0
  Source: 140.173.8.3/32, 1/0/660/0
  Source: 146.137.28.69/32, 1/0/584/0
  Source: 171.69.60.189/32, 4/0/447/0
  Source: 204.162.119.8/32, 2/0/834/0
Group: 224.0.1.40, Source count: 1, Group pkt count: 3606
  RP-tree: 0/0/0/0
  Source: 171.69.214.50/32, 3606/0/48/0, RPF Failed: 1203
Group: 224.2.201.241, Source count: 36, Group pkt count: 54152
  RP-tree: 7/0/108/0
```
Multicast route byte and packet statistics are supported only for the first 1024 multicast routes. Output interface statistics are not maintained.

### Displaying IP MFIB

You can display all routes in the MFIB, including routes that might not exist directly in the upper-layer routing protocol database but that are used to accelerate fast switching. These routes appear in the MFIB, even if dense-mode forwarding is in use.

To display various MFIB routing routes, perform one of these tasks:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# show ip mfib</td>
<td>Displays the (S,G) and (*,G) routes that are used for packet forwarding. Displays counts for fast, slow, and partially-switched packets for every multicast route.</td>
</tr>
<tr>
<td>Switch# show ip mfib all</td>
<td>Displays all routes in the MFIB, including routes that may not exist directly in the upper-layer routing protocol database, but that are used to accelerate fast switching. These routes include the (S/M,224/4) routes.</td>
</tr>
<tr>
<td>Switch# show ip mfib log [n]</td>
<td>Displays a log of the most recent n MFIB related events, most recent first.</td>
</tr>
<tr>
<td>Switch# show ip mfib counters</td>
<td>Displays counts of MFIB related events. Only non-zero counters are shown.</td>
</tr>
</tbody>
</table>

The following is sample output from the `show ip mfib` command.

**IP Multicast Forwarding Information Base**

**Entry Flags:** C – Directly Connected, S – Signal,
IC – Internal Copy

**Interface Flags:** A – Accept, F – Forward, S – Signal,
NP – Not platform switched

**Packets:** Fast/Partial/Slow Bytes: Fast/Partial/Slow:
(171.69.10.13, 224.0.1.40), flags (IC)
Packets: 2292/2292/0, Bytes: 518803/0/518803
Vlan7 (A)
Vlan100 (F NS)
Vlan105 (F NS)
(*, 224.0.1.60), flags ()
Packets: 2292/0/0, Bytes: 518803/0/0
Vlan7 (A NS)
(*, 224.0.1.75), flags ()
Vlan7 (A NS)
(10.34.2.92, 239.192.128.80), flags ()
Packets: 24579/100/0, 2113788/15000/0 bytes
Vlan7 (F NS)
Vlan100 (A)
(*, 239.193.100.70), flags ()
Packets: 1/0/0, 1500/0/0 bytes
Vlan7 (A)...

The fast-switched packet count represents the number of packets that were switched in hardware on the corresponding route.

The partially switched packet counter represents the number of times that a fast-switched packet was also copied to the CPU for software processing or for forwarding to one or more non-platform switched interfaces (such as a PimTunnel interface).

The slow-switched packet count represents the number of packets that were switched completely in software on the corresponding route.

## Displaying Bidirectional PIM Information

To display Bidir-PIM information, use the following commands, as needed:

**Command**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# show ip pim interface [type number] [df</td>
<td>count] [rp-address]</td>
</tr>
<tr>
<td>Switch(config)# show ip pim rp [mapping</td>
<td>metric] [rp-address]</td>
</tr>
</tbody>
</table>

## Displaying PIM Statistics

The following is sample output from the `show ip pim interface` command:

```
Switch# show ip pim interface

Address          Interface          Mode    Neighbor  Query     DR
                Count     Interval
198.92.37.6      Ethernet0          Dense   2         30        198.92.37.33
198.92.36.129    Ethernet1          Dense   2         30        198.92.36.131
10.1.37.2        Tunnel0            Dense   1         30        0.0.0.0
```

The following is sample output from the `show ip pim interface` command with a `count`:

```
Switch# show ip pim interface count

Address          Interface          FS  Mpackets In/Out
```
Chapter 29      Configuring IP Multicast

Configuration Examples

The following is sample output from the show ip pim interface command with a count when IP multicast is enabled. The example lists the PIM interfaces that are fast-switched and process-switched, and the packet counts for these. The H is added to interfaces where IP multicast is enabled.

Switch# show ip pim interface count

States: FS - Fast Switched, H - Hardware Switched
Address          Interface          FS  Mpackets In/Out
192.1.10.2       Vlan10             * H 40886/0
192.1.11.2       Vlan11             * H 0/40554
192.1.12.2       Vlan12             * H 0/40554
192.1.23.2       Vlan23             * 0/0
192.1.24.2       Vlan24             * 0/0

Clearing Tables and Databases

You can remove all contents of a particular cache, table, or database. Clearing a cache, table, or database might be necessary when the contents of the particular structure have become, or are suspected to be, invalid.

To clear IP multicast caches, tables, and databases, perform one of these tasks:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# clear ip mroute</td>
<td>Deletes entries from the IP routing table.</td>
</tr>
<tr>
<td>Switch# clear ip mfib counters</td>
<td>Deletes all per-route and global MFIB counters.</td>
</tr>
</tbody>
</table>

Note: IP multicast routes can be regenerated in response to protocol events and as data packets arrive.

Configuration Examples

The following sections provide IP multicast routing configuration examples:

- PIM Dense Mode: Example, page 29-26
- PIM Sparse Mode: Example, page 29-27
- Bidirectional PIM Mode: Example, page 29-27
- Sparse Mode with a Single Static RP: Example, page 29-27
- Sparse Mode with Auto-RP: Example, page 29-28

PIM Dense Mode: Example

This example is a configuration of dense-mode PIM on an Ethernet interface:

ip multicast-routing
interface ethernet 0
PIM Sparse Mode: Example

This example is a configuration of sparse-mode PIM. The RP router is the router with the address 10.8.0.20.

```
ip multicast-routing
ip pim rp-address 10.8.0.20 1
interface ethernet 1
ip pim sparse-mode
```

Bidirectional PIM Mode: Example

By default a bidirectional RP advertises all groups as bidirectional. You can use an access list on the RP to specify a list of groups to be advertised as bidirectional. Groups with the deny keyword will operate in dense mode. A different, nonbidirectional RP address, is required for groups that operate in sparse mode, because a single access list only allows either a permit or deny keyword.

The following example shows how to configure an RP for both sparse and bidirectional mode groups. 224/8 and 227/8 are bidirectional groups, 226/8 is sparse mode, and 225/8 is dense mode. The RP must be configured to use different IP addresses for sparse and bidirectional mode operations. Two loopback interfaces are used to allow this configuration and the addresses of these interfaces must be routed throughout the PIM domain so that the other routers in the PIM domain can receive Auto-RP announcements and communicate with the RP:

```
ip multicast-routing !Enable IP multicast routing
ip pim bidir-enable !Enable bidir-PIM
!
interface loopback 0
  description One Loopback address for this routers Bidir Mode RP function
  ip address 10.0.1.1 255.255.255.0
  ip pim sparse-dense-mode
!
interface loopback 1
  description One Loopback address for this routers Sparse Mode RP function
  ip address 10.0.2.1 255.255.255.0
  ip pim sparse-dense-mode
  ip pim send-rp-announce Loopback0 scope 10 group-list 45 bidir
  ip pim send-rp-announce Loopback1 scope 10 group-list 46
  ip pim send-rp-discovery scope 10
  access-list 45 permit 224.0.0.0 0.255.255.255
  access-list 45 permit 227.0.0.0 0.255.255.255
  access-list 45 deny 225.0.0.0 0.255.255.255
  access-list 46 permit 226.0.0.0 0.255.255.255
```

Sparse Mode with a Single Static RP: Example

The following example sets the PIM RP address to 192.168.1.1 for all multicast groups and defines all groups to operate in sparse mode:

```
ip multicast-routing
interface ethernet 1
  ip pim sparse-mode
  ip pim rp-address 192.168.1.1
no ip pim dm-fallback
```
Chapter 29      Configuring IP Multicast

Configuration Examples

Note

The same RP cannot be used for both bidirectional and sparse mode groups.

The following example sets the PIM RP address to 172.16.1.1 for the multicast group 225.2.2.2 only:

```
access list 1 225.2.2.2 0.0.0.0
ip pim rp-address 172.17.1.1
```

Sparse Mode with Auto-RP: Example

The following example configures sparse mode with Auto-RP:

```
ip multicast-routing
ip pim autorp listener
ip pim send-rp-announce Loopback0 scope 16 group-list 1
ip pim send-rp-discovery Loopback1 scope 16
no ip pim dm-fallback
access-list 1 permit 239.254.2.0 0.0.0.255
access-list 1 permit 239.254.3.0 0.0.0.255
.
.
access-list 10 permit 224.0.1.39
access-list 10 permit 224.0.1.40
access-list 10 permit 239.254.2.0 0.0.0.255
access-list 10 permit 239.254.3.0 0.0.0.255
```
Configuring Policy-Based Routing

This chapter describes the tasks for configuring policy-based routing (PBR) on a Catalyst 4500 series switch and includes these major sections:

- Overview of Policy-Based Routing, page 30-1
- Policy-Based Routing Configuration Task List, page 30-6
- Policy-Based Routing Configuration Examples, page 30-8

Note
For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

Note
To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature or refer to the software release notes for a specific release.

Overview of Policy-Based Routing

This section contains the following subsections:

- About PBR, page 30-2
- Using Policy-Based Routing, page 30-5

PBR gives you a flexible method of routing packets by allowing you to define policies for traffic flows, lessening reliance on routes derived from routing protocols. To this end, PBR gives you more control over routing by extending and complementing the existing mechanisms provided by routing protocols. PBR allows you to specify paths for certain traffic, such as priority traffic over a high-cost link.
You can set up PBR as a way to route packets based on configured policies. For example, you can implement routing policies to allow or deny paths based on the identity of a particular end system, or an application protocol.

PBR allows you to perform the following tasks:

- Classify traffic based on extended access list criteria.
- Route packets to specific traffic-engineered paths.

Policies can be based on IP address, port numbers, or protocols. For a simple policy, use any one of these descriptors; for a complicated policy, use all of them.

**About PBR**

All packets received on an interface with PBR enabled are passed through enhanced packet filters known as route maps. The route maps used by PBR dictate the policy, determining to where the packets are forwarded.

Route maps are composed of statements. The route map statements can be marked as permit or deny, and they are interpreted in the following ways:

- If a statement is marked as deny, the packets meeting the match criteria are sent back through the normal forwarding channels and destination-based routing is performed.
- If the statement is marked as permit and a packet matches the access-lists, then the first valid set clause is applied to that packet.

This is explained in more detail in the section *Understanding Route-Maps*, page 30-2.

You specify PBR on the incoming interface (the interface on which packets are received), not outgoing interface.

**Understanding Route-Maps**

PBR is implemented by applying a route-map on an incoming interface. A given interface can have only one route-map configured.

A route-map is configured at the global configuration parser mode. You can then apply this route-map on one or more interfaces (in the interface configuration parser sub-mode).

A route-map is comprised of one or more route-map statements. Each statement has a sequence number, as well as a permit or deny clause.

Each route-map statement contains **match** and **set** commands. The **match** command denotes the match criteria to be applied on the packet data. The **set** command denote the PBR action to be taken on the packet.

The following example shows a single route-map called rm-test and six route-map statements:

```
routemap rm-test permit 21
match ip address 101
set ip next-hop 21.1.1.1
!
routemap rm-test permit 22
match ip address 102
set ip next-hop 22.2.2.1
!
routemap rm-test permit 23
match ip address 101 2102
set interface vlan23
```
Chapter 30  Configuring Policy-Based Routing

Overview of Policy-Based Routing

! route-map rm-test deny 24
  match ip address 104
  set ip next-hop 24.4.4.1
! route-map rm-test deny 25
  match ip address 105
  set ip next-hop 25.5.5.1
! route-map rm-test permit 26
  match ip address 2104
  set ip next-hop 26.6.6.1

The numbers 21, 22, ... 26 are the sequence numbers of the route-map statements.

The following topics are discussed:

- PBR Route-Map Processing Logic, page 30-3
- PBR Route-Map Processing Logic Example, page 30-4

PBR Route-Map Processing Logic

When a packet is received on an interface configured with a route-map, the forwarding logic processes each route-map statement according to the sequence number.

If the route-map statement encountered is a route-map...permit statement:

- The packet is matched against the criteria in the match command. This command may refer to an ACL that may itself have one or more permit and/or deny expressions. The packet is matched against the expressions in the ACL, and a permit/deny decision is reached.
- If the decision reached is permit, then the PBR logic executes the action specified by the set command on the packet.
- If the decision reached is deny, then the PBR action (specified in the set command) is not applied. Instead the processing logic moves forward to look at the next route-map statement in the sequence (the statement with the next higher sequence number). If no next statement exists, PBR processing terminates, and the packet is routed using the default IP routing table.

If the route-map statement encountered is a route-map...deny statement:

- The packet is matched against the criteria given in the match command. This command may refer to an ACL that may itself have one or more permit and/or deny expressions. The packet is matched against the expressions in the ACL, and a permit/deny decision is reached.
- If the criteria decision is permit, then the PBR processing terminates, and the packet is routed using the default IP routing table.
- If the criteria decision is deny, then the PBR processing logic moves forward to look at the next route-map statement in the sequence (the statement with the next higher sequence number). If no next statement exists, PBR processing terminates, and the packet is routed using the default IP routing table.

Note

The set command has no effect inside a route-map... deny statement.
PBR Route-Map Processing Logic Example

Consider a route-map called rm-test defined as follows:

```plaintext
access-list 101 permit tcp host 61.1.1.1 host 133.3.3.1 eq 101
access-list 102 deny tcp host 61.1.1.1 host 133.3.3.1 eq 102
access-list 2102 permit tcp host 61.1.1.1 host 133.3.3.1 eq 102
access-list 104 deny tcp host 61.1.1.1 host 133.3.3.1 eq 104
access-list 2104 permit tcp host 61.1.1.1 host 133.3.3.1 eq 104
access-list 105 permit tcp host 61.1.1.1 host 133.3.3.1 eq 105

route-map rm-test permit 21
  match ip address 101
  set ip next-hop 21.1.1.1

route-map rm-test permit 22
  match ip address 102
  set ip next-hop 22.2.2.1

route-map rm-test permit 23
  match ip address 101 2102
  set interface vlan23

route-map rm-test deny 24
  match ip address 104
  set ip next-hop 24.4.4.1

route-map rm-test deny 25
  match ip address 105
  set ip next-hop 25.5.5.1

route-map rm-test permit 26
  match ip address 2104
  set ip next-hop 26.6.6.1
```

- TCP packet from 61.1.1.1 to 133.3.3.1 with destination port 101
  - Matches ACL 101 in sequence #21.
  - PBR is switched through next-hop 21.1.1.1.

Note: ACL 101 is also matched in sequence #23, but the processing doesn't reach that point.

- TCP packet from 61.1.1.1 to 133.3.3.1 with destination port 102
  - In sequence #21, the ACL 101 action denies this packet (because all ACLs have an implicit deny). Processing advances to sequence #22.
  - In sequence #22, ACL 102 matches TCP port 102, but the ACL action is deny. Processing advances to sequence #23.
  - In sequence #23, ACL 2102 matches TCP port 102, and the ACL action is permit.
  - Packet is switched to output interface VLAN 23.
• TCP packet from 61.1.1.1 to 133.3.3.1 with destination port 105
  - Processing moves from sequence #21 to #24, because all ACLs in these sequence numbers have a deny action for port 105.
  - In sequence #25, ACL 105 has a permit action for TCP port 105.
  - The route-map deny takes effect, and the packet is routed using the default IP routing table.

Understanding PBR

The Catalyst 4500 Supervisor Engine 7-E supports matching route-map actions with a packet by installing entries in the TCAM that match the set of packets described by the ACLs in the match criteria of the route map. These TCAM entries point at adjacencies that either perform the necessary output actions or forward the packet to software if either hardware does not support the action or its resources are exhausted.

If the route-map specifies a set interface ... action, packets that match the match statement are routed in software. Similarly, if the route-map specifies a set default interface... action and there is no matching IP route for the packet, the packet is routed in software.

The Catalyst 4500 Supervisor Engine 7-E supports hardware PBR switching only for set ip next-hop... and set ip default next-hop actions.

Note

The scale of hardware-based PBR is determined by TCAM size and the time required for the CPU to flatten the ACL before programming into hardware. The latter will noticeably increase if a PBR policy requires a considerable number of class-maps. For example, a PBR policy of 1,200 class-maps may require 60-90 minutes of “flatten” time before programming into hardware. This process may repeat if an adjacency change requires PBR reprogramming.

Using Policy-Based Routing

You can enable PBR to change the routing path of certain packets from the default path that would be chosen by IP routing. For example, PBR can be used to provide the following functionality:

• equal access
• protocol-sensitive routing
• source-sensitive routing
• routing based on interactive versus batch traffic
• routing based on dedicated links

Some applications or traffic can benefit from source-specific routing; for example, you can transfer stock records to a corporate office on a higher-bandwidth, higher-cost link for a short time while sending routine application data, such as e-mail, over a lower-bandwidth, lower-cost link.

Note

PBR configuration is only allowed on interfaces belonging to the global routing table. PBR is not supported on interfaces that belong to VRFs.
Policy-Based Routing Configuration Task List

To configure PBR, perform the tasks described in the following sections. The task in the first section is required; the tasks in the remaining sections are optional. See the end of this chapter for the section “Policy-Based Routing Configuration Examples.”

- Enabling PBR (Required)
- Enabling Local PBR (Optional)

Enabling PBR

To enable PBR, you must create a route map that specifies the match criteria and the resulting action if all of the match clauses are met. Then you must apply that route-map on a particular interface. All packets arriving on the specified interface matching the match clauses are subject to PBR.

To enable PBR on an interface, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> Switch(config)# route-map map-tag [permit</td>
<td>deny] [sequence-number]</td>
</tr>
<tr>
<td><strong>Step 2</strong> Switch(config-route-map)# match ip address {access-list-number</td>
<td>name} [...access-list-number</td>
</tr>
</tbody>
</table>

Perform Step 3, 4, 5, or 6

| Step 3 | Switch(config-route-map)# set ip next-hop ip-address [... ip-address] | Specifies the next-hop IP address to which matching packets are sent. The next-hop IP address specified here must belong to a subnet that is directly connected to this switch. If more than one next-hop IP address is specified, the first usable next-hop is chosen for routing matching packets. If the next-hop is (or becomes) unavailable for some reason, the next one in the list is chosen. |

Or
Chapter 30  Configuring Policy-Based Routing

Policy-Based Routing Configuration Task List

Step 4  
Switch(config-route-map)# set interface
interface-type interface-number
[... type number]

Or

Specifies the output interface from which the packet will be sent. This action specifies that the packet is forwarded out of the local interface. The interface must be a Layer 3 interface (not a switchport).

Packets are forwarded on the specified interface only if one of the following conditions is met:

- The destination IP address in the packet lies within the IP subnet to which the specified interface belongs.
- The destination IP address in the packet is reachable through the specified interface (as per the IP routing table).

If the destination IP address on the packet does not meet either of these conditions, the packet is dropped. This action forces matching packets to be switched in software.

Step 5  
Switch(config-route-map)# set ip default
next-hop ip-address [... ip-address]

Or

Sets next hop to which to route the packet if there is no explicit route for the destination IP address in the packet.

Before forwarding the packet to the next hop, the switch looks up the packet’s destination address in the unicast routing table. If a match is found, the packet is forwarded by way of the routing table. If no match is found, the packet is forwarded to the specified next hop.

Step 6  
Switch(config-route-map)# set default
interface interface-type interface-number
[...type ...number]

Specifies the output interface from which the packet will be sent if there is no explicit route for this destination. Before forwarding the packet to the next hop, the switch looks up the packet’s destination address in the unicast routing table. If a match is found, the packet is forwarded via the routing table. If no match is found, the packet is forwarded to the specified output interface.

Packets are forwarded on the specified interface only if one of the following conditions is met:

- The destination IP address in the packet lies within the IP subnet to which the specified interface belongs.
- The destination IP address in the packet is reachable through the specified interface (as per the IP routing table).

If the destination IP address on the packet does not meet either of these conditions, the packet is dropped. This action forces matching packets to be switched in software.

Step 7  
Switch(config-route-map)# interface
interface-type interface-number

Specifies the interface. This command puts the switch into interface configuration mode.

Step 8  
Switch(config-if)# ip policy route-map map-tag

Identifies the route map to use for PBR. One interface can only have one route map tag, but you can have multiple route map entries with different sequence numbers. These entries are evaluated in sequence number order until the first match. If there is no match, packets are routed as usual.
The set commands can be used in conjunction with each other. These commands are evaluated in the order shown in Step 3 in the previous task table. A usable next hop implies an interface. Once the local switch finds a next hop and a usable interface, it routes the packet.

### Enabling Local PBR

Packets that are generated by the switch are not normally policy-routed. To enable local PBR for such packets, indicate which route map the switch should use by performing this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# ip local policy route-map map-tag</td>
<td>Identifies the route map to use for local PBR.</td>
</tr>
</tbody>
</table>

All packets originating on the switch are then be subject to local PBR. Use the show ip local policy command to display the route map used for local PBR, if one exists.

### Unsupported Commands

The following PBR commands in config-route-map mode are in the CLI but not supported in Cisco IOS for the switches. If you attempt to use these commands, an error message displays.

- match-length
- set ip qos
- set ip tos
- set ip precedence

### Policy-Based Routing Configuration Examples

The following sections provide PBR configuration examples:

- Equal Access, page 30-8
- Differing Next Hops, page 30-9
- Deny ACE, page 30-9

For information on how to configure policy-based routing, see the section “Policy-Based Routing Configuration Task List” in this chapter.

### Equal Access

The following example provides two sources with equal access to two different service providers. Packets arriving on interface fastethernet 3/1 from the source 1.1.1.1 are sent to the switch at 6.6.6.6 if the switch has no explicit route for the destination of the packet. Packets arriving from the source 2.2.2.2 are sent to the switch at 7.7.7.7 if the switch has no explicit route for the destination of the packet. All other packets for which the switch has no explicit route to the destination are discarded.
Switch (config)# access-list 1 permit ip 1.1.1.1
access-list 1 permit ip 1.1.1.1
interface fastethernet 3/1
    ip policy route-map equal-access

route-map equal-access permit 10
    match ip address 1
    set ip default next-hop 6.6.6.6
route-map equal-access permit 20
    match ip address 2
    set ip default next-hop 7.7.7.7
route-map equal-access permit 30
    set default interface null0

Note
If the packets you want to drop do not match either of the first two route-map clauses, then change | set default interface null0 to set interface null0.

Differing Next Hops

The following example illustrates how to route traffic from different sources to different places (next hops). Packets arriving from source 1.1.1.1 are sent to the next hop at 3.3.3.3; packets arriving from source 2.2.2.2 are sent to the next hop at 3.3.3.5.

access-list 1 permit ip 1.1.1.1
access-list 2 permit ip 2.2.2.2
interface fastethernet 3/1
    ip policy route-map Texas
route-map Texas permit 10
    match ip address 1
    set ip next-hop 3.3.3.3
route-map Texas permit 20
    match ip address 2
    set ip next-hop 3.3.3.5

Deny ACE

The following example illustrates how to stop processing a given route map sequence, and to jump to the next sequence. Packets arriving from source 1.1.1.1 skip sequence 10 and jump to sequence 20. All other packets from subnet 1.1.1.0 follow the set statement in sequence 10.

access-list 1 deny ip 1.1.1.1
access-list 1 permit ip 1.1.1.0 0.0.0.255
access-list 2 permit ip 1.1.1.1
access-list 2 permit ip 2.2.2.2
interface fastethernet 3/1
    ip policy route-map Texas
route-map Texas permit 10
    match ip address 1
    set ip next-hop 3.3.3.3
route-map Texas permit 20
    match ip address 2
    set ip next-hop 3.3.3.5
Configuring VRF-lite

Virtual Private Networks (VPNs) provide a secure way for customers to share bandwidth over an ISP backbone network. A VPN is a collection of sites sharing a common routing table. A customer site is connected to the service provider network by one or more interfaces, and the service provider associates each interface with a VPN routing table. A VPN routing table is called a VPN routing/forwarding (VRF) table.

With the VRF-lite feature, the Catalyst 4500 series switch supports multiple VPN routing/forwarding instances in customer edge devices. (VRF-lite is also termed multi-VRF CE, or multi-VRF Customer Edge Device). VRF-lite allows a service provider to support two or more VPNs with overlapping IP addresses using one interface.

Note
Starting with Cisco IOS Release 12.2(52)SG, the Catalyst 4500 switch supports VRF lite NSF support with routing protocols OSPF/EIGRP/BGP.

Note
The switch does not use Multiprotocol Label Switching (MPLS) to support VPNs. For information about MPLS VRF, refer to the Cisco IOS Switching Services Configuration Guide at:

This chapter includes these topics:
- VRF-lite Overview, page 31-2
- Default VRF-lite Configuration, page 31-3
- VRF-lite Configuration Guidelines, page 31-4
- Configuring VRFs, page 31-5
- Configuring VRF-Aware Services, page 31-6
- Configuring Multicast VRFs, page 31-10
- Configuring a VPN Routing Session, page 31-11
- Configuring BGP PE to CE Routing Sessions, page 31-11
- VRF-lite Configuration Example, page 31-12
- Displaying VRF-lite Status, page 31-17
VRF-lite Overview

VRF-lite is a feature that enables a service provider to support two or more VPNs, where IP addresses can be overlapped among the VPNs. VRF-lite uses input interfaces to distinguish routes for different VPNs and forms virtual packet-forwarding tables by associating one or more Layer 3 interfaces with each VRF. Interfaces in a VRF can be either physical, such as Ethernet ports, or logical, such as VLAN SVIs, but a Layer 3 interface cannot belong to more than one VRF at any time.

Note

VRF-lite interfaces must be Layer 3 interfaces.

VRF-lite includes these devices:

- Customer edge (CE) devices provide customer access to the service provider network over a data link to one or more provider edge routers. The CE device advertises the site’s local routes to the provider edge router and learns the remote VPN routes from it. A Catalyst 4500 series switch can be a CE.
- Provider edge (PE) routers exchange routing information with CE devices by using static routing or a routing protocol such as BGP, RIPv1, or RIPv2.
- The PE is only required to maintain VPN routes for those VPNs to which it is directly attached, eliminating the need for the PE to maintain all of the service provider VPN routes. Each PE router maintains a VRF for each of its directly connected sites. Multiple interfaces on a PE router can be associated with a single VRF if all of these sites participate in the same VPN. Each VPN is mapped to a specified VRF. After learning local VPN routes from CEs, a PE router exchanges VPN routing information with other PE routers by using internal BGP (iBPG).
- Provider routers (or core routers) are any routers in the service provider network that do not attach to CE devices.

With VRF-lite, multiple customers can share one CE, and only one physical link is used between the CE and the PE. The shared CE maintains separate VRF tables for each customer and switches or routes packets for each customer based on its own routing table. VRF-lite extends limited PE functionality to a CE device, giving it the ability to maintain separate VRF tables to extend the privacy and security of a VPN to the branch office.

Figure 31-1 shows a configuration where each Catalyst 4500 series switch acts as multiple virtual CEs. Because VRF-lite is a Layer 3 feature, each interface in a VRF must be a Layer 3 interface.
This is the packet-forwarding process in a VRF-lite CE-enabled network as shown in Figure 31-1:

- When the CE receives a packet from a VPN, it looks up the routing table based on the input interface. When a route is found, the CE forwards the packet to the PE.
- When the ingress PE receives a packet from the CE, it performs a VRF lookup. When a route is found, the router adds a corresponding MPLS label to the packet and sends it to the MPLS network.
- When an egress PE receives a packet from the network, it strips the label and uses the label to identify the correct VPN routing table. Then the egress PE performs the normal route lookup. When a route is found, it forwards the packet to the correct adjacency.
- When a CE receives a packet from an egress PE, it uses the input interface to look up the correct VPN routing table. If a route is found, the CE forwards the packet within the VPN.

To configure VRF, create a VRF table and specify the Layer 3 interface associated with the VRF. Then configure the routing protocols in the VPN and between the CE and the PE. BGP is the preferred routing protocol used to distribute VPN routing information across the provider’s backbone. The VRF-lite network has three major components:

- VPN route target communities—Lists of all other members of a VPN community. You need to configure VPN route targets for each VPN community member.
- Multiprotocol BGP peering of VPN community PE routers—Propagates VRF reachability information to all members of a VPN community. You need to configure BGP peering in all PE routers within a VPN community.
- VPN forwarding—Transports all traffic between all VPN community members across a VPN service-provider network.

### Default VRF-lite Configuration

Table 31-1 shows the default VRF configuration.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>VRF</td>
<td>Disabled. No VRFs are defined.</td>
</tr>
<tr>
<td>Maps</td>
<td>No import maps, export maps, or route maps are defined.</td>
</tr>
</tbody>
</table>
Consider these points when configuring VRF in your network:

- A switch with VRF-lite is shared by multiple customers, and all customers have their own routing tables.
- Because customers use different VRF tables, the same IP addresses can be reused. Overlapped IP addresses are allowed in different VPNs.
- VRF-lite lets multiple customers share the same physical link between the PE and the CE. Trunk ports with multiple VLANs separate packets among customers. All customers have their own VLANs.
- VRF-lite does not support all MPLS-VRF functionality: label exchange, LDP adjacency, or labeled packets.
- For the PE router, there is no difference between using VRF-lite or using multiple CEs. In Figure 31-1, multiple virtual Layer 3 interfaces are connected to the VRF-lite device.
- The Catalyst 4500 series switch supports configuring VRF by using physical ports, VLAN SVIs, or a combination of both. The SVIs can be connected through an access port or a trunk port.
- A customer can use multiple VLANs as long as they do not overlap with those of other customers. A customer’s VLANs are mapped to a specific routing table ID that is used to identify the appropriate routing tables stored on the switch.
- The Layer 3 TCAM resource is shared between all VRFs. To ensure that any one VRF has sufficient CAM space, use the `maximum routes` command.
- A Catalyst 4500 series switch using VRF can support one global network and up to 64 VRFs. The total number of routes supported is limited by the size of the TCAM.
- Most routing protocols (BGP, OSPF, EIGRP, RIP and static routing) can be used between the CE and the PE. However, we recommend using external BGP (EBGP) for these reasons:
  - BGP does not require multiple algorithms to communicate with multiple CEs.
  - BGP is designed for passing routing information between systems run by different administrations.
  - BGP makes it easy to pass attributes of the routes to the CE.
- VRF-lite does not support IGRP and ISIS.
- VRF-lite does not affect the packet switching rate.
- Starting with Cisco IOS Release 12.2(50)SG, Multicast and VRF can be configured together on a Layer 3 interface.
- The Catalyst 4500 series switch supports all the PIM protocols (PIM-SM, PIM-DM, PIM-SSM, PIM BiDIR).
- IPv4 Multicast VRF, not IPv6 Multicast VRF, is supported on Supervisor Engine 7-E.

### Table 31-1  Default VRF Configuration (continued)

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>VRF maximum routes</td>
<td>None.</td>
</tr>
<tr>
<td>Forwarding table</td>
<td>The default for an interface is the global routing table.</td>
</tr>
</tbody>
</table>
The **capability vrf-lite** subcommand under **router ospf** should be used when configuring OSPF as the routing protocol between the PE and the CE.

## Configuring VRFs

To configure one or more VRFs, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# <code>configure terminal</code> Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# <code>ip routing</code> Enables IP routing.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config)# <code>ip vrf vrf-name</code> Names the VRF, and enter VRF configuration mode.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config-vrf)# <code>rd route-distinguisher</code> Creates a VRF table by specifying a route distinguisher. Enter either an AS number and an arbitrary number (xxx:y) or an IP address and arbitrary number (A.B.C.D:y).</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch(config-vrf)# `route-target {export</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Switch(config-vrf)# <code>import map route-map</code> (Optional) Associates a route map with the VRF.</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>Switch(config-vrf)# <code>interface interface-id</code> Enters interface configuration mode and specify the Layer 3 interface to be associated with the VRF. The interface can be a routed port or SVI.</td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>Switch(config-if)# <code>ip vrf forwarding vrf-name</code> Associates the VRF with the Layer 3 interface.</td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>Switch(config-if)# <code>end</code> Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 10</strong></td>
<td>Switch# `show ip vrf [brief</td>
</tr>
<tr>
<td><strong>Step 11</strong></td>
<td>Switch# <code>copy running-config startup-config</code> (Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

**Note**

Use the **no ip vrf vrf-name** global configuration command to delete a VRF and to remove all interfaces from it. Use the **no ip vrf forwarding** interface configuration command to remove an interface from the VRF.
Configuring VRF-Aware Services

IP services can be configured on global interfaces, and these services run within the global routing instance. IP services are enhanced to run on multiple routing instances; they are VRF-aware. Any configured VRF in the system can be specified for a VRF-aware service.

VRF-Aware services are implemented in platform-independent modules. VRF means multiple routing instances in Cisco IOS. Each platform has its own limit on the number of VRFs it supports.

VRF-aware services have the following characteristics:

- The user can ping a host in a user-specified VRF.
- ARP entries are learned in separate VRFs. The user can display Address Resolution Protocol (ARP) entries for specific VRFs.

These services are VRF-Aware:

- ARP
- Ping
- Simple Network Management Protocol (SNMP)
- Unicast Reverse Path Forwarding (uRPF)
- Syslog
- Traceroute
- FTP and TFTP
- Telnet and SSH
- NTP

Note

For complete syntax and usage information for the following commands, see the switch command reference for this release and see the Cisco IOS Switching Services Command Reference at: http://www.cisco.com/en/US/docs/ios/ipswitch/command/reference/isw_book.html

User Interface for ARP

To configure VRF-aware ARP, follow these steps.

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# arp vrf vrf-name &lt;ip-address&gt; mac-address&gt; ARPA</td>
<td>Create a static arp entry in the specified VRF.</td>
</tr>
<tr>
<td>Switch# show ip arp vrf vrf-name</td>
<td>Displays the ARP table (static and dynamic entries) in the specified VRF.</td>
</tr>
</tbody>
</table>
User Interface for PING

To perform a VRF-aware ping, enter the following command:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# ping vrf vrf-name ip-host</td>
<td>Ping an IP host or address in the specified VRF.</td>
</tr>
</tbody>
</table>

User Interface for SNMP

To configure VRF-aware services for SNMP, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# snmp-server trap authentication vrf</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config)# snmp-server engineID remote host vrf vpn-instance engine-id string</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config)# snmp-server host host vrf vpn-instance traps community</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch(config)# snmp-server host host vrf vpn-instance informs community</td>
</tr>
<tr>
<td>Step 6</td>
<td>Switch(config)# snmp-server user user group remote host vrf vpn-instance security model</td>
</tr>
<tr>
<td>Step 7</td>
<td>Switch(config)# end</td>
</tr>
</tbody>
</table>

User Interface for uRPF

You can configure uRPF on an interface assigned to a VRF. Source lookup is performed in the VRF table.

To configure VRF-aware services for uRPF, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# interface interface-id</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config-if)# no switchport</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config-if)# ip vrf forwarding vrf-name</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch(config-if-vrf)# ip address ip-address subnet-mask</td>
</tr>
</tbody>
</table>
Configuring VRF-Aware Services

Chapter 31      Configuring VRF-lite

To configure VRF-aware services for Syslog, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 6</td>
<td><code>Switch(config-if-vrf)# ip verify unicast source reachable-via rx allow-default</code></td>
</tr>
<tr>
<td>Step 7</td>
<td><code>Switch(config-if-vrf)# end</code></td>
</tr>
</tbody>
</table>

User Interface for Syslog

To configure VRF-aware services for Syslog, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>Switch# configure terminal</code></td>
</tr>
<tr>
<td>Step 2</td>
<td><code>Switch(config)# logging on</code></td>
</tr>
<tr>
<td>Step 3</td>
<td><code>Switch(config)# logging host ip-address vrf vrf-name</code></td>
</tr>
<tr>
<td>Step 4</td>
<td><code>Switch(config)# logging buffered logging buffered size debugging</code></td>
</tr>
<tr>
<td>Step 5</td>
<td><code>Switch(config)# logging trap debugging</code></td>
</tr>
<tr>
<td>Step 6</td>
<td><code>Switch(config)# logging facility facility</code></td>
</tr>
<tr>
<td>Step 7</td>
<td><code>Switch(config)# end</code></td>
</tr>
</tbody>
</table>

User Interface for Traceroute

To configure VRF-aware services for traceroute, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>traceroute vrf vrf-name ipaddress</code></td>
<td>Specifies the name of a VPN VRF in which to find the destination address.</td>
</tr>
</tbody>
</table>

User Interface for FTP and TFTP

So that FTP and TFTP are VRF-aware, you must configure some FTP/TFTP CLIs. For example, if you want to use a VRF table that is attached to an interface, say E1/0, you need to configure the CLI `ip [t]ftp source-interface E1/0` to inform [t]ftp to use a specific routing table. In this example, the VRF table is used to look up the destination IP address. These changes are backward-compatible and do not affect existing behavior. That is, you can use the source-interface CLI to send packets out a particular interface even if no VRF is configured on that interface.
To specify the source IP address for FTP connections, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# [no] ip ftp source-interface interface-type interface-number</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config)# end</td>
</tr>
</tbody>
</table>

To specify the IP address of an interface as the source address for TFTP connections, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# [no] ip tftp source-interface interface-type interface-number</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config)# end</td>
</tr>
</tbody>
</table>

**User Interface for Telnet and SSH**

To configure VRF-aware Telnet and SSH, enter these commands:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# telnet &lt;ip-address&gt;/vrf vrf-name</td>
<td>Telnet to an ip host or address in the specified VRF.</td>
</tr>
<tr>
<td>Switch# ssh -l &lt;username&gt; -vrf vrf-name ip-host</td>
<td>SSH to an ip host or address in the specified VRF.</td>
</tr>
</tbody>
</table>

**User Interface for NTP**

To configure VRF-aware NTP, enter these commands:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# ntp server vrf vrf-name ip-host</td>
<td>Configure NTP server in the specified VRF.</td>
</tr>
<tr>
<td>Switch# ntp peer vrf vrf-name ip-host</td>
<td>Configure NTP peer in the specified VRF.</td>
</tr>
</tbody>
</table>
Configuring Multicast VRFs

To configure multicast within a VRF table, follow these steps.

**Note**
For complete syntax and usage information for the following commands, see the switch command reference for this release and see the Cisco IOS Switching Services Command Reference at: http://www.cisco.com/en/US/docs/ios/ipswitch/command/reference/isw_book.html

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# ip routing</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config)# ip vrf vrf-name</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config-vrf)# ip multicast-routing vrf vrf-name</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch(config-vrf)# rd route-distinguisher</td>
</tr>
<tr>
<td>Step 6</td>
<td>Switch(config-vrf)# route-target {export</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>Step 7</td>
<td>Switch(config-vrf)# import map route-map</td>
</tr>
<tr>
<td>Step 8</td>
<td>Switch(config-vrf)# interface interface-id</td>
</tr>
<tr>
<td>Step 9</td>
<td>Switch(config-if)# ip vrf forwarding vrf-name</td>
</tr>
<tr>
<td>Step 10</td>
<td>Switch(config-if)# ip address ip-address mask</td>
</tr>
<tr>
<td>Step 11</td>
<td>Switch(config-if)# ip pim {sparse-dense mode</td>
</tr>
<tr>
<td>Step 12</td>
<td>Switch(config-if)# end</td>
</tr>
<tr>
<td>Step 13</td>
<td>Switch# show ip vrf [brief</td>
</tr>
<tr>
<td>Step 14</td>
<td>Switch# copy running-config startup-config</td>
</tr>
</tbody>
</table>

For more information about configuring a multicast within a Multi-VRF CE, see the Cisco IOS IP Multicast Configuration Guide, Release 12.4.

Use the no ip vrf vrf-name global configuration command to delete a VRF and to remove all interfaces from it. Use the no ip vrf forwarding interface configuration command to remove an interface from the VRF.
Configuring a VPN Routing Session

Routing within the VPN can be configured with any supported routing protocol (RIP, OSPF, or BGP) or with static routing. The configuration shown here is for OSPF, but the process is the same for other protocols.

To configure OSPF in the VPN, perform this task:

1. Use the `no router ospf process-id vrf vrf-name` global configuration command to disassociate the VPN forwarding table from the OSPF routing process.

   ```
   Switch(config) #
   ip vrf VRF-RED
   Switch(config-vrf) #
   rd 1:1
   Switch(config-vrf) #
   exit
   Switch(config) #
   router ospf virtual-name
   Switch(config-router)#
   log-adjacency-changes
   (Optional) Logs changes in the adjacency state. This is the default state.
   Switch(config-router)#
   redistribute bgp autonomous-system-number subnets
   Sets the switch to redistribute information from the BGP network to the OSPF network.
   Switch(config-router)#
   network network-number area area-id
   Defines a network address and mask on which OSPF runs and the area ID for that network address.
   Switch(config-router)#
   end
   Returns to privileged EXEC mode.
   Switch(config-router)#
   show ip ospf process-id
   Verifies the configuration of the OSPF network.
   Switch(config-router)#
   copy running-config startup-config
   (Optional) Saves your entries in the configuration file.
   ```

Use the `no router ospf process-id vrf vrf-name` global configuration command to disassociate the VPN forwarding table from the OSPF routing process.

The following examples configure a single VRF named VRF-RED:

```
Switch(config)# ip vrf VRF-RED
Switch(config-vrf)# rd 1:1
Switch(config-vrf)# exit
Switch(config)# router eigrp virtual-name
Switch(config-router)# address-family ipv4 vrf VRF-RED autonomous-system 1
Switch(config-router) # network 10.0.0.0 0.0.0.255
Switch(config-router) # topology base
Switch(config-router-topology) # default-metric 10000 100 255 1 1500
Switch(config-router-topology) # exit-af-topology
Switch(config-router-topology) # exit-address-family
```

Configuring BGP PE to CE Routing Sessions

To configure a BGP PE to CE routing session, perform this task:

1. Use the `configure terminal` command to enter global configuration mode.

   ```
   Switch(config)# configure terminal
   Enters global configuration mode.
   ```

   ```
   Switch(config)# router bgp autonomous-system-number
   Configures the BGP routing process with the AS number passed to other BGP routers and enters router configuration mode.
   ```
### VRF-lite Configuration Example

**Step 3**

```
Switch(config-router)# network network-number mask network-mask
```
Specifies a network and mask to announce using BGP.

**Step 4**

```
Switch(config-router)# redistribute ospf process-id match internal
```
Sets the switch to redistribute OSPF internal routes.

**Step 5**

```
Switch(config-router)# network network-number area area-id
```
Defines a network address and mask on which OSPF runs and the area ID for that network address.

**Step 6**

```Switch(config-router-af)# address-family ipv4 vrf vrf-name
```
Defines BGP parameters for PE to CE routing sessions and enters VRF address-family mode.

**Step 7**

```Switch(config-router-af)# neighbor address remote-as as-number
```
Defines a BGP session between PE and CE routers.

**Step 8**

```Switch(config-router-af)# neighbor address activate
```
Activates the advertisement of the IPv4 address family.

**Step 9**

```Switch(config-router-af)# end
```
Returns to privileged EXEC mode.

**Step 10**

```Switch# show ip bgp [ipv4] [neighbors]
```
Verifies BGP configuration.

**Step 11**

```Switch# copy running-config startup-config
```
(Optional) Saves your entries in the configuration file.

Use the `no router bgp autonomous-system-number` global configuration command to delete the BGP routing process. Use the command with keywords to delete routing characteristics.

---

**Figure 31-2** is a simplified example of the physical connections in a network similar to that in Figure 31-1. OSPF is the protocol used in VPN1, VPN2, and the global network. BGP is used in the CE to PE connections. The example commands show how to configure the CE switch S8 and include the VRF configuration for switches S20 and S11 and the PE router commands related to traffic with switch S8. Commands for configuring the other switches are not included but would be similar.

CE = Customer edge device
PE = Provider edge router
Configuring Switch S8

On switch S8, enable routing and configure VRF.

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# ip routing
Switch(config)# ip vrf v11
Switch(config-vrf)# rd 800:1
Switch(config-vrf)# route-target export 800:1
Switch(config-vrf)# route-target import 800:1
Switch(config-vrf)# exit
Switch(config)# ip vrf v12
Switch(config-vrf)# rd 800:2
Switch(config-vrf)# route-target export 800:2
Switch(config-vrf)# route-target import 800:2
Switch(config-vrf)# exit

Configure the loopback and physical interfaces on switch S8. Fast Ethernet interface 3/5 is a trunk connection to the PE. Interfaces 3/7 and 3/11 connect to VPNs:

Switch(config)# interface loopback1
Switch(config-if)# ip vrf forwarding v11
Switch(config-if)# ip address 8.8.1.8 255.255.255.0
Switch(config-if)# exit

Switch(config)# interface loopback2
Switch(config-if)# ip vrf forwarding v12
Switch(config-if)# ip address 8.8.2.8 255.255.255.0
Switch(config-if)# exit

Switch(config)# interface FastEthernet3/5
Switch(config-if)# switchport trunk encapsulation dot1q
Switch(config-if)# switchport mode trunk
Switch(config-if)# no ip address
Switch(config-if)# exit

Switch(config)# interface FastEthernet3/8
Switch(config-if)# switchport access vlan 208
Switch(config-if)# no ip address
Switch(config-if)# exit

Switch(config)# interface FastEthernet3/11
Switch(config-if)# switchport trunk encapsulation dot1q
Switch(config-if)# switchport mode trunk
Switch(config-if)# no ip address
Switch(config-if)# exit

Configure the VLANs used on switch S8. VLAN 10 is used by VRF 11 between the CE and the PE. VLAN 20 is used by VRF 12 between the CE and the PE. VLANs 118 and 208 are used for VRF for the VPNs that include switch S11 and switch S20, respectively:

Switch(config)# interface Vlan10
Switch(config-if)# ip vrf forwarding v11
Switch(config-if)# ip address 38.0.0.8 255.255.255.0
Switch(config-if)# exit
Chapter 31      Configuring VRF-lite

VRF-lite Configuration Example

Switch(config)# interface Vlan20
Switch(config-if)# ip vrf forwarding v12
Switch(config-if)# ip address 83.0.0.8 255.255.255.0
Switch(config-if)# exit

Switch(config)# interface Vlan118
Switch(config-if)# ip vrf forwarding v12
Switch(config-if)# ip address 118.0.0.8 255.255.255.0
Switch(config-if)# exit

Switch(config)# interface Vlan208
Switch(config-if)# ip vrf forwarding v11
Switch(config-if)# ip address 208.0.0.8 255.255.255.0
Switch(config-if)# exit

Configure OSPF routing in VPN1 and VPN2:

Switch(config)# router ospf 1 vrf vl1
Switch(config-router)# redistribute bgp 800 subnets
Switch(config-router)# network 208.0.0.0 0.0.0.255 area 0
Switch(config-router)# exit
Switch(config)# router ospf 2 vrf vl2
Switch(config-router)# redistribute bgp 800 subnets
Switch(config-router)# network 118.0.0.0 0.0.0.255 area 0
Switch(config-router)# exit

Configure BGP for CE to PE routing:

Switch(config)# router bgp 800
Switch(config-router)# address-family ipv4 vrf vl12
Switch(config-router-af)# redistribute ospf 2 match internal
Switch(config-router-af)# neighbor 83.0.0.3 remote-as 100
Switch(config-router-af)# neighbor 83.0.0.3 activate
Switch(config-router-af)# network 8.8.2.0 mask 255.255.255.0
Switch(config-router-af)# exit
Switch(config-router-af)# address-family ipv4 vrf vl11
Switch(config-router-af)# redistribute ospf 1 match internal
Switch(config-router-af)# neighbor 38.0.0.3 remote-as 100
Switch(config-router-af)# neighbor 38.0.0.3 activate
Switch(config-router-af)# network 8.8.1.0 mask 255.255.255.0
Switch(config-router-af)# end

Configuring Switch S20

Configure S20 to connect to CE:

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# ip routing
Switch(config)# interface Fast Ethernet 0/7
Switch(config-if)# no switchport
Switch(config-if)# ip address 208.0.0.20 255.255.255.0
Switch(config-if)# exit
Switch(config)# router ospf 101
Switch(config-router)# network 208.0.0.0 0.0.0.255 area 0
Switch(config-router)# end
Chapter 31      Configuring VRF-lite

VRF-lite Configuration Example

Configuring Switch S11

Configure S11 to connect to CE:

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# ip routing
Switch(config)# interface Gigabit Ethernet 0/3
Switch(config-if)# switchport trunk encapsulation dot1q
Switch(config-if)# switchport mode trunk
Switch(config-if)# no ip address
Switch(config-if)# exit

Switch(config)# interface Vlan118
Switch(config-if)# ip address 118.0.0.11 255.255.255.0
Switch(config-if)# exit

Switch(config)# router ospf 101
Switch(config-router)# network 118.0.0.0 0.0.0.255 area 0
Switch(config-router)# end

Configuring the PE Switch S3

On switch S3 (the router), these commands configure only the connections to switch S8:

Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# ip vrf v1
Router(config-vrf)# rd 100:1
Router(config-vrf)# route-target export 100:1
Router(config-vrf)# route-target import 100:1
Router(config-vrf)# exit

Router(config)# ip vrf v2
Router(config-vrf)# rd 100:2
Router(config-vrf)# route-target export 100:2
Router(config-vrf)# route-target import 100:2
Router(config-vrf)# exit

Router(config)# ip cef
Router(config)# interface Loopback1
Router(config-if)# ip vrf forwarding v1
Router(config-if)# ip address 3.3.1.3 255.255.255.0
Router(config-if)# exit

Router(config)# interface Loopback2
Router(config-if)# ip vrf forwarding v2
Router(config-if)# ip address 3.3.2.3 255.255.255.0
Router(config-if)# exit

Router(config)# interface Fast Ethernet3/0.10
Router(config-if)# encapsulation dot1q 10
Router(config-if)# ip vrf forwarding v1
Router(config-if)# ip address 38.0.0.3 255.255.255.0
Router(config-if)# exit

Router(config)# interface Fast Ethernet3/0.20
Router(config-if)# encapsulation dot1q 20
Router(config-if)# ip vrf forwarding v2
Router(config-if)# ip address 83.0.0.3 255.255.255.0
Router(config-if)# exit
Chapter 31  Configuring VRF-lite

Displaying VRF-lite Status

To display information about VRF-lite configuration and status, enter one of the following commands:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# show ip protocols vrf vrf-name</td>
<td>Displays routing protocol information associated with a VRF.</td>
</tr>
<tr>
<td>Switch# show ip route vrf vrf-name [connected] [protocol [as-number]] [list] [mobile] [odr] [profile] [static] [summary] [supernets-only]</td>
<td>Displays IP routing table information associated with a VRF.</td>
</tr>
<tr>
<td>Switch# show ip vrf [brief</td>
<td>detail</td>
</tr>
<tr>
<td>Switch# show ip mroute vrf instance-name &lt;a.b.c.d</td>
<td>active</td>
</tr>
</tbody>
</table>

This example shows how to display multicast route table information within a VRF instance:

Switch# show ip mroute vrf mcast2 234.34.10.18
IP Multicast Routing Table
Flags: D – Dense, S – Sparse, B – Bidir Group, s – SSM Group, C – Connected,
L – Local, P – Pruned, R – RP-bit set, F – Register flag,
T – SPT-bit set, J – Join SPT, M – MSDP created entry,
X – Proxy Join Timer Running, A – Candidate for MSDP Advertisement,
U – URD, I – Received Source Specific Host Report,
Z – Multicast Tunnel, z – MDT-data group sender,
Y – Joined MDT-data group, y – Sending to MDT-data group,
V – RD & Vector, v – Vector
Outgoing interface flags: H – Hardware switched, A – Assert winner
Timers: Uptime/Expires
Interface state: Interface, Next-Hop or VCD, State/Mode
(*, 234.34.10.18), 13:39:21/00:02:58, RP 1.1.1.1, flags: BC
Bidir-Upstream: Vlan134, RPF nbr 172.16.34.1
Outgoing interface list:
Vlan45, Forward/Sparse-Dense, 00:00:02/00:02:57, H
Vlan134, Bidir-Upstream/Sparse-Dense, 13:35:54/00:00:00, H

Note: For more information about the information in the displays, refer to the Cisco IOS Switching Services Command Reference at:
Configuring Flexible NetFlow

Flow is defined as a unique set of key fields attributes, which might include fields of packet, packet routing attributes, and input and output interface information. A NetFlow feature defines a flow as a sequence of packets that have the same values for the feature key fields. Flexible Netflow (FNF) allows you to collect and optionally export a flow record that specifies various flow attributes. Netflow collection supports IP, IPv6 and Layer 2 traffic.

Note
This chapter provides Catalyst 4500 switch specific information. For platform independent configuration and command information refer to the following links

Cisco IOS Flexible NetFlow Configuration Guide:

Cisco IOS Flexible NetFlow Command Reference:

The following items apply to the Catalyst 4500 series switch:

1. The Catalyst 4500 series switch supports ingress flow statistics collection for switched and routed packets; it does not support Flexible Netflow on egress traffic.

2. Supervisor Engine 7-E supports a 100,000 entry hardware flow table, which is shared across all the ports and VLANs on the switch. To limit the number of table entries on a given interface or VLAN, enter the cache entries number command.

The following example illustrates how to configure the flow monitor m1 cache to hold 1000 entries. With this configuration, interface gig 3/1 can create a maximum of 1000 flows and interface gig 3/2 can create a maximum of 1000 flows:

```
flow exporter e1
   ! exporter specifies where the flow records are send to
destination 20.1.20.4

flow record r1
   ! record specifies packet fields to collect
match ipv4 source address
match ipv4 destination address
collect counter bytes long
collect counter packets long
collect timestamp sysuptime first
collect timestamp sysuptime last
```
Chapter 32 Configuring Flexible NetFlow

! flow monitor m1
! monitor refers record configuration and optionally exporter
! configuration. It specifies the cache size i.e. how many unique flow
! records to collect
record r1
exporter e1
    cache timeout active 60
    cache timeout inactive 30
    cache entries 1000

! interface GigabitEthernet 3/1
    ! layer2-switched allows collection of flow records even when the packet is
    ! bridged
    ip flow monitor m1 layer2-switched input

! interface GigabitEthernet 3/2
    ip flow monitor m1 input

3. Flow collection is supported on multiple targets (Port, VLAN, per-port per-VLAN (FNF can be
   enabled on a specific VLAN on a given port)) and on a port-channel (FNF is configured on the
   port-channel interface, rather than individual member ports).
4. 64 unique flow record configurations are supported.
5. Flow QoS/UBRL and FNF cannot be configured on the same target. (For information on Flow-based
   QoS, see the section Flow-based QoS, page 33-10.)
6. 14,000 unique IPv6 addresses can be monitored.
7. On a given target, one monitor per traffic type is allowed. However, you can configure multiple
   monitors on the same target for different traffic types.
   For example, the following configuration is allowed:
   
   vlan config 10
   ip flow monitor <name> input
   ipv6 flow monitor <name> input

   The following configuration is not allowed:
   
   ! interface GigabitEthernet 3/1
   ip flow monitor m1 input
   ip flow monitor m2 input

8. On a given target monitoring Layer 2 and Layer 3, simultaneous traffic is not supported:
   
   interface channel-group 1
   datalink flow monitor m1 input
   ip flow monitor m2 input

9. Selection of Layer 2 and Layer 3 packet fields in a single flow record definition is not allowed.
   However, packet COS and Layer 3 packet field selection is allowed.
10. Only permanent and normal flow cache types are supported.
11. Supervisor 7-E does not support predefined records like traditional routers (record neflow ipv4
    original-input).
12. Interface option not supported with Cos, Tos, TTL or Packet length options.
13. The configuration of the flow exporter does not support the option output features.
14. Flow aging in flow cache is controlled through active and in-active timer configuration. The minimum for active and in-active aging timers is 5 seconds. The timers must be in units of 5 seconds.

*Note* Flows in the hardware table are deleted after 5 seconds of in-activity irrespective of the active or in-active timer configuration values. This allows you to create new hardware flows quickly.

15. First and Last-seen flow timestamp accuracy is within 3 seconds.

16. 2048 Flow monitors and records are supported.

- When TTL is configured as a flow field, the following values are reported for a given packet TTL value. *Table 32-1* lists the packet TTL and reported values.

### Configuring Flexible NetFlow

**Configuring Flow Monitor Cache Values**

Setting active cache timeout to a small value may cause the flows to be exported more frequently to the remote collector. This also causes software to delete flows from the local cache after exporting. So, cache statistics reported by switch may not display the actual flows being monitored.
Configuring Quality of Service

This chapter describes how to configure quality of service (QoS) with either automatic QoS (auto-QoS) commands or standard QoS commands on a switch running Supervisor Engine 7-E. It describes how to specify QoS configuration on different types of interfaces (access, Layer 2 trunk, Layer 3 routed, Etherchannel) as well as VLANs. It also describes how to specify different QoS configurations on different VLANs on a given interface (per-port per-VLAN QoS).

Supervisor Engine 7-E supports a QoS configuration model known as MQC (Modular QoS CLI). Please refer to the appropriate configuration section for the supervisor engine on which QoS will be configured. For more information about MQC, see the “Modular Quality of Service Command-Line Interface” section of the Cisco IOS Quality of Service Solutions Configuration Guide, Release 12.3.

This chapter consists of these sections:

- Overview of QoS on the Catalyst 4500 Series Switch, page 33-1
- Configuring QoS, page 33-11
- Configuring Auto-QoS, page 33-43

Note
For complete syntax and usage information for the switch commands used in this chapter, first look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it will be found in the larger Cisco IOS library. Refer to the Cisco IOS Command Reference and related publications at this location:

Overview of QoS on the Catalyst 4500 Series Switch

Typically, networks operate on a best-effort delivery basis, which means that all traffic has equal priority and an equal chance of being delivered in a timely manner. When congestion occurs, all traffic has an equal chance of being dropped.

QoS selects network traffic (both unicast and multicast), prioritizes it according to its relative importance, and uses congestion avoidance to provide priority-indexed treatment; QoS can also limit the bandwidth used by network traffic. QoS can make network performance more predictable and bandwidth utilization more effective.
Overview of QoS on the Catalyst 4500 Series Switch

This section contains the following subsections:

- Prioritization, page 33-2
- QoS Terminology, page 33-3
- Basic QoS Model, page 33-5
- Classification, page 33-6
- Policing and Marking, page 33-8
- Queueing and Scheduling, page 33-8
- Packet Modification, page 33-9
- Per Port Per VLAN QoS, page 33-10
- Flow-based QoS, page 33-10

Prioritization

QoS implementation is based on the DiffServ architecture. This architecture specifies that each packet is classified upon entry into the network. The classification is carried in the IP packet header, using 6 bits from the deprecated IP type of service (TOS) field to carry the classification (class) information. Classification can also be carried in the Layer 2 frame. These special bits in the Layer 2 frame or a Layer 3 packet are described here and shown in Figure 33-1:

- Prioritization values in Layer 2 frames:
  - Layer 2 Inter-Switch Link (ISL) frame headers have a 1-byte User field that carries an IEEE 802.1p class of service (CoS) value in the three least-significant bits. On interfaces configured as Layer 2 ISL trunks, all traffic is in ISL frames.
  - Layer 2 802.1Q frame headers have a 2-byte Tag Control Information field that carries the CoS value in the three most-significant bits, which are called the User Priority bits. On interfaces configured as Layer 2 802.1Q trunks, all traffic is in 802.1Q frames except for traffic in the native VLAN.
  - Other frame types cannot carry Layer 2 CoS values.
  - Layer 2 CoS values range from 0 for low priority to 7 for high priority.

- Prioritization bits in Layer 3 packets:
  - Layer 3 IP packets can carry either an IP precedence value or a Differentiated Services Code Point (DSCP) value. QoS supports the use of either value because DSCP values are backward-compatible with IP precedence values.
  - IP precedence values range from 0 to 7.
  - DSCP values range from 0 to 63.

IP precedence or DSCP

All switches and routers across the Internet rely on the class information to provide the same forwarding treatment to packets with the same class information and different treatment to packets with different class information. The class information in the packet can be assigned by end hosts or by switches or routers along the way, based on a configured policy, detailed examination of the packet, or both. Detailed examination of the packet is expected to happen closer to the edge of the network so that the core switches and routers are not overloaded.

Switches and routers along the path can use the class information to limit the amount of resources allocated per traffic class. The behavior of an individual device when handling traffic in the DiffServ architecture is called per-hop behavior. If all devices along a path provide a consistent per-hop behavior, you can construct an end-to-end QoS solution.

Implementing QoS in your network can be a simple or complex task and depends on the QoS features offered by your internetworking devices, the traffic types and patterns in your network, and the granularity of control you need over incoming and outgoing traffic.

QoS Terminology

The following terms are used when discussing QoS features:

- **Packets** carry traffic at Layer 3.
- **Frames** carry traffic at Layer 2. Layer 2 frames carry Layer 3 packets.
- **Labels** are prioritization values carried in Layer 3 packets and Layer 2 frames:
  - Layer 2 class of service (CoS) values, which range between zero for low priority and seven for high priority:
    - Layer 2 Inter-Switch Link (ISL) frame headers have a 1-byte User field that carries an IEEE 802.1p CoS value in the three least significant bits.
Layer 2 802.1Q frame headers have a 2-byte Tag Control Information field that carries the CoS value in the three most significant bits, which are called the User Priority bits.

Other frame types cannot carry Layer 2 CoS values.

**Note**

On interfaces configured as Layer 2 ISL trunks, all traffic is in ISL frames. On interfaces configured as Layer 2 802.1Q trunks, all traffic is in 802.1Q frames except for traffic in the native VLAN.

- Layer 3 IP precedence values—The IP version 4 specification defines the three most significant bits of the 1-byte ToS field as IP precedence. IP precedence values range between zero for low priority and seven for high priority.

- Layer 3 differentiated services code point (DSCP) values—The Internet Engineering Task Force (IETF) has defined the six most significant bits of the 1-byte IP ToS field as the DSCP. The per-hop behavior represented by a particular DSCP value is configurable. DSCP values range between 0 and 63.

**Note**

Layer 3 IP packets can carry either an IP precedence value or a DSCP value. QoS supports the use of either value, since DSCP values are backwards compatible with IP precedence values. See Table 33-1.

Overview of QoS on the Catalyst 4500 Series Switch

Classification is the selection of traffic to be marked.

Marking, according to RFC 2475, is the process of setting a Layer 3 DSCP value in a packet; in this publication, the definition of marking is extended to include setting Layer 2 CoS values.

Policing is limiting bandwidth used by a flow of traffic. Policing can mark or drop traffic.

**Basic QoS Model**

Figure 33-2 illustrates a high-level flow of Supervisor Engine 7-E QoS function.

**Figure 33-2 QoS Packet Processing**

Input → Packet Reception → Input QoS Classification → Input Policing and Marking → Forwarding Lookup

Output → Output QoS Classification → Output Policing and Marking → Active Queue Management → Port/Queue Scheduling (Sharing/Shaping) → Packet Transmission
The QoS model proceeds as follows:

- **Step 1** The incoming packet is classified (based on different packet fields, receive port and/or VLAN) to belong to a traffic class.
- **Step 2** Depending on the traffic class, the packet is rate-limited/policed and its priority is optionally marked (typically at the edge of the network) so that lower priority packets are dropped or marked with lower priority in the packet fields (DSCP and CoS).
- **Step 3** After the packet has been marked, it is looked up for forwarding. This action obtains the transmit port and VLAN to transmit the packet.
- **Step 4** The packet is classified in the output direction based on the transmit port and/or VLAN. The classification takes into account any marking of the packet by input QoS.
- **Step 5** Depending on the output classification, the packet is policed, its priority is optionally (re-)marked, and the transmit queue for the packet is determined depending on the traffic class.
- **Step 6** The transmit queue state is dynamically monitored via the AQM (Active Queue Management) algorithm and drop threshold configuration to determine whether the packet should be dropped or enqueued for transmission.
- **Step 7** If eligible for transmission, the packet is enqueued to a transmit queue. The transmit queue is selected based on output QoS classification criteria. The selected queue provides the desired behavior in terms of latency and bandwidth.

## Classification

Classification is the process of distinguishing one kind of traffic from another by examining the fields in the packet. Classification is enabled when a QoS policy-map is attached to an interface.

You specify which fields in the frame or packet that you want to use to classify incoming traffic.

For non-IP traffic, you have the following classification options:

- CoS value in the VLAN tag of the incoming frame is used to classify the packet.
- If the frame does not contain a CoS value, the port's default CoS value ("0") is used for the classification.
  
  Perform the classification based on a configured MAC ACL, which examines the fields in the Layer 2 header.

For IP traffic, you have the following classification options:

- IP DSCP or IP Precedence in the incoming packet is used for classification. DSCP values range from 0 to 63.
- Perform the classification based on a configured IP standard or extended ACL, which examines various fields in the IP header.

## Classification Based on QoS ACLs

A packet can be classified for QoS using multiple match criteria, and the classification can specify whether the packet should match all of the specified match criteria or at least one of the match criteria. To define a QoS classifier, you can provide the match criteria using the `match` statements in a class map.
In the 'match' statements, you can specify the fields in the packet to match on, or you can use IP standard or IP extended ACLs or MAC ACLs. For more information, see the “Classification Based on Class Maps and Policy Maps” section on page 33-7.

If the class map is configured to match all the match criteria, then a packet must satisfy all the match statements in the class map before the QoS action is taken. The QoS action for the packet is not taken if the packet does not match even one match criterion in the class map.

If the class map is configured to match at least one match criterion, then a packet must satisfy at least one of the match statements in the class map before the QoS action is taken. The QoS action for the packet is not taken if the packet does not match any match criteria in the class map.

**Note**

When you use the IP standard and IP extended ACLs, the permit and deny ACEs in the ACL have a slightly different meaning in the QoS context.

- If a packet encounters (and satisfies) an ACE with a “permit,” then the packet “matches” the match criterion in the QoS classification.
- If a packet encounters (and satisfies) an ACE with a “deny,” then the packet “does not match” the match criterion in the QoS classification.
- If no match with a permit action is encountered and all the ACEs have been examined, then the packet “does not match” the criterion in the QoS classification.

**Note**

When creating an access list, remember that, by default, the end of the access list contains an implicit deny statement for everything if it did not find a match before reaching the end.

After a traffic class has been defined with the class map, you can create a policy that defines the QoS actions for a traffic class. A policy might contain multiple classes with actions specified for each one of them. A policy might include commands to classify the class as a particular aggregate (for example, assign a DSCP) or rate limit the class. This policy is then attached to a particular port on which it becomes effective.

You implement IP ACLs to classify IP traffic by using the `access-list` global configuration command.

When a class-map is created with the `match-all` keyword, you cannot include both IP and MAC ACLs as match criteria.

### Classification Based on Class Maps and Policy Maps

A class map is a mechanism that you use to isolate and name a specific traffic flow (or class) from all other traffic. The class map defines the criterion used to match against a specific traffic flow to further classify it; the criteria can include matching the access group defined by the ACL or matching a specific list of DSCP, IP precedence, or L2 CoS values. If you have more than one type of traffic that you want to classify, you can create another class map and use a different name. After a packet is matched against the class-map criteria, you can specify the QoS actions via a policy map.

A policy map specifies the QoS actions for the traffic classes. Actions can include setting a specific CoS, DSCP, or IP precedence value; policing the traffic to a specified rate; specifying the traffic bandwidth limitations; shaping the traffic to a specified rate. Before a policy map can be effective, you must attach it to an interface.

You create a class map by using the `class-map` global configuration command. When you enter the `class-map` command, the switch enters the class-map configuration mode. In this mode, you define the match criteria for the traffic by using the `match` class-map configuration command.
You create and name a policy map by using the **policy-map** global configuration command. When you enter this command, the switch enters the policy-map configuration mode. In this mode, you specify the actions to take on a specific traffic class by using the set, **police**, **bandwidth**, or **shape** policy-map configuration and policy-map class configuration commands. To make the policy map effective, you attach it to an interface by using the **service-policy** interface configuration command.

The policy map can also contain commands that define the policer, (the bandwidth limitations of the traffic) and the action to take if the limits are exceeded. For more information, see the **“Policing and Marking” section on page 33-8.**

A policy map also has these characteristics:

- A policy map can contain up to 254 class statements.
- You can have different classes within a policy map.

### Policing and Marking

Policing involves creating a policer that specifies the bandwidth limits for the traffic. Packets that exceed the limits are *out of profile* or *nonconforming*. Each policer specifies the action to take for packets that are in or out of profile. These actions, carried out by the marker, include passing through the packet without modification, dropping the packet, or marking down the packet with a new DSCP value that is obtained from the configurable policed-DSCP map. You can configure policer within a policy map with the **police** command in policy-map class configuration mode. For information on the policed-DSCP map, see the **“Queueing and Scheduling” section on page 33-8.**

When configuring policing and policers, keep these items in mind:

- On Supervisor Engine 7-E, policers account only for the Layer 2 header length when calculating policer rates. In contrast, shapers account for header length as well as IPG in rate calculations.
- By default, no policers are configured.
- Only the average rate and committed burst parameters are configurable.
- After you configure the policy map and policing actions, attach the policy to an ingress or egress interface by using the **service-policy** interface configuration command.
- For 2 rate 3 colors (2r3c) policers, if no explicit violation-action is specified, the exceed-action is used as the violate-action.

### Queueing and Scheduling

Supervisor Engine 7-E hardware supports 8 transmit queues per port. Once the decision has been made to forward a packet out a port, the output QoS classification determines the transmit queue into which the packet must be enqueued.

Queues are assigned when an output policy attached to a port with one or more queuing related actions for one or more classes of traffic. Because there are only eight queues per port, there are at most eight traffic classes (including **class-default**, the reserved class) with queuing action(s). Classes of traffic that do not have any queuing action are referred to as non-queuing classes. Non-queuing class traffic use the queue corresponding to **class-default**.
Active Queue Management

Active queue management (AQM) is the pro-active approach of informing you about congestion before a buffer overflow occurs. AQM is done using Dynamic buffer limiting (DBL). DBL tracks the queue length for each traffic flow in the switch. When the queue length of a flow exceeds its limit, DBL drops packets.

Sharing Link Bandwidth Among Transmit Queues

The eight transmit queues for a transmit port share the available link bandwidth of that transmit port. You can set the link bandwidth to be shared differently among the transmit queues using the `bandwidth` command in the `policy-map class` configuration command in class mode.

With this command, you assign the minimum guaranteed bandwidth for each transmit queue. By default, all queues are scheduled in a round robin manner.

Strict Priority / Low Latency Queueing

On Supervisor Engine 7-E, you can only configure one transmit queue on a port as strict priority (termed Low Latency Queue, or LLQ).

LLQ provides strict-priority queuing for a traffic class. It enables delay-sensitive data, such as voice, to be sent before packets in other queues. The priority queue is serviced first until it is empty or until it falls under its shaped rate. Only one traffic stream can be destined for the priority queue per class-level policy. You enable the priority queue for a traffic class with the `priority policy-map class` configuration command in class mode.

Traffic Shaping

Traffic Shaping provides the ability to control the rate of outgoing traffic in order to make sure that the traffic conforms to the maximum rate of transmission contracted for it. Traffic that meets certain profile can be shaped to meet the downstream traffic rate requirements to handle any data rate mismatches.

Each transmit queue can be configured to transmit a maximum rate using the `shape` command in the `policy-map class` configuration command in class mode.

The configuration allows you to specify the maximum rate of traffic. Any traffic that exceeds the configured shape rate is queued and transmitted at the configured rate. If the burst of traffic exceeds the size of the queue, packets are dropped to maintain transmission at the configured shape rate.

Packet Modification

A packet is classified, policed, and queued to provide QoS. Packet modifications can occur during this process:

- For IP packets, classification involves assigning a DSCP to the packet. However, the packet is not modified at this stage; only an indication of the assigned DSCP is carried along. The reason for this is that QoS classification and ACL lookup occur in parallel, and it is possible that the ACL specifies that the packet should be denied and logged. In this situation, the packet is forwarded with its original DSCP to the CPU, where it is again processed through ACL software.
For non-IP packets, classification involves assigning an internal DSCP to the packet, but because there is no DSCP in the non-IP packet, no overwrite occurs. Instead, the internal DSCP is used both for queuing and scheduling decisions and for writing the CoS priority value in the tag if the packet is being transmitted on either an ISL or 802.1Q trunk port.

During policing, IP and non-IP packets can have another DSCP assigned to them (if they are out of profile and the policer specifies a markdown DSCP). Once again, the DSCP in the packet is not modified, but an indication of the marked-down value is carried along. For IP packets, the packet modification occurs at a later stage.

### Per Port Per VLAN QoS

Per-port per-VLAN QoS (PVQoS) offers differentiated quality-of-services to individual VLANs on a trunk port. It enables service providers to rate limit individual VLAN-based services on each trunk port to a business or a residence. In an enterprise Voice-over-IP environment, it can be used to rate limit voice VLAN even if an attacker impersonates an IP phone. A per-port per-VLAN service policy can be separately applied to either ingress or egress traffic. For configuration details see “Enabling Per-Port Per-VLAN QoS” section on page 33-33.

### Flow-based QoS

**Note**

Before reading this section, you should be familiar with implementing Flexible Netflow (Chapter 32, “Configuring Flexible NetFlow”) and QoS implementation in this chapter.

Flow based QoS enables microflow policing and marking capability to dynamically learn traffic flows. It also rate limits each unique flow to an individual rate. Flow based QoS is available on Supervisor Engine 7-E with the built-in NetFlow hardware support. It can be applied to ingress traffic on both switched and routed interfaces with flow masks defined using Flexible Netflow (FNF). It supports up to 100,000 individual flows in hardware and up to 512 unique policer configuration. Flow based QoS is typically used in environments where per-user, granular rate-limiting required. For example, per-flow outbound and inbound traffic rate might differ. Flow based QoS is also referred to as User Based Rate Limiting (UBRL).

A flow is defined as a stream of packets having the same properties as those defined by the key fields in the FNF flow record. A new flow is created when the value of data in packet’s key fields is unique with respect to the flow that already exist.

A flow based QoS policy is possesses one or more classmaps matching on a FNF flow record. Such a classmap must be configured as `match-all` to match all the match criteria specified in the classmap. When a flow based QoS policy is attached to a QoS target, ingress traffic on the target is first classified based on the classification rules specified in the class-map. If the classifier has FNF flow record, the key fields specified in the FNF flow record are applied on the classified traffic to create flows provided the flow does not already exist. The corresponding policy actions (policing and marking) are then applied to these individual flows. Flow-based policers (termed `microflow policers`) rate limit each unique flow. Flows are dynamically created and inactive flows are periodically aged out.

Flow based QoS policy can be attached to QoS targets such as port (P), vlan (V), per-port-per-vlan (PV), and EtherChannel but only in the ingress direction.

For details on how to enable FNF, refer to the “Applying Flow-based QoS Policy” section on page 33-39.
Configuring QoS

**Note**
HQoS is not supported on Supervisor Engine 7-E.

Topics include:
- MQC-based QoS Configuration, page 33-11
- Platform-supported Classification Criteria and QoS Features, page 33-11
- Platform Hardware Capabilities, page 33-12
- Prerequisites for Applying a QoS Service Policy, page 33-13
- Restrictions for Applying a QoS Service Policy, page 33-13
- Classification, page 33-13
- Policing, page 33-14
- Marking Network Traffic, page 33-16
- Shaping, Sharing (Bandwidth), Priority Queuing, Queue-limiting and DBL, page 33-23
- Enabling Per-Port Per-VLAN QoS, page 33-33
- Applying Flow-based QoS Policy, page 33-39

**MQC-based QoS Configuration**

Starting with Cisco IOS Release 15.0(1)XO, a switch using Supervisor Engine 7-E employs the MQC model of QoS. To apply QoS, you use the Modular QoS Command-Line Interface (MQC), which is a CLI structure that allows you to complete the following tasks:
- Specify the matching criteria used to define a traffic class.
- Create a traffic policy (policy map). The traffic policy defines the QoS policy actions to be taken for each traffic class.
- Apply the policy actions specified in the policy map to an interface, VLAN, or port and VLAN.

For more information about the MQC, see the “Modular Quality of Service Command-Line Interface” section of the *Cisco IOS Quality of Service Solutions Configuration Guide, Release 12.3*.

**Note**
The incoming traffic is considered trusted by default. Only when the trusted boundary feature is enabled on an interface can the port enter untrusted mode. In this mode, the switch marks the DSCP value of an IP packet and the CoS value of the VLAN tag on the Ethernet frame as “0”.

**Platform-supported Classification Criteria and QoS Features**

The following table provides a summary of various classification criteria and actions supported on the Supervisor Engine 7-E. For details, refer to the *Catalyst 4500 Series Switch Command Reference*. 
### Configuring QoS

#### Supported classification actions

<table>
<thead>
<tr>
<th>Supported classification actions</th>
<th>Descriptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>match access-group</td>
<td>Configures the match criteria for a class map on the basis of the specified ACL.</td>
</tr>
<tr>
<td>match any</td>
<td>Configures the match criteria for a class map to be successful match criteria for all packets.</td>
</tr>
<tr>
<td>match cos</td>
<td>Matches a packet based on a Layer 2 class of service (CoS) marking.</td>
</tr>
<tr>
<td>match ([ip]\ dscp)</td>
<td>Identifies a specific IP differentiated service code point (DSCP) value as a match criterion. Up to eight DSCP values can be included in one match statement.</td>
</tr>
<tr>
<td>match ([ip]\ precedence)</td>
<td>Identifies IP precedence values as match criteria.</td>
</tr>
<tr>
<td>match protocol</td>
<td>Configures the match criteria for a class map on the basis of the specified protocol.</td>
</tr>
<tr>
<td>match qos-group</td>
<td>Identifies a specific QoS group value as a match criterion. Applies only on the egress direction.</td>
</tr>
</tbody>
</table>

#### Supported QoS Features

<table>
<thead>
<tr>
<th>Supported QoS Features</th>
<th>Descriptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>police</td>
<td>Configures traffic policing.</td>
</tr>
<tr>
<td>police (percent)</td>
<td>Configures traffic policing on the basis of a percentage of bandwidth available on an interface.</td>
</tr>
<tr>
<td>police (two rates)</td>
<td>Configures traffic policing using two rates, the committed information rate (CIR) and the peak information rate (PIR).</td>
</tr>
<tr>
<td>set cos</td>
<td>Sets the Layer 2 class of service (CoS) value of an outgoing packet.</td>
</tr>
<tr>
<td>set dscp</td>
<td>Marks a packet by setting the differentiated services code point (DSCP) value in the type of service (ToS) byte of IPv4 or traffic class byte of IPv6 packet.</td>
</tr>
<tr>
<td>set precedence</td>
<td>Sets the precedence value in the packet header.</td>
</tr>
<tr>
<td>set qos-group</td>
<td>Sets a QoS group identifier (ID) that can be used later to classify packets.</td>
</tr>
<tr>
<td>table map support</td>
<td>Unconditional marking of one packet field based on another packet field.</td>
</tr>
<tr>
<td>priority</td>
<td>Gives priority to a class of traffic belonging to a policy map.</td>
</tr>
<tr>
<td>shape</td>
<td>Shapes traffic to the indicated bit rate according to the algorithm specified.</td>
</tr>
<tr>
<td>bandwidth</td>
<td>Provides a guaranteed minimum bandwidth to each of the eight queues.</td>
</tr>
<tr>
<td>dbl</td>
<td>Dynamic buffer limit.</td>
</tr>
<tr>
<td>queue-limit</td>
<td>Specifies the maximum number of packets a transmit queue can hold.</td>
</tr>
</tbody>
</table>

### Platform Hardware Capabilities

#### Qos Actions

<table>
<thead>
<tr>
<th>Qos Actions</th>
<th>Numbers of entries supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>Classification</td>
<td>64k input and 64k output classification entries are supported. A given policy can use at most 24k ACLs</td>
</tr>
<tr>
<td>Policing</td>
<td>16K policers are supported. Policers are allocated to given direction in blocks of 2k. For example, 2k policers can be used in for input and 14k policers can be used for output. Single rate policers uses one policer entry. Single Rate Three Color Marker (srTCM) (RFC 2697) and Two Rate Three Color Marker (trTCM) (RFC 2698) uses two policer entries</td>
</tr>
</tbody>
</table>
Chapter 33  Configuring Quality of Service

Configuring QoS

Prerequisites for Applying a QoS Service Policy

Unlike the Switch QoS model, there is no prerequisite for enabling QoS on various targets. Just the attachment of a service policy enables QoS and detachment of that policy disables QoS on that target.

Restrictions for Applying a QoS Service Policy

Traffic marking can be configured on an interface, a VLAN, or a port and VLAN. An interface can be a Layer 2 access port, a Layer 2 switch trunk, a Layer 3 routed port, or an EtherChannel. A policy is attached to a VLAN using the `vlan configuration` mode.

Attaching QoS service policy to VLANs and EtherChannel is described in the “Policy Associations” section on page 33-37.

Classification

Supervisor Engine 7-E supports classification of Layer 2, IP, IPv6 packets, and ARP packets marking performed on input can be matched in the output direction. The previous table lists the full set of capabilities. By default, the Supervisor Engine 7-E also supports classification resources sharing.

By default, when the same policy is attached to a port or a VLAN or on per-port per-vlan targets, ACL entries are shared on the Supervisor Engine 7-E. Even though CAM entries are shared, QoS actions is unique on each target.

For example:

```plaintext
class-map cl
  match ip dscp 50
Policy Map p1
  class cl
    police rate 1 m burst 200000
```

If policy-map p1 is applied to interfaces Gig 1/1 and Gig 1/2, 1 CAM entry is used (one ACE that matches IP packets), but 2 policers are allocated (one per target). So, all IP packets with dscp 50 are policed to 1 mbps on interface Gig 1/1 and packets on interface Gig 1/2 are policed to 1 mbps.

Note

With Cisco IOS Release 12.2(46)SG, you can issue the `match protocol arp` command. For details, see the Catalyst 4500 Series Switch Cisco IOS Command Reference.

Classification Statistics

Supervisor 7-E supports only packet based classification statistics.

<table>
<thead>
<tr>
<th>Qos Actions</th>
<th>Numbers of entries supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>Marking</td>
<td>Marking of CoS and DSCP/Precedence is supported through two marking tables, each capable of supporting 512 entries. There are separate tables for each direction.</td>
</tr>
<tr>
<td>Queuing</td>
<td>The queue size is Configurable with the maximum number of entries configurable per port depending on the chassis and line card type.</td>
</tr>
<tr>
<td>DBL</td>
<td>You can enable DBL action on all configured class-maps.</td>
</tr>
</tbody>
</table>
Supervisor 7-E supports TCAM resource sharing. When a policy-map is applied on multiple targets, the command `show policy-map interface` displays the aggregate classification statistics, not those specific to an interface.

**Note**

To obtain per interface policy-map stats, you should configure a unique policy-map name on each interface.

When a policy-map is attached to a port-channel member ports, classification statistics are not displayed.

### Configuring a Policy Map

You can attach only one policy map to an interface. Policy maps can contain one or more policy-map classes, each with different match criteria and actions.

Configure a separate policy-map class in the policy map for each type of traffic that an interface receives. Put all commands for each type of traffic in the same policy-map class. QoS does not attempt to apply commands from more than one policy-map class to matched traffic.

### Creating a Policy Map

To create a policy map, enter this command:

```
Switch(config)# [no] policy-map policy_name
```

This command creates a policy map with a user-specified name. Use the `no` keyword to delete the policy map.

### Attaching a Policy Map to an Interface

To create a policy map, enter this command:

```
Switch(config-if)# [no] service-policy input policy_map_name
```

This command attaches a policy map to the input direction of the interface. Use the `no` keyword to detach a policy map from an interface.

```
Switch(config-if)# end
```

Exits configuration mode.

```
Switch# show policy-map interface {vlan vlan_ID | {fastethernet | gigabitethernet} slot/interface}
```

Verifies the configuration.

### Policing

Supervisor Engine 7-E supports policers in the following operation modes:

- Single Rate Policer Two Color Marker
This kind of policer is configured with just the committed rate (CIR) and normal burst and it has only conform and exceed actions.

This is the only form supported in the Supervisor Engine II-Plus to V-10GE based systems.

- Single Rate Three Color Marker (srTCM) (RFC 2697)
- Two Rate Three Color Marker (trTCM) (RFC 2698)
- Color Blind Mode

Policing accuracy of 0.75% of configured policer rate.

Supervisor Engine 7-E supports 16384 (16 x 1024, 16K) single rate, single burst policers. 16K policers are organized as 8 banks of 2K policers. The policer banks are dynamically assigned (input or output policer bank) by the software depending on the QoS configuration. So, the 16K policers are dynamically partitioned by software as follows:

- 0 Input Policers and 16K Output Policers
- 2K Input Policers and 14K Output Policers
- 4K Input Policers and 12K Output Policers
- 6K Input Policers and 10K Output Policers
- 8K Input Policers and 8K Output Policers
- 10K Input Policers and 6K Output Policers
- 12K Input Policers and 4K Output Policers
- 14K Input Policers and 2K Output Policers
- 16K Input Policers and 0 Output Policers

These numbers represent individual policer entries in the hardware that support a single rate and burst parameter. Based on this, Supervisor Engines 7-E supports the following number of policers:

- 16K Single Rate Policer with Single Burst (Two Color Marker)
- 8K Single Rate Three Color Marker (srTCM)
- 8K Two Rate Three Color Marker (trTCM)

These policers are partitioned between Input and Output in chunks of 2K policer banks. The different types of policers can all co-exist in the system. However, a given type of policer (srTCM, trTCM etc.) is configurable as a block of 128 policers.

Note
Two policers are reserved for internal use.

How to Implement Policing

For details on how to implement the policing features on a Catalyst 4500 series switch, refer to the Cisco IOS documentation at the following link:

Platform Restrictions

Platform restrictions include the following:

- Multi-policer actions can be specified (setting CoS and IP DSCP is supported).
- When unconditional marking and policer based marking exists on the same field (cos or dscp or precedence), policer-based marking is preferred.
- If policer based service-policy is attached to both a port and a VLAN, port-based policing is preferred by default. To over-ride a specific VLAN policy on a given port, then you must configure a per-port per-vlan policy.
- You should not delete a port-channel with a per-port, per-VLAN QoS policy.

**Workaround:** Before deleting the port-channel, do the following:

1. Remove any per-port per-VLAN QoS policies, if any.
2. Remove the VLAN configuration on the port-channel with the `no vlan-range` command.

Marking Network Traffic

Marking network traffic allows you to set or modify the attributes of traffic (that is, packets) belonging to a specific class or category. When used in conjunction with network traffic classification, marking network traffic is the foundation for enabling many quality of service (QoS) features on your network. This module contains conceptual information and the configuration tasks for marking network traffic.

Information About Marking Network Traffic

To mark network traffic, you should understand the following concepts:

- “Purpose of Marking Network Traffic” section on page 33-16
- “Benefits of Marking Network Traffic” section on page 33-17
- “Two Methods for Marking Traffic Attributes” section on page 33-17

Purpose of Marking Network Traffic

Traffic marking is used to identify certain traffic types for unique handling, effectively partitioning network traffic into different categories.
After the network traffic is organized into classes by traffic classification, traffic marking allows you to mark (that is, set or change) a value (attribute) for the traffic belonging to a specific class. For instance, you may want to change the class of service (CoS) value from 2 to 1 in one class, or you may want to change the differentiated services code point (DSCP) value from 3 to 2 in another class. In this module, these values are referred to as attributes or marking fields.

Attributes that can be set and modified include the following:

- CoS value of a tagged Ethernet frame
- DSCP/Precedence value in the Type of Service (ToS) byte of IPv4.
- QoS group identifier (ID)
- DSCP /Precedence value in the traffic class byte of IPv6

**Benefits of Marking Network Traffic**

Traffic marking allows you to fine-tune the attributes for traffic on your network. This increased granularity helps isolate traffic that requires special handling, and thus, helps to achieve optimal application performance.

Traffic marking allows you to determine how traffic will be treated, based on how the attributes for the network traffic are set. It allows you to segment network traffic into multiple priority levels or classes of service based on those attributes, as follows:

- Traffic marking is often used to set the IP precedence or IP DSCP values for traffic entering a network. Networking devices within your network can then use the newly marked IP precedence values to determine how traffic should be treated. For example, voice traffic can be marked with a particular IP precedence or DSCP and strict priority can then be configured to put all packets of that marking into that queue. In this case, the marking was used to identify traffic for strict priority queue.
- Traffic marking can be used to identify traffic for any class-based QoS feature (any feature available in policy map class configuration mode, although some restrictions exist).
- Traffic marking can be used to assign traffic to a QoS group within a switch. The switch can use the QoS groups to determine how to prioritize traffic for transmission. The QoS group value is usually used for one of the two following reasons:
  - To leverage a large range of traffic classes. The QoS group value has 64 different individual markings, similar to DSCP.
  - If changing the Precedence or DSCP value is undesirable.

**Two Methods for Marking Traffic Attributes**

Note

This section describes Unconditional marking, which differs from Policer-based marking. Unconditional marking is based solely on classification.

**Method One: Unconditional Explicit Marking (using the set command)**

You specify the traffic attribute you want to change with a set command configured in a policy map. The following table lists the available set commands and the corresponding attribute. For details on the set command, refer to the *Catalyst 4500 Series Switch Command Reference.*
Configuring QoS

Chapter 33

Configuring Quality of Service

If you are using individual set commands, those set commands are specified in a policy map. The following is a sample of a policy map configured with one of the set commands listed in Table 33-2.

In this sample configuration, the set cos command has been configured in the policy map (policy1) to mark the CoS attribute:

```
enable
configure terminal
policy map p1
class class1
   set cos 3
end
```

For information on configuring a policy map, see the “Creating a Policy Map” section on page 33-14.

The final task is to attach the policy map to the interface. For information on attaching the policy map to the interface, see the “Attaching a Policy Map to an Interface” section on page 33-14.

Method Two: Unconditional Tablemap-based Marking

You can create a table map that can be used to mark traffic attributes. A table map is a kind of two-way conversion chart that lists and maps one traffic attribute to another. A table map supports a many-to-one type of conversion and mapping scheme. The table map establishes a to-from relationship for the traffic attributes and defines the change to be made to the attribute. That is, an attribute is set to one value that is taken from another value. The values are based on the specific attribute being changed. For instance, the Precedence attribute can be a number from 0 to 7, while the DSCP attribute can be a number from 0 to 63.

The following is a sample table map configuration:

```
table-map table-map1
   map from 0 to 1
   map from 2 to 3
exit
```

The following table lists the traffic attributes for which a to-from relationship can be established using the table map.

### Table 33-2  set Commands and Applicable Packet Types

<table>
<thead>
<tr>
<th>set Commands</th>
<th>Traffic Attribute</th>
<th>Packet Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>set cos</td>
<td>Layer 2 CoS value of the outgoing traffic</td>
<td>Ethernet IPv4, IPv6</td>
</tr>
<tr>
<td>set dscp</td>
<td>DSCP value in the ToS byte</td>
<td>IPv4, IPv6</td>
</tr>
<tr>
<td>set precedence</td>
<td>precedence value in the packet header</td>
<td>IPv4, IPv6</td>
</tr>
<tr>
<td>set qos-group</td>
<td>QoS group ID</td>
<td>Ethernet, IPv4, IPv6</td>
</tr>
</tbody>
</table>

### Table 33-3  Traffic Attributes for Which a To-From Relationship Can Be Established

<table>
<thead>
<tr>
<th>The “To” Attribute</th>
<th>The “From” Attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>Precedence</td>
<td>CoS, QoS group, DSCP, Precedence</td>
</tr>
<tr>
<td>DSCP</td>
<td>COS, QoS group, DSCP, Precedence</td>
</tr>
<tr>
<td>CoS</td>
<td>DSCP, QoS group, CoS, Precedence</td>
</tr>
</tbody>
</table>

The following is an example of a policy map (policy2) configured to use the table map (table-map1) created earlier:
Policy map policy
   class class-default
       set cos dscp table table-map
exit

In this example, a mapping relationship was created between the CoS attribute and the DSCP attribute as defined in the table map.

For information on configuring a policy map to use a table map, “Configuring a Policy Map” section on page 33-14.

The final task is to attach the policy map to the interface. For information on attaching the policy map to the interface, see the “Attaching a Policy Map to an Interface” section on page 33-14.

Marking Action Drivers

A marking action can be triggered based on one of the two QoS processing steps.

Classification based: In this case, all the traffic matching a class is marked using either explicit or tablemap based method. This method is referred to as unconditional marking.

Policer result-based: In this case, a class of traffic is marked differently based on the policer result (conform/exceed/violate) applicable to that packet. This method is referred to as conditional marking.

Traffic Marking Procedure Flowchart

Figure 33-3 illustrates the order of the procedures for configuring traffic marking.
Restrictions for Marking Network Traffic

The following restrictions apply to packet marking actions:

- QoS-group can be marked only in the input direction and can only support unconditional explicit marking.
- Only explicit marking is supported for policer-based marking.

Multi-attribute Marking Support

 Supervisor Engine 7-E can mark more than one QoS attribute of a packet matching a class of traffic. For example, DSCP, CoS, and QoS-group can all be set together, using either explicit or tablemap-based marking.
Note
When using unconditional explicit marking of multiple fields or policer-based multi-field, multi-region (conform/exceed/violate) marking the number of tablemaps that can be setup in TOS or COS marking tables will be less than the maximum supported.

Hardware Capabilities for Marking

Supervisor Engine 7-E provides a 256 entry marking action table where each entry specifies the type of marking actions on COS and DSCP/precedence fields as well as policer action to transmit/markdown/drop a packet. One such table is supported for each direction, input and output. This table is used for both unconditional marking as well as policer-based marking. It can be used to support 256 unique marking actions or 64 unique policer-based actions or a combinations of the two.

For each of the marking fields (COS and DSCP), the Supervisor Engine 7-E provides 512 entry marking tables for each direction. These are similar to mapping tables available on supervisor engines that support the switch QoS model. However, these provide an ability to have multiple unique mapping tables that are setup by the user.

For example, the TOS marking table provides marking of DSCP/Precedence fields and can be used as one of the following:

- 8 different tablemaps with each mapping the 64 DSCP or qos-group values to another DSCP
- 64 (32) different tablemaps with each one mapping 8 CoS (16 CoS and CFi) values to DSCP in input (output) direction
- a combination of above two types of tablemaps

Similar mappings are available on the 512 entry COS marking table.

Configuring the Policy Map Marking Action

This section describes how to establish unconditional marking action for network traffic.

As a prerequisites, create class map (ipp5) and a policy map. (Refer to the “Configuring a Policy Map” section on page 33-14).

Note
On the Supervisor Engine 7-E, the marking action command options have been extended (refer to Table 33-2 on page 33-18 and Table 33-3 on page 33-18).

Configuring Tablemap-based Unconditional Marking

To configure table-map based unconditional marking, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# table-map name</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config-tablemap)# map from from_value to to_value</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config-tablemap)# exit</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch(config)# policy-map name</td>
</tr>
</tbody>
</table>
## Chapter 33 Configuring Quality of Service

### Configuring QoS

The following example shows how to enable marking action using table-map.

```
Switch(config)# table-map dscp2Cos
Switch(config-tablemap)# map from 8 to 1
Switch(config-tablemap)# exit
Switch(config)# policy-map pl
Switch(config-pmap)# class ipp5
Switch(config-pmap-c)# set cos dscp table dscp2Cos
Switch(config-pmap-c)# end
Switch# show policy-map pl
Policy Map pl
  Class ipp5
    set cos dscp table dscp2Qos
```

```
Switch# show table-map dscp2Cos
Table Map dscp2Cos
  from 8 to 1
  default copy
```

### Configuring Policer Result-based Conditional Marking

To configure policer result-based conditional marking, setup a single rate or dual rate policer. Refer to the “How to Implement Policing” section on page 33-15.

This example shows how to configure a two rate three-color policer with explicit actions for each policer region:

```
Switch# configure terminal
Switch(config-pmap-c)# policer cir percent 20 pir percent 30
Switch(config-pmap-c-policer)# conform-action set-cos-transmit 3 set-dscp-transmit 10
Switch(config-pmap-c-policer)# exceed-action set-cos-transmit 4 set-dscp-transmit 20
Switch(config-pmap-c-policer)# violate action drop
Switch# show policy-map pl
Policy Map polic
  Class ipp5
    police cir percent 20 pir percent 30
      conform-action set-cos-transmit 3
      conform-action set-dscp-transmit af11
      exceed-action set-cos-transmit 4
      exceed-action set-dscp-transmit af22
      violate-action drop
```

### Marking Statistics

The marking statistics indicate the number of packets that are marked.

---

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 6</strong></td>
<td>Switch(config-p)# class name</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>Switch(config-p-c)# set cos</td>
</tr>
<tr>
<td></td>
<td>dscp</td>
</tr>
<tr>
<td></td>
<td>prec cos</td>
</tr>
<tr>
<td></td>
<td>dscp</td>
</tr>
<tr>
<td></td>
<td>prec</td>
</tr>
<tr>
<td></td>
<td>qos-group</td>
</tr>
<tr>
<td></td>
<td>[table name]</td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>Switch(config-p-c)# end</td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>Switch# show policy-map name</td>
</tr>
<tr>
<td><strong>Step 10</strong></td>
<td>Switch# show table-map name</td>
</tr>
</tbody>
</table>
For unconditional marking, the *classification entry* points to an entry in the marking action table that in turn indicates the fields in the packet that are marked. Therefore, the classification statistics by itself indicates the unconditional marking statistics.

For a conditional marking using policer, provided the policer is a packet rate policer, you cannot determine the number packets marked because the policer only provides byte statistics for different policing results.

**Shaping, Sharing (Bandwidth), Priority Queuing, Queue-limiting and DBL**

Supervisor Engine 7-E supports the Classification-based (class-based) mode for transmit queue selection. In this mode, the transmit queue selection is based on the Output QoS classification lookup.

---

**Note**

Only output (egress) queuing is supported.

---

The Supervisor Engine 7-E hardware supports 8 transmit queues per port. Once the forwarding decision has been made to forward a packet out a port, the output QoS classification determines the transmit queue into which the packet needs to be enqueued.

By default, in Supervisor Engine 7-E, without any service policies associated with a port, there are two queues (a control packet queue and a default queue) with no guarantee as to the bandwidth or kind of prioritization. The only exception is that system generated control packets are enqueued into control packet queue so that control traffic receives some minimum link bandwidth.

Queues are assigned when an output policy attached to a port with one or more queuing related actions for one or more classes of traffic. Because there are only eight queues per port, there can be at most eight classes of traffic (including the reserved class, class-default) with queuing action(s). Classes of traffic that do not have any queuing action are referred to as *non-queuing* classes. Non-queuing class traffic ends up using the queue corresponding to class-class-default.

When a queuing policy (a policy with queuing action) is attached, the control packet queue is deleted and the control packets are enqueued into respective queue per their classification. Note that this differs from the way control-traffic was prioritized in the Catalyst 4924, Catalyst 4948, Catalyst 4948-10GE, and the Supervisor Engines II+, II+10GE, VI, V, and V-10GE. On these platforms, by default, control traffic was guaranteed 25 per cent of the link bandwidth whether QoS was configured. If this same behavior is required on Supervisor Engine 7-E, an egress QoS class must be configured to match IP Precedence 6 and 7 traffic, and a bandwidth guarantee must be configured.

Dynamic resizing of queues (queue limit class-map action) is supported through the use of the `queue-limit` command. Based on the chassis and line card type, all eight queues on a port are configured with equal queue size.

**Shaping**

Shaping enables you to delay out-of-profile packets in queues so that they conform to a specified profile. Shaping is distinct from policing. Policing drops packets that exceed a configured threshold, whereas shaping *buffers* packets so that traffic remains within a given threshold. Shaping offers greater *smoothness* in handling traffic than policing. You enable average-rate traffic shaping on a traffic class with the `policy-map` class configuration command.

Supervisor Engine 7-E supports a range of 32kbps to 10 gbps for shaping, with a precision of approximately +/- 0.75 per cent.
When a queuing class is configured without any explicit shape configuration, the queue shape is set to the link rate.

To configure class-level shaping in a service policy, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# policy-map policy-map-name</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config-pmap)# class class-name</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config-pmap-class)# shape average (cir-bps [optional_postfix]</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch(config-pmap-class)# exit</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Switch(config-pmap)# exit</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>Switch(config)# interface interface-id</td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>Switch(config)# service-policy output policy-map-name</td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td><strong>Step 10</strong></td>
<td>Switch# show policy-map [policy-map-name [class class-map-name]] or Switch# show policy-map interface interface-id</td>
</tr>
<tr>
<td><strong>Step 11</strong></td>
<td>Switch# copy running-config startup-config</td>
</tr>
</tbody>
</table>

To delete an existing policy map, use the **no policy-map policy-map-name** global configuration command. To delete an existing class, use the **no class class-name policy-map** configuration command. To disable the average-rate traffic shaping, use the **no shape average policy-map** class configuration command.

This example shows how to configure class-level, average-rate shaping. It limits traffic class class1 to a data transmission rate of 256 kbps:

```
Switch# configure terminal
Switch(config)# policy-map policy1
```
This example shows how to configure class-level, average shape percentage to 32% of link bandwidth for queuing-class traffic:

```
Switch# configure terminal
Switch(config)# policy-map queuing-policy
Switch(config-pmap)# class queuing-class
Switch(config-pmap-c)# shape average percent 32
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
Switch(config)# interface gigabitethernet1/1
Switch(config-if)# service-policy output queuing-policy1
Switch(config-if)# end
Switch#
```

```
Switch# show policy-map queuing-policy
Policy Map queuing-policy
Class queuing-class
  Average Rate Traffic Shaping
  cir 32%
```

Sharing(bandwidth)

The bandwidth assigned to a class of traffic is the minimum bandwidth that is guaranteed to the class during congestion. Transmit Queue Sharing is the process by which output link bandwidth is shared among multiple queues of a given port.

Supervisor Engine 7-E supports a range of 32 kbps to 10 gbps for sharing, with a precision of approximately +/- 0.75 per cent. The sum of configured bandwidth across all queuing classes should not exceed the link bandwidth.

To configure class-level bandwidth action in a service policy, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# policy-map policy-map-name</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config-pmap)# class class-name</td>
</tr>
</tbody>
</table>
Configuring QoS

Chapter 33  Configuring Quality of Service

To delete an existing policy map, use the `no policy-map policy-map-name` global configuration command. To delete an existing class, use the `no class class-name policy-map` configuration command. To return to the default bandwidth, use the `no bandwidth policy-map` class configuration command.

This example shows how to create a class-level policy map called `policy11` for three classes called `prec1`, `prec2`, and `prec3`. In the policy for these classes, 30 percent of the available bandwidth is assigned to the queue for the first class, 20 percent is assigned to the queue for the second class, and 10 percent is assigned to the queue for the third class.

```
Switch # configure terminal
Switch(config)# policy-map policy11
Switch(config-pmap)# class prec1
Switch(config-pmap-c)# bandwidth percent 30
Switch(config-pmap-c)# exit
Switch(config-pmap)# class prec2
Switch(config-pmap-c)# bandwidth percent 20
Switch(config-pmap-c)# exit
Switch(config-pmap)# class prec3
Switch(config-pmap-c)# bandwidth percent 10
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
Switch(config)# interface gigabitethernet1/1
Switch(config-if)# service-policy output policy11
```
Switch(config-if)# end
Switch #

Switch# show policy-map policy11
Policy Map policy11
  Class prec1
    bandwidth percent 30
  Class prec2
    bandwidth percent 20
  Class prec3
    bandwidth percent 10

This example shows how to create a class-level policy map called policy11 for three classes called prec1, prec2, and prec3. In the policy for these classes, 300 mbps of the available bandwidth is assigned to the queue for the first class, 200 mbps is assigned to the queue for the second class, and 100 mbps is assigned to the queue for the third class.

Switch # configure terminal
Switch(config)# policy-map policy11
Switch(config-pmap)# class prec1
Switch(config-pmap-c)# bandwidth 300000
Switch(config-pmap-c)# exit
Switch(config-pmap)# class prec2
Switch(config-pmap-c)# bandwidth 200000
Switch(config-pmap-c)# exit
Switch(config-pmap)# class prec3
Switch(config-pmap-c)# bandwidth 100000
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
Switch(config)# interface gigabitethernet1/1
Switch(config-if)# service-policy output policy11
Switch(config-if)# end
Switch #

Switch# show policy-map policy11
Policy Map policy11
  Class prec1
    bandwidth 300000 (kbps)
  Class prec2
    bandwidth 200000 (kbps)
  Class prec3
    bandwidth 100000 (kbps)

When a queuing class is configured without any explicit share/bandwidth configuration, because the queue is not guaranteed any minimum bandwidth, the hardware queue is programmed to get a share of any unallocated bandwidth on the port as shown in the following example.

If there is no bandwidth remaining for the new queue or if the unallocated bandwidth is not sufficient to meet the minimum configurable rate (32kbps) for all queues which do not have any explicit share/bandwidth configuration, then the policy association is rejected.

For example, if there are two queues as given below

```
policy-map queue-policy
  class q1
    bandwidth percent 10
  class q2
    bandwidth percent 20
```

then the bandwidth allocation for the queues is as follows

```
q1 = 10%
q2 = 20%
```
class-default = 70%

Similarly, when another queuing class (say q3) is added without any explicit bandwidth (say, just a shape command), then the bandwidth allocation is

\[
q1 = 10%
q2 = 20%
q3 = \min(35\%, \text{q3-shape-rate})
class-default = \max(35\%, (100 - (q1 + q2 + q3)))
\]

### Priority queuing

On Supervisor Engine 7-E only one transmit queue on a port can be configured as *strict priority* (termed Low Latency Queue, or LLQ).

LLQ provides strict-priority queuing for a traffic class. It enables delay-sensitive data, such as voice, to be sent before packets in other queues. The priority queue is serviced first until it is empty or until it is under its shape rate. Only one traffic stream can be destined for the priority queue per class-level policy. You enable the priority queue for a traffic class with the *priority policy-map class* configuration command at the class mode.

A LLQ can starve other queues unless it is rate limited. Supervisor Engine 7-E does not support *conditional policing* where a 2-parameter policer (rate, burst) becomes effective when the queue is congested (based on queue length). However, it supports application of an unconditional policer to rate limit packets enqueued to the strict priority queue.

When a priority queue is configured on one class of a policy map, only *bandwidth remaining* is accepted on other classes, guaranteeing a minimum bandwidth for other classes from the remaining bandwidth of what is left after using the priority queue. When a priority queue is configured with a policer, then either *bandwidth* or *bandwidth remaining* is accepted on other classes.

**Note**

Use *bandwidth* or *bandwidth remaining* on all classes. You cannot apply *bandwidth* on one class and *bandwidth remaining* on another class within a policy map.

To enable class-level priority queuing in a service policy, follow these steps:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong>&lt;br&gt;Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong>&lt;br&gt;Switch(config)# policy-map policy-map-name</td>
<td>Creates a policy map by entering the policy-map name, and enter policy-map configuration mode. By default, no policy maps are defined.</td>
</tr>
<tr>
<td><strong>Step 3</strong>&lt;br&gt;Switch(config-pmap)# class class-name</td>
<td>Specifies the name of the class whose traffic policy you want to create or change, and enter policy-map class configuration mode. By default, no traffic classes are defined.</td>
</tr>
<tr>
<td><strong>Step 4</strong>&lt;br&gt;Switch(config-pmap-class)# priority</td>
<td>Enables the strict-priority queue, and give priority to a class of traffic. By default, strict-priority queuing is disabled.</td>
</tr>
<tr>
<td><strong>Step 5</strong>&lt;br&gt;Switch(config-pmap-class)# exit</td>
<td>Returns to policy-map configuration mode.</td>
</tr>
<tr>
<td><strong>Step 6</strong>&lt;br&gt;Switch(config-pmap)# exit</td>
<td>Returns to global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 7</strong>&lt;br&gt;Switch(config)# interface interface-id</td>
<td>Specifies a physical port and enter interface configuration mode.</td>
</tr>
</tbody>
</table>
To delete an existing policy map, use the `no policy-map policy-map-name` global configuration command. To disable the priority queue, use the `no priority policy-map class` configuration command.

This example shows how to configure a class-level policy called `policy1`. Class 1 is configured as the priority queue, which is serviced first until it is empty.

```
Switch# configure terminal
Switch(config)# policy-map policy1
Switch(config-pmap)# class class1
Switch(config-pmap-c)# priority
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
Switch(config)# interface gigabitethernet1/1
Switch(config-if)# service-policy output policy1
Switch(config-if)# end
Switch #
```

### Queue-limiting

When a class-based queue is instantiated on a physical port, it is set up with a default size. This size represents the number of queue entries in which packets belonging to that class of traffic can be queued. The scheduler moves packets from the queue that are ready for transmission, based on the queue shape, bandwidth, and priority configuration.

The queue-limit provides the maximum number of packets that can be in the queue at any given time. When the queue is full, an attempt to enqueue any further packets results in tail drop. However, if dynamic buffer limiting (DBL) is enabled on the queue, packets get a probabilistic drop based on the DBL algorithm, even when the queue is not full.

The `queue-limit` command can be configured under a class only when queue scheduling, such as bandwidth, shape, or priority is already configured. The only exception to this requirement is the support of the stand-alone `queue-limit` command on the class-default class.
Queue Memory

The number of queue entries that can be allocated has to be a multiple of 8 and can range from 16 to 8184. When a class-based queue is instantiated on a physical port, it is given a default number of entries. This default queue size is based on the number of slots in the chassis and the number of front-panel ports in each slot.

Supervisor Engine 7-E has 1M (1,048,576) queue entries of which the system sets aside 100K (102,400) queue entries in a free reserve pool. Of the remaining queue entries, the drop port is provided 8184 entries, 24576 entries for recirculation ports and the CPU ports are assigned 8656 entries. The remaining entries are divided equally among the slots in the chassis. In a redundant chassis the two supervisor slots are treated as one for the purpose of this entries distribution. Within each slot the number of queue entries are equally divided among the front-panel ports present on the line card in that slot.

When the user configuration for queue entries on an interface exceeds its dedicated quota, the system attempts to satisfy the configuration from the free reserve pool. The entries from the free reserve pool are allocated to interfaces on a first-come first-served basis.

Service Policy Association

When a QoS service-policy with queuing actions is configured, but no explicit queue-limit command is attached in the egress direction on a physical interface, each of the class-based queues gets the same number of queue entries from within the dedicated quota for that physical port. When a queue is explicitly given a size using the queue-limit command, the switch tries to allocate all the entries from within the dedicated quota for the interface. If the required number of entries is greater than the dedicated quota for the interface, the switch tries to allocate the entries from the free reserve.

The queue entries associated with a queue always have to be consecutive. This requirement can result in fragmentation of the 512K of the queue entries that are shared across the switch. For example, an interface may not have enough entries for a queue in its dedicated quota and thus have to use the free reserve to set up that queue. In this case, the queue entries from the dedicated quota remain unused because they cannot be shared with any other port or slot.

When the QoS service-policy associated with an interface is removed, any queue entries taken from the free reserve are returned to the free reserve pool. The interface queuing configuration reverts to two queues — class-default and the control-packet queue with default shape, bandwidth, and size. The control-packet queue is set up with size 16 whereas the default queue is set up with the maximum size possible based on the dedicated quota for that interface.

Queue Allocation Failure

The switch might not be able to satisfy the explicit queue size required on one or more queues on an interface because of fragmentation of queue memory or lack of enough free reserve entries. In this scenario, the switch logs an error message to notify you of the failure. The QoS service-policy is left configured on the interface. You can fix the error by removing the QoS service-policy and examining the current usage of the queue entries from the free reserve by other ports on the switch.

To configure class-level queue-limit in a service policy, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# policy-map policy-map-name</td>
</tr>
</tbody>
</table>
To remove the explicit queue size use the `no queue-limit` command under the class in a policy-map.

This example shows how to configure a class-based queue with an explicit `queue-limit` command. It limits traffic class `class1` to a queue of size 4048:

```plaintext
Switch# configure terminal
Switch(config)# policy-map policy1
Switch(config-pmap)# class class1
Switch(config-pmap-c)# shape average 256000
Switch(config-pmap-c)# queue-limit 4048
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
Switch(config)# interface gigabitethernet1/1
Switch(config-if)# service-policy output policy1
Switch(config-if)# end
Switch#
```

To verify the configuration:

```plaintext
Switch# show policy-map policy1
Switch# show policy-map interface gigabitethernet1/1
```

```
Policy Map policy1
class class1
```

```
Policy Map policy1
```

```
```

(Optional) Saves your entries in the configuration file.

```
Switch# copy running-config startup-config
```
Active Queue Management (AQM) via Dynamic Buffer Limiting (DBL)

AQM provides buffering control of traffic flows prior to queuing a packet into a transmit queue of a port. This is of significant interest in a shared memory switch, ensuring that certain flows do not hog the switch packet memory.

Note
Supervisor Engine 7-E supports active switch buffer management via DBL.

Except for the default class of traffic (class class-default), you can configure DBL action only when at least one of the other queuing action is configured.

To configure class-level dbl action along with shaping in a service policy, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# <code>configure terminal</code> Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# <code>policy-map</code> <em>policy-map-name</em> Creates a policy map by entering the policy-map name, and enter policy-map configuration mode. By default, no policy maps are defined.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config-pmap)# <code>class</code> <em>class-name</em> Specifies the name of the class whose traffic policy you want to create or change, and enter policy-map class configuration mode. By default, no traffic classes are defined.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config-pmap-class)# <code>shape</code> <em>average cir-bps</em> Enables average-rate traffic shaping. Specify the committed information rate, the bit rate that traffic is shaped to, in bps. The range is 32000 to 10000000000 bps. By default, average-rate traffic shaping is disabled.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch(config-pmap-class)# <code>dbl</code> Enables DBL on the queue associated with this class of traffic</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Switch(config-pmap-class)# <code>exit</code> Returns to policy-map configuration mode.</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>Switch(config-pmap)# <code>exit</code> Returns to global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>Switch(config)# <code>interface</code> <em>interface-id</em> Specifies a physical port and enter interface configuration mode.</td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>Switch(config-interface)# <code>service-policy output</code> <em>policy-map-name</em> Specifies the policy-map name, and apply it a physical interface.</td>
</tr>
<tr>
<td><strong>Step 10</strong></td>
<td>Switch(config-interface)# <code>end</code> Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 11</strong></td>
<td>Switch# <code>show policy-map</code> <em>policy-map-name</em> <code>[class class-map-name]</code></td>
</tr>
<tr>
<td><strong>Step 12</strong></td>
<td>Switch# <code>copy running-config startup-config</code> (Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>
To delete an existing policy map, use the `no policy-map policy-map-name` global configuration command. To delete an existing class, use the `no class class-name policy-map` configuration command. To disable DBL on the associated queue, use the `no dbl policy-map class` configuration command.

The following example shows how to configure class-level, DBL action along with average-rate shaping. It enables DBL on the queue associated with traffic-class `class1`.

```
Switch# configure terminal
Switch(config)# policy-map policy1
Switch(config-pmap)# class class1
Switch(config-pmap-c)# shape average 256000
Switch(config-pmap-c)# db1
Switch(config-pmap-c)# exit
Switch(config)# interface gigabitethernet1/1
Switch(config-if)# service-policy output policy1
Switch(config-if)# end
Switch#

Switch# show policy-map policy1
Policy Map policy1
  Class class1
    shape average 256000
dbl
```

**Transmit Queue Statistics**

Transmit queue statistics are visible by entering the `show policy-map interface` command:

```
Switch# show policy-map interface gigabitEthernet 1/1
GigabitEthernet1/1

Service-policy output: queuing-policy

  Class-map: queuing-class (match-all)
    1833956 packets
    Match: cos 1
    Queueing
      (total drops) 1006239
      (bytes output) 56284756
      shape (average) cir 320000000, bc 1280000, be 1280000
      target shape rate 320000000

  Class-map: class-default (match-any)
    1 packets
    Match: any
      (total drops) 0
      (bytes output) 2104
```

**Enabling Per-Port Per-VLAN QoS**

The per-port per-VLAN QoS feature enables you to specify different QoS configurations on different VLANs on a given interface. Typically, you use this feature on trunk or voice VLANs (Cisco IP Phone) ports, as they belong to multiple VLANs.
To configure per-port per-VLAN QoS, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch(config)# interface (fastethernet</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config-if)# vlan-range vlan_range</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config-if-vlan-range)# service-policy (input</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config-if-vlan-range)# exit</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch(config-if)# end</td>
</tr>
<tr>
<td>Step 6</td>
<td>Switch# show policy-map interface interface_name</td>
</tr>
</tbody>
</table>

**Example 1**

Figure 33-4 displays a sample topology for configuring PVQoS. The trunk port gi3/1 is comprised of multiple VLANs (101 and 102). Within a port, you can create your own service policy per VLAN. This policy, performed in hardware, might consist of ingress and egress Policing or giving precedence to voice packet over data.

![Per-Port Per-VLAN Topology](image)

The following configuration file shows how to perform ingress and egress policing per VLAN using the policy-map P31_QOS applied to port Gigabit Ethernet 3/1:

```plaintext
ip access-list 101 permit ip host 1.2.2.2 any
ip access-list 103 permit ip any any

Class-map match-all RT
  match ip access-group 101

Class-map Match all PD
```
match ip access-group 103

Policy-map P31_QoS
Class RT
Police 200m 16k conform transmit exceed drop
Class PD
Police 100m 16k conform transmit exceed drop

Interface Gigabit 3/1
Switchport
Switchport trunk encapsulation dot1q
Switchport trunk allowed vlan 101-102
Vlan range 101
Service-policy input P31_QoS
Service-policy output P31_QoS
Vlan range 102
Service-policy input P32_QoS
Service-policy output P32_QoS

Example 2

Let us assume that interface Gigabit Ethernet 6/1 is a trunk port and belongs to VLANs 20, 300-301, and 400. The following example shows how to apply policy-map p1 for traffic in VLANs 20 and 400 and policy map p2 to traffic in VLANs 300 through 301:

Switch# configure terminal
Switch(config)# interface gigabitethernet 6/1
Switch(config-if)# vlan-range 20,400
Switch(config-if-vlan-range)# service-policy input p1
Switch(config-if-vlan-range)# exit
Switch(config-if)# vlan-range 300-301
Switch(config-if-vlan-range)# service-policy output p2
Switch(config-if-vlan-range)# end
Switch#

Example 3

The following command shows how to display policy-map statistics on VLAN 20 configured on Gigabit Ethernet interface 6/1:

Switch# show policy-map interface gigabitEthernet 6/1 vlan 20

GigabitEthernet6/1 vlan 20

Service-policy input: p1

Class-map: c1 (match-all)
  0 packets
  Match: cos 1
  Match: access-group 100
  police:
    cir 100000000 bps, bc 3125000 bytes
    conformed 0 bytes; actions:
    transmit
    exceeded 0 bytes; actions:
    drop
    conformed 0000 bps, exceed 0000 bps

Class-map: class-default (match-any)
  0 packets
  Match: any
Example 4

The following command shows how to display policy-map statistics on all VLANs configured on Gigabit Ethernet interface 6/1:

Switch# show policy-map interface gigabitEthernet 6/1

GigabitEthernet6/1 vlan 20

Service-policy input: p1

Class-map: c1 (match-all)
0 packets
Match: cos  1
Match: access-group 100
police:
cir 100000000 bps, bc 3125000 bytes
conformed 0 bytes; actions:
transmit
exceeded 0 bytes; actions:
drop
conformed 0000 bps, exceed 0000 bps

Class-map: class-default (match-any)
0 packets
Match: any

GigabitEthernet6/1 vlan 300

Service-policy output: p2

Class-map: c1 (match-all)
0 packets
Match: cos  1
Match: access-group 100
QoS Set
dscp 50
police:
cir 200000000 bps, bc 6250000 bytes
conformed 0 bytes; actions:
transmit
exceeded 0 bytes; actions:
drop
conformed 0000 bps, exceed 0000 bps

Class-map: class-default (match-any)
0 packets
Match: any

GigabitEthernet6/1 vlan 301

Service-policy output: p2

Class-map: c1 (match-all)
0 packets
Match: cos  1
Match: access-group 100
QoS Set
dscp 50
police:
cir 200000000 bps, bc 6250000 bytes
conformed 0 bytes; actions:
transmit
exceeded 0 bytes; actions:
Policy Associations

Supervisor Engine 7-E supports per-port, per-VLAN policies. The associated policies are attached to the interface, VLAN, and a specific VLAN on a given port, respectively.

A policy can be associated with a variety of objects. The following table lists the objects and the actions allowed.

<table>
<thead>
<tr>
<th>Object</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Physical port</td>
<td>Policing, marking, and queuing</td>
</tr>
<tr>
<td>VLAN</td>
<td>Policing and marking</td>
</tr>
<tr>
<td>Port and VLAN (PV)</td>
<td>Policing and marking</td>
</tr>
<tr>
<td>EtherChannel</td>
<td>Policing and marking</td>
</tr>
<tr>
<td>EtherChannel member port</td>
<td>Queuing</td>
</tr>
</tbody>
</table>

Qos Action Restrictions

- The same actions cannot be performed multiple times in a given direction on different targets. In other words, it is not possible to police the packets both on port and VLAN in the input direction. However, the user can police on the input port and on the output VLAN.
- Queuing actions are only allowed in the egress direction and only on the physical port.
- Percentage-based actions like policer cannot be configured on a VLAN, Port and VLAN (PV) and EtherChannel.
- Port channel or VLAN configuration can only have a policing or a marking action, not a queueing action.

Qos Policy priorities

- If a policy on a port and a VLAN are configured with conflicting actions (such as policing or marking actions on both a port and VLAN), the port policy is picked.
- If policy on a VLAN on a given port must be over-written, the user can configure PV policy.

Qos Policy merging

Applicable policies are applied to a given packet in given direction. For example, if you configure egress VLAN-based police and marking, followed by selective queuing on the port, then actions from both policies will be applied for this packet.

The following policy-map configuration restrictions are imposed on an EtherChannel:
- only policing and marking actions are supported at the EtherChannel level
- only queuing actions are supported at the physical member port level

A packet can be marked (dscp or cos fields) by the EtherChannel policy. If the physical member port policy uses a classification based on dscp or cos fields, it must be based on the marked (modified) value. To ensure proper operation, the following restriction is placed on the EtherChannel.
The classification criteria for the policy-map on the physical member ports has to be based only on one type of field:

- dscp
- precedence
- cos
- any non marking field (no dscp or cos based classification)

Classification criteria for the policy-map on the physical member ports cannot be based on a combination of fields. This restriction ensures that if the EtherChannel policy is marking down dscp or cos, the marked (modified) value-based classification can be implemented in hardware.

**Note**

Classification criteria for the policy-map on the physical member ports cannot be modified to add a new type of field.

Auto-QoS is not supported on EtherChannel or its member ports. A physical port configured with Auto-QoS is not allowed to become a member of a physical port.

**Software QoS**

At the highest level, there are two types of locally sourced traffic (such as control protocol packets, pings, and telnets) from the switch: high priority traffic (typically the control protocol packets like OSPF Hellos and STP) and low priority packets (all other packet types).

The QoS treatment for locally-sourced packets differs for the two types.

Supervisor Engine 7-E provides a way to apply QoS to packets processed in the software path. The packets that get this QoS treatment in software can be classified into two types: software switched packets and software generated packets.

On reception, software switched packets are sent to the CPU that in turn sends them out of another interface. For such packets, input software QoS provides input marking and output software QoS provides output marking and queue selection.

The software generated packets are the ones locally sourced by the switch. The type of output software QoS processing applied to these packets is the same as the one applied to software switched packets. The only difference in the two is that the software switched packets take input marking of the packet into account for output classification purpose.

**High Priority Packets**

High priority packets are marked as one of the following:

- internally with PAK_PRIORITY
- with IP Precedence of 6 (for IP packets)
- with CoS of 6 (for VLAN Tagged packets)

These packets behave as follows:

- They are not dropped because of any policing, AQM, drop thresholds (or any feature that can drop a packet) configured as per the egress service policy. However, they might be dropped because of hardware resource constraints (packet buffers, queue full, etc.).
- They are classified and marked as per the marking configuration of the egress service policy that could be a port or VLAN (refer to the “Policy Associations” section on page 33-37).
Configuring QoS

These high priority packets are enqueued to queue on the egress port based on the following criteria:

- If there is no egress queuing policy on the port, the packet is queued to a control packet queue that is setup separately from the default queue and has 5 percent of the link bandwidth reserved for it.
- If there is an egress queuing policy on the port, the queue is selected based on the classification criteria applicable to the packet.

Low Priority Packets

Packets that are not considered high priority (as described previously) are considered unimportant. These include locally sourced pings, telnet, and other protocol packets. They undergo the same treatment as any other packet that is transiting the given transmit port including egress classification, marking and queuing.

Applying Flow-based QoS Policy

Flow based QoS enables microflow policing and marking capability to dynamically learn traffic flows, It also rate limits each unique flow to an individual rate. Flow based QoS is available on Supervisor Engine 7-E with the built-in NetFlow hardware support.

For more overview information, refer to the “Flow-based QoS” section on page 33-10.

The following steps show how to apply Flow based QoS policy to QoS targets:

1. Create a FNF flow record by specifying the key fields that identify unique flows. You can use any FNF flow records that are associated with the FNF monitor.
2. Create a class-map to specify the set of match criteria. Include the FNF flow record from Step 1 in the class-map match criteria using the `match flow record` command. Then, configure the class-map to match all the match criteria with `class-map match-all class_name`.
3. Create a policy-map and define actions associated with class-map from Step 2.
4. Attach the policy to one or more QoS targets.

Examples

The following examples illustrate how to configure Flow based QoS policy and apply microflow policers on individual flows.

Example 1

This example assumes there are multiple users (identified by source IP address) on the subnet 192.168.10.*. The configuration below shows how to configure a flow based QoS policy that uses micro policing to limit the per-user traffic with the source address in the range of 192.168.10.*. The microflow policer is configured with a CIR of 1Mbps, “conform action” as transmit, and “exceed action” as drop.

1. Define an ACL to match traffic with specified source address.

```
Switch(config)# ip access-list extended UserGroup1
Switch(config-ext-nacl)# permit ip 192.168.10.0 0.0.0.255 any
Switch(config-ext-nacl)# exit
Switch(config)#
```
Step 2: Define a flow record to create flows with source address as key.

Switch(config)# flow record r1
Switch(config-flow-record)# match ipv4 source address
Switch(config-flow-record)# exit
Switch(config)#

Step 3: Configure classmap to match on the UserGroup1 and specify flow record definition for flow creation.

Switch(config)# class-map match-all c1
Switch(config-cmap)# match access-group name UserGroup1
Switch(config-cmap)# match flow record r1
Switch(config-cmap)# exit
Switch(config)#

Step 4: Configure flow based QoS policy-map with microflow policing action for the matching traffic.

Switch(config)# policy-map p1
Switch(config-pmap)# class c1
Switch(config-pmap-c)# police cir 1m
Switch(config-pmap-c-police)# conform-action transmit
Switch(config-pmap-c-police)# exceed-action drop
Switch(config-pmap-c-police)# exit
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit

Step 5: Attach flow QoS policy to the interface.

Switch(config)# interface gigabitEthernet3/1
Switch(config-if)# service-policy input p1
Switch(config-if)#

Use the show commands (described in the policy and marking sections of this chapter) to display the policy-map configuration and interface specific policy-map statistics.

Example 2.

This example assumes there are multiple users (identified by source IP address) on subnets 192.168.10.* and 172.20.55.*. The first requirement is to police with a CIR of 500Kbps and a PIR of 650Kbps on any TCP traffic originating from 192 network to any destination at any given time. The exceed action keyword marks down the dscp value to 32. The second requirement is to police per-user traffic originating from 172 network to CIR of 2Mbps and unconditionally mark the traffic with dscp 10.

Step 1: Define an ACL to match traffic with specified source address.

Switch(config)# ip access-list extended UserGroup1
Switch(config-ext-nacl)# permit ip 192.168.10.0 0.0.0.255 any
Switch(config-ext-nacl)# exit
Switch(config)# ip access-list extended UserGroup2
Switch(config-ext-nacl)# permit ip 172.20.55.0 0.0.0.255 any
Switch(config-ext-nacl)# exit
Switch(config)#

Step 2: Define a flow record to create flows with source address as key.

Switch(config)# flow record r1
Switch(config-flow-record)# match ipv4 source address
Switch(config-flow-record)# match ipv4 destination address
Switch(config-flow-record)# match transport tcp source-port
Switch(config-flow-record)# match transport tcp destination-port
Switch(config-flow-record)# exit
Switch(config)# flow record r2
Switch(config-flow-record)# match ipv4 source address
Switch(config-flow-record)# exit
Switch(config)#

**Step 3: Configure classmap to match on the UserGroup1 and specify flow record definition for flow creation.**

Switch(config)# class-map match-all c1
Switch(config-cmap)# match access-group name UserGroup1
Switch(config-cmap)# match flow record r1
Switch(config-cmap)# exit
Switch(config)# class-map match-all c2
Switch(config-cmap)# match access-group name UserGroup2
Switch(config-cmap)# match flow record r2
Switch(config-cmap)# exit
Switch(config)#

**Step 4: Configure flow based QoS policy-map with microflow policing action for the matching traffic.**

Switch(config)# policy-map p1
Switch(config-pmap)# class c1
Switch(config-pmap-c)# police cir 500k pir 650k
Switch(config-pmap-c-police)# conform-action transmit
Switch(config-pmap-c-police)# exceed-action set-dscp-transmit 32
Switch(config-pmap-c-police)# violate-action drop
Switch(config-pmap-c-police)# exit
Switch(config-pmap-c)# exit
Switch(config-pmap-c)# exit
Switch(config-pmap-c)# exit
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
Switch(config-pmap)# class c2
Switch(config-pmap-c)# set dscp 10
Switch(config-pmap-c)# police cir 2m
Switch(config-pmap-c-police)# conform-action transmit
Switch(config-pmap-c-police)# exceed-action drop
Switch(config-pmap-c-police)# exit
Switch(config-pmap-c)# exit
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit

**Step 5: Attach flow QoS policy to the interface.**

Switch(config)# interface gigabitEthernet3/1
Switch(config-if)# service-policy input p1
Switch(config-if)# exit

Use the show commands described in the QoS section to display the policy-map configuration and interface specific policy-map statistics.

**Example 3**

Assume that there are two active flows on FastEthernet interface 6/1:

<table>
<thead>
<tr>
<th>SrcIp</th>
<th>DstIp</th>
<th>IPProt</th>
<th>SrcL4Port</th>
<th>DstL4Port</th>
</tr>
</thead>
<tbody>
<tr>
<td>192.168.10.10</td>
<td>192.168.20.20</td>
<td>20</td>
<td>6789</td>
<td>81</td>
</tr>
<tr>
<td>192.168.10.10</td>
<td>192.168.20.20</td>
<td>20</td>
<td>6789</td>
<td>21</td>
</tr>
</tbody>
</table>

With the following configuration, each flow is policed to 1000000 bps with an allowed 9000 burst value.

Switch(config)# flow record r1
Switch(config-flow-record)# match ipv4 source address
Switch(config-flow-record)# match ipv4 destination address
Switch(config-flow-record)# match transport tcp source-port
Switch(config-flow-record)# match transport tcp destination-port
Switch(config-flow-record)# match transport udp source-port
Switch(config-flow-record)# match transport udp destination-port
Switch(config-flow-record)# exit
Switch(config)# class-map match-all c1
Switch(config-cmap)# match flow record r1
Switch(config-cmap)# exit
Switch(config)# policy-map p1
Switch(config-pmap)# class c1
Switch(config-pmap-c)# police 1000000 9000
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
Switch(config)# interface fastEthernet 6/1
Switch(config-if)# service-policy input p1
Switch(config-if)# end

Configuration Guidelines

The general guidelines for creating, configuring, modifying, deleting a flow based QoS policy and attaching (and detaching) a flow based QoS policy to a supported target is the same as described in the QoS section. The following description and restriction applies to Flow based QoS policy:

- A classmap can have multiple match statements but only one FNF flow record can be specified in a class-map.
- A flow record must have at least one key field before it can be used in a classmap. Non-key fields can be present in the flow record. However, all the non-key fields are ignored by microflow QoS. Only key-fields are used for flow creation.
- If a FNF flow record is referenced in any class-map, the flow record cannot be modified. Remove the flow record from all classmaps before modifying it.
- A classmap with a FNF flow record must be configured as **match-all**; traffic hitting the class-map must satisfy all match criteria in the class-map.
- A policy can contain multiple classes and each class-map may contain the same or different FNF flow record.
- Flow based QoS policy and FNF monitor both cannot be applied on the same target at the same time.
- When the interface mode changes from switchport to routed port and vice versa, any Flow QoS policy attached to the port remains applied after the mode change.
- There are 3 types of FNF flow records: ipv4, ipv6, and datalink. The datalink flow record is mutually exclusive with the ipv4 and ipv6 flow records; a classmap with the datalink flow record cannot co-exist with classmap having a ipv4 or ipv6 flow record in the same policy and vice-versa.
- Classmap class-default is not editable; it cannot be configured with the match flow record. Instead, you can configure the policy with a class-map that uses a match any filter and the flow record.
- Traffic is classified in the same order in which class-map is defined in a policy. Hence, if a FNF flow record is the only match statement in a class-map, the classifier matches all packets of the type identified by the flow record. This means that any subsequent class-map in the same policy matching on the same traffic type will be redundant and will never be hit.
- Policers associated with classmap having flow record are called **microflow policers**. The CIR and PIR rates for microflow policers cannot be configured using the percent keyword.
• Flow records within the same policy must include appropriate key fields to ensure flows created from different classmaps are unique and distinct. Otherwise, the resulting flows from different classmap cannot be distinguished. In such cases, policy actions corresponding to the classmap which created the first flow in hardware will apply and results will not be always as expected.
• Flows from traffic received on different QoS targets are distinct even if the same policy is applied to those targets.
• A flow is aged out if the it is inactive for more than 5 seconds; there is no traffic matching the flow for a period longer than 5 sec.
• When a flow is aged out, policer state information associated with the flow is also deleted. When a new flow is created, the policer instance for the flow is re-initialized.
• Flows created by flow based QoS policy exist in hardware only and cannot be exported (as with FNF monitor).
• Per-flow statistics are not available for flows created by flow based QoS policy.
• Class-map statistics indicate the number of packets matching the classifier. It does not represent individual flow stats.
• Policer statistics show the aggregate policer statistics of individual flow.
• Information about the flows created by hardware are not available and not displayed in the show commands associated with QoS policy-map. Only class-map and policer statistics are displayed in the output of the `show policy-map` commands.

## Configuring Auto-QoS

**Note** Auto-QoS cannot be applied to EtherChannel interfaces or VLANs.

Unlike auto-QoS on Supervisor Engines II-Plus to V-10GE, auto-QoS on Supervisor Engine 7-E employs the MQC model. This means that instead of using certain global configurations (like qos and qos db), auto-QoS applied to any interface on a switch with Supervisor Engine 7-E configures several global class-maps and policy-maps.

Auto-QoS matches traffic and assigns each matched packet to qos-groups. This allows the output policy map to put specific qos-groups into specific queues, including into the priority queue.

We need QoS in both directions, both on inbound and outbound. Inbound, the switch port needs to trust the DSCP in the packet (done by default). Outbound, the switch port needs to give voice packets "front of line" priority. If voice is delayed too long by waiting behind other packets in the outbound queue, the end host drops the packet because it arrives outside of the receive window for that packet.

**Note** QoS is a two way street. So, it might work in one direction and not in the other.

There are three policy maps that must be defined (2 inbound and 1 outbound):

- One that trusts COS inbound
- One that trusts DSCP inbound
- A generalized one that puts voice packets in the priority queue outbound

You only want to use the following:
• Trust DSCP policy-map inbound

• General policy-map for voice outbound

On all ports. The problem with COS is that packets on the native VLAN is marked as zero.

The class maps used for input matching are as follows:

! for control traffic between the phone and the callmanager
! and phone to phone [Bearer] DSCP matching
! Note: Control traffic can be either AF31 or CS3. So, we match to both values and assign
! them to different qos-groups when matching DSCP and only a single group when matching COS.

class-map match-all AutoQos-VoIP-Control-Dscp26
  match dscp af31

class-map match-all AutoQos-VoIP-Control-Dscp24
  match dscp cs3

class-map match-all AutoQos-VoIP-Bearer-Dscp
  match dscp ef

! for control traffic and phone to phone [Bearer] COS matching
! Note: Both CS3 and AF31 control traffic maps to COS 3

class-map match-all AutoQos-VoIP-Control-Cos
  match cos 3

class-map match-all AutoQos-VoIP-Bearer-Cos
  match cos 5

The class maps are intended to identify control and data (bearer) voice traffic for either an Layer 2 or
Layer 3 interface.

The 2 Input policy maps, one for matching DSCP and one for matching COS, where DSCP and COS are
set to an assigned qos-group used in outbound policy-maps are as follows:

policy-map AutoQos-VoIP-Input-Dscp-Policy
  class AutoQos-VoIP-Bearer-Dscp
    set qos-group 46

class AutoQos-VoIP-Control-Dscp26
  set qos-group 26

class AutoQos-VoIP-Control-Dscp24
  set qos-group 24

! Note: For COS, Control traffic only has a single COS value of 3 (versus DSCP which has 2
! values to match). So, only 2 class-maps instead of 3 like above.

policy-map AutoQos-VoIP-Input-Cos-Policy
  class AutoQos-VoIP-Bearer-Cos
    set qos-group 46

class AutoQos-VoIP-Control-Cos
  set qos-group 24

The class maps used for Output matching are as follows:

! Since we assigned matched traffic to a qos-group on input,
! we only need to match the qos-group on output

! Note: Any other traffic not matched on input and assigned to a qos-group goes into the
class-default queue

! for control traffic (CS3 and AF31)

class-map match-all AutoQos-VoIP-Control-QosGroup24
  match qos-group 24

class-map match-all AutoQos-VoIP-Control-QosGroup26
  match qos-group 26
! For phone to phone (Bearer EF) traffic

class-map match-all AutoQos-VoIP-Bearer-QosGroup
  match qos-group 46

The output policy maps are as follows:

! Each class maps to a different qos-group with
! class-default taking any traffic not assigned to a qos-group

! Note: in this example, the outbound policy map drops voice packets when the priority queue exceeds 33% utilization of the link. Each deployment must establish their own upper bound for voice packets.

policy-map AutoQos-VoIP-Output-Policy
  class AutoQos-VoIP-Bearer-QosGroup
  set dscp ef
  set cos 5
  priority
  police cir percent 33
  class AutoQos-VoIP-Control-QosGroup26
  set dscp af31
  set cos 3
  bandwidth remaining percent 5
  class AutoQos-VoIP-Control-QosGroup24
  set dscp cs3
  set cos 3
  bandwidth remaining percent 5
  class class-default
  dbl

Note: There are no default cos-to-dscp or dscp-to-cos mappings on the. Values must be explicitly set for trunks.

The three policy maps are defined as follows:

- policy-map AutoQos-VoIP-Input-Dscp-Policy
  This policy map is applied as an input service policy on an Layer 3 interface (such as an uplink connection to a neighboring switch) when auto-QoS is configured on the port.

- policy-map AutoQos-VoIP-Input-Cos-Policy
  This policy map is applied as an input service policy on an Layer 2 interface that could be either an uplink connection or a port hooked to a Cisco IP Phone.

- policy-map AutoQos-VoIP-Output-Policy
  This policy map is applied as an output policy for any port on which auto-QoS is configured, establishing policy governing egress traffic on the port based on whether it is voice data or control traffic.

The purpose of the input policy maps is to identify voice data or control traffic and mark it as such as it traverses the switch. The output policy map matches the packets on the marking occurring on ingress and then applies egress parameters such as bandwidth, policing and/or priority queuing.

The invocation of auto-QoS on a switch employing Supervisor Engine 7-E uses the same config commands used on Supervisor Engines II-Plus to V-10GE.

For switch-to-switch connections, the [no] auto qos voip trust command is used to apply an input and output service policy on the interface:

  service-policy input AutoQos-VoIP-Input-Cos-Policy

OR
service-policy input AutoQos-VoIP-Input-Dscp-Policy

AND

service-policy output AutoQos-VoIP-Output-Policy

The selection of the input policy depends on whether the port is Layer 2 or Layer 3. For Layer 2, the policy trusts the Cos setting in the received packets. For Layer 3 ports, it relies on the DSCP value contained in the packets.

For phone connected ports, the [no] auto qos voice cisco-phone command is used to apply the following service policy to the port:

qos trust device cisco-phone

service-policy input AutoQos-VoIP-Input-Cos-Policy

AND

service-policy output AutoQos-VoIP-Output-Policy

It establishes a trusted boundary that recognizes Cisco IP Phones and trusts the Cos setting of the packets from the phone. If a Cisco IP Phone is not detected, the Cos field is ignored and the packets are not classified as voice traffic. Upon detecting a Cisco phone, the ingress packets are marked based on the Cos value in the packets. This marking is used on egress for proper traffic classification and handling.
Configuring Voice Interfaces

This chapter describes how to configure voice interfaces for the Catalyst 4500 series switches.

This chapter includes the following major sections:

- About Voice Interfaces, page 34-1
- Configuring a Port to Connect to a Cisco 7960 IP Phone, page 34-3
- Configuring Voice Ports for Voice and Data Traffic, page 34-3
- Overriding the CoS Priority of Incoming Frames, page 34-5
- Configuring Power, page 34-5

**Note**

For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

**About Voice Interfaces**

Catalyst 4500 series switches can connect to a Cisco 7960 IP phone and carry IP voice traffic. If necessary, the switch can supply electrical power to the circuit connecting it to the Cisco 7960 IP phone.

Because the sound quality of an IP telephone call can deteriorate if the data is unevenly sent, the switch uses quality of service (QoS) based on IEEE 802.1p class of service (CoS). QoS uses classification and scheduling to transmit network traffic from the switch in a predictable manner. See Chapter 33, “Configuring Quality of Service,” for more information on QoS.

You can configure the Cisco 7960 IP phone to forward traffic with an 802.1p priority. Use the CLI to configure a Catalyst 4500 series switch to honor or ignore a traffic priority assigned by a Cisco 7960 IP phone.
About Voice Interfaces

The Cisco 7960 IP phone contains an integrated three-port 10/100 switch. The ports are dedicated connections as described below:

- Port 1 connects to the Catalyst 4500 series switch or other device that supports voice-over-IP.
- Port 2 is an internal 10/100 interface that carries the phone traffic.
- Port 3 connects to a PC or other device.

Figure 34-1 shows one way to configure a Cisco 7960 IP phone.

Figure 34-1 Cisco 7960 IP Phone Connected to a Catalyst 4500 Series Switch

Cisco IP Phone Voice Traffic

You can configure an access port with an attached Cisco IP Phone to use one VLAN for voice traffic and another VLAN for data traffic from a device attached to the phone. You can configure access ports on the switch to send Cisco Discovery Protocol (CDP) packets that instruct an attached phone to send voice traffic to the switch in any of these ways:

- In the voice VLAN tagged with a Layer 2 CoS priority value
- In the access VLAN tagged with a Layer 2 CoS priority value
- In the access VLAN, untagged (no Layer 2 CoS priority value)

Note In all configurations, the voice traffic carries a Layer 3 IP precedence value (the default is 5 for voice traffic and 3 for voice control traffic).

Cisco IP Phone Data Traffic

The switch can also process tagged data traffic (traffic in IEEE 802.1Q or IEEE 802.1p frame types) from the device attached to the access port on the Cisco IP Phone (see Figure 34-1). You can configure Layer 2 access ports on the switch to send CDP packets that instruct the attached phone to configure the phone access port in one of these modes:

- In trusted mode, all traffic received through the access port on the Cisco IP Phone passes through the phone unchanged.
- In untrusted mode, all traffic in IEEE 802.1Q or IEEE 802.1p frames received through the access port on the Cisco IP Phone receive a configured Layer 2 CoS value. The default Layer 2 CoS value is 0. Untrusted mode is the default.

Note Untagged traffic from the device attached to the Cisco IP Phone passes through the phone unchanged, regardless of the trust state of the access port on the phone.
Configuring a Port to Connect to a Cisco 7960 IP Phone

Because a Cisco 7960 IP phone also supports connection to a PC or another device, an interface connecting a Catalyst 4500 series switch to a Cisco 7960 IP phone can carry a mix of voice and data traffic.

There are three configurations for a port connected to a Cisco 7960 IP phone:

- All traffic is transmitted according to the default CoS priority of the port. This is the default.
- Voice traffic is given a higher priority by the phone (CoS priority is always 5), and all traffic is in the same VLAN.
- Voice and data traffic are carried on separate VLANs.

To configure a port to instruct the phone to give voice traffic a higher priority and to forward all traffic through the 802.1Q native VLAN, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# interface {fastethernet</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config-if)# switchport voice vlan dot1p</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config-if)# end</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch# show interface {fastethernet</td>
</tr>
</tbody>
</table>

Configuring Voice Ports for Voice and Data Traffic

Because voice and data traffic can travel through the same voice port, you should specify a different VLAN for each type of traffic. You can configure a switch port to forward voice and data traffic on different VLANs.

Note

For information on configuring sticky port security on voice VLANs, see the Configuring Port Security on Voice Ports, page 38-22.

Note

For information on using 802.1X with voice VLANs, see the “Using 802.1X with Voice VLAN Ports” section on page 36-19.

To configure a port to receive voice and data traffic from a Cisco IP Phone on different VLANs, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# interface {fastethernet</td>
</tr>
</tbody>
</table>
Chapter 34    Configuring Voice Interfaces

In the following example, VLAN 1 carries data traffic, and VLAN 2 carries voice traffic. In this
collection, you must connect all Cisco IP phones and other voice-related devices to switch ports that
belong to VLAN 2.

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fastEthernet 3/1
Switch(config-if)# switchport mode access
Switch(config-if)# switchport voice vlan vlan_num
Switch(config-if)# switchport access vlan data_vlan_num
Switch(config-if)# end
Switch# show interface (fastethernet | gigabitethernet) slot/port switchport

<table>
<thead>
<tr>
<th>Step</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 3</td>
<td>Switch(config-if)# switchport mode access</td>
<td>Configures the interface as an access port. The voice VLAN is active only on access ports.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config-if)# switchport voice vlan vlan_num</td>
<td>Instructs the Cisco IP phone to forward all voice traffic through a specified VLAN. The Cisco IP phone forwards the traffic with an 802.1p priority of 5.</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch(config-if)# switchport access vlan data_vlan_num</td>
<td>Configures the access VLAN (the data VLAN) on the port</td>
</tr>
<tr>
<td>Step 6</td>
<td>Switch(config-if)# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Step 7</td>
<td>Switch# show interface (fastethernet</td>
<td>gigabitethernet) slot/port switchport</td>
</tr>
</tbody>
</table>
Overriding the CoS Priority of Incoming Frames

A PC or another data device can connect to a Cisco 7960 IP phone port. The PC can generate packets with an assigned CoS value. You can also use the switch CLI to override the priority of frames arriving on the phone port from connected devices, and you can set the phone port to accept (trust) the priority of frames arriving on the port.

To override the CoS priority setting received from the non-voice port on the Cisco 7960 IP phone, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# interface (fastethernet</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config-if)# [no] qos trust extend cos 3</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config-if)# end</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch# show interface (fastethernet</td>
</tr>
</tbody>
</table>

Configuring Power

The Catalyst 4500 series switch senses if it is connected to a Cisco 7960 IP phone. The Catalyst 4500 series switch can supply Power over Ethernet (PoE) to the Cisco 7960 IP phone if there is no power on the circuit. The Cisco 7960 IP phone can also be connected to an AC power source and supply its own power to the voice circuit. If there is power on the circuit, the switch does not supply it.

You can configure the switch not to supply power to the Cisco 7960 IP phone and to disable the detection mechanism. For information on the CLI commands that you can use to supply PoE to a Cisco 7960 IP phone, see Chapter 11, “Configuring Power over Ethernet.”
Configuring Private VLANs

This chapter describes how to implement private VLANs (PVLANs) on Catalyst 4500 series switches. It also provides restrictions, procedures, and configuration examples.

This chapter includes the following major sections:

- Command List, page 35-1
- Private VLANs, page 35-2
- Configuring PVLANs, page 35-10

Note

For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

Command List

This table lists the commands most commonly used with PVLANs.

<table>
<thead>
<tr>

<td></td>
</tr>
<tr>
<td>add secondary_vlan_list</td>
<td></td>
<td></td>
</tr>
<tr>
<td>remove secondary_vlan_list</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Private VLANs

The private VLAN feature addresses two problems that service providers face when using VLANs:

- The switch supports up to 1005 active VLANs. If a service provider assigns one VLAN per customer, this limits the numbers of customers the service provider can support.
- To enable IP routing, each VLAN is assigned a subnet address space or a block of addresses, which can result in wasting the unused IP addresses, and cause IP address management problems.

<table>

| switchport private-vlan trunk native vlan vlan_id | Configures a VLAN to which untagged packets (as in IEEE 802.1Q tagging) are assigned on a PVLAN trunk port. | Configuring a Layer 2 Interface as an Isolated PVLAN Trunk Port, page 35-18
Using private VLANs provides scalability and IP address management benefits for service providers and Layer 2 security for customers. Private VLANs partition a regular VLAN domain into subdomains. A subdomain is represented by a pair of VLANs: a primary VLAN and a secondary VLAN. A private VLAN can have multiple VLAN pairs, one pair for each subdomain. All VLAN pairs in a private VLAN share the same primary VLAN. The secondary VLAN ID differentiates one subdomain from another. See Figure 35-1.

There are two types of secondary VLANs:

- **Isolated VLANs**—Ports within an isolated VLAN cannot communicate with each other at the Layer 2 level.
- **Community VLANs**—Ports within a community VLAN can communicate with each other but cannot communicate with ports in other communities at the Layer 2 level.

A promiscuous port can serve only one primary VLAN, one isolated VLAN, and multiple community VLANs. Layer 3 gateways are typically connected to the switch through a promiscuous port.

In a switched environment, you can assign an individual private VLAN and associated IP subnet to each individual or common group of end stations. The end stations need to communicate only with a default gateway to communicate outside the private VLAN.

You can use private VLANs to control access to end stations in these ways:

- Configure selected interfaces connected to end stations as isolated ports to prevent any communication at Layer 2. For example, if the end stations are servers, this configuration prevents Layer 2 communication between the servers.
- Configure interfaces connected to default gateways and selected end stations (such as, backup servers) as promiscuous ports to allow all end stations access to a default gateway.
• Reduce VLAN and IP subnet consumption; you can prevent traffic between end stations even though they are in the same VLAN and IP subnet.

With a promiscuous port, you can connect a wide range of devices as access points to a PVLAN. For example, you can connect a promiscuous port to the server port of a LocalDirector to connect an isolated VLAN or a number of community VLANs to the server. LocalDirector can load balance the servers present in the isolated or community VLANs, or use a promiscuous port to monitor or back up all the PVLAN servers from an administration workstation.

This section includes the following topics:
• Definition Table, page 35-4
• Private VLANs across Multiple Switches, page 35-5
• Private-VLAN Interaction with Other Features, page 35-8

Definition Table

<table>

<tr>
<td>Isolated Port</td>
<td>An isolated port is a host port that belongs to an isolated secondary VLAN. It has complete Layer 2 separation from other ports within the same private VLAN, except for the promiscuous ports. Private VLANs block all traffic to isolated ports except traffic from promiscuous ports. Traffic received from an isolated port is forwarded only to promiscuous ports.</td>
</tr>
<tr>
<td>Isolated VLAN</td>
<td>Isolated VLAN — A private VLAN has only one isolated VLAN. An isolated VLAN is a secondary VLAN that carries unidirectional traffic upstream from the hosts toward the promiscuous ports and the gateway.</td>
</tr>
</tbody>
</table>
### Private VLANs across Multiple Switches

This section discusses the following topics:

- Standard Trunk Ports, page 35-5
- Isolated Private VLAN Trunk Ports, page 35-6
- Promiscuous Private VLAN Trunk Ports, page 35-8

### Standard Trunk Ports

As with regular VLANs, private VLANs can span multiple switches. A trunk port carries the primary VLAN and secondary VLANs to a neighboring switch. The trunk port treats the private VLAN as any other VLAN. A feature of private VLANs across multiple switches is that traffic from an isolated port in switch A does not reach an isolated port on Switch B. See Figure 35-2.

To maintain the security of your private-VLAN configuration and to avoid other use of the VLANs configured as private VLANs, configure private VLANs on all intermediate devices, including devices that have no private-VLAN ports.

**Note**

- Trunk ports carry traffic from regular VLANs and also from primary, isolated, and community VLANs.
- You should use standard trunk ports if both switches undergoing trunking support PVLANs.

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary VLAN</td>
<td>Primary VLAN—A private VLAN has only one primary VLAN. Every port in a private VLAN is a member of the primary VLAN. The primary VLAN carries unidirectional traffic downstream from the promiscuous ports to the (isolated and community) host ports and to other promiscuous ports.</td>
</tr>
</tbody>
</table>
| Private VLAN Trunk Port     | A PVLAN trunk port can carry multiple secondary (isolated only) and non-PVLANs. Packets are received and transmitted with secondary or regular VLAN tags on the PVLAN trunk ports.  
**Note** Only IEEE 802.1q encapsulation is supported. |
| Promiscuous Port            | A promiscuous port belongs to the primary VLAN and can communicate with all interfaces, including the community and isolated host ports and private VLAN trunk ports that belong to the secondary VLANs associated with the primary VLAN. |
| Promiscuous Trunk Port      | A promiscuous trunk port can carry multiple primary and normal VLANs. Packets are received and transmitted with primary or regular VLAN tags. Other than that, the port behaves just like a promiscuous access port.  
**Note** Only IEEE 802.1q encapsulation is supported. |
Private VLANs

Because VTP does not support private VLANs, you must manually configure private VLANs on all switches in the Layer 2 network. If you do not configure the primary and secondary VLAN association in some switches in the network, the Layer 2 databases in these switches are not merged. This can result in unnecessary flooding of private-VLAN traffic on those switches.

Isolated Private VLAN Trunk Ports

You would use a isolated PVLAN trunk ports when you would anticipate using PVLAN isolated host ports to carry multiple VLANs, either normal VLANs or for multiple PVLAN domains. This makes it useful for connecting a downstream switch that does not support PVLANs (like Catalyst 2950).

**Figure 35-2 Private VLANs across Switches**

VLAN 100 = Primary VLAN  
VLAN 201 = Secondary isolated VLAN  
VLAN 202 = Secondary community VLAN

---

Because VTP does not support private VLANs, you must manually configure private VLANs on all switches in the Layer 2 network. If you do not configure the primary and secondary VLAN association in some switches in the network, the Layer 2 databases in these switches are not merged. This can result in unnecessary flooding of private-VLAN traffic on those switches.

**Isolated Private VLAN Trunk Ports**

You would use a isolated PVLAN trunk ports when you would anticipate using PVLAN isolated host ports to carry multiple VLANs, either normal VLANs or for multiple PVLAN domains. This makes it useful for connecting a downstream switch that does not support PVLANs (like Catalyst 2950).
Chapter 35  Configuring Private VLANs

Figure 35-3  Isolated PVLAN Trunk Ports

In this illustration, a Catalyst 4500 switch is being used to connect a downstream switch that does not support PVLANs.

Traffic being sent in the downstream direction towards host1 from the router is received by the Catalyst 4500 series switch on the promiscuous port and in the primary VLAN (VLAN 10). The packets are then switched out of the isolated PVLAN trunk, but rather than being tagged with the primary VLAN (VLAN 10) they are instead transmitted with the isolated VLAN’s tag (VLAN 11). In this way, when the packets arrive on the non-PVLAN switch, they can be bridged to the destination host’s access port.

Traffic in the upstream direction is sent by host1 to the non-PVLAN switch, arriving in VLAN 11. The packets are then transmitted to the Catalyst 4500 series switch tagged with that VLAN’s tag (VLAN 11) over the trunk port. On the Catalyst 4500 series switch, VLAN 11 is configured as the isolated vlan, and the traffic is forwarded as if it came from an isolated host port.

Note
When an isolated trunk is used in this fashion, the Catalyst 4500 series switch provides isolation between the isolated trunk and directly connected hosts (such as host3), but not between hosts connected to the non-PVLAN switch (such as host1 and host2). Isolation between these hosts must be provided by the non-PVLAN switch, using a feature such as protected ports on a Catalyst 2950.

For details on protected ports, see the URL:
Promiscuous Private VLAN Trunk Ports

PVLAN Promiscuous Trunks are used in situations where one would normally use a PVLAN promiscuous host port but where it is necessary to carry multiple vlans, either normal vlans or for multiple PVLAN domains. This makes it useful for connecting an upstream router that does not support Private VLANs, such as a Cisco 7200.

![Figure 35-4 Promiscuous PVLAN Trunk Ports](image)

In this illustration, a Catalyst 4500 series switch is being used to connect a PVLAN domain to an upstream router which does not support PVLANs. Traffic being sent upstream by host1 arrives on the Catalyst 4500 series switch in the community VLAN (VLAN 12). When this traffic is bridged onto the promiscuous PVLAN trunk towards the router, it is tagged with the primary VLAN (VLAN 10), so that it can be routed via the correct subinterface configured on the router.

Traffic in the downstream direction is received on the promiscuous PVLAN trunk port by the Catalyst 4500 switch in the primary VLAN (VLAN 10), just as if it had been received on a promiscuous host port. It can then be bridged to the destination host as in any PVLAN domain.

PVLAN promiscuous trunks interact with VLAN QoS. Refer to the section “PVLANs and VLAN ACL/QoS” section on page 35-9.

Private-VLAN Interaction with Other Features

Private VLANs have specific interaction with some other features, described in these sections:

- **PVLANs and VLAN ACL/QoS**, page 35-9
- **Private VLANs and Unicast, Broadcast, and Multicast Traffic**, page 35-9
- **Private VLANs and SVIs**, page 35-10
- **Per-Virtual-Port Error Disable on Private Vlans**, page 35-10

For details, see the section “PVLAN Configuration Guidelines and Restrictions” on page 11.
### PVLANs and VLAN ACL/QoS

PVLAN ports use primary and secondary VLANs, as follows:

- A packet received on a PVLAN host port belongs to the secondary VLAN.
- A packet received on a PVLAN trunk port belongs to the secondary VLAN if the packet is tagged with a secondary VLAN or if the packet is untagged and the native VLAN on the port is a secondary VLAN.

A packet received on a PVLAN host or trunk port and assigned to a secondary VLAN is bridged on the secondary VLAN. Because of this bridging, the secondary VLAN ACL as well as the secondary VLAN QoS (on input direction) apply.

When a packet is transmitted out of a PVLAN host or trunk port, the packet logically belongs to the primary VLAN. This relationship applies even though the packet may be transmitted with the secondary VLAN tagging for PVLAN trunk ports. In this situation, the primary VLAN ACL and the primary VLAN QoS on output apply to the packet.

- Similarly, a packet received on a PVLAN promiscuous access port belongs to primary VLAN.
- A packet received on a PVLAN promiscuous trunk port could belong to the primary VLAN or normal VLAN depending on incoming VLAN.

For traffic flowing in normal VLAN on promiscuous trunk ports, normal VLAN ACL and QoS policies apply. For traffic flowing in a private VLAN domain, a packet received on a promiscuous port is bridged in primary VLAN. Therefore, the primary VLAN ACL and QoS policies apply on input.

When a packet is transmitted out of a promiscuous trunk port, the packet could logically belong to secondary VLAN if received from a secondary port, or in primary VLAN if bridged from another promiscuous port. Because we cannot differentiate between both packets, all VLAN QoS policies are ignored on packets egressing promiscuous trunk ports.

### Private VLANs and Unicast, Broadcast, and Multicast Traffic

In regular VLANs, devices in the same VLAN can communicate with each other at the Layer 2 level, but devices connected to interfaces in different VLANs must communicate at the Layer 3 level. In private VLANs, the promiscuous ports are members of the primary VLAN, while the host ports belong to secondary VLANs. Because the secondary VLAN is associated to the primary VLAN, members of the these VLANs can communicate with each other at the Layer 2 level.

In a regular VLAN, broadcasts are forwarded to all ports in that VLAN. Private VLAN broadcast forwarding depends on the port sending the broadcast:

- An isolated port sends a broadcast only to the promiscuous ports or trunk ports.
- A community port sends a broadcast to all promiscuous ports, trunk ports, and ports in the same community VLAN.
- A promiscuous port sends a broadcast to all ports in the private VLAN (other promiscuous ports, trunk ports, isolated ports, and community ports).

Multicast traffic is routed or bridged across private-VLAN boundaries and within a single community VLAN. Multicast traffic is not forwarded between ports in the same isolated VLAN or between ports in different secondary VLANs.
Private VLANs and SVIs

In a Layer 3 switch, a switch virtual interface (SVI) represents the Layer 3 interface of a VLAN. Layer 3 devices communicate with a private VLAN only through the primary VLAN and not through secondary VLANs. Configure Layer 3 VLAN interfaces (SVIs) only for primary VLANs. You cannot configure Layer 3 VLAN interfaces for secondary VLANs. SVIs for secondary VLANs are inactive while the VLAN is configured as a secondary VLAN.

- If you try to configure a VLAN with an active SVI as a secondary VLAN, the configuration is not allowed until you disable the SVI.
- If you try to create an SVI on a VLAN that is configured as a secondary VLAN and the secondary VLAN is already mapped at Layer 3, the SVI is not created, and an error is returned. If the SVI is not mapped at Layer 3, the SVI is created, but it is automatically shut down.

When the primary VLAN is associated with and mapped to the secondary VLAN, any configuration on the primary VLAN is propagated to the secondary VLAN SVIs. For example, if you assign an IP subnet to the primary VLAN SVI, this subnet is the IP subnet address of the entire private VLAN.

Per-Virtual-Port Error Disable on Private Vlans

For private VLANs, per-vp error disable behavior is defined as follows:

- On a PVLAN promiscuous or promiscuous trunk ports, if a violation occurs on the primary VLAN, it is error disabled.
- On a PVLAN host or trunk port, if a violation occurs on the secondary VLAN, the associated primary VLAN is error disabled.
- On a standard trunk port that carries both primary and secondary VLANs, if a violation occurs on the primary VLAN, this VLAN and all its associated secondary VLANs are error disabled. If a violation occurs on a secondary VLAN, the associated primary VLAN and all its associated secondary VLANs are error disabled.

Configuring PVLANs

These sections describe how to configure PVLANs:

- Tasks for Configuring Private VLANs, page 35-11
- Default Private-VLAN Configuration, page 35-11
- PVLAN Configuration Guidelines and Restrictions, page 35-11
- Configuring a VLAN as a PVLAN, page 35-13
- Associating a Secondary VLAN with a Primary VLAN, page 35-14
- Configuring a Layer 2 Interface as a PVLAN Promiscuous Port, page 35-16
- Configuring a Layer 2 Interface as a PVLAN Host Port, page 35-17
- Configuring a Layer 2 Interface as an Isolated PVLAN Trunk Port, page 35-18
- Configuring a Layer 2 Interface as a Promiscuous PVLAN Trunk Port, page 35-19
- Permitting Routing of Secondary VLAN Ingress Traffic, page 35-21
Tasks for Configuring Private VLANs

To configure a PVLAN, follow these steps:

**Step 1** Set VTP mode to transparent. See the “VLAN Trunking Protocol” section on page 12-7.

**Step 2** Create the secondary VLANs. See the “Configuring a VLAN as a PVLAN” section on page 35-13.

**Step 3** Create the primary VLAN. See the “Configuring a VLAN as a PVLAN” section on page 35-13.

**Step 4** Associate the secondary VLAN to the primary VLAN. See the “Associating a Secondary VLAN with a Primary VLAN” section on page 35-14.

**Note** Only one isolated VLAN can be mapped to a primary VLAN, but more than one community VLAN can be mapped to a primary VLAN.

**Step 5** Configure an interface as an isolated or community host or trunk port. See the “Configuring a Layer 2 Interface as a PVLAN Host Port” section on page 35-17 and “Configuring a Layer 2 Interface as an Isolated PVLAN Trunk Port” section on page 35-18.

**Step 6** Associate the isolated port or community port to the primary-secondary VLAN pair. See the “Associating a Secondary VLAN with a Primary VLAN” section on page 35-14.

**Step 7** Configure an interface as a promiscuous port. See the “Configuring a Layer 2 Interface as a PVLAN Promiscuous Port” section on page 35-16.

**Step 8** Map the promiscuous port to the primary-secondary VLAN pair. See the “Configuring a Layer 2 Interface as a PVLAN Promiscuous Port” section on page 35-16.

**Step 9** If you plan to use inter-VLAN routing, configure the primary SVI, and map secondary VLANs to the primary. See the “Permitting Routing of Secondary VLAN Ingress Traffic” section on page 35-21.

**Step 10** Verify private-VLAN configuration. See the “Switch#” section on page 35-22.

Default Private-VLAN Configuration

No private VLANs are configured.

PVLAN Configuration Guidelines and Restrictions

Follow these guidelines when configuring PVLANs:

- To configure a PVLAN correctly, enable VTP in transparent mode in VTP version 1 and VTP version 2. (VTP version 3 enables you to create it in server mode).

  You cannot change the VTP mode to client or server for PVLANs.

- Do not include VLAN 1 or VLANs 1002 through 1005 in PVLANs.

- Use only PVLAN commands to assign ports to primary, isolated, or community VLANs.

  Layer 2 interfaces on primary, isolated, or community VLANs are inactive in PVLANs. Layer 2 trunk interfaces remain in the STP forwarding state.
You cannot configure Layer 3 VLAN interfaces for secondary VLANs. Layer 3 VLAN interfaces for isolated and community (secondary) VLANs are inactive while the VLAN is configured as an isolated or community VLAN.

Do not configure private VLAN ports as EtherChannels. While a port is part of the private VLAN configuration, its associated EtherChannel configuration is inactive.

Do not apply dynamic access control entries (ACEs) to primary VLANs. Cisco IOS dynamic ACL configuration applied to a primary VLAN is inactive while the VLAN is part of the PVLAN configuration.

To prevent spanning tree loops due to misconfigurations, enable PortFast on the PVLAN trunk ports with the `spanning-tree portfast trunk` command.

Any VLAN ACL configured on a secondary VLAN is effective in the input direction, and any VLAN ACL configured on the primary VLAN associated with the secondary VLAN is effective in the output direction.

You can stop Layer 3 switching on an isolated or community VLAN by deleting the mapping of that VLAN with its primary VLAN.

PVLAN ports can be on different network devices as long as the devices are trunk-connected and the primary and secondary VLANs remain associated with the trunk.

Isolated ports on two different devices cannot communicate with each other, but community VLAN ports can.

Private VLANs support the following SPAN features:
- You can configure a private VLAN port as a SPAN source port.
- You can use VLAN-based SPAN (VSPAN) on primary, isolated, and community VLANs or use SPAN on only one VLAN to monitor egress or ingress traffic separately.

For more information about SPAN, see Chapter 46, “Configuring SPAN and RSPAN.”

A primary VLAN can be associated with multiple community VLANs, but only one isolated VLAN.

An isolated or community VLAN can be associated with only one primary VLAN.

If you delete a VLAN used in a private VLAN configuration, the private VLAN ports associated with the VLAN become inactive.

VTP does not support private VLANs. You must configure private VLANs on each device in which you plan to use private VLAN ports.

To maintain the security of your PVLAN configuration and avoid other use of VLANs configured as PVLANs, configure PVLANs on all intermediate devices, even if the devices have no PVLAN ports.

Prune the PVLANs from trunks on devices that carry no traffic in the PVLANs.

With port ACLS functionality available, you can apply Cisco IOS ACLS to secondary VLAN ports and Cisco IOS ACLS to PVLANs (VACLs). For more information on VACLs, see Chapter 42, “Configuring Network Security with ACLs.”

You can apply different quality of service (QoS) configurations to primary, isolated, and community VLANs. (See Chapter 33, “Configuring Quality of Service.”) Cisco IOS ACLs applied to the Layer 3 VLAN interface of a primary VLAN automatically apply to the associated isolated and community VLANs.

On a PVLAN trunk port a secondary VLAN ACL is applied on ingress traffic and a primary VLAN ACL is applied on egress traffic.
• On a promiscuous port the primary VLAN ACL is applied on ingress traffic.
• Both PVLAN secondary and promiscuous trunk ports support only IEEE 802.1q encapsulation.
• Community VLANs cannot be propagated or carried over private VLAN trunks.
• ARP entries learned on Layer 3 PVLAN interfaces are termed “sticky” ARP entries (we recommend that you display and verify PVLAN interface ARP entries).
• For security reasons, PVLAN port sticky ARP entries do not age out. Connecting a device with a different MAC address but with the same IP address generates an error message and the ARP entry is not created.
• Because PVLAN port sticky ARP entries do not age out, you must manually remove the entries if you change the MAC address. To overwrite a sticky ARP entry, first delete the entry with the `no arp` command, then overwrite the entry with the `arp` command.
• In a DHCP environment, if you shut down your PC, it is not possible to give your IP address to someone else. To solve this problem, the Catalyst 4500 series switch supports the `no ip sticky-arp` command. This command promotes IP address overwriting and reuse in a DHCP environment.
• Normal VLANs can be carried on a promiscuous or isolated trunk port.
• The default native VLAN for promiscuous trunk port is VLAN 1, the management VLAN. All untagged packets are forwarded in the native VLAN. Either the primary VLANs or a regular VLAN can be configured as native VLAN.
• Promiscuous trunks cannot be configured to carry secondary VLANs. If a secondary VLAN is specified in the allowed VLAN list, the configuration is accepted but the port is not operational/forwarding in the secondary VLAN. This includes even those VLANs that are of secondary but not associated with any primary VLAN on given port.
• On a promiscuous trunk port, the primary VLAN ACL and QoS are applied on ingress traffic coming in primary VLANs.
• On a promiscuous trunk port, no VLAN ACL or QoS is applied to the egress traffic. This is because for upstream direction, traffic in private VLAN logically flows in the secondary VLAN. Due to VLAN translation in hardware, information about received secondary VLANs has been lost. Hence, no policies are applied. This restriction also applies to traffic bridged from other ports in the same primary VLANs.
• Do not configure port security on PVLAN promiscuous trunk port and vice versa.
  If port security is enabled on a promiscuous trunk port, that port may behave in an unpredictable manner because this functionality is not supported.
• Do not configure IEEE 802.1X on a PVLAN promiscuous trunk port.

---

**Configuring a VLAN as a PVLAN**

To configure a VLAN as a PVLAN, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td>Enters configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td>Switch(config)# vlan vlan_ID</td>
<td>Enters VLAN configuration mode.</td>
</tr>
</tbody>
</table>

---

*Note* Community private VLAN trunk ports are not supported.
This example shows how to configure VLAN 202 as a primary VLAN and verify the configuration:

Switch# configure terminal
Switch(config)# vlan 202
Switch(config-vlan)# private-vlan primary
Switch(config-vlan)# end
Switch# show vlan private-vlan
Primary Secondary Type Interfaces
--------- --------- ----------------- ------------------------------------------
202       primary

This example shows how to configure VLAN 303 as a community VLAN and verify the configuration:

Switch# configure terminal
Switch(config)# vlan 303
Switch(config-vlan)# private-vlan community
Switch(config-vlan)# end
Switch# show vlan private-vlan
Primary Secondary Type Interfaces
--------- --------- ----------------- ------------------------------------------
202       primary
303       community

This example shows how to configure VLAN 440 as an isolated VLAN and verify the configuration:

Switch# configure terminal
Switch(config)# vlan 440
Switch(config-vlan)# private-vlan isolated
Switch(config-vlan)# end
Switch# show vlan private-vlan
Primary Secondary Type Interfaces
--------- --------- ----------------- ------------------------------------------
202       primary
303       community
440       isolated

### Associating a Secondary VLAN with a Primary VLAN

To associate secondary VLANs with a primary VLAN, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 Switch# configure terminal</td>
<td>Enters configuration mode.</td>
</tr>
<tr>
<td>Step 2 Switch(config)# vlan primary_vlan_ID</td>
<td>Enters VLAN configuration mode for the primary VLAN.</td>
</tr>
</tbody>
</table>
When you associate secondary VLANs with a primary VLAN, note the following:

- The `secondary_vlan_list` parameter cannot contain spaces. It can contain multiple comma-separated items. Each item can be a single private VLAN ID or a hyphenated range of private VLAN IDs.
- The `secondary_vlan_list` parameter can contain multiple community VLAN IDs.
- The `secondary_vlan_list` parameter can contain only one isolated VLAN ID.
- Enter a `secondary_vlan_list` or use the `add` keyword with a `secondary_vlan_list` to associate secondary VLANs with a primary VLAN.
- Use the `remove` keyword with a `secondary_vlan_list` to clear the association between secondary VLANs and a primary VLAN.
- The command does not take effect until you exit VLAN configuration submode.

This example shows how to associate community VLANs 303 through 307 and 309 and isolated VLAN 440 with primary VLAN 202 and verify the configuration:

```
Switch# configure terminal
Switch(config)# vlan 202
Switch(config-vlan)# private-vlan association 303-307,309,440
Switch(config-vlan)# end
Switch# show vlan private-vlan
```

<table>
<thead>
<tr>
<th>Primary</th>
<th>Secondary</th>
<th>Type</th>
<th>Interfaces</th>
</tr>
</thead>
<tbody>
<tr>
<td>202</td>
<td>303</td>
<td>community</td>
<td></td>
</tr>
<tr>
<td>202</td>
<td>304</td>
<td>community</td>
<td></td>
</tr>
<tr>
<td>202</td>
<td>305</td>
<td>community</td>
<td></td>
</tr>
<tr>
<td>202</td>
<td>306</td>
<td>community</td>
<td></td>
</tr>
<tr>
<td>202</td>
<td>307</td>
<td>community</td>
<td></td>
</tr>
<tr>
<td>202</td>
<td>309</td>
<td>community</td>
<td></td>
</tr>
<tr>
<td>202</td>
<td>440</td>
<td>isolated</td>
<td></td>
</tr>
<tr>
<td></td>
<td>308</td>
<td>community</td>
<td></td>
</tr>
</tbody>
</table>

**Note**

The secondary VLAN 308 has no associated primary VLAN.
Configuring a Layer 2 Interface as a PVLAN Promiscuous Port

To configure a Layer 2 interface as a PVLAN promiscuous port, perform this task:

### Command |
<table>
<thead>
<tr>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
</tr>
<tr>
<td><code>Switch# configure terminal</code></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
</tr>
<tr>
<td>`Switch(config)# interface {fastethernet</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
</tr>
<tr>
<td>`Switch(config-if)# switchport mode private-vlan {host</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
</tr>
<tr>
<td>`Switch(config-if)# [no] switchport private-vlan mapping [trunk] primary_vlan_ID {secondary_vlan_list</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
</tr>
<tr>
<td><code>Switch(config-if)# end</code></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
</tr>
<tr>
<td>`Switch# show interfaces {fastethernet</td>
</tr>
</tbody>
</table>

**Note**

The maximum number of unique PVLAN pairs supported by the `switchport private-vlan mapping` command is 1000.

When you configure a Layer 2 interface as a PVLAN promiscuous port, note the following:

- The `secondary_vlan_list` parameter cannot contain spaces. It can contain multiple comma-separated items. Each item can be a single PVLAN ID or a hyphenated range of PVLAN IDs.
- Enter a `secondary_vlan_list` or use the `add` keyword with a `secondary_vlan_list` to map the secondary VLANs to the PVLAN promiscuous port.
- Use the `remove` keyword with a `secondary_vlan_list` to clear the mapping between secondary VLANs and the PVLAN promiscuous port.

This example shows how to configure interface FastEthernet 5/2 as a PVLAN promiscuous port, map it to a PVLAN, and verify the configuration:

```
Switch# configure terminal
Switch(config)# interface fastethernet 5/2
Switch(config-if)# switchport mode private-vlan promiscuous
Switch(config-if)# switchport private-vlan mapping 200 2
Switch(config-if)# end
Switch# show interfaces fastethernet 5/2 switchport
Name:Fa5/2
Switchport:Enabled
Administrative Mode:private-vlan promiscuous
Operational Mode:private-vlan promiscuous
Administrative Trunking Encapsulation:negotiate
Operational Trunking Encapsulation: native
Negotiation of Trunking: Off
Access Mode VLAN:1 (default)
Trunking Native Mode VLAN:1 (default)
Voice VLAN: none
Administrative Private VLAN Host Association: none
Administrative Private VLAN Promiscuous Mapping:200 (VLAN0200) 2 (VLAN0002)
Private VLAN Trunk Native VLAN: none
```

Software Configuration Guide—Release IOS-XE 3.1.0 SG
Configuring a Layer 2 Interface as a PVLAN Host Port

To configure a Layer 2 interface as a PVLAN host port, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>

<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config-if)# switchport mode private-vlan {host</td>
</tr>
<tr>
<td></td>
<td>Configures a Layer 2 interface as a PVLAN trunk port.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config-if)# [no] switchport private-vlan association trunk primary_vlan_ID secondary_vlan_ID</td>
</tr>
<tr>
<td></td>
<td>Configures association between primary VLANs and secondary VLANs the PVLAN trunk port with a PVLAN.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> Multiple PVLAN pairs can be specified using this command so that a PVLAN trunk port can carry multiple secondary VLANs. If an association is specified for the existing primary VLAN, the existing association is replaced. If there is no trunk association, any packets received on secondary VLANs are dropped. You can use the <strong>no</strong> keyword to delete all associations from the primary VLAN.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch(config-if)# [no] switchport private-vlan trunk allowed vlan vlan_list all</td>
</tr>
<tr>
<td></td>
<td>Configures a list of allowed normal VLANs on a PVLAN trunk port. You can use the <strong>no</strong> keyword to remove all allowed normal VLANs on a PVLAN trunk port.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Switch(config-if)# switchport private-vlan trunk native vlan vlan_id</td>
</tr>
<tr>
<td></td>
<td>Configures a VLAN to which untagged packets (as in IEEE 802.1Q tagging) are assigned on a PVLAN trunk port. If there is no native VLAN configured, all untagged packets are dropped. If the native VLAN is a secondary VLAN and the port does not have the association for the secondary VLAN, the untagged packets are dropped. You can use the <strong>no</strong> keyword to remove all native VLANs on a PVLAN trunk port.</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>Switch(config-if)# end</td>
</tr>
<tr>
<td></td>
<td>Exits configuration mode.</td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>Switch# show interfaces {fastethernet</td>
</tr>
<tr>
<td></td>
<td>Verifies the configuration.</td>

## Configuring a Layer 2 Interface as a Promiscuous PVLAN Trunk Port

To configure a Layer 2 interface as a promiscuous PVLAN trunk port, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td>Enters global configuration mode.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# interface (fastethernet</td>
</tr>
<tr>
<td>Specifies the LAN interface to configure.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config-if)# switchport mode private-vlan (host</td>
</tr>
<tr>
<td>Configures a Layer 2 interface as a PVLAN promiscuous trunk port.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config-if)# [no] switchport private-vlan mapping [trunk] primary_vlan_ID (secondary_vlan_list</td>
</tr>
<tr>
<td>Maps the promiscuous PVLAN port to a primary VLAN and to selected secondary VLANs. This command offers 3 levels of removal. See the examples that follow this table.</td>
<td></td>
</tr>
</tbody>
</table>
Configuring PVLANs

Chapter 35  Configuring Private VLANs

### Step 5

```
Switch(config-if)# end
```

Exits configuration mode.

### Step 6

```
Switch# show interfaces {fastethernet | gigabitethernet | tengigabitethernet} slot/port switchport
```

Verifies the configuration.

---

**Note**

The maximum number of unique PVLAN pairs supported by the `switchport private-vlan mapping trunk` command is 500. For example, 500 isolated secondary VLANs could map to 500 primary VLANs, because only one isolated VLAN association per primary VLAN is supported. Or, 500 community secondary VLANs could map to one primary VLAN. Or, 250 community secondary VLANs could map to 1 primary VLAN, and another 250 community secondary VLANs could map to another primary VLAN for a total of 500 pairs.

---

**Note**

By default, when you configure the mode to private VLAN trunk *promiscuous*, the native VLAN is set to 1.

The `[no] switchport private-vlan mapping trunk` command provides the following three levels of removal:

- Remove one or more secondary VLANs from the list. For example:
  ```
  Switch(config-if)# switchport private-vlan mapping trunk 2 remove 222
  ```

- Remove the entire mapping of PVLAN promiscuous trunk port to the specified primary VLAN (and all of its selected secondary VLANs). For example:
  ```
  Switch(config-if)# no switchport private-vlan mapping trunk 2
  ```

- Remove the mapping of a PVLAN promiscuous trunk port to all previously configured primary VLANs (and all of their selected secondary VLANs). For example:
  ```
  Switch(config-if)# no switchport private-vlan mapping trunk
  ```

When you configure a Layer 2 interface as a PVLAN promiscuous port, note the following:

- Multiple private VLAN pairs can be specified using the `switchport private-vlan mapping trunk` command so that a promiscuous trunk port can carry multiple primary VLANs.

- The `secondary_vlan_list` parameter cannot contain spaces. It can contain multiple comma-separated items. Each item can be a single PVLAN ID or a hyphenated range of PVLAN IDs.

- Enter a `secondary_vlan_list` or use the `add` keyword with a `secondary_vlan_list` to map the secondary VLANs to the PVLAN promiscuous port.

- Use the `remove` keyword with a `secondary_vlan_list` to clear the mapping between secondary VLANs and the PVLAN promiscuous port.

This example shows how to configure interface FastEthernet 5/2 as a promiscuous trunk port and to verify the configuration:

```
Switch# configure terminal
Switch(config)# interface fastethernet 5/2
Switch(config-if)# switchport mode private-vlan trunk promiscuous
Switch(config-if)# switchport private-vlan trunk native vlan 10
Switch(config-if)# switchport private-vlan trunk allowed vlan 10, 3-4
Switch(config-if)# switchport private-vlan mapping trunk 3 301, 302
Switch(config-if)# end
```
Switch# show interfaces fastethernet 5/2 switchport
Name: Fa5/2
Switchport: Enabled
Administrative Mode: private-vlan trunk promiscuous
Operational Mode: private-vlan trunk promiscuous
Administrative Trunking Encapsulation: negotiate
Operational Trunking Encapsulation: dot1q
Negotiation of Trunking: On
Access Mode VLAN: 1 (default)
Trunking Native Mode VLAN: 1 (default)
Administrative Native VLAN tagging: enabled
Voice VLAN: none
Administrative private-vlan host-association: none
Administrative private-vlan mapping: none
Administrative private-vlan trunk native VLAN: 10
Administrative private-vlan trunk Native VLAN tagging: enabled
Administrative private-vlan trunk encapsulation: dot1q
Administrative private-vlan trunk normal VLANs: 3-4,10
Administrative private-vlan trunk associations: none
Administrative private-vlan trunk mappings:
  3 (VLAN0003) 301 (VLAN0301) 302 (VLAN0302)
Operational private-vlan:
  3 (VLAN0003) 301 (VLAN0301) 302 (VLAN0302)
Trunking VLANs Enabled: ALL
Pruning VLANs Enabled: 2-1001
Capture Mode Disabled
Capture VLANs Allowed: ALL
Unknown unicast blocked: disabled
Unknown multicast blocked: disabled
Appliance trust: none

Permitting Routing of Secondary VLAN Ingress Traffic

**Note**
Isolated and community VLANs are both called secondary VLANs.

To permit routing of secondary VLAN ingress traffic, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# interface vlan primary_vlan_ID</td>
</tr>
<tr>
<td></td>
<td>Enters interface configuration mode for the primary VLAN.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config-if)# [no] private-vlan mapping primary_vlan_ID (secondary_vlan_list</td>
</tr>
<tr>
<td></td>
<td>To permit routing on the secondary VLAN ingress traffic, map the secondary VLAN to the primary VLAN. You can use the no keyword to delete all associations from the primary VLAN.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config-if)# end</td>
</tr>
<tr>
<td></td>
<td>Exits configuration mode.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch# show interface private-vlan mapping</td>
</tr>
<tr>
<td></td>
<td>Verifies the configuration.</td>
</tr>
</tbody>
</table>
When you permit routing on the secondary VLAN ingress traffic, note the following:

- The **private-vlan mapping** interface configuration command only affects private VLAN ingress traffic that is Layer 3 switched.
- The `secondary_vlan_list` parameter cannot contain spaces. It can contain multiple comma-separated items. Each item can be a single private VLAN ID or a hyphenated range of private VLAN IDs.
- Enter a `secondary_vlan_list` parameter or use the `add` keyword with a `secondary_vlan_list` parameter to map the secondary VLANs to the primary VLAN.
- Use the `remove` keyword with a `secondary_vlan_list` parameter to clear the mapping between secondary VLANs and the primary VLAN.

This example shows how to permit routing of secondary VLAN ingress traffic from private VLANs 303 through 307, 309, and 440 and verify the configuration:

```
Switch# configure terminal
Switch(config)# interface vlan 202
Switch(config-if)# private-vlan mapping add 303-307,309,440
Switch(config-if)# end
Switch# show interfaces private-vlan mapping
Interface  Secondary VLAN  Type
----------  --------------  ---------------
    vlan202    303            community
    vlan202    304            community
    vlan202    305            community
    vlan202    306            community
    vlan202    307            community
    vlan202    309            community
    vlan202    440            isolated
Switch#
```
CHAPTER 36

Configuring 802.1X Port-Based Authentication

This chapter describes how to configure IEEE 802.1X port-based authentication on the Catalyst 4500 series switch to prevent unauthorized client devices from gaining access to the network.

This chapter includes the following major sections:

- About 802.1X Port-Based Authentication, page 36-1
- Configuring 802.1X Port-Based Authentication, page 36-22
- Displaying 802.1X Statistics and Status, page 36-67
- Displaying Authentication Details, page 36-67
- Cisco IOS Security Features in Cisco IOS XE 3.1.0 SG Release, page 36-71

Note

For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

About 802.1X Port-Based Authentication

802.1X defines 802.1X port-based authentication as a client-server based access control and authentication protocol that restricts unauthorized clients from connecting to a LAN through publicly accessible ports. An authentication server validates each supplicant (client) connected to an authenticator (network access switch) port before making available any services offered by the switch or the LAN.

Note

802.1X support requires an authentication server that is configured for Remote Authentication Dial-In User Service (RADIUS). 802.1X authentication does not work unless the network access switch can route packets to the configured RADIUS server. To verify that the switch can route packets, you must ping the server from the switch.
Until a client is authenticated, only Extensible Authentication Protocol over LAN (EAPOL) traffic is allowed through the port to which the client is connected. After authentication succeeds, normal traffic can pass through the port.

To configure 802.1X port-based authentication, you need to understand the concepts in these sections:

- Device Roles, page 36-2
- 802.1X and Network Access Control, page 36-3
- Authentication Initiation and Message Exchange, page 36-3
- Ports in Authorized and Unauthorized States, page 36-4
- 802.1X Host Mode, page 36-6
- Using 802.1X with VLAN Assignment, page 36-9
- Using 802.1X for Guest VLANs, page 36-10
- Using 802.1X with MAC Authentication Bypass, page 36-11
- Using 802.1X with Web-Based Authentication, page 36-13
- Using 802.1X with Inaccessible Authentication Bypass, page 36-13
- Using 802.1X with Unidirectional Controlled Port, page 36-14
- Using 802.1X with Authentication Failed VLAN Assignment, page 36-14
- Using 802.1X with Port Security, page 36-16

**Device Roles**

With 802.1X port-based authentication, network devices have specific roles. Figure 36-1 shows the role of each device, which is described below.

**Figure 36-1 802.1X Device Roles**
Chapter 36 Configuring 802.1X Port-Based Authentication

About 802.1X Port-Based Authentication

- **Client**—The workstation that requests access to the LAN, and responds to requests from the switch. The workstation must be running 802.1X-compliant client software.
- **Authenticator**—Controls physical access to the network based on the authentication status of the client. The Catalyst 4500 series switch acts as an intermediary between the client and the authentication server, requesting identity information from the client, verifying that information with the authentication server, and relaying a response to the client. The switch encapsulates and decapsulates the Extensible Authentication Protocol (EAP) frames and interacts with the RADIUS authentication server.

When the switch receives EAPOL frames and relays them to the authentication server, the Ethernet header is stripped and the remaining EAP frame is reencapsulated in the RADIUS format. The EAP frames are not modified or examined during encapsulation, and the authentication server must support EAP within the native frame format. When the switch receives frames from the authentication server, the frame header is removed from the server, leaving the EAP frame, which is then encapsulated for Ethernet and sent to the client.

- **Authentication server**—Performs the actual authentication of the client. The authentication server validates the identity of the client and notifies the switch that the client is authorized to access the LAN and switch services. (The only supported authentication server is the RADIUS authentication server with EAP extensions; it is available in Cisco Secure Access Control Server version 3.2 and later.)

802.1X and Network Access Control

Network Access Control is a feature that allows port access policies to be influenced by the anti-virus posture of the authenticating device.

Anti-virus posture includes such elements as the operating system running on the device, the operating system version, whether anti-virus software is installed, what version of anti-virus signatures is available, etc. If the authenticating device has a NAC-aware 802.1X supplicant and the authentication server is configured to support NAC via 802.1X, anti-virus posture information is automatically included as part of the 802.1X authentication exchange.

For information on NAC, refer to the URL:

Authentication Initiation and Message Exchange

The switch or the client can initiate authentication. If you enable authentication on a port with the `authentication port-control auto` interface configuration command (in Cisco IOS Release 12.2(46)SG and earlier releases), the switch must initiate authentication when it determines that the port link state has changed. It then sends an EAP-request/identity frame to the client to request its identity (typically, the switch sends an initial identity/request frame followed by one or more requests for authentication information). Upon receipt of the frame, the client responds with an EAP-response/identity frame.
However, if during bootup, the client does not receive an EAP-request/identity frame from the switch, the client can initiate authentication by sending an EAPOL-start frame, which prompts the switch to request the client’s identity.

If 802.1X is not enabled or supported on the network access switch, any EAPOL frames from the client are dropped. If the client does not receive an EAP-request/identity frame after three attempts to start authentication, the client transmits frames as if the port is in the authorized state. A port in the authorized state means that the client has been successfully authenticated. When the client supplies its identity, the switch begins its role as the intermediary, passing EAP frames between the client and the authentication server until authentication succeeds or fails. If the authentication succeeds, the switch port becomes authorized.

The specific exchange of EAP frames depends on the authentication method being used. Figure 36-2 shows a message exchange that is initiated by the client using the One-Time Password (OTP) authentication method with an authentication server.

**Figure 36-2  Message Exchange**

---

**Ports in Authorized and Unauthorized States**

The switch port state determines whether the client is granted access to the network. The port starts in the unauthorized state. While in this state, the port disallows all ingress and egress traffic except for 802.1X protocol packets. When a client is successfully authenticated, the port transitions to the authorized state, allowing all traffic for the client to flow normally.

If a non-802.1X capable client is connected to an unauthorized 802.1X port, the switch requests the client’s identity. In this situation, the client does not respond to the request, the port remains in the unauthorized state, and the client is not granted access to the network. If a guest VLAN is configured on a port that connects to a client that does not support 802.1X, the port is placed in the configured guest VLAN and in the authorized state. For more information, see the “Using 802.1X for Guest VLANs” section on page 36-10.
In contrast, when an 802.1X-enabled client connects to a port that is not running the 802.1X protocol, the client initiates the authentication process by sending the EAPOL-start frame. When no response is received, the client sends the request a fixed number of times. Because no response is received, the client begins sending frames as if the port is in the authorized state.

You can control the port authorization state with the `authentication port-control interface` configuration command and these keywords:

- **force-authorized**—Disables 802.1X authentication and causes the port to transition to the authorized state without requiring authentication exchange. The port transmits and receives normal traffic without 802.1X-based authentication of the client. This setting is the default.

- **force-unauthorized**—Causes the port to remain in the unauthorized state, ignoring all attempts by the client to authenticate. The switch cannot provide authentication services to the client through the interface.

- **auto**—Enables 802.1X authentication and causes the port to begin in the unauthorized state, allowing only EAPOL frames to be sent and received through the port. The authentication process begins when the link state of the port transitions from down to up or when an EAPOL-start frame is received. The switch requests the identity of the client and begins relaying authentication messages between the client and the authentication server. The switch can uniquely identify each client attempting to access the network by the client’s MAC address.

If the client is successfully authenticated (receives an Accept frame from the authentication server), the port state changes to authorized, and all frames from the authenticated client are allowed through the port. If authentication fails, the port remains in the unauthorized state, but authentication can be retried. If the authentication server cannot be reached, the switch can retransmit the request. If no response is received from the server after the specified number of attempts, authentication fails and network access is not granted.

If the link state of a port transitions from up to down, or if an EAPOL-logoff frame is received by the port, the port returns to the unauthorized state.

*Figure 36-3* shows the authentication process.

If Multidomain Authentication (MDA) is enabled on a port, this flow can be used with some exceptions that are applicable to voice authorization. For more information on MDA, see the “Using Multiple Domain Authentication and Multiple Authentication” section on page 36-20.
Chapter 36  Configuring 802.1X Port-Based Authentication

Figure 36-3  Authentication Flowchart

802.1X Host Mode

The 802.1X port’s host mode determines whether more than one client can be authenticated on the port and how authentication is enforced. You can configure an 802.1X port to use any of the five host modes described in the following sections. In addition, each mode may be modified to allow pre-authentication open access:

- Single-Host Mode, page 36-7
- Multiple-Hosts Mode, page 36-7
- Multidomain Authentication Mode, page 36-7
- Multiauthentication Mode, page 36-8
- Pre-Authentication Open Access, page 36-8

1 = This occurs if the switch does not detect EAPOL packets from the client.
Single-Host Mode

You can configure an 802.1X port for single-host or multiple-hosts mode. In single-host mode (see Figure 36-1 on page 36-2), only one client can be connected to the 802.1X-enabled switch port. The switch detects the client by sending an EAPOL frame when the port link state changes to the up state. If a client leaves or is replaced with another client, the switch changes the port link state to down, and the port returns to the unauthorized state.

Multiple-Hosts Mode

In multiple-hosts mode, you can attach multiple hosts to a single 802.1X-enabled port. Figure 36-4 on page 36-7 shows 802.1X port-based authentication in a wireless LAN. In this mode, only one of the attached clients must be authorized for all clients to be granted network access. If the port becomes unauthorized (re-authentication fails or an EAPOL-logoff message is received), the switch denies network access to all of the attached clients. In this topology, the wireless access point is responsible for authenticating the clients attached to it, and it also acts as a client to the switch.

With multiple-hosts mode enabled, use 802.1X authentication to authenticate the port and port security to manage network access for all MAC addresses, including that of the client.

Multidomain Authentication Mode

Multidomain Authentication (MDA), which allows an IP phone (Cisco or third-party) and a single host behind the IP phone to authenticate independently, using 802.1X, MAC authentication bypass (MAB) or (for the host only) web-based authentication. In this application, multidomain refers to two domains — data and voice — and only two MAC addresses are allowed per port. A switch can place the host in the data VLAN and the IP phone in the voice VLAN, even though they appear on the same switch port. The data VLAN and the voice VLAN can be specified in the CLI configuration. The devices are identified as either data or voice depending on the vendor-specific attributes (VSAs) received from the authentication, authorization, and accounting (AAA) server. The data and voice VLANs can also be obtained from the VSAs received from the (AAA) server during authentication.
Figure 36-5 shows a typical MDA application with a single host behind an IP phone connected to the 802.1X-enabled port. Because the client is not directly connected to the switch, the switch cannot detect a loss of port link if the client is disconnected. To prevent another device from using the established authentication of the disconnected client later, Cisco IP phones send a Cisco Discovery Protocol (CDP) host presence type length value (TLV) to notify the switch of changes in the attached client’s port link state.

For details on how to configure MDA, see the “Using Multiple Domain Authentication and Multiple Authentication” section on page 36-20.

Multiauthentication Mode

Available starting in Cisco IOS Release 12.2(50)SG, multiauthentication mode allows one client on the voice VLAN and multiple authenticated clients on the data VLAN. When a hub or access point is connected to an 802.1X port, multiauthentication mode provides enhanced security over multiple-hosts mode by requiring authentication of each connected client. For non-802.1X devices, use MAB or web-based authentication as the fallback method for individual host authentications, allowing you to authenticate different hosts through different methods on a single port.

Multiauthentication also supports MDA functionality on the voice VLAN by assigning authenticated devices to either a data or voice VLAN depending on the VSAs received from the authentication server.

Note

When a port is in multiauthentication mode, all VLAN assignment features including RADIUS server supplied VLAN assignment, Guest VLAN, Inaccessible Authentication Bypass, and Authentication Failed VLAN does not activate for data devices. However, RADIUS server supplied VLAN assignment is possible for voice devices.

Pre-Authentication Open Access

Starting with Cisco IOS Release 12.2(50)SG, any of the four host modes may be additionally configured to allow a device to gain network access before authentication. This pre-authentication open access is useful in an application such as the Pre-boot eXecution Environment (PXE), where a device must access the network to download a bootable image containing an authentication client.

Enable pre-authentication open access by entering the `authentication open` command after host mode configuration. It acts as an extension to the configured host mode. For example, if pre-authentication open access is enabled with single-host mode, then the port allows only one MAC address. When pre-authentication open access is enabled, initial traffic on the port is restricted only by whatever other access restriction, independent of 802.1X, is configured on the port. If no access restriction other than 802.1X is configured on the port, then a client device has full access on the configured VLAN.
Using 802.1X with VLAN Assignment

VLAN assignment allows you to limit network access for certain users. With the VLAN assignment, 802.1X-authenticated ports are assigned to a VLAN based on the username of the client connected to that port. The RADIUS server database maintains the username-to-VLAN mappings. After successful 802.1X authentication of the port, the RADIUS server sends the VLAN assignment to the switch. The VLAN can be a standard VLAN or a private VLAN (PVLAN).

On platforms that support PVLANs, you can isolate hosts by assigning ports into PVLANs.

When configured on the switch and the RADIUS server, 802.1X with VLAN assignment has these characteristics:

- If no VLAN is supplied by the RADIUS server, the port is configured in its access VLAN or isolated PVLAN when authentication succeeds.
- If the authentication server provides invalid VLAN information, the port remains unauthorized. This situation prevents ports from appearing unexpectedly in an inappropriate VLAN due to a configuration error.
- If the multiauthentication mode is enabled on an 802.1X port, the VLAN assignment is ignored for data devices. VLAN assignment is possible for voice device even if the port is configured in multiauthentication mode.
- If the authentication server provides valid VLAN information, the port is authorized and placed in the specified VLAN when authentication succeeds.
- If the multiple-hosts mode is enabled, all hosts are in the same VLAN as the first authenticated user.
- If 802.1X is disabled on the port, the port is returned to the configured access VLAN.
- A port must be configured as an access port (which can be assigned only into “regular” VLANs), or as a PVLAN host port (which can be assigned only into PVLANs). Configuring a port as a PVLAN host port implies that all hosts on the port are assigned into PVLANs, whether their posture is compliant or non-compliant. If the type of the VLAN named in the Access-Accept does not match the type of VLAN expected to be assigned to the port (regular VLAN to access port, secondary PVLAN to PVLAN host port), the VLAN assignment fails.
- If a guest VLAN is configured to handle non-responsive hosts, the type of VLAN configured as the guest VLAN must match the port type (that is, guest VLANs configured on access ports must be standard VLANs, and guest VLANs configured on PVLAN host ports must be PVLANs). If the guest VLAN’s type does not match the port type, non-responsive hosts are treated as if no guest VLAN is configured (that is, they are denied network access).
- To assign a port into a PVLAN, the named VLAN must be a secondary PVLAN. The switch determines the implied primary VLAN from the locally configured secondary-primary association.

**Note**

If you change the access VLAN or PVLAN host VLAN mapping on a port that is already authorized in a RADIUS assigned VLAN, the port remains in the RADIUS assigned VLAN.

To configure VLAN assignment you need to perform these tasks:

- Enable AAA authorization with the `network` keyword to allow interface configuration from the RADIUS server. For an illustration of how to apply the `aaa authorization network group radius` command, refer to the section “Enabling 802.1X Authentication” on page 24.
Enabling 802.1X. (The VLAN assignment feature is automatically enabled when you configure 802.1X on an access port.)

Assign vendor-specific tunnel attributes in the RADIUS server. To ensure proper VLAN assignment, the RADIUS server must return these attributes to the switch:

- Tunnel-Type = VLAN
- Tunnel-Medium-Type = 802
- Tunnel-Private-Group-ID = VLAN NAME

Using 802.1X for Guest VLANs

Guest VLANs allow you to enable non-802.1X-capable hosts to access networks that use 802.1X authentication. For example, use guest VLANs when you upgrade your system to support 802.1X authentication.

Guest VLANs are supported on individual ports. Any VLAN functions as a guest VLAN provided its type matches the port type. If a port is already forwarding on the guest VLAN and you enable 802.1X support on the network interface of the host, the port is immediately moved out of the guest VLAN and the authenticator waits for authentication to occur.

Enabling 802.1X authentication on a port starts the 802.1X protocol. If the host fails to respond to packets from the authenticator within a certain amount of time, the authenticator brings the port up in the configured guest VLAN.

If the port is configured as a PVLAN host port, the guest VLAN must be a secondary PVLAN. If the port is configured as an access port, the guest VLAN must be a regular VLAN. If the guest VLAN configured on a port is not appropriate for the type of the port, the switch behaves as if no guest VLAN is configured (that is, non-responsive hosts are denied network access).

For details on how to configure guest VLANs, see the “Configuring 802.1X with Guest VLANs” section on page 36-46.

Usage Guidelines for Using 802.1X Authentication with Guest VLANs

The usage guidelines for using 802.1X authentication with guest VLANs are as follows:

- When you reconfigure a guest VLAN to a different VLAN, any authentication failed ports are also moved and the ports stay in their current authorized state.
- When you shut down or remove a guest VLAN from the VLAN database, any authentication failed ports are immediately moved to an unauthorized state and the authentication process is restarted.

Note: No periodic reauthentication is allowed with guest VLANs.
Usage Guidelines for Using 802.1X Authentication with Guest VLANs on Windows-XP Hosts

The usage guidelines for using 802.1X authentication with guest VLANs on Windows-XP hosts are as follows:

- If the host fails to respond to the authenticator, the port attempts to connect three times (with a 30 second timeout between each attempt). After this time, the login/password window does not appear on the host, so you must unplug and reconnect the network interface cable.

- Hosts responding with an incorrect login/password fail authentication. Hosts failing authentication are not put in the guest VLAN. The first time that a host fails authentication, the quiet-period timer starts, and no activity occurs for the duration of the quiet-period timer. When the quiet-period timer expires, the host is presented with the login/password window. If the host fails authentication for the second time, the quiet-period timer starts again, and no activity occurs for the duration of the quiet-period timer. The host is presented with the login/password window a third time. If the host fails authentication the third time, the port is placed in the unauthorized state, and you must disconnect and reconnect the network interface cable.

Using 802.1X with MAC Authentication Bypass

The 802.1X protocol has 3 entities: client (supplicant), authenticator, and authentication server. Typically, the host PC runs the supplicant software and tries to authenticate itself by sending its credentials to the authenticator which in turn relays that info to the authentication server for authentication.

However, not all hosts may have supplicant functionality. Devices that cannot authenticate themselves using 802.1X but still need network access can use MAC Authentication Bypass (MAB), which uses the connecting device’s MAC address to grant or deny network access.

Typically, you would use this feature on ports where devices such as printers are connected. Such devices do not have 802.1X supplicant functionality.

In a typical deployment, the RADIUS server maintains a database of MAC addresses that require access. When this feature detects a new MAC address on a port, it generates a RADIUS request with both username and password as the device’s MAC address. After authorization succeeds, the port is accessible to the particular device through the same code path that 802.1X authentication would take when processing an 802.1X supplicant. If authentication fails, the port moves to the guest VLAN if configured, or it remains unauthorized.

The Catalyst 4500 series switch also supports re-authentication of MACs on a per port level. Be aware that the re-authentication functionality is by 802.1X and is not MAB specific. In the re-authentication mode, a port stays in the previous RADIUS-sent VLAN and tries to re-authenticate itself. If the re-authentication succeeds, the port stays in the RADIUS-sent VLAN. Otherwise, the port becomes unauthorized and moves to the guest VLAN if one is configured.

For details on how to configure MAB, see the “Configuring 802.1X with MAC Authentication Bypass” section on page 36-48.
Feature Interaction

This section lists feature interactions and restrictions when MAB is enabled. If a feature is not listed, assume that it interacts seamlessly with MAB (such as Unidirectional Controlled Port).

- MAB can only be enabled if 802.1X is configured on a port. MAB functions as a fall back mechanism for authorizing MACs. If you configure both MAB and 802.1X on a port, the port attempts to authenticate using 802.1X. If the host fails to respond to EAPOL requests and MAB is configured, the 802.1X port is opened up to listen to packets and to grab a MAC address, rather than attempt to authenticate endlessly.

Based on the default 802.1X timer values, the transition between mechanisms takes approximately 90 seconds. You can shorten the time by reducing the value of the transmission period time, which affects the frequency of EAPOL transmission. A smaller timer value results in EAPOLs sent during a shorter period of time. With MAB enabled, after 802.1X performs one full set of EAPOLs, the learned MAC address is forwarded to the authentication server for processing.

The MAB module performs authorization for the first MAC address detected on the wire. The port is considered authorized once a valid MAC address is received that RADIUS approves of.

802.1X authentication can re-start if an EAPOL packet is received on a port that was initially authorized as a result of MAB.

Figure 36-6 shows the message exchange during MAB.

- The authentication-failed VLAN is used only with dot1x-authentication-failed users. MAB is not attempted with dot1x-authentication-failed users. If 802.1X authentication fails, a port moves to the authentication-failed VLAN (if configured) whether MAB is configured or not.
• When both MAB and guest VLAN are configured and no EAPOL packets are received on a port, the 802.1X state-machine is moved to a MAB state where it opens the port to listen to traffic and grab MAC addresses. The port remains in this state forever waiting to see a MAC on the port. A detected MAC address that fails authorization causes the port to be moved to the guest VLAN if configured. While in a guest VLAN, a port is open to all traffic on the specified guest VLAN. Therefore, non-802.1X supplicants that normally would be authorized but are in guest VLAN due to the earlier detection of a device that failed authorization, would remain in the guest VLAN indefinitely. However, loss of link or the detection of an EAPOL on the wire causes a transition out of the guest VLAN and back to the default 802.1X mode.

• Once a new MAC has been authenticated by MAB, the responsibility to limit access falls upon the 802.1X Authenticator (or port security) to secure the port. The 802.1X default host parameter is defined only for a single host. If the port is changed to multi-user host, port security must be employed to enforce the number of MAC addresses allowed thru this port.

• Catalyst 4500 series switch supports MAB with VVID, with the restriction that the MAC address appears on a port data VLAN only. All IP phone MACs learned via CDP are allowed on voice VLANs.

• MAB and VMPS are mutually exclusive because their functionality overlaps.

Using 802.1X with Web-Based Authentication

The web-based authentication feature, known as Web Authentication Proxy, enables you to authenticate end users on host systems that do not run the IEEE 802.1X supplicant.

When configuring web-based authentication, note the following guidelines:

• Fallback to web-based authentication is configured on switch ports in access mode. Ports in trunk mode are not supported.

• Fallback to web-based authentication is not supported on EtherChannels or EtherChannel members.

• Although fallback to web-based authentication is an interface-specific configuration, the web-based authentication fallback behavior is defined in a global fallback profile. If the global fallback configuration changes, the new profile is not used until the next instance of authentication fallback.

For detailed information on configuring web-based authentication, see Chapter 37, “Configuring Web-Based Authentication.”

Using 802.1X with Inaccessible Authentication Bypass

When a switch cannot reach the configured RADIUS servers and clients (supplicants) cannot be authenticated, you can configure a switch to allow network access to hosts connected to critical ports that are enabled for Inaccessible Authentication Bypass.

When this feature is enabled, a switch monitors the status of the configured RADIUS servers. If no RADIUS servers are available, ports with Inaccessible Authentication Bypass enabled are authorized. You can specify a Inaccessible Authentication Bypass VLAN on a per-port basis.

Ports that were already authorized when RADIUS becomes unavailable are unaffected by Inaccessible Authentication Bypass.

When RADIUS becomes available, critically-authorized ports may be configured to automatically reauthenticate themselves.
For details on how to configure Inaccessible Authentication Bypass, see the “Configuring 802.1X with Inaccessible Authentication Bypass” section on page 36-50.

Using 802.1X with Unidirectional Controlled Port

Unidirectional Controlled Port is a combined hardware/software feature that allows dormant PCs to be “powered on” based on the receipt of a specific Ethernet frame, known as the magic packet. Generally, Unidirectional Controlled Port is used in environments where administrators plan to manage remote systems during off-hours, when it’s likely that the systems have been powered down.

Use of Unidirectional Controlled Port with hosts attached through 802.1X ports presents a unique problem; when the host powers down, a 802.1X port becomes unauthorized. In this state, the port allows the receipt and transmission of EAPoL packets only. Therefore, the Unidirectional Controlled Port magic packet cannot reach the host; without powering up, the PC cannot authenticate and open the port.

Unidirectional Controlled Port solves this problem by allowing packets to be transmitted on unauthorized 802.1X ports.

Note

Unidirectional Controlled Port only works when Spanning Tree Portfast is enabled on the port.

For details on how to configure 802.1X with Unidirectional Controlled Port, see the “Configuring 802.1X with Unidirectional Controlled Port” section on page 36-52

Unidirectional State

A unidirectional controlled port is typically configured when a connected host might enter a sleeping mode or power-down state. When either occurs, the host does not exchange traffic with other devices in the network. A host connected to the unidirectional port cannot send traffic to the network; it can only receive traffic from other devices in the network.

When you configure a port as unidirectional (with the authentication control-direction in interface configuration command), the port will receive traffic in VLANs on that port, but it is not put into a spanning-tree forwarding state. If a VLAN contains only unauthenticated ports, any SVI on that VLAN will be in a down state, during which packets will not be routed into the VLAN. For the SVI to be up, and so enable packets to be routed into the VLAN, at least one port in the VLAN must either be authenticated or in the spanning-tree forwarding state.

Bidirectional State

When you configure a port as bidirectional with the authentication control-direction both interface configuration command (or the dot1x control-direction both interface configuration command for Cisco IOS Release 12.2(46) or earlier), the port is access-controlled in both directions. In this state, except for EAPOL packets, a switch port does not receive or send packets.

Using 802.1X with Authentication Failed VLAN Assignment

Authentication-failed VLAN assignment allows you to provide access for authentication failed users on a per-port basis. Authentication failed users are end hosts that are 802.1X-capable but do not have valid credentials in an authentication server or end hosts that do not give any username and password combination in the authentication pop-up window on the user side.
If a user fails the authentication process, that port is placed in the authentication-failed VLAN. The port remains in the authentication-failed VLAN until the reauthentication timer expires. When the reauthentication timer expires the switch starts sending the port re-authentication requests. If the port fails reauthentication it remains in the authentication-failed VLAN. If the port is successfully reauthenticated, the port is moved either to the VLAN sent by RADIUS server or to the newly authenticated ports configured VLAN; the location depends on whether RADIUS is configured to send VLAN information.

**Note**

When enabling periodic reauthentication (see the “Enabling Periodic Reauthentication” section on page 36-61), only local reauthentication timer values are allowed. You cannot use a RADIUS server to assign the reauthentication timer value.

You can set the maximum number of authentication attempts that the authenticator sends before moving a port into the authentication-failed VLAN. The authenticator keeps a count of the failed authentication attempts for each port. A failed authentication attempt is either an empty response or an EAP failure. The authenticator tracks any mix of failed authentication attempts towards the authentication attempt count. After the maximum number of attempts is reached the port is placed in the authentication-failed VLAN until the reauthentication timer expires again.

**Note**

RADIUS may send a response without an EAP packet in it when it does not support EAP, and sometimes third party RADIUS servers also send empty responses. When this happens, the authentication attempt counter is incremented.

For details on how to configure Authentication Failed VLAN Assignment, see the “Configuring 802.1X with Authentication Failed” section on page 36-53.

**Usage Guidelines for Using Authentication Failed VLAN Assignment**

- You should enable reauthentication. The ports in authentication-failed VLANs do not receive reauthentication attempts if reauthentication is disabled. In order to start the reauthentication process the authentication-failed VLAN must receive a link down event or an EAP logoff event from the port. If the host is behind a hub, you may never get a link down event and may not detect the new host until the next reauthentication occurs. Therefore, it is recommended to have re-authentication enabled in that case.

- EAP failure messages are not sent to the user. If the user fails authentication the port is moved to an authentication-failed VLAN and an EAP success message is sent to the user. Because the user is not notified of the authentication failure there may be confusion as to why there is restricted access to the network. A EAP Success message is sent for the following reasons:
  - If the EAP Success message is not sent, the user tries to authenticate every 60 seconds (by default) by sending an EAP-start message.
  - In some cases, users have configured DHCP to EAP-Success and unless the user sees a success, DHCP does not work on the port.

- Sometimes a user caches an incorrect username and password combination after receiving a EAP success message from the authenticator and reuses that information in every re-authentication. Until the user passes the correct username and password combination the port remains in the authentication-failed VLAN.
Chapter 36  Configuring 802.1X Port-Based Authentication

About 802.1X Port-Based Authentication

- When an authentication failed port is moved to an unauthorized state the authentication process is restarted. If you should fail the authentication process again the authenticator waits in the held state. After you have correctly reauthenticated all 802.1X ports are reinitialized and treated as normal 802.1X ports.
- When you reconfigure an authentication-failed VLAN to a different VLAN, any authentication failed ports are also moved and the ports stay in their current authorized state.
- When you shut down or remove an authentication-failed VLAN from the VLAN database, any authentication failed ports are immediately moved to an unauthorized state and the authentication process is restarted. The authenticator does not wait in a held state because the authentication-failed VLAN configuration still exists. While the authentication-failed VLAN is inactive, all authentication attempts are counted, and as soon as the VLAN becomes active the port is placed in the authentication-failed VLAN.
- If you reconfigure the maximum number of authentication failures allowed by the VLAN, the change takes affect after the reauthentication timer expires.
- Internal VLANs that are used for Layer 3 ports cannot be configured as authentication-failed VLANs.
- The authentication-failed VLAN is supported only in single-host mode (the default port mode).
- When a port is placed in an authentication-failed VLAN the user’s MAC address is added to the mac-address-table. If a new MAC address appears on the port, it is treated as a security violation.
- When an authentication failed port is moved to an authentication-failed VLAN, the Catalyst 4500 series switch does not transmit a RADIUS-Account Start Message like it does for regular 802.1X authentication.

Using 802.1X with Port Security

You can enable port security on an 802.1X port in either single- or multiple-host mode. (To do so, you must configure port security with the `switchport port-security` interface configuration command.) When you enable port security and 802.1X on a port, 802.1X authenticates the port, and port security manages the number of MAC addresses allowed on that port, including that of the client. Hence, 802.1X port with port security allows you to limit the number or group of clients that can access the network.

For information on selecting multi-host mode, see the “Resetting the 802.1X Configuration to the Default Values” section on page 36-66.

These examples describe the interaction between 802.1X and port security on a switch:

- When a client is authenticated, and the port security table is not full, the client’s MAC address is added to the port security list of secure hosts. The port then proceeds to come up normally.
  
  When a client is authenticated and manually configured for port security, it is guaranteed an entry in the secure host table (unless port security static aging has been enabled).
  
  A security violation occurs if an additional host is learned on the port. The action taken depends on which feature (802.1X or port security) detects the security violation:
  
  - If 802.1X detects the violation, the action is to err-disable the port.
  - If port security detects the violation, the action is to shutdown or restrict the port (the action is configurable).
The following describes when port security and 802.1X security violations occur:

- In single host mode, after the port is authorized, any MAC address received other than the client’s causes a 802.1X security violation.
- In single host mode, if installation of an 802.1X client’s MAC address fails because port security has already reached its limit (due to a configured secure MAC addresses), a port security violation is triggered.
- In multi host mode, once the port is authorized, any additional MAC addresses that cannot be installed because the port security has reached its limit triggers a port security violation.

- When an 802.1X client logs off, the port transitions back to an unauthenticated state, and all dynamic entries in the secure host table are cleared, including the entry for the client. Normal authentication then ensues.
- If you administratively shut down the port, the port becomes unauthenticated, and all dynamic entries are removed from the secure host table.
- Only 802.1X can remove the client’s MAC address from the port security table. Note that in multi host mode, with the exception of the client’s MAC address, all MAC addresses that are learned by port security can be deleted using port security CLIs.
- Whenever port security ages out a 802.1X client’s MAC address, 802.1X attempts to reauthenticate the client. Only if the reauthentication succeeds is the client’s MAC address be retained in the port security table.
- All of the 802.1X client’s MAC addresses are tagged with (dot1x) when you display the port security table by using CLI.

### Using 802.1X Authentication with ACL Assignments and Redirect URLs

You can download per-host policies such as ACLs and redirect URLs to the switch from the RADIUS server during 802.1X or MAB authentication of the host. ACL download is also supported with web authentication after a fallback from 802.1X or MAB.

When the 802.1X host mode of the port is either single-host, MDA, or multiauthentication, the downloaded ACLs (DACLs) are modified to use the authenticated host’s IP address as the source address. When the host mode is multiple-hosts, the source address is configured as ANY, and the downloaded ACLs or redirects apply to all devices on the port.

If no ACLs are provided during the authentication of a host, the static default ACL configured on the port is applied to the host. On a voice VLAN port, only the static default ACL of the port is applied to the phone.

Topics include:

- Cisco Secure ACS and AV Pairs for URL-Redirect, page 36-17
- ACLs, page 36-18

For details on how to configure downloadable ACL and URL redirect, refer to the “Configuring 802.1X Authentication with ACL Assignments and Redirect URLs” section on page 36-32.

### Cisco Secure ACS and AV Pairs for URL-Redirect

When downloadable ACL is enabled, Cisco Secure ACS provides AAA services through RADIUS. You can set these Attribute-Value (AV) pairs on the Cisco Secure ACS with RADIUS cisco-av-pair vendor-specific attributes (VSAs).
CiscoSecure-Defined-ACL specifies the names of the DACLs on the Cisco Secure ACS. The switch receives the ACL name through the CiscoSecure-Defined-ACL AV pair in the format:

\#ACL#-IP-name-number

name is the ACL name. number is the version number (like 31783768).

The Auth-Manager code verifies whether the access control entries (ACEs) of the specified downloadable ACL were previously downloaded. If not, the Auth-Manager code sends an AAA request with the downloadable ACL name as the username so that the ACEs are downloaded. The downloadable ACL is then created as a named ACL on the switch. This ACL has ACEs with a source address of any and does not have an implicit deny statement at the end. When the downloadable ACL is applied to an interface after authentication completes, the source address changes from any to the host source IP address depending on the host mode of the interface. The ACEs are prepended to the downloadable ACL applied to the switch interface to which the endpoint device is connected. If traffic matches the CiscoSecure-Defined-ACL ACEs, the appropriate actions are taken.

url-redirect and url-redirect-acl specify the local URL policy on the switch. The switches use these cisco-av-pair VSAs as follows:

- url-redirect = <HTTP or HTTPS URL>
- url-redirect-acl = switch ACL name or number

These AV pairs enable the switch to intercept an HTTP or HTTPS request from the endpoint device and forward the client web browser to the specified redirect address from which the latest antivirus files can be downloaded. The url-redirect AV pair on the Cisco Secure ACS contains the URL to which the web browser is redirected. The url-redirect-acl AV pair contains the name or number of an ACL that specifies the HTTP or HTTPS traffic to be redirected. Traffic that matches a permit entry in the redirect ACL is redirected.

Note

The redirect or default ACL must be defined on the switch.

ACLs

If downloadable ACL is configured for a particular client on the authentication server, you must configure a default port ACL on a client-facing switch port.

If the default ACL is configured on the switch and the Cisco Secure ACS sends a host access policy to the switch, it applies the policy to traffic from the host connected to a switch port. If the policy does not apply, the switch applies the default ACL. If the Cisco Secure ACS sends the switch a downloadable ACL, this ACL takes precedence over the default ACL already configured on the switch port. However, if the switch receives a host access policy from the Cisco Secure ACS, but the default ACL is not configured, the authorization failure is declared.

For details on how to configure a downloadable policy, refer to the “Configuring a Downloadable Policy” section on page 36-37.

Using 802.1X with RADIUS-Provided Session Timeouts

You can specify whether a switch uses a locally configured or a RADIUS-provided reauthentication timeout. If the switch is configured to use the local timeout, it reauthenticates the host when the timer expires.
If the switch is configured to use the RADIUS-provided timeout, it scans the RADIUS Access-Accept message for the Session-Timeout and optional Termination-Action attributes. The switch uses the value of the Session-Timeout attribute to determine the duration of the session, and it uses the value of the Termination-Action attribute to determine the switch action when the session's timer expires.

If the Termination-Action attribute is present and its value is RADIUS-Request, the switch reauthenticates the host. If the Termination-Action attribute is not present, or its value is Default, the switch terminates the session.

Note

The supplicant on the port detects that its session has been terminated and attempts to initiate a new session. Unless the authentication server treats this new session differently, the client may see only a brief interruption in network connectivity as the switch sets up a new session.

If the switch is configured to use the RADIUS-supplied timeout, but the Access-Accept message does not include a Session-Timeout attribute, the switch never reauthenticates the supplicant. This behavior is consistent with Cisco's wireless access points.

For details on how to configure RADIUS-provided session timeouts, see the “Configuring RADIUS-Provided Session Timeouts” section on page 36-45.

Using 802.1X with Voice VLAN Ports

A voice VLAN port is a special access port associated with two VLAN identifiers:

- Voice VLAN ID (VVID) to carry voice traffic to and from the IP phone. The VVID is used to configure the IP phone connected to the port.
- Port VLAN ID (PVID) to carry the data traffic to and from the workstation connected to the switch through the IP phone. The PVID is the native VLAN of the port.

Each port that you configure for a voice VLAN is associated with a VVID and a PVID. This configuration allows voice traffic and data traffic to be separated onto different VLANs.

A voice VLAN port becomes active when a link exists whether the port is AUTHORIZED or UNAUTHORIZED. All traffic exiting the voice VLAN is obtained correctly and appears in the MAC address table. Cisco IP phones do not relay CDP messages from other devices. So, if several Cisco IP phones are connected in a series, the switch recognizes only the one directly connected to it. When 802.1X is enabled on a voice VLAN port, the switch drops packets from unrecognized Cisco IP phones more than one hop away.

When 802.1X is enabled on a port, you cannot configure a PVID that is equal to a VVID. For more information about voice VLANs, see Chapter 34, “Configuring Voice Interfaces.”

Observe the following feature interactions:

- 802.1X VLAN assignment cannot assign to the port the same VLAN as the voice VLAN; otherwise, the 802.1X authentication fails. The same holds true for dynamic VLAN assignment.
- 802.1X guest VLAN works with the 802.1X voice VLAN port feature. However, the guest VLAN cannot be the same as the voice VLAN.
- 802.1X port security works with the 802.1X voice VLAN port feature and is configured per port. Two MAC addresses must be configured: one for the Cisco IP phone MAC address on the VVID and one for the PC MAC address on PVID.

However, you cannot use the 802.1X voice VLAN port feature with 802.1X port security’s sticky MAC address configuration and statically configured MAC address configuration.
Using Multiple Domain Authentication and Multiple Authentication

Multiple Domain Authentication (MDA) allows both a data device and a voice device, such as an IP phone (Cisco or 3rd party non-Cisco), to authenticate on the same switch port, which is divided into a data domain and a voice domain.

Multiple Authentication allows multiple data devices and a voice device. When a voice VLAN is configured on a multi-authentication port, the port can perform authentication in the voice domain as on an MDA port.

MDA does not enforce the order of device authentication. For best results, however, you should authenticate a voice device before you authenticate a data device on an MDA-enabled port.

Observe the following guidelines for configuring MDA:

- It is highly recommended that you enable CoPP on an MDA-enabled port to protect against a DoS attack. Refer to Chapter 39, “Configuring Control Plane Policing.”
- To configure a switch port for MDA or Multiple Authentication, see the “Configuring Multiple Domain Authentication and Multiple Authorization” section on page 36-29.
- You must configure the voice VLAN for the IP phone when the host mode is set to multidomain. For more information, see Chapter 34, “Configuring Voice Interfaces.”
- To authorize a voice device, the AAA server must be configured to send a Cisco Attribute-Value (AV) pair attribute with a value of device-traffic-class=voice. Without this value, the switch treats the voice device as a data device.
- The guest VLAN and restricted VLAN features only apply to the data devices on an MDA-enabled port. The switch treats a voice device that fails authorization as a data device.
- If more than one device attempts authorization on either the voice or the data domain of a port, it is error disabled.
- Until a device is authorized, the port drops its traffic. Non-Cisco IP phones or voice devices are allowed into both the data and voice VLANs. The data VLAN allows the voice device to contact a DHCP server to obtain an IP address and acquire the voice VLAN information. After the voice device starts sending on the voice VLAN, its access to the data VLAN is blocked. A security violation may occur in MDA if the voice device continues to send traffic on the data VLAN.
- MDA can use MAC authentication bypass as a fallback mechanism to allow the switch port to connect to devices that do not support 802.1X authentication. This is especially useful for 3rd-party phones without 802.1X supplicant. For more information, see the “Using 802.1X with MAC Authentication Bypass” section on page 36-11.
• When a data or a voice device is detected on a port, its MAC address is blocked until authorization succeeds. If the authorization fails, the MAC address remains blocked for 5 minutes.
• If more than one device is detected on the data VLAN or more than one voice device is detected on the voice VLAN while a port is unauthorized, the port is error disabled.
• When a port host mode is changed from single- or multihost to multidomain mode, an authorized data device remains authorized on the port. However, a Cisco IP phone that has been allowed on the port in the voice VLAN is automatically removed and must be reauthenticated on that port.
• Active fallback mechanisms such as guest VLAN and restricted VLAN remain configured after a port changes from single- or multihost mode to multidomain mode.
• Switching a port host mode from multidomain to single- or multihost mode removes all authorized devices from the port.
• If a data domain is authorized first and placed in the guest VLAN, non-802.1X-capable voice devices need to tag their packets on the voice VLAN to trigger authentication.
• We do not recommend per-user ACLs with an MDA-enabled port. An authorized device with a per-user ACL policy might impact traffic on both the voice and data VLANs of the port. If used, only one device on the port should enforce per-user ACLs.

How 802.1X Fails on a Port

802.1X may fail on a port in three ways: timeout, explicit failure, and protocol timeout.

Timeout—A switch attempts 802.1X at link up but the attached endpoint is not 802.1X-capable. After the configured number of retries and timeouts, the switch attempts the next authentication method if one is configured (like MAB). If MAB fails, the switch deploys the Guest VLAN (also called the no-response VLAN), if configured. The Guest VLAN is configured with the authentication event no-response interface command.

Explicit Failure—A switch and the endpoint perform the entire 802.1X authentication sequence and the result is an explicit failure (usually indicated by an Access-Reject from the RADIUS server to the switch and an EAP-Failure sent from the switch to the endpoint). In this case, the switch attempts MAB (if "authentication event failure action next-method" is configured) or deploy the AuthFail VLAN (if "authentication event failure action authorize vlan" is configured).

Protocol Timeout—A switch and the endpoint start the 802.1X authentication process but do not complete it. For example, the endpoint may send an 802.1X EAPoL-Start message and then stop responding to the switch (perhaps, because the endpoint lacks a credential or because it is waiting for end user to enter some information). In this case, the switch knows that the connected device is EAPoL-capable, so it will not deploy the Guest VLAN after timing out. Instead, it restarts authentication after a timeout. The switch continues to label the port as EAPoL-capable until a physical link down event is detected. To force the switch to deploy the Guest VLAN in the case of a protocol timeout, configure dot1x guest-vlan supplicant globally. If the port is configured for hostmode multi-domain authentication, the switch behaves as if dot1x guest-vlan supplicant is configured.

Supported Topologies

The 802.1X port-based authentication supports two topologies:

• Point-to-point
• Wireless LAN
Chapter 36 Configuring 802.1X Port-Based Authentication

In a point-to-point configuration (see Figure 36-1 on page 36-2), only one client can be connected to the 802.1X-enabled switch port when the multi-host mode is not enabled (the default). The switch detects the client when the port link state changes to the up state. If a client leaves or is replaced with another client, the switch changes the port link state to down, and the port returns to the unauthorized state.

For 802.1X port-based authentication in a wireless LAN (Figure 36-7), you must configure the 802.1X port as a multiple-host port that is authorized as a wireless access point once the client is authenticated. (See the “Resetting the 802.1X Configuration to the Default Values” section on page 36-66.) When the port is authorized, all other hosts that are indirectly attached to the port are granted access to the network. If the port becomes unauthorized (reauthentication fails or an EAPOL-logoff message is received), the switch denies access to the network for all wireless access point-attached clients. In this topology, the wireless access point is responsible for authenticating clients attached to it, and the wireless access point acts as a client to the switch.

Figure 36-7 Wireless LAN Example

Note
Although we recommend using the authentication commands described in this section, legacy 802.1X commands in 12.2(46)SG and earlier releases are still accepted.

To configure 802.1X, follow this procedure:

Step 1 Enable 802.1X authentication. See the “Enabling 802.1X Authentication” section on page 36-24.
Step 2 Configure switch to RADIUS server communication. See the “Configuring Switch-to-RADIUS-Server Communication” section on page 36-27.
Step 3 Adjust the 802.1X timer values. See the “Changing the Quiet Period” section on page 36-63.
Step 4 Configure optional features. See the “Configuring RADIUS-Provided Session Timeouts” section on page 36-45.

These sections describe how to configure 802.1X:
- Default 802.1X Configuration, page 36-23
- 802.1X Configuration Guidelines, page 36-24
- Enabling 802.1X Authentication, page 36-24 (required)

Chapter 36  Configuring 802.1X Port-Based Authentication

802.1X Configuration Guidelines

This section describes the guidelines for configuring 802.1X authentication:

- The 802.1X protocol is supported only on Layer 2 static access, PVLAN host ports, and Layer 3 routed ports. You cannot configure 802.1X for any other port modes.

- If you are planning to use VLAN assignment, be aware that the features use general AAA commands. For information on how to configure AAA, refer to the “Enabling 802.1X Authentication” section on page 36-24. Alternatively, you can refer to the Cisco IOS security documentation:

Enabling 802.1X Authentication

To enable 802.1X port-based authentication, you first must enable 802.1X globally on your switch, then enable AAA and specify the authentication method list. A method list describes the sequence and authentication methods that must be queried to authenticate a user.
Chapter 36  Configuring 802.1X Port-Based Authentication

The software uses the first method listed in the method list to authenticate users; if that method fails to respond, the software selects the next authentication method in the list. This process continues until there is successful communication with a listed authentication method or until all defined methods are exhausted. If authentication fails at any point in this cycle, the authentication process stops, and no other authentication methods are attempted.

Note

To allow VLAN assignment, you must enable AAA authorization to configure the switch for all network-related service requests.

To configure 802.1X port-based authentication, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# dot1x system-auth-control</td>
</tr>
<tr>
<td></td>
<td>Enables 802.1X on your switch.</td>
</tr>
<tr>
<td></td>
<td>To disable 802.1X globally on the switch, use the no dot1x system-auth-control command.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config)# aaa new-model</td>
</tr>
<tr>
<td></td>
<td>Enables AAA.</td>
</tr>
<tr>
<td></td>
<td>To disable AAA, use the no aaa new-model command.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config)# aaa authentication dot1x {default} method1 [method2...]</td>
</tr>
<tr>
<td></td>
<td>Creates an 802.1X AAA authentication method list.</td>
</tr>
<tr>
<td></td>
<td>To create a default list that is used when a named list is not specified in the authentication command, use the default keyword followed by the methods that are to be used in default situations. The default method list is automatically applied to all interfaces.</td>
</tr>
<tr>
<td></td>
<td>Enter at least one of these keywords:</td>
</tr>
<tr>
<td></td>
<td>* group radius—Use the list of all RADIUS servers for authentication.</td>
</tr>
<tr>
<td></td>
<td>* none—Use no authentication. The client is automatically authenticated by the switch without using the information supplied by the client.</td>
</tr>
<tr>
<td></td>
<td>To disable 802.1X AAA authentication, use the no aaa authentication dot1x {default</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch(config)# aaa authorization network (default) group radius</td>
</tr>
<tr>
<td></td>
<td>(Optional) Configures the switch for user RADIUS authorization for all network-related service requests, such as VLAN assignment.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Switch(config)# interface interface-id</td>
</tr>
<tr>
<td></td>
<td>Enters interface configuration mode and specifies the interface to be enabled for 802.1X authentication.</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>Switch(config-if)# switchport mode access</td>
</tr>
<tr>
<td></td>
<td>Specifies a nontrunking, nontagged single VLAN Layer 2 interface.</td>

<td>Refer to the “Default 802.1X Configuration” section on page 36-23.</td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>Switch(config-if)# authentication port-control auto</td>
</tr>
<tr>
<td></td>
<td>Enables 802.1X authentication on the interface.</td>
</tr>
<tr>
<td><strong>Step 10</strong></td>
<td>Switch(config-if)# end</td>
</tr>
<tr>
<td></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
</tbody>
</table>
Configuring 802.1X Port-Based Authentication

Chapter 36  Configuring 802.1X Port-Based Authentication

Configuring 802.1X Port-Based Authentication

**Note**
Enabling Spanning Tree PortFast ensures that a port comes up immediately after authorization.

**Note**
Whenever you configure any 802.1X parameter on a port, a dot1x authenticator is automatically created on the port. As a result *dot1x pae authenticator* appears in the configuration. This is to ensure that dot1x authentication still works on legacy configurations without manual intervention. This is likely to change in future releases.

This example shows how to enable 802.1X and AAA on Fast Ethernet port 2/1, and how to verify the configuration:

```plaintext
Switch# configure terminal
Switch(config)# dot1x system-auth-control
Switch(config)# aaa new-model
Switch(config)# aaa authentication dot1x default group radius
Switch(config)# interface fastethernet2/1
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication port-control auto
Switch(config-if)# end

Configuring Switch-to-RADIUS-Server Communication

A RADIUS security server is identified by its host name or IP address, host name and specific UDP port number, or IP address and specific UDP port numbers. The combination of the IP address and UDP port number creates a unique identifier, which enables RADIUS requests to be sent to multiple UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service—for example, authentication—the second host entry configured acts as the fail-over backup to the first one. The RADIUS host entries are tried in the order they were configured.
To configure the RADIUS server parameters on the switch, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong> Switch(config)# radius-server host hostname</td>
<td>auth-port port-number [acct-port port-number] [test username name]</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>

</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> Switch(config-if)# radius deadtime min</td>
<td>(Optional) Configures the number of minutes before a dead RADIUS server is tested to check whether it has come back up. The default is 1 minute.</td>
</tr>
<tr>
<td><strong>Step 4</strong> Switch(config-if)# radius dead-criteria time seconds tries num</td>
<td>(Optional) Configures the criteria used to decide whether a RADIUS server is dead. The time parameter specifies the number of seconds after which a request to the server is unanswered before it is considered dead. The tries parameter specifies the number of times a request to the server is unanswered before it is considered dead.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Chapter 36  Configuring 802.1X Port-Based Authentication

This example shows how to specify the server with IP address 172.120.39.46 as the RADIUS server. The first command specifies port 1612 as the authorization port, sets the encryption key to rad123.

The second command dictates that key matches are performed on the RADIUS server:

Switch# configure terminal
Switch(config)# radius-server host 172.120.39.46 auth-port 1612 key rad123
Switch(config)# ip radius source-interface g3/2
Switch(config)# end
Switch#

You can globally configure the timeout, retransmission, and encryption key values for all RADIUS servers by using the `radius-server host` global configuration command. If you want to configure these options on a per-server basis, use the `radius-server timeout`, `radius-server retransmit`, and the `radius-server key` global configuration commands.

You also need to create a AAA client setting on the RADIUS server. These settings include the IP address of the switch and the key string to be shared by both the server and the switch.

### Configuring Multiple Domain Authentication and Multiple Authorization

To configure MDA and Multiple Authentication, perform this task.

<table>
<thead>
<tr>
<th>Step</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>2</td>
<td>Switch(config)# radius-server vsa send authentication</td>
<td>Configures the network access server to recognize and use vendor-specific attributes (VSAs).</td>
</tr>
<tr>
<td>3</td>
<td>Switch(config)# interface interface-id</td>
<td>Specifies the port to which multiple hosts are indirectly attached, and enters interface configuration mode.</td>
</tr>
</tbody>
</table>

Command Purpose

<table>
<thead>
<tr>
<th>Step</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>Switch(config)# ip radius source-interface m/p</td>
<td>Establishes the IP address to be used as the source address for all outgoing RADIUS packets.</td>
</tr>
<tr>
<td>5</td>
<td>Switch(config)# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>6</td>
<td>Switch# show running-config</td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td>7</td>
<td>Switch# copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>
Chapter 36  Configuring 802.1X Port-Based Authentication

This example shows how to enable 802.1X authentication and to allow multiple hosts:

```
Switch(config)# interface gigabitethernet2/1
Switch(config-if)# authentication port-control auto
Switch(config-if)# authentication host-mode multi-host
Switch(config-if)# end
```

This example shows how to enable MDA and to allow both a host and a 802.1X voice device (a Cisco or third-party phone with 802.1X supplicant) on the port:

```
Switch# conf terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface FastEthernet3/1
Switch(config-if)# shut
Switch(config-if)# switchport access vlan 12
Switch(config-if)# switchport mode access
Switch(config-if)# switchport voice vlan 10
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication port-control auto
Switch(config-if)# authentication host-mode multi-domain
Switch(config-if)# no shut
Switch(config-if)# end
```
This example shows how to enable MDA and to allow both a host and a non-802.1X voice device on the port:

Switch# conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface FastEthernet3/1
Switch(config-if)# shut
Switch(config-if)# switchport access vlan 12
Switch(config-if)# switchport mode access
Switch(config-if)# switchport voice vlan 10
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication port-control auto
Switch(config-if)# authentication host-mode multi-domain
Switch(config-if)# mab eap
Switch(config-if)# no shut
Switch(config-if)# end

This example shows how to verify the dot1x MDA settings on interface FastEthernet3/1:

Switch# show dot1x interface FastEthernet3/1 detail

Dot1x Info for FastEthernet3/1
-----------------------------------
PAE = AUTHENTICATOR
PortControl = AUTO
ControlDirection = Both
HostMode = MULTI_DOMAIN
ReAuthentication = Disabled
QuietPeriod = 60
ServerTimeout = 30
SuppTimeout = 30
ReAuthPeriod = 3600 (Locally configured)
ReAuthMax = 2
MaxReq = 2
TxPeriod = 30
RateLimitPeriod = 0

Dot1x Authenticator Client List
---------------------------------
Domain = DATA
Supplicant = 0000.0000.ab01
  Auth SM State = AUTHENTICATED
  Auth BEND SM Stat = IDLE
Port Status = AUTHORIZED
Authentication Method = Dot1x
Authorized By = Authentication Server
Vlan Policy = 12

Domain = VOICE
Supplicant = 0060.b057.4687
  Auth SM State = AUTHENTICATED
  Auth BEND SM Stat = IDLE
Port Status = AUTHORIZED
Authentication Method = Dot1x
Authorized By = Authentication Server

Switch#

This example shows how to enable MDA and to authentication of multiple hosts and a voice device on an IEEE 802.1x-authorized port:

Switch# conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface FastEthernet3/1
Switch(config-if)# shut
Switch(config-if)# switchport access vlan 12
Switch(config-if)# switchport mode access
Switch(config-if)# switchport voice vlan 10
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication port-control auto
Switch(config-if)# authentication host-mode multi-auth
Switch(config-if)# map eap
Switch(config-if)# no shut
Switch(config-if)# end

Configuring 802.1X Port-Based Authentication

Configuring 802.1X Port-Based Authentication with ACL Assignments and Redirect URLs

Topics include:
- Downloadable ACL, page 36-32
- URL-Redirect, page 36-34
- Configuring a Downloadable Policy, page 36-37

Downloadable ACL

The Downloadable ACL feature enables you to download device specific authorization policies from the authentication server. These policies activate after authentication succeeds for the respective client and the client's IP address has been populated in the IP device tracking table. (Downloadable ACL is applied on the port, once the port is authenticated and the IP device tracking table has the host IP address entry).

The following sections illustrate the configuration needed to complement the related authentication (802.1X or MAB) configuration. (No unique configuration is required on the switch. All of the configuration is on the ACS.) After authentication succeeds, enter the `show ip access-list` command to display the downloadable ACLs.

Switch Configuration

**Step 1** Configure the IP device tracking table.

Switch(config)# ip device tracking

**Step 2** Configure RADIUS VSA to forward authentication.

Switch(config)# radius-server vsa send authentication

**Step 3** Configure Static ACL (PACL) for the interface.

Switch(config)# int g2/9
Switch(config-if)# ip access-group pac1-4 in

Sample Interface Configuration

Switch# show running-configuration interface g2/9
Building configuration...

Current configuration : 617 bytes
!
interface GigabitEthernet2/9
switchport
switchport access vlan 29
switchport mode access
switchport voice vlan 1234
access-group mode prefer port
ip access-group pacl-4 in
speed 100
duplex full
authentication event fail action authorize vlan 111
authentication event server dead action authorize vlan 333
authentication event server alive action reinitialize
authentication host-mode multi-auth
authentication order dot1x
authentication port-control auto
authentication timer restart 100
authentication timer reauthenticate 20
authentication timer inactivity 200
mab eap
dot1x pae authenticator
end

Switch#
Switch# show ip access-list pacl-4
10 permit ip host 1.1.1.1 host 2.2.2.2
20 permit icmp host 1.1.1.1 host 2.2.2.2
Switch#

Debug Commands for DACL

The IP device tracking table contains the host IP address learned through ARP or DHCP.

The following commands displays the constraints on the IP device tracking table:

Switch# show ip device tracking all
IP Device Tracking = Enabled
IP Device Tracking Probe Count = 3
IP Device Tracking Probe Interval = 30

<table>
<thead>
<tr>
<th>IP Address</th>
<th>MAC Address</th>
<th>Interface</th>
<th>STATE</th>
</tr>
</thead>
<tbody>
<tr>
<td>50.0.0.12</td>
<td>0015.60a4.5e84</td>
<td>GigabitEthernet2/9</td>
<td>ACTIVE</td>
</tr>
</tbody>
</table>

The following command shows that the EPM (Policy Enforced Module) session contains the DACL downloaded from ACS:

Switch# show epm session ip 50.0.0.12
Admission feature : DOT1X
AAA Policies :
ACS ACL : xACSACLx-IP-auth-48b79b6e

The following command reveals the contents of the downloadable ACL:

Switch# show ip accesslists xACSACLx-IP-auth-48b79b6e
Extended IP access list xACSACLx-IP-auth-48b79b6e (per-user)
10 permit udp any any
Switch(config)#

Cisco ACS Configuration for DACL

Note

Only Cisco ACS supports DACL.
Follow these steps to ensure correct functioning of the ACS configuration required for DACL:

**Step 1**
Configure a downloadable IP ACL on the window that appears when you select Radius Shared Profile > Downloadable IP ACL Content:

![Figure 36-8 Shared Profile Components](image)

**Downloadable IP ACL Content**

- **Name:** auth
- **ACL Definitions**

![Figure 36-9 Downloadable ACLs](image)

**Step 2**
Attach this DACL with the USER on the window that appears when you select User > DACLs:

**URL-Redirect**

This configuration consists of two configurations: one on ACS, and one on the switch.

**ACS configuration**

To configure two Cisco-AV pairs, add the following statements under the user or group Cisco IOS/PIX 6x RADIUS attributes:

```
url-redirect-acl=urlacl
url-redirect=http://www.cisco.com
```

**Note**
A default port ACL must be configured on the interface.
Switch configuration

To configure the switch for URL redirect, do the following:

**Step 1** Configure the IP device tracking table.
Switch(config)# ip device tracking

**Step 2** Configure RADIUS with the `send authentication` command.
Switch(config)# radius-server vsa send authentication

**Step 3** Configure the URL redirect ACL (URLACL).
Switch# ip access-list urlacl
    10 permit tcp any any
Switch#

**Step 4** Configure static ACL (PACL) for the interface.
Switch(config)# int g2/9
Switch(config-if)# ip access-group pacl-4 in

Sample Interface Configuration

Switch# show running-configuration int g2/9
Building configuration...

Current configuration : 617 bytes
!
interface GigabitEthernet2/9
    switchport
    switchport access vlan 29
    switchport mode access
    switchport voice vlan 1234
    access-group mode prefer port
    ip access-group pacl-4 in
    speed 100
duplex full
    authentication event fail action authorize vlan 111
    authentication event server dead action authorize vlan 333
    authentication event server alive action reinitialize
    authentication host-mode multi-auth
    authentication order dot1x
    authentication port-control auto
    authentication timer restart 100
    authentication timer reauthenticate 20
    authentication timer inactivity 200
    mab
dot1x pae authenticator
end

Switch#

Switch# show access-list pacl-4
    10 permit ip host 1.1.1.1 host 2.2.2.2
    20 permit icmp host 1.1.1.1 host 2.2.2.2
Switch#
Verify URL-redirect with the following commands.

The `show ip device tracking` command illustrates the constraints on the IP device tracking table:

```
Switch(config)# show ip device tracking all
IP Device Tracking = Enabled
IP Device Tracking Probe Count = 3
IP Device Tracking Probe Interval = 30
```

<table>
<thead>
<tr>
<th>IP Address</th>
<th>MAC Address</th>
<th>Interface</th>
<th>STATE</th>
</tr>
</thead>
<tbody>
<tr>
<td>50.0.0.12</td>
<td>0015.60a4.5e84</td>
<td>GigabitEthernet2/9</td>
<td>ACTIVE</td>
</tr>
</tbody>
</table>

The `show epm session ip` command displays the EPM session table for a particular host. Observe the URL-redirect-acl and URL-redirect URL information that downloads from the ACS.

```
Switch# show epm session ip 50.0.0.12
Admission feature : DOT1X
AAA Policies               :
URL Redirect ACL : urlacl
URL Redirect : http://www.cisco.com
```

For more information about AV pairs that are supported by Cisco IOS software, see the ACS configuration and command reference documentation about the software releases running on the AAA clients.

**Guidelines and Restrictions for DACL and URL Redirect**

For downloadable ACL or URL redirect, the ACL source must be ANY (permit TCP ANY host 1.1.1.1 eq 80 or permit TCP ANY host 1.1.1.1 eq 443).
## Configuring a Downloadable Policy

To configure downloadable policies, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>Switch# configure terminal</strong></td>
</tr>
<tr>
<td></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><strong>Switch(config)# access-list</strong></td>
</tr>
<tr>
<td></td>
<td>**access-list-number {deny</td>
</tr>
<tr>
<td></td>
<td><strong>source [source-wildcard] [log]</strong></td>
</tr>
<tr>
<td></td>
<td>Defines the default port ACL through a source address and wildcard.</td>
</tr>
<tr>
<td></td>
<td>The <em>access-list-number</em> is a decimal from 1 to 99 or 1300 to 1999.</td>
</tr>
<tr>
<td></td>
<td>Enter <em>deny</em> or <em>permit</em> to specify whether to deny or permit access if conditions match.</td>
</tr>
<tr>
<td></td>
<td><em>source</em> is the address of the network or host from which the packet is sent, specified as follows:</td>
</tr>
<tr>
<td></td>
<td>• The 32-bit quantity in dotted-decimal format</td>
</tr>
<tr>
<td></td>
<td>• The keyword <em>any</em> as an abbreviation for source and source-wildcard value of 0.0.0.0 255.255.255.255</td>
</tr>
<tr>
<td></td>
<td>You do not need a source-wildcard value.</td>
</tr>
<tr>
<td></td>
<td>• The keyword <em>host</em> as an abbreviation for source and source-wildcard of source 0.0.0.0.</td>
</tr>
<tr>
<td></td>
<td>(Optional) Applies the source-wildcard wildcard bits to the source.</td>
</tr>
<tr>
<td></td>
<td>(Optional) Enters log to cause an informational logging message about the packet that matches the entry to be sent to the console.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><strong>Switch(config-if)# interface</strong></td>
</tr>
<tr>
<td></td>
<td><strong>interface-id</strong></td>
</tr>
<tr>
<td></td>
<td>Enters interface configuration mode.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><strong>Switch(config-if)# ip access-group</strong></td>
</tr>
<tr>
<td></td>
<td>**(access-list-number</td>
</tr>
<tr>
<td></td>
<td>Controls access to the specified interface.</td>
</tr>
<tr>
<td></td>
<td>This step is mandatory for a functioning downloaded policy.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><strong>Switch(config)# exit</strong></td>
</tr>
<tr>
<td></td>
<td>Returns to global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td><strong>Switch(config)# aaa new-model</strong></td>
</tr>
<tr>
<td></td>
<td>Enables AAA.</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td><strong>Switch(config)# aaa authorization</strong></td>
</tr>
<tr>
<td></td>
<td><strong>network default local</strong></td>
</tr>
<tr>
<td></td>
<td>Sets the authorization method to local. To remove the authorization method, use the <em>no aaa authorization network default local</em> command.</td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td><strong>Switch(config)# ip device tracking</strong></td>
</tr>
<tr>
<td></td>
<td>Enables the IP device tracking table.</td>
</tr>
<tr>
<td></td>
<td>To disable the IP device tracking table, use the <em>no ip device tracking</em> global configuration commands.</td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td><strong>Switch(config)# ip device tracking</strong></td>
</tr>
<tr>
<td></td>
<td>**{probe {count count</td>
</tr>
<tr>
<td></td>
<td>(Optional) Configures these parameters for the IP device tracking table:</td>
</tr>
<tr>
<td></td>
<td>• <em>count</em> - Number of times that the switch sends the ARP probe. The range is 1 to 5. The default is 3.</td>
</tr>
<tr>
<td></td>
<td>• <em>interval</em> - Number of seconds that the switch waits for a response before resending the ARP probe. The range is 30 to 300 seconds. The default is 30 seconds.</td>
</tr>
<tr>
<td><strong>Step 10</strong></td>
<td><strong>Switch(config)# radius-server vsa send authentication</strong></td>
</tr>
<tr>
<td></td>
<td>Configures the network access server to recognize and use vendor-specific attributes.</td>
</tr>
<tr>
<td><strong>Step 11</strong></td>
<td><strong>Switch(config)# end</strong></td>
</tr>
<tr>
<td></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
</tbody>
</table>

**Note** The downloadable ACL must be operational.
Chapter 36  Configuring 802.1X Port-Based Authentication

Configuring 802.1X Port-Based Authentication

The following example illustrates how to configure a switch for downloadable policy:

```
Switch# config terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# aaa new-model
Switch(config)# aaa authorization network default local
Switch(config)# ip device tracking
Switch(config)# ip access-list extended default_acl
Switch(config-ext-nacl)# permit ip any any
Switch(config-ext-nacl)# exit
Switch(config)# radius-server vsa send authentication
Switch(config)# int fastEthernet 2/13
Switch(config-if)# ip access-group default_acl in
Switch(config-if)# exit
```

Configuring 802.1X Authentication with Per-User ACL and Filter-ID ACL

Topics include:

- Per-User ACL and Filter-ID ACL, page 36-38
- Configuring a Per-User ACL and Filter-ID ACL, page 36-44

Per-User ACL and Filter-ID ACL

Prior to Cisco IOS Release 12.2(52)SG, the Cat4K platform only supported downloadable ACLs, which work with the Cisco ACS server but not with third-party AAA servers. With Cisco IOS Release 12.2(52)SG, the Catalyst 4500 switch offers the Filter-ID/Per-user-acl enhancement(s), which allow ACL policy enforcement using a third-party AAA server.

The Filter-ID feature provides the following capabilities:

- Filter-ID option allows an administrator to define the ACL name on the AAA server using IETF standard Radius attribute. The ACL itself must be pre-configured locally on the switch.

The Per-user-acl feature provides the following capabilities:

- Per-user ACL allows an administrator to define the per-user ACL on the AAA server using Cisco Radius AV pairs. This allows third-party AAA server to interoperate by loading Cisco Radius dictionary. Cisco radius dictionary has **Cisco Radius AV pairs** configured as a VSA.

Note  The Radius Vendor-specific attributes (VSAs) allow vendors to support their own proprietary RADIUS attributes that are not included in standard radius attributes.
## Switch Configuration

**Step 1** Configure the IP device tracking table.

Switch(config)# ip device tracking

**Step 2** Configure Static ACL (PACL) for the interface.

Switch(config)# int g2/9
Switch(config-if)# ip access-group pacl-4 in

### Sample Interface Configuration

Switch# show running-configuration interface g2/9
Building configuration...

Current configuration : 617 bytes
!
interface GigabitEthernet2/9
  switchport
  switchport access vlan 29
  switchport mode access
  switchport voice vlan 1234
  access-group mode prefer port
  ip access-group pacl-4 in
  speed 100
duplex full
authentication event fail action authorize vlan 111
authentication event server dead action authorize vlan 333
authentication event server alive action reinitialize
authentication host-mode multi-auth
authentication order dot1x
authentication port-control auto
authentication timer restart 100
authentication timer reauthenticate 20
authentication timer inactivity 200
mab eap
dot1x pae authenticator
end

Switch# show ip access-list pacl-4
  10 permit ip host 1.1.1.1 host 2.2.2.2
  20 permit icmp host 1.1.1.1 host 2.2.2.2
Switch#

### Per-User-Acl configuration in ACS

In the Group/User Setting page, scroll down to the Cisco IOS/PIX 6.x RADIUS Attributes section. Select the box next to [009001 cisco-av-pair] and enter the elements of the per-user ACL. Per-user ACLS take this format:

```
<protocol>:inacl#<sequence number>=<ACE>
```

<protocol> can be either "ip" for IP-based ACLs or "mac" for MAC-based ACLs.

In the following example, members of the group you are configuring are denied all access to the 10.100.60.0 subnet, denied http access to the server at 10.100.10.116, and permitted everywhere else.
Note

outbound ACLs (outacl) are not supported.

Filter-Id configuration in ACS:

In the Group/User Setting page, scroll down to the "IETF RADIUS Attributes" section. Select the box next to [011] Filter-Id and enter the ACL to apply for members of this group (Figure 36-11).

The Filter-Id takes this format:

<ACL>.in
<ACL> is the number of the ACL that was configured on the switch in the previous step.
Figure 36-11  Configuring the Filter-ID Attribute

![Diagram showing Group Setup with configuration options for IETF RADIUS Attributes, including Service-Type, Framed-Protocol, Framed-IP-Netmask, Framed-Routing, and Filter-ID.]

Outbound ACLs (e.g. "100.out") are not supported.

Debug Commands for Per-User ACL and Filter-ID ACL

The IP device tracking table contains the host IP address learned through ARP or DHCP. The following command displays the constraints on the IP device tracking table:

```
Switch# show ip device tracking all
IP Device Tracking = Enabled
IP Device Tracking Probe Count = 3
IP Device Tracking Probe Interval = 30
------------------------------------------------------------
IP Address MAC Address Interface STATE
------------------------------------------------------------
50.0.0.12 0015.60a4.5e84 GigabitEthernet2/9 ACTIVE
```

Software Configuration Guide—Release IOS-XE 3.1.0 SG
The following command shows that the EPM (Policy Enforced Module) session contains the per-user-acl from ACS:

```
Switch# show epm session ip 50.0.0.12
Admission feature : DOT1X
AAA Policies :
Per-User ACL : deny ip any host 20.20.10.10
```

The following command reveals the contents of the per-user-acl (note that per-user-acl are shown above the default port ACL configured on the interface, 151 is the default port ACL in the following example):

```
Switch# show access-list
Extended IP access list 151
    deny ip host 20.20.0.3 host 20.20.10.10
    10 permit ip any any (57 estimate matches)
```

The following commands reveals the number of sessions and the corresponding client ip addresses,

```
Switch# show epm session summary
EPM Session Information

-----------------------
Total sessions seen so far : 1
Total active sessions      : 1
Session IP Address :
-------------------
50.0.0.12
```

The following command shows that the EPM (Policy Enforced Module) session contains the per-user-acl(both ip and mac acl from ACS):

```
Switch# show epm session ip 50.0.0.12
Admission feature : DOT1X
AAA Policies :
Per-User ACL : deny ip any host 20.20.10.10
Per-User ACL : deny any host 0000.AAAA.AAAA
```

The following command reveals the contents of the per-user-acl (note that per-user-acl are shown above the default port acl configured on the interface, 151 is the default port acl in the example below):

```
Switch# show access-list
Extended IP access list 151
    deny ip host 20.20.0.3 host 20.20.10.10
    10 permit ip any any (57 estimate matches)
```

.. (check for the mac access-list created)..

```
Extended MAC access list PerUser_MAC_ACL-589079192 (per-user)
    deny any host 0000.aaaa.aaaa
```

..
The following command shows that the EPM (Policy Enforced Module) session contains the Filter-Id 155 from ACS:

```
Note

The 156 IP extended acl is to be pre-configured on the switch, so that the policy enforcement can happen.
```

Switch# show ip access-list 156
Extended IP access list 156
  10 deny ip any host 155.155.155.156
  20 deny ip any 156.100.60.0 0.0.0.255
  30 deny tcp any host 156.100.10.116 eq www

Switch# show epm session ip 50.0.0.12
Admission feature : DOT1X
AAA Policies :
  Filter-Id               : 155

The following command reveals the contents of the Filter-Id applied on the interface:

Switch# show ip access-list int <gi6/3>

Switch# show ip access-list interface gi6/3
deny ip host 20.20.0.2 host 155.155.155.156
deny ip host 20.20.0.2 156.100.60.0 0.0.0.255
deny tcp host 20.20.0.2 host 156.100.10.116 eq www

### Guidelines and Restrictions for Per-User-ACL and Filter-ID ACL

For Per-User-ACL and Filter-ID ACL, the ACL source must be ANY (permit TCP ANY host 1.1.1.1 eq 80 or permit TCP ANY host 1.1.1.1 eq 443).
## Configuring a Per-User ACL and Filter-ID ACL

To configure Per-User-ACL and Filter-ID ACL, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>Command</strong> <code>configure terminal</code></td>
</tr>
</tbody>
</table>
| **Step 2**                                                             | **Command** `access-list access-list-number (deny | permit) source [source-wildcard] [log]`                                                   | Defines the default port ACL through a source address and wildcard. The `access-list-number` is a decimal from 1 to 99 or 1300 to 1999. Enter `deny` or `permit` to specify whether to deny or permit access if conditions match.  
`source` is the address of the network or host from which the packet is sent, specified as follows:  
- The 32-bit quantity in dotted-decimal format  
- The keyword `any` as an abbreviation for source and source-wildcard value of 0.0.0.0 255.255.255.255  
  You do not need a source-wildcard value.  
- The keyword `host` as an abbreviation for source and source-wildcard of source 0.0.0.0.  
(Optional) Applies the source-wildcard wildcard bits to the source.  
(Optional) Enters `log` to cause an informational logging message about the packet that matches the entry to be sent to the console. |
| **Step 3**                                                             | **Command** `interface interface-id`                                                      | Enters interface configuration mode. |
| **Step 4**                                                             | **Command** `ip access-group {access-list-number | name} in`                                | Controls access to the specified interface.  
This step is mandatory for a functioning downloaded policy. |
| **Step 5**                                                             | **Command** `exit`                                                                        | Returns to global configuration mode. |
| **Step 6**                                                             | **Command** `aaa new-model`                                                               | Enables AAA. |
| **Step 7**                                                             | **Command** `aaa authorization network default local`                                     | Sets the authorization method to local. To remove the authorization method, use the `no aaa authorization network default local` command. |
| **Step 8**                                                             | **Command** `ip device tracking`                                                          | Enables the IP device tracking table.  
To disable the IP device tracking table, use the `no ip device tracking` global configuration commands. |
| **Step 9**                                                             | **Command** `ip device tracking {probe {count count | interval interval}}`                  | (Optional) Configures these parameters for the IP device tracking table:  
- `count` - Number of times that the switch sends the ARP probe. The range is 1 to 5. The default is 3.  
- `interval` - Number of seconds that the switch waits for a response before resending the ARP probe. The range is 30 to 300 seconds. The default is 30 seconds. |
| **Step 10**                                                            | **Command** `end`                                                                         | Returns to privileged EXEC mode. |
Chapter 36 Configuring 802.1X Port-Based Authentication

Configuring 802.1X Port-Based Authentication

The following example illustrates how to configure a switch for downloadable policy:

```plaintext
Switch# config terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# aaa new-model
Switch(config)# aaa authorization network default local
Switch(config)# ip device tracking
Switch(config)# ip access-list extended default_acl
Switch(config-ext-nacl)# permit ip any any
Switch(config-ext-nacl)# exit
Switch(config)# int fastEthernet 2/13
Switch(config-if)# ip access-group default_acl in
Switch(config-if)# exit
```

Configuring RADIUS-Provided Session Timeouts

You can configure the Catalyst 4500 series switch to use a RADIUS-provided reauthentication timeout.

To configure RADIUS-provided timeouts, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Configure terminal Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# interface interface-id Enters interface configuration mode.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config-if)# switchport mode access Specifies a nontrunking, nontagged single VLAN Layer 2 interface.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config-if)# dot1x pae authenticator Enables 802.1X authentication on the port with default parameters. Refer to the “Default 802.1X Configuration” section on page 36-23.</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch(config-if)# authentication timer reauthenticate {interface</td>
</tr>
<tr>
<td>Step 6</td>
<td>Switch(config-if)# end Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Step 7</td>
<td>Switch# show dot1x interface interface-id details Verifies your entries.</td>
</tr>
<tr>
<td>Step 8</td>
<td>Switch # copy running-config startup-config (Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

This example shows how to configure a switch to derive the re-authentication period from the server and to verify the configuration:

```plaintext
Switch# configure terminal
Switch(config)# interface f7/1
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication timer reauthenticate server
Switch(config-if)# end
```
Configuring 802.1X with Guest VLANs

You can configure a guest VLAN for each 802.1X port on the Catalyst 4500 series switch to provide limited services to clients, such as downloading the 802.1X client. These clients might be upgrading their system for 802.1X authentication, and some hosts, such as Windows 98 systems, might not be 802.1X-capable.

When you enable a guest VLAN on an 802.1X port, the Catalyst 4500 series switch assigns clients to a guest VLAN provided the authentication server does not receive a response to its EAPOL request (or identity frame), or the EAPOL packets are not sent by the client.

Starting with Cisco IOS Release 12.2(25)EWA, the Catalyst 4500 series switch maintains the EAPOL packet history. If another EAPOL packet is detected on the interface during the lifetime of the link, network access is denied. The EAPOL history is reset upon loss of the link.

Any number of 802.1X-incapable clients are allowed access when the switch port is moved to the guest VLAN. If an 802.1X-capable client joins the same port on which the guest VLAN is configured, the port is put into the unauthorized state in the user-configured access VLAN, and authentication is restarted.

Guest VLANs are supported on 802.1X ports in single-host or multiple-hosts mode.

Note
When a port is put into a guest VLAN, it is automatically placed into multihost mode, and an unlimited number of hosts can connect through the port. Changing the multihost configuration does not effect a port in a guest VLAN.

Note
Except for an RSPAN VLAN or a voice VLAN, you can configure any active VLAN as an 802.1X guest VLAN.
To configure 802.1X with guest VLAN on a port, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# interface interface-id</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>switchport mode access or switchport mode private-vlan host</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config-if)# dot1x pae authenticator</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>authentication event no-response action authorize vlan vlan-id</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>authentication port-control auto</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>Switch(config-if)# end</td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>Switch(config)# end</td>
</tr>
</tbody>
</table>

This example shows how to enable regular VLAN 50 on Fast Ethernet 4/3 as a guest VLAN on a static access port:

```
Switch# configure terminal
Switch(config)# interface fa4/3
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication event no-response action authorize vlan 50
Switch(config-if)# authentication port-control auto
Switch(config-if)# end
Switch#
```

This example shows how to enable a secondary PVLAN 100 as a guest VLAN on a PVLAN host port:

```
Switch# configure terminal
Switch(config)# interface fa4/3
Switch(config-if)# switchport mode private-vlan host
Switch(config-if)# authentication port-control auto
Switch(config-if)# authentication event no-response action authorize vlan 100
Switch(config-if)# end
Switch#
```

To allow supplicants into a guest VLAN on a switch, perform this task:
Chapter 36  Configuring 802.1X Port-Based Authentication

### Configuring 802.1X Port-Based Authentication

This example shows how to enable the guest VLAN feature and to specify VLAN 5 as a guest VLAN:

```
Switch# configure terminal
Switch(config)# dot1x guest-vlan supplicant
Switch(config)# interface gigabitethernet5/9
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication event no-response action authorize vlan 5
Switch(config-if)# authentication port-control auto
Switch(config-if)# end
Switch#
```

### Configuring 802.1X with MAC Authentication Bypass

To enable MAB, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 1 Switch(config)# interface interface-id</td>
<td>Specifies the port to be configured, and enters interface configuration mode.</td>
</tr>
</tbody>
</table>
Removing a 802.1X MAB configuration from a port does not impact the authorized or authenticated state of the port. If the port is in an unauthenticated state, it remains in that state. If the port is in an authenticated state because of MAB, the switch reverts to the 802.1X Authenticator. If the port was already authorized with a MAC address and the MAB configuration was removed, the port remains in an authorized state until re-authentication occurs. At that time, if an 802.1X supplicant is detected on the wire, the MAC address is removed.

This example shows how to enable MAB on Gigabit Ethernet interface 3/3 and to verify the configuration:

```
Switch# configure terminal
Switch(config)# interface gigabitethernet3/3
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication port-control auto
Switch(config-if)# mab
Switch(config-if)# end
Switch# show mab interface 3/3 details
MAB details for GigabitEthernet3/3
-------------------------------------
Mac-Auth-Bypass = Enabled
MAB Client List
----------------
Client MAC       = 0001.0001.0001
Session ID       = C0A8016F0000002304175914
MAB SM state     = TERMINATE
Auth Status      = AUTHORIZED
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 3</td>
<td>Switch(config-if)# switchport mode access or Switch(config-if)# switchport mode private-vlan host</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config-if)# dot1x pae authenticator</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch(config-if)# authentication port-control auto</td>
</tr>
<tr>
<td>Step 6</td>
<td>Switch(config-if)# mab [eap]</td>
</tr>
<tr>
<td>Step 7</td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td>Step 8</td>
<td>Switch# show mab interface interface-id details</td>
</tr>
<tr>
<td>Step 9</td>
<td>Switch# copy running-config startup-config</td>
</tr>
</tbody>
</table>

---

Note

Removing a 802.1X MAB configuration from a port does not impact the authorized or authenticated state of the port. If the port is in an unauthenticated state, it remains in that state. If the port is in an authenticated state because of MAB, the switch reverts to the 802.1X Authenticator. If the port was already authorized with a MAC address and the MAB configuration was removed, the port remains in an authorized state until re-authentication occurs. At that time, if an 802.1X supplicant is detected on the wire, the MAC address is removed.

This example shows how to enable MAB on Gigabit Ethernet interface 3/3 and to verify the configuration:

```
Switch# configure terminal
Switch(config)# interface gigabitethernet3/3
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication port-control auto
Switch(config-if)# mab
Switch(config-if)# end
Switch# show mab interface 3/3 details
MAB details for GigabitEthernet3/3
-------------------------------------
Mac-Auth-Bypass = Enabled
MAB Client List
----------------
Client MAC       = 0001.0001.0001
Session ID       = C0A8016F0000002304175914
MAB SM state     = TERMINATE
Auth Status      = AUTHORIZED
```
### Configuring 802.1X with Inaccessible Authentication Bypass

#### Caution
You must configure the switch to monitor the state of the RADIUS server as described in the section Configuring Switch-to-RADIUS-Server Communication, page 36-27 for Inaccessible Authentication Bypass to work properly. Specifically, you must configure the RADIUS test username, idle-time, deadtime and dead-criteria. Failure to do so results in the switch failing to detect that the RADIUS server has gone down, or prematurely marking a dead RADIUS server as alive again.

To configure a port as a critical port and to enable the Inaccessible Authentication Bypass feature, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# authentication critical eapol</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config)# authentication critical recovery delay msec</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config)# interface interface-id</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch(config-if)# switchport mode access or Switch(config-if)# switchport mode private-vlan host</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Switch(config-if)# dot1x pae authenticator</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>Switch(config-if)# authentication port-control auto</td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>Switch(config-if)# authentication event server dead action authorize [vlan vlan-id]</td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>Switch(config-if)# authentication event server alive action reinitialize</td>
</tr>
<tr>
<td><strong>Step 10</strong></td>
<td>Switch(config)# end</td>
</tr>
</tbody>
</table>
Chapter 36      Configuring 802.1X Port-Based Authentication

Configuring 802.1X Port-Based Authentication

The following example shows a full configuration of 802.1X with Inaccessible Authentication Bypass, including required AAA and RADIUS configuration as specified in the “Enabling 802.1X Authentication” section on page 36-24 and “Configuring Switch-to-RADIUS-Server Communication” section on page 36-27.

The RADIUS server configured is at IP address 10.1.2.3, using port 1645 for authentication and 1646 for accounting. The RADIUS secret key is mykey. The username used for the test server probes is randomuser. The test probes for both living and dead servers are generated once per minute. The interface FastEthernet 3/1 is configured to critically authenticate into VLAN 17 when AAA becomes unresponsive, and to reinitialize automatically when AAA becomes available again.

Switch# configure terminal
Switch(config)# aaa new-model
Switch(config)# aaa authentication dot1x default group radius
Switch(config)# dot1x system-auth-control
Switch(config)# radius-server host 10.1.2.3 auth-port 1645 acct-port 1646 test username randomuser idle-time 1 key mykey
Switch(config)# radius deadtime 1
Switch(config)# radius dead-criteria time 15 tries 3
Switch(config)# interface f3/1
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication port-control auto
Switch(config-if)# authentication event server dead action authorize vlan 17
Switch(config-if)# end
Switch# show dot1x int fastethernet 3/1 details

(Optional) Saves your entries in the configuration file.

Command | Purpose
--- | ---
Switch# show dot1x interface interface-id details | (Optional) Verifies your entries.
Switch# copy running-config startup-config | (Optional) Saves your entries in the configuration file.

The following table shows the command purpose:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# show dot1x interface interface-id details</td>
<td>(Optional) Verifies your entries.</td>
</tr>
<tr>
<td>Switch# copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>
Chapter 36 Configuring 802.1X Port-Based Authentication

Configuring 802.1X with Unidirectional Controlled Port

To configure unidirectional controlled port, perform this task:

```
Step 1
Switch# configure terminal
Enters global configuration mode.

Step 2
Switch(config)# interface interface-id
Specifies the port to be configured and enters interface configuration mode.

Step 3
Switch(config-if)# switchport mode access
or Switch(config-if)# switchport mode private-vlan host
Specifies a nontrunking, nontagged single VLAN Layer 2 interface.

Step 4
Switch(config-if)# dot1x pae authenticator
Enables 802.1X authentication on the port with default parameters.
Refer to the “Default 802.1X Configuration” section on page 36-23.

Step 5
Switch(config-if)# authentication port-control auto
Enables 802.1X authentication on the interface.

Step 6
Switch(config-if)# authentication control-direction {in | both}
Enables unidirectional port control on each port.

Step 7
Switch(config)# end
Returns to privileged EXEC mode.

Step 8
Switch# show dot1x interface interface-id details
(Optional) Verifies your entries.

Step 9
Switch# copy running-config startup-config
(Optional) Saves your entries in the configuration file.
```

**Note**
Unidirectional Controlled Port only works when Spanning Tree Portfast is enabled on the port. Unidirectional Controlled Port and Spanning Tree Portfast should be configured on a switch port that connects to a host. If two such ports are connected together with an Ethernet cable, high CPU utilization may result because host learning is flapping between the two ports.

This example shows how to enable unidirectional port control:

```
Switch# configure terminal
Switch(config)# interface gigabitethernet3/3
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication port-control auto
Switch(config-if)# authentication control-direction in
Switch(config-if)# end
Switch# show dot1x int g3/3
Dot1x Info for GigabitEthernet3/3
-----------------------------------
PAE                       = AUTHENTICATOR
PortControl               = AUTO
ControlDirection          = In
HostMode                  = SINGLE_HOST
```

ReAuthentication       = Disabled
QuietPeriod           = 60
ServerTimeout         = 30
SuppTimeout           = 30
ReAuthPeriod          = 3600 (Locally configured)
ReAuthMax             = 2
MaxReq                = 2
TxPeriod              = 30
RateLimitPeriod       = 0

Switch#

Configuring 802.1X with Authentication Failed

By configuring authentication-failed VLAN alignment on any Layer 2 port on the Catalyst 4500 series switch, you can provide limited network services to clients that fail the authentication process.

Note

Use the authentication-failed VLAN assignment with other security features, such as Dynamic ARP Inspection (DAI), Dynamic Host Configuration Protocol (DHCP) snooping, and IP Source Guard. Each of these features can be enabled and disabled independently on the authentication-failed VLAN.

To configure 802.1X with authentication-failed VLAN assignment, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# interface interface-id</td>
</tr>
<tr>
<td></td>
<td>Enters interface configuration mode and specifies the interface to be</td>
</tr>
<tr>
<td></td>
<td>enabled for 802.1X authentication.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config-if)# switchport mode access</td>
</tr>
<tr>
<td></td>
<td>Specifies a nontrunking, nontagged single VLAN Layer 2 interface.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config-if)# authentication port-control auto</td>
</tr>
<tr>
<td></td>
<td>Enables 802.1X authentication on the interface.</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch(config-if)# authentication event fail action authorize vlan vlan-id</td>
</tr>
<tr>
<td></td>
<td>Enables authentication-failed VLAN on a particular interface.</td>
</tr>
<tr>
<td></td>
<td>To disable the authentication-failed VLAN feature on a particular port,</td>
</tr>
<tr>
<td></td>
<td>use the no authentication event fail action authorize vlan interface</td>
</tr>
<tr>
<td></td>
<td>configuration command.</td>
</tr>
<tr>
<td>Step 6</td>
<td>Switch(config-if)# authentication event fail retry max-attempts action [authorize vlan vlan-id</td>
</tr>
<tr>
<td></td>
<td>next-method]</td>
</tr>
<tr>
<td></td>
<td>Configure a maximum number of attempts before the port is moved to</td>
</tr>
<tr>
<td></td>
<td>authentication-failed VLAN.</td>
</tr>
<tr>
<td></td>
<td>Default is 3 attempts.</td>
</tr>
<tr>
<td>Step 7</td>
<td>Switch(config-if)# end</td>
</tr>
<tr>
<td></td>
<td>Returns to configuration mode.</td>
</tr>
<tr>
<td>Step 8</td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Step 9</td>
<td>Switch# show dot1x interface interface-id details</td>
</tr>
<tr>
<td></td>
<td>(Optional) Verifies your entries.</td>
</tr>
<tr>
<td>Step 10</td>
<td>Switch# copy running-config startup-config</td>
</tr>
<tr>
<td></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>
Chapter 36 Configuring 802.1X Port-Based Authentication

This example shows how to enable a regular VLAN 40 on Fast Ethernet 4/3 as a authentication-failed VLAN on a static access port:

```
Switch# configure terminal
Switch(config)# interface gigabitEthernet3/1
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication port-control auto
Switch(config-if)# authentication event fail retry 5 action authorize vlan 40
Switch(config-if)# end
Switch# show dot1x all
Sysauthcontrol              Enabled
Dot1x Protocol Version            2
Dot1x Info for GigabitEthernet3/1
-----------------------------------
PAE                       = AUTHENTICATOR
PortControl               = AUTO
ControlDirection          = Both
HostMode                  = SINGLE_HOST
QuietPeriod               = 60
ServerTimeout             = 0
SuppTimeout               = 30
ReAuthMax                 = 2
MaxReq                    = 2
TxPeriod                  = 30
Switch#
```

Configuring 802.1X with Voice VLAN

**Note**
You must configure 802.1X and voice VLAN simultaneously.

**Note**
You cannot configure an authentication-failed VLAN and a voice VLAN on the same port. When you try to configure these two features on the same port, a syslog message appears.

To enable 802.1X with voice VLAN, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong> Switch(config)# interface interface-id</td>
<td>Enters interface configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong> Switch(config-if)# switchport access vlan vlan-id</td>
<td>Sets the VLAN for a switched interface in access mode.</td>
</tr>
<tr>
<td><strong>Step 4</strong> Switch(config-if)# switchport mode access</td>
<td>Specifies a nontrunking, nontagged single VLAN Layer 2 interface.</td>
</tr>
<tr>
<td><strong>Step 5</strong> Switch(config-if)# switchport voice vlan vlan-id</td>
<td>Sets the voice VLAN for the interface.</td>
</tr>
<tr>
<td><strong>Step 6</strong> Switch(config-if)# dot1x pae authenticator</td>
<td>Enables 802.1X authentication on the port with default parameters. Refer to the “Default 802.1X Configuration” section on page 36-23.</td>
</tr>
<tr>
<td><strong>Step 7</strong> Switch(config-if)# authentication port-control auto</td>
<td>Enables 802.1X authentication on the interface.</td>
</tr>
</tbody>
</table>
Chapter 36  Configuring 802.1X Port-Based Authentication

Configuring 802.1X Port-Based Authentication

This example shows how to enable 802.1X with voice VLAN feature on Fast Ethernet interface 5/9:

```
Switch# configure terminal
Switch(config)# interface fastethernet5/9
Switch(config-if)# switchport access vlan 2
Switch(config-if)# switchport mode access
Switch(config-if)# switchport voice vlan 10
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication port-control auto
Switch(config-if)# end
Switch(config)# end
Switch#
```

**Configuring 802.1X with VLAN Assignment**

For enabling dynamic VLAN assignment, there is no additional configuration required in the switch. For configuring MDA or Multi-authentication refer "Configuring Multiple Domain Authentication and Multiple Authorization" section on page 39-29. To enable VLAN assignment, Cisco ACS Server has to be configured correspondingly.

To enable 802.1X with VLAN assignment, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong> Switch(config)# interface interface-id</td>
<td>Enters interface configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong> Switch(config-if)# switchport access vlan-id</td>
<td>Sets the VLAN for a switched interface in access mode.</td>
</tr>
<tr>
<td><strong>Step 4</strong> Switch(config-if)# switchport mode access</td>
<td>Specifies a nontrunking, nontagged single VLAN Layer 2 interface.</td>
</tr>
<tr>
<td><strong>Step 5</strong> Switch(config-if)# switchport voice vlan-id</td>
<td>Sets the voice VLAN for the interface.</td>
</tr>
<tr>
<td><strong>Step 6</strong> Switch(config-if)# authentication host-mode multi-domain</td>
<td>Enables MDA on the interface.</td>
</tr>
<tr>
<td><strong>Step 7</strong> Switch(config-if)# authentication port-control auto</td>
<td>Enables 802.1X authentication on the interface.</td>
</tr>
<tr>
<td><strong>Step 8</strong> Switch(config-if)# dot1x pae authenticator</td>
<td>Enables 802.1X authentication on the port with default parameters. Refer to the “Default 802.1X Configuration” section on page 36-23.</td>
</tr>
<tr>
<td><strong>Step 9</strong> Switch(config)# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
</tbody>
</table>
Chapter 36      Configuring 802.1X Port-Based Authentication

The following example shows how to configure MDA on an interface and 802.1X as the authentication mechanism:

Note You must configure VLAN assignment in the ACS server. No configuration changes are required on the switch.

Cisco ACS Configuration for VLAN Assignment

The procedure for enabling MDA with Voice VLAN assignment is the same as that for activating MDA except for one step: Configure a VLAN for dynamic VLAN Assignment after selecting User > IETF RADIUS Attributes (Figure 36-12). This step ensures correct functioning of the ACS configuration required for dynamic VLAN assignment.

Figure 36-12      User Setup
Chapter 36 Configuring 802.1X Port-Based Authentication

The procedure is the same for voice devices except that the AAA server must be configured to send a Cisco Attribute-Value (AV) pair attribute with a value of device-traffic-class=voice.

**Enabling Fallback Authentication**

On a port in multiauthentication mode, either or both of MAB and web-based authentication can be configured as fallback authentication methods for non-802.1X hosts (those that do not respond to EAPOL). You can configure the order and priority of the authentication methods.

For detailed configuration information for MAB, see the “Configuring 802.1X with MAC Authentication Bypass” section on page 36-48.

For detailed configuration information for web-based authentication, see Chapter 37, “Configuring Web-Based Authentication.”

**Note** When Webauth and other authentication methods are configured on an MDA or multiauthentication port, downloadable ACL policies must be configured for all devices attached to that port.

To enable fallback authentication, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1: Switch(config)# ip admission name rule-name proxy http</td>
<td>Configures an authentication rule for web-based authentication.</td>
</tr>
<tr>
<td>Step 2: Switch(config)# fallback profile profile-name</td>
<td>Creates a fallback profile for web-based authentication.</td>
</tr>
<tr>
<td>Step 3: Switch(config-fallback-profile)# ip access-group rule-name in</td>
<td>Specifies the default ACL to apply to network traffic before web-based authentication.</td>
</tr>
<tr>
<td>Step 4: Switch(config-fallback-profile)# ip admission name rule-name</td>
<td>Associates an IP admission rule with the profile and specifies that a client connecting by web-based authentication uses this rule.</td>
</tr>
<tr>
<td>Step 5: Switch(config-fallback-profile)# exit</td>
<td>Returns to global configuration mode.</td>
</tr>
<tr>
<td>Step 6: Switch(config)# interface type slot/port</td>
<td>Specifies the port to be configured and enters interface configuration mode. type = fastethernet, gigabitethernet, or tengigabitethernet</td>
</tr>
<tr>
<td>Step 7: Switch(config-if)# authentication port-control auto</td>
<td>Enables authentication on the port.</td>
</tr>
<tr>
<td>Step 8: Switch(config-if)# authentication order method1 [method2] [method3]</td>
<td>(Optional) Specifies the fallback order of authentication methods to be used. The three values of method, in the default order, are dot1x, mab, and webauth. The specified order also determines the relative priority of the methods for reauthentication (highest to lowest).</td>
</tr>
<tr>
<td>Step 9: Switch(config-if)# authentication priority method1 [method2] [method3]</td>
<td>(Optional) Overrides the relative priority of authentication methods to be used. The three values of method, in the default order of priority, are dot1x, mab, and webauth.</td>
</tr>
</tbody>
</table>
Chapter 36  Configuring 802.1X Port-Based Authentication

### Configuring 802.1X Port-Based Authentication

This example shows how to enable 802.1X fallback to MAB, and then to enable web-based authentication, on an 802.1X-enabled port:

```plaintext
Switch(config)# ip admission name rule1 proxy http
Switch(config)# fallback profile fallback1
Switch(config-fallback-profile)# ip access-group default-policy in
Switch(config-fallback-profile)# ip admission rule1
Switch(config-fallback-profile)# exit
Switch(config-if)# interface gigabit5/9
Switch(config-if)# switchport mode access
Switch(config-if)# authentication port-control auto
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication order dot1x mab webauth
Switch(config-if)# mab eap
Switch(config-if)# authentication fallback fallback1
Switch(config-if)# exit
Switch(config)# ip device tracking
Switch(config)# exit
```

### Command Purpose

<table>
<thead>
<tr>
<th>Step</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>Switch(config-if)# authentication event fail action next-method</td>
</tr>
<tr>
<td></td>
<td>Specifies that the next configured authentication method be applied if authentication fails.</td>
</tr>
<tr>
<td>11</td>
<td>Switch(config-if)# mab [eap]</td>
</tr>
<tr>
<td></td>
<td>Enables MAC authentication bypass. The optional eap keyword specifies that the EAP extension be used during RADIUS authentication.</td>
</tr>
<tr>
<td>12</td>
<td>Switch(config-if)# authentication fallback profile-name</td>
</tr>
<tr>
<td></td>
<td>Enables web-based authentication using the specified profile.</td>
</tr>
<tr>
<td>13</td>
<td>Switch(config-if)# authentication violation [shutdown</td>
</tr>
<tr>
<td></td>
<td>(Optional) Configures the disposition of the port if a security violation occurs. The default action is to shut down the port. If the restrict keyword is configured, the port does not shutdown, but trap entries are installed for the violating MAC address, and traffic from that MAC address is dropped.</td>
</tr>
<tr>
<td>14</td>
<td>Switch(config-if)# authentication timer inactivity {seconds</td>
</tr>
<tr>
<td></td>
<td>(Optional) Configures the inactivity timeout value for MAB and 802.1X. By default, inactivity aging is disabled for a port.</td>
</tr>
<tr>
<td></td>
<td>* seconds—Specifies inactivity timeout period. The range is from 1 to 65535 seconds.</td>
</tr>
<tr>
<td></td>
<td>* server—Specifies that the inactivity timeout period value be obtained from the authentication server.</td>
</tr>
<tr>
<td>15</td>
<td>Switch(config-if)# authentication timer restart seconds</td>
</tr>
<tr>
<td></td>
<td>(Optional) Specifies a period after which the authentication process restarts in an attempt to authenticate an unauthorized port.</td>
</tr>
<tr>
<td></td>
<td>* seconds—Specifies the restart period. The range is from 1 to 65535 seconds.</td>
</tr>
<tr>
<td>16</td>
<td>Switch(config-if)# exit</td>
</tr>
<tr>
<td></td>
<td>Returns to global configuration mode.</td>
</tr>
<tr>
<td>17</td>
<td>Switch(config)# ip device tracking</td>
</tr>
<tr>
<td></td>
<td>Enables the IP device tracking table, which is required for web-based authentication.</td>
</tr>
<tr>
<td>18</td>
<td>Switch(config)# exit</td>
</tr>
<tr>
<td></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>19</td>
<td>Switch# show dot1x interface type slot/port</td>
</tr>
<tr>
<td></td>
<td>Verifies your entries.</td>
</tr>
</tbody>
</table>
To determine if a host has been authenticated using 802.1X when fallback authentication is configured on the port, enter the following commands:

```
Switch# show authentication sessions interface g7/2
```

<table>
<thead>
<tr>
<th>Interface: GigabitEthernet7/2</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAC Address: 0060.b057.4687</td>

Switch# show ip admission cache

Authentication Proxy Cache
Total Sessions: 1 Init Sessions: 0
Client IP 10.5.63.13 Port 4643, timeout 1000, state ESTAB
Enabling Periodic Reauthentication

You can enable periodic 802.1X client reauthentication and specify how often it occurs. If you do not specify a time value before enabling reauthentication, the interval between reauthentication attempts is 3600 seconds.

Automatic 802.1X client reauthentication is a per-interface setting and can be set for clients connected to individual ports. To manually reauthenticate the client connected to a specific port, see the “Changing the Quiet Period” section on page 36-63.

To enable periodic reauthentication of the client and to configure the number of seconds between reauthentication attempts, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# interface interface-id</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config-if)# switchport mode access</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config-if)# dot1x pae authenticator</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch(config-if)# authentication periodic</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Switch(config-if)# authentication timer reauthenticate {seconds / server}</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>Switch(config-if)# authentication port-control auto</td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>Switch(config-if)# end</td>
</tr>
</tbody>
</table>

This example shows how to enable periodic reauthentication and set the number of seconds between reauthentication attempts to 4000:

```
Switch# configure terminal
Switch(config)# interface fastethernet5/9
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication periodic
Switch(config-if)# authentication timer reauthenticate 4000
Switch(config-if)# authentication port-control auto
Switch(config-if)# end
```
Enabling Multiple Hosts

You can attach multiple hosts (clients) to a single 802.1X-enabled port as shown in Figure 36-7 on page 36-22. In this mode, when the port is authorized, all other hosts that are indirectly attached to the port are granted access to the network. If the port becomes unauthorized (reauthentication fails or an EAPOL-logoff message is received), the switch denies access to the network for all wireless access point-attached clients.

To allow multiple hosts (clients) on an 802.1X-authorized port that has the `dot1x port-control` interface configuration command set to `auto`, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# interface interface-id</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config-if)# switchport mode access</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config-if)# dot1x pae authenticator</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch(config-if)# authentication host-mode multi-host</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Switch(config-if)# authentication port-control auto</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>Switch(config-if)# end</td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>Switch# show dot1x all interface interface-id</td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>Switch# copy running-config startup-config</td>
</tr>
</tbody>
</table>

This example shows how to enable 802.1X on Fast Ethernet interface 5/9 and to allow multiple hosts:

```
Switch# configure terminal
Switch(config)# interface fastethernet5/9
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# authentication host-mode multi-host
Switch(config-if)# authentication port-control auto
Switch(config-if)# end
Switch#
```
Changing the Quiet Period

When the switch cannot authenticate the client, the switch remains idle for a set period of time, and then tries again. The idle time is determined by the quiet-period value. A failed authentication of the client might occur because the client provided an invalid password. You can provide a faster response time to the user by entering a number smaller than the default.

To change the quiet period, perform this task:

This example shows how to set the quiet period on the switch to 30 seconds:

```
Switch# configure terminal
Switch(config)# interface fastethernet4/1
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# dot1x timeout quiet-period 30
Switch(config-if)# authentication port-control auto
Switch(config-if)# end
```

Changing the Switch-to-Client Retransmission Time

The client responds to the EAP-request/identity frame from the switch with an EAP-response/identity frame. If the switch does not receive this response, it waits a set period of time (known as the retransmission time) and then retransmits the frame.
You should change the default value of this command only to adjust for unusual circumstances, such as unreliable links or specific behavioral problems with certain clients and authentication servers.

To change the amount of time that the switch waits for client notification, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# interface interface-id</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config-if)# switchport mode access</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config-if)# dot1x pae authenticator</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch(config-if)# dot1x timeout tx-period seconds</td>
</tr>
<tr>
<td>Step 6</td>
<td>Switch(config-if)# authentication port-control auto</td>
</tr>
<tr>
<td>Step 7</td>
<td>Switch(config-if)# end</td>
</tr>
<tr>
<td>Step 8</td>
<td>Switch# show dot1x all</td>
</tr>
<tr>
<td>Step 9</td>
<td>Switch# copy running-config startup-config</td>
</tr>
</tbody>
</table>

This example shows how to set the retransmission time to 60 seconds:

```
Switch# configure terminal
Switch(config)# interface fastethernet5/9
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# dot1x timeout tx-period 60
Switch(config-if)# authentication port-control auto
Switch(config-if)# end
Switch# 
```

### Setting the Switch-to-Client Frame-Retransmission Number

In addition to changing the switch-to-client retransmission times, you can change the number of times that the switch sends EAP-Request/Identity and other EAP-Request frames to the client before restarting the authentication process. The number of EAP-Request/Identity retransmissions is controlled by the dot1x max-reauth-req command; the number of retransmissions for other EAP-Request frames is controlled by the dot1x max-req command.
Chapter 36  Configuring 802.1X Port-Based Authentication

You should change the default values of these commands only to adjust for unusual circumstances such as unreliable links or specific behavioral problems with certain clients and authentication servers.

To set the switch-to-client frame-retransmission numbers, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# interface interface-id</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config-if)# switchport mode access</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config-if)# dot1x pae authenticator</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch(config-if)# dot1x max-reauth-req count</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Switch(config-if)# authentication port-control auto</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>Switch(config-if)# end</td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>Switch# show dot1x all</td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>Switch# copy running-config startup-config</td>
</tr>
</tbody>
</table>

This example shows how to set 5 as the number of times that the switch retransmits an EAP-request/identity request before restarting the authentication process:

```
Switch# configure terminal
Switch(config)# interface fastethernet5/9
Switch(config-if)# switchport mode access
Switch(config-if)# dot1x pae authenticator
Switch(config-if)# dot1x max-reauth-req 5
Switch(config-if)# authentication port-control auto
Switch(config-if)# end
Switch#
```
Manually Reauthenticating a Client Connected to a Port

You can manually reauthenticate a client connected to a specific port at any time by entering the `dot1x re-authenticate interface` privileged EXEC command. If you want to enable or disable periodic reauthentication, see the “Enabling Periodic Reauthentication” section on page 36-61.

This example shows how to manually reauthenticate the client connected to Fast Ethernet port 1/1:

```
Switch# dot1x re-authenticate interface fastethernet1/1
Starting reauthentication on FastEthernet1/1
```

Initializing the 802.1X Authentication State

The `dot1x initialize` command causes the authentication process to be restarted irrespective of the state it is in currently.

This example shows how to restart the authentication process on Fast Ethernet port 1/1:

```
Switch# dot1x initialize interface fastethernet1/1
```

This example shows how to restart the authentication process on all ports of the switch:

```
Switch# dot1x initialize
```

Removing 802.1X Client Information

The `clear dot1x` command causes all existing supplicants to be completely deleted from an interface or from all the interfaces on a switch.

This example shows how to remove 802.1X client information on Fast Ethernet port 1/1:

```
Switch# clear dot1x interface fastethernet1/1
```

This example shows how to remove 802.1X client information on all ports of the switch:

```
Switch# clear dot1x all
```

Resetting the 802.1X Configuration to the Default Values

To reset the 802.1X configuration to the default values, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 2 Switch(config)# dot1x default</td>
<td>Resets the configurable 802.1X parameters to the default values.</td>
</tr>
<tr>
<td>Step 3 Switch(config)# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Step 4 Switch# show dot1x all</td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td>Step 5 Switch# copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>
Displaying 802.1X Statistics and Status

To display 802.1X statistics for all interfaces, use the `show dot1x all statistics` privileged EXEC command.

To display the 802.1X administrative and operational status for the switch, use the `show dot1x all details` privileged EXEC command. To display the 802.1X administrative and operational status for a specific interface, use the `show dot1x interface details` privileged EXEC command.

Displaying Authentication Details

Topics in this section include:

- Determining the Authentication Methods Registered with the Auth Manager, page 36-67
- Displaying the Auth Manager Summary for an Interface, page 36-67
- Displaying the Summary of All Auth Manager Sessions on the Switch, page 36-68
- Displaying a Summary of All Auth Manager Sessions on the Switch Authorized for a Specified Authentication Method, page 36-68
- Verifying the Auth Manager Session for an Interface, page 36-68
- Displaying MAB Details, page 36-70
- EPM Logging, page 36-70

Determining the Authentication Methods Registered with the Auth Manager

Enter the following:

```
Switch# show authentication registrations
Handle  Priority  Name
3        0       dot1x
2        1       mab
1        2       webauth
```

Displaying the Auth Manager Summary for an Interface

In the following example, MAB has been configured for a higher priority (lower value) than 802.1X:

```
Switch# show authentication int gi1/5
Client list:
Interface  MAC Address   Method  Domain  Status          Session ID
Gi1/5     000f.23c4.a401  mab     DATA     Authz Success  0A3462B10000000D24F80B58
Gi1/5     0014.bf5d.d26d  dot1x   DATA     Authz Success  0A3462B10000000E29811B94

Available methods list:
Handle  Priority  Name
3        0       dot1x
2        1       mab

Runnable methods list:
Handle  Priority  Name
2        0       mab
3        1       dot1x
```

Auth Status = AUTHORIZED

EPM Logging

EPM logging enables you to display EPM logging messages with the `epm logging` command in global configuration mode. To disable EPM logging, enter `no epm logging`.

Logging messages are displayed during the following events:
POLICY_APP_SUCCESS - Policy application success events on Named ACLs, Proxy ACLs, and service policies, URL redirect policies.

POLICY_APP_FAILURE - Policy application failure conditions like unconfigured policies, wrong policies, download request failures and download failures from AAA.

IPEVENT - IP assignment, IP release and IP wait events for clients.

AAA - AAA events (like download requests, or download successes from AAA)

Example 1

Switch# conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# epm logging
Switch#
*May 15 08:31:26.561: %EPM-6-POLICY_REQ: IP=100.0.0.222| MAC=0000.0000.0001| AUDITSESID=0A050B2C000000030004956C| AUTHTYPE=DOT1X| EVENT=REMOVE
*May 15 08:31:26.581: %AUTHMGR-5-START: Starting 'dot1x' for client (0000.0000.0001) on Interface Fa9/25
*May 15 08:31:26.681: %DOT1X-5-SUCCESS: Authentication successful for client (0000.0000.0001) on Interface Fa9/25
*May 15 08:31:26.681: %AUTHMGR-7-RESULT: Authentication result 'success' from 'dot1x' for client (0000.0000.0001) on Interface Fa9/25

Example 2

Switch# conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# epm logging
Switch(config)# int f9/25
Switch(config-if)# shut
Switch(config-if)# no shut
*May 15 08:41:56.329: %EPM-6-IPEVENT: IP=100.0.0.222| MAC=0000.0000.0001| AUDITSESID=0A050B2C0000026108FB7924| AUTHTYPE=DOT1X| EVENT=IP-RELEASE
*May 15 08:41:56.333: %EPM-6-IPEVENT: IP=100.0.0.222| MAC=0000.0000.0001| AUDITSESID=0A050B2C0000026108FB7924| AUTHTYPE=DOT1X| EVENT=IP-WAIT

-Cisco IOS Security Features in Cisco IOS XE 3.1.0 SG Release

This document provides a list of security software features that are supported in Cisco IOS XE 3.1.0 SG. Links to the feature documentation are included.

Feature guides may contain information about more than one feature. To find information about a specific feature within a feature guide, see the Feature Information table at the end of the guide.

Feature guides document features that are supported on many different software releases and platforms. Your Cisco software release or platform may not support all the features documented in a feature guide. See the Feature Information table at the end of the feature guide for information about which features in that guide are supported in your software release. Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Role-Based Access Control CLI Commands

Authentication Proxy Accounting for HTTP

Enhanced Password Security

IEEE 802.1X - Flexible Authentication

Image Verification

Manual Certificate Enrollment via TFTP

Configuring Web-Based Authentication

This chapter describes how to configure web-based authentication. It consists of these sections:

- About Web-Based Authentication, page 37-1
- Configuring Web-Based Authentication, page 37-5
- Displaying Web-Based Authentication Status, page 37-13

Note

For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

About Web-Based Authentication

The web-based authentication feature, known as Web Authentication Proxy, enables you to authenticate end users on host systems that do not run the IEEE 802.1X supplicant.

When you initiate an HTTP session, web-based authentication intercepts ingress HTTP packets from the host and sends an HTML login page to the user. The user keys in their credentials, which the web-based authentication feature sends to the AAA server for authentication.

If authentication succeeds, web-based authentication sends a Login-Successful HTML page to the host and applies the access policies returned by the AAA server.

If authentication fails, web-based authentication forwards a Login-Fail HTML page to the user, prompting the user to retry the login. If the user exceeds the maximum number of attempts, web-based authentication forwards a Login-Expired HTML page to the host and the user is placed on a watch list for a waiting period.

These sections describe the role of web-based authentication as part of the authentication, authorization, and accounting (AAA) system:

- Device Roles, page 37-2
- Host Detection, page 37-2
Device Roles

With web-based authentication, the devices in the network have specific role (Figure 37-1).

The roles are as follows:

- **Client**—The device (workstation) that requests access to the LAN and switch services and responds to requests from the switch. The workstation must be running an HTML browser with Java Script enabled.

- **Authentication server**—Performs the actual authentication of the client. The authentication server validates the identity of the client and notifies the switch that the client is authorized to access the LAN and switch services or that the client is denied.

- **Switch**—Controls the physical access to the network based on the authentication status of the client. The switch acts as an intermediary (proxy) between the client and the authentication server, requesting identity information from the client, verifying that information with the authentication server, and relaying a response to the client.

Host Detection

The switch maintains an IP device tracking table to store information about detected hosts.

- **Note**

  By default, the IP device tracking feature is disabled on a switch. You must enable the IP device tracking feature to use web-based authentication.

For Layer 3 interfaces, web-based authentication sets an HTTP intercept ACL when the feature is configured on the interface (or when the interface is put in service).
For Layer 2 interfaces, web-based authentication detects IP hosts using the following mechanisms:

- ARP based trigger—ARP redirect ACL allows web-based authentication to detect hosts with static IP address or dynamically acquired IP address.
- Dynamic ARP Inspection
- DHCP snooping—Web-based authentication is notified when the switch creates a DHCP binding entry for the host.

**Session Creation**

When web-based authentication detects a new host, it creates a session as follows:

- Checks for Auth bypass
  
  If the host IP is not on the exception list, web-based authentication sends a nonresponsive host (NRH) request to the server.
  
  If the server response is Access Accepted, authorization is bypassed for this host. The session is established.

- Sets up the HTTP Intercept ACL
  
  If the server response to the NRH request is Access Rejected, the HTTP intercept ACL is activated and the session waits for HTTP traffic from the host.

**Authentication Process**

When you enable web-based authentication, the following events occur:

- The user initiates an HTTP session.
- The HTTP traffic is intercepted, and authorization is initiated. The switch sends the login page to the user. The user enters a username and password on the login page, and the switch sends the entries to the authentication server.
- If the client identity is valid and the authentication succeeds, the switch downloads and activates the user’s access policy from the authentication server. The login success page is sent to the user.
- If the authentication fails, the switch sends the login fail page. The user retries the login. If the maximum number of attempts fails, the switch sends the login expired page and the host is placed in a watch list. After the watch list times out, the user can retry the authentication process.
- If the authentication server does not respond to the switch, and if an AAA fail policy is configured, the switch applies the failure access policy to the host. The login success page is sent to the user. (See the “Customization of the Authentication Proxy Web Pages” section on page 37-4.)
- The switch reauthenticates a client when the host does not respond to an ARP probe on a Layer 2 interface, or the host does not send any traffic within the idle timeout on a Layer 3 interface.
- The feature applies the downloaded timeout or the locally configured session timeout.
- If the terminate action is RADIUS, the feature sends a nonresponsive host (NRH) request to the server. The terminate action is included in the response from the server.
- If the terminate action is default, the session is dismantled and the applied policy is removed.
Chapter 37  Configuring Web-Based Authentication

Customization of the Authentication Proxy Web Pages

During the web-based authentication process, the internal HTTP server of the switch hosts four HTML pages for delivery to an authenticating client. The four pages allow the server to notify you of the following four states of the authentication process:

- **Login**—Your credentials are requested
- **Success**—The login was successful
- **Fail**—The login failed
- **Expire**—The login session has expired because of excessive login failures

You can substitute your custom HTML pages for the four default internal HTML pages, or you can specify a URL to which you are redirected upon successful authentication, effectively replacing the internal Success page.

Web-based Authentication Interactions with Other Features

These sections describe web-based authentication interactions with these features:

- **Port Security**, page 37-4
- **LAN Port IP**, page 37-4
- **ACLs**, page 37-5
- **Context-Based Access Control**, page 37-5
- **802.1X Authentication**, page 37-5
- **EtherChannel**, page 37-5
- **Switchover**, page 37-5

**Port Security**

You can configure web-based authentication and port security on the same port. (You configure port security on the port with the `switchport port-security` interface configuration command.) When you enable port security and web-based authentication on a port, web-based authentication authenticates the port, and port security manages network access for all MAC addresses, including that of the client. You can then limit the number or group of clients that can access the network through the port.

For more information about enabling port security, see Chapter 38, “Configuring Port Security.”

**LAN Port IP**

You can configure LAN port IP (LPIP) and Layer 2 web-based authentication on the same port. The host is authenticated using web-based authentication first, followed by LPIP posture validation. The LPIP host policy overrides the web-based authentication host policy.

If the web-based authentication idle timer expires, the NAC policy is removed. The host is authenticated and posture is validated again.
Chapter 37      Configuring Web-Based Authentication

ACLs

If you configure a VLAN ACL or Cisco IOS ACL on an interface, the ACL is applied to the host traffic only after the web-based authentication host policy is applied.

For Layer 2 web-based authentication, you must configure a port ACL (PACL) as the default access policy for ingress traffic from hosts connected to the port. After authentication, the web-based authentication host policy overrides the PACL.

You cannot configure a MAC ACL and web-based authentication on the same interface.

You cannot configure web-based authentication on a port whose access VLAN is configured for VACL capture.

Context-Based Access Control

Web-based authentication cannot be configured on a Layer 2 port if context-based access control (CBAC) is configured on the Layer 3 VLAN interface of the port’s VLAN.

802.1X Authentication

You cannot configure web-based authentication on the same port as 802.1X authentication except as a fallback authentication method.

EtherChannel

You can configure web-based authentication on a Layer 2 EtherChannel interface. The web-based authentication configuration applies to all member channels.

Switchover

On Catalyst 4500 series switches with redundant supervisor engines in RPR mode, information about currently authenticated hosts is maintained during a switchover. You do not need to reauthenticate.

Configuring Web-Based Authentication

These sections describe how to configure web-based authentication:

- Default Web-Based Authentication Configuration, page 37-6
- Web-Based Authentication Configuration Guidelines and Restrictions, page 37-6
- Web-Based Authentication Configuration Task List, page 37-7
- Configuring the Authentication Rule and Interfaces, page 37-7
- Configuring AAA Authentication, page 37-8
- Configuring Switch-to-RADIUS-Server Communication, page 37-8
- Configuring the HTTP Server, page 37-10
- Configuring the Web-Based Authentication Parameters, page 37-13
- Removing Web-Based Authentication Cache Entries, page 37-13
Default Web-Based Authentication Configuration

Table 37-1 shows the default web-based authentication configuration.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>AAA</td>
<td>Disabled</td>
</tr>
<tr>
<td>RADIUS server</td>
<td></td>
</tr>
<tr>

<td>None specified</td>
</tr>
<tr>
<td>• UDP authentication port</td>
<td>1812</td>
</tr>
<tr>
<td>• Key</td>
<td>None specified</td>
</tr>
<tr>
<td>Default value of inactivity timeout</td>
<td>3600 seconds</td>
</tr>
<tr>
<td>Inactivity timeout</td>
<td>Enabled</td>
</tr>
</tbody>
</table>

Web-Based Authentication Configuration Guidelines and Restrictions

These are the web-based authentication configuration guidelines:

- Web authentication requires two Cisco Attribute-Value (AV) pair attributes:
  
  The first attribute, priv-lvl=15, must always be set to 15. This sets the privilege level of the user who is logging into the switch.

  The second attribute is an access list to be applied for web-authenticated hosts. The syntax is similar to 802.1x per-user access control lists (ACLs). However, instead of ip:inacl, this attribute must begin with proxyacl, and the source field in each entry must be any. (After authentication, the client IP address replaces the any field when the ACL is applied.)

  For example:
  
  ```
  proxyacl# 10=permit ip any 10.0.0.0 0.255.255.255
  proxyacl# 20=permit ip any 11.1.0.0 0.0.255.255
  proxyacl# 30=permit udp any any eq syslog
  proxyacl# 40=permit udp any any eq tftp
  ```

  - Note: The proxyacl entry determines the type of allowed network access.

  - Web-based authentication is an ingress-only feature.

  - You can configure web-based authentication only on access ports. Web-based authentication is not supported on trunk ports, EtherChannel member ports, or dynamic trunk ports.

  - You must configure the default ACL on the interface before configuring web-based authentication.

  - On Layer 2 interfaces, you cannot authenticate hosts with static ARP cache assignment. These hosts are not detected by the web-based authentication feature, because they do not send ARP messages.

  - By default, the IP device tracking feature is disabled on a switch. You must enable the IP device tracking feature to use web-based authentication.

  - You must configure at least one IP address to run the HTTP server on the switch. You must also configure routes to reach each host IP address. The HTTP server sends the HTTP login page to the host.
• Hosts that are more than one hop away may experience traffic disruption if an STP topology change results in the host traffic arriving on a different port. This is because ARP and DHCP updates may not be sent after a Layer 2 (STP) topology change.
• Web-based authentication does not support VLAN assignment as a downloadable host policy.
• Starting with Cisco IOS Release 12.2(50)SG, you can apply downloadable ACLs (DACLs) from the RADIUS server.
• Web-based authentication is not supported for IPv6 traffic.

Web-Based Authentication Configuration Task List

To configure the web-based authentication feature, perform the following tasks:

• Configuring the Authentication Rule and Interfaces, page 37-7
• Configuring AAA Authentication, page 37-8
• Configuring Switch-to-RADIUS-Server Communication, page 37-8
• Configuring the HTTP Server, page 37-10
• Configuring the Web-Based Authentication Parameters, page 37-13
• Removing Web-Based Authentication Cache Entries, page 37-13

Configuring the Authentication Rule and Interfaces

To configure web-based authentication, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch(config)# ip admission name name proxy http</td>
</tr>
<tr>
<td></td>
<td>Configures an authentication rule for web-based authorization.</td>
</tr>
<tr>
<td></td>
<td>Switch(config)# no ip admission name name</td>
</tr>
<tr>
<td></td>
<td>Removes the authentication rule.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# interface type slot/port</td>
</tr>
<tr>
<td></td>
<td>Enters interface configuration mode and specifies the ingress Layer 2 or Layer 3 interface to be enabled for web-based authentication.</td>
</tr>
<tr>
<td></td>
<td>type can be fastethernet, gigabit ethernet, or tengigabitethernet</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config-if)# ip access-group name</td>
</tr>
<tr>
<td></td>
<td>Applies the default ACL.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config-if)# ip admission name</td>
</tr>
<tr>
<td></td>
<td>Configures web-based authentication on the specified interface.</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch(config-if)# exit</td>
</tr>
<tr>
<td></td>
<td>Returns to configuration mode.</td>
</tr>
<tr>
<td>Step 6</td>
<td>Switch(config)# ip device tracking</td>
</tr>
<tr>
<td></td>
<td>Enables the IP device tracking table.</td>
</tr>
<tr>
<td>Step 7</td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Step 8</td>
<td>Switch# show ip admission configuration</td>
</tr>
<tr>
<td></td>
<td>Displays the configuration.</td>
</tr>
</tbody>
</table>

This example shows how to enable web-based authentication on Fast Ethernet port 5/1:

Switch(config)# ip admission name webauth1 proxy http
Switch(config)# interface fastethernet 5/1
Switch(config-if)# ip admission webauth1
Switch(config-if)# exit
Switch(config)# ip device tracking

This example shows how to verify the configuration:
Switch# show ip admission configuration
Authentication Proxy Banner not configured
Authentication global cache time is 60 minutes
Authentication global absolute time is 0 minutes
Authentication global init state time is 2 minutes
Authentication Proxy Watch-list is disabled

Authentication Proxy Rule Configuration
Auth-proxy name webauth1
http list not specified inactivity-time 60 minutes

Authentication Proxy Auditing is disabled
Max Login attempts per user is 5

Configuring AAA Authentication

To enable web-based authentication, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables AAA functionality. Disables AAA functionality.</td>
</tr>
<tr>
<td>Switch(config)# aaa new-model</td>
<td>Enables AAA functionality.</td>
</tr>
<tr>
<td>Switch(config)# no aaa new-model</td>
<td>Disables AAA functionality.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Defines the list of authentication methods at login.</td>
</tr>
<tr>
<td>Switch(config)# aaa authentication login default group (tacacs+</td>
<td>radius)</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Creates an authorization method list for web-based authorization. Clears the configured method list.</td>
</tr>
<tr>
<td>Switch(config)# aaa authorization auth-proxy default group (tacacs+</td>
<td>radius)</td>
</tr>
<tr>
<td>Switch(config)# no aaa authorization auth-proxy default group (tacacs+</td>
<td>radius)</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Specifies an AAA server. For RADIUS servers, see the section “Configuring Switch-to-RADIUS-Server Communication” section on page 37-8.</td>
</tr>
<tr>
<td>Switch(config)# tacacs-server host (hostname</td>
<td>ip_address)</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Configures the authorization and encryption key used between the switch and the TACACS server.</td>
</tr>
<tr>
<td>Switch(config)# tacacs-server key (key-data)</td>
<td></td>
</tr>
</tbody>
</table>

Configuring Switch-to-RADIUS-Server Communication

RADIUS security servers are identified by one of the following:
- Host name
- Host IP address
- Host name and specific UDP port numbers
The combination of the IP address and UDP port number creates a unique identifier, which enables RADIUS requests to be sent to multiple UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service (for example, authentication) the second host entry that is configured functions as the failover backup to the first one. The RADIUS host entries are chosen in the order that they were configured.

To configure the RADIUS server parameters, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>Switch(config)# ip radius source-interface interface_name</td>
<td>Specifies that the RADIUS packets have the IP address of the indicated interface.</td>
</tr>
<tr>
<td>Switch(config)# no ip radius source-interface</td>
<td>Prevents the RADIUS packets from having the IP address of the previously indicated interface.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td>Switch(config)# radius-server host {hostname</td>
<td>ip-address} test username username</td>
</tr>
<tr>
<td>Switch(config)# no radius-server host {hostname</td>
<td>ip-address}</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td></td>
</tr>
<tr>
<td>Switch(config)# radius-server key string</td>
<td>Configures the authorization and encryption key used between the switch and the RADIUS daemon running on the RADIUS server.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td></td>
</tr>
<tr>
<td>Switch(config)# radius-server vsa send authentication</td>
<td>Enables downloading of an ACL from the RADIUS server. This feature was introduced in Cisco IOS Release 12.2(50)SG.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td></td>
</tr>
<tr>
<td>Switch(config)# radius-server dead-criteria tries num-tries</td>
<td>Specifies the number of unanswered transmits to a RADIUS server before considering the server to be inactive. The range of <strong>num-tries</strong> is 1 to 100.</td>
</tr>
</tbody>
</table>

When you configure the RADIUS server parameters, do the following:

- Specify the **key string** on a separate command line.
- For **key string**, specify the authentication and encryption key used between the switch and the RADIUS daemon running on the RADIUS server. The key is a text string that must match the encryption key used on the RADIUS server.
- When you specify the **key string**, use spaces within and at the end of the key. If you use spaces in the key, do not enclose the key in quotation marks unless the quotation marks are part of the key. This key must match the encryption used on the RADIUS daemon.
- You can globally configure the timeout, retransmission, and encryption key values for all RADIUS servers with the **radius-server host** global configuration command. If you want to configure these options on a per-server basis, use the **radius-server timeout**, **radius-server retransmit**, and the
radius-server key global configuration commands. For more information, see the
Cisco IOS Security Configuration Guide, Release 12.2, publication and the
Cisco IOS Security Command Reference, Release 12.2, publication at this URL:

Note
You need to configure some settings on the RADIUS server, including: the IP address of the switch, the
key string to be shared by both the server and the switch, and the downloadable ACL (DACL). (Starting
with Cisco IOS Release 12.2(50)SG, Catalyst 4500 series switches support DACLs.) For more
information, see the RADIUS server documentation.

This example shows how to configure the RADIUS server parameters on a switch:
Switch(config)# ip radius source-interface Vlan80
Switch(config)# radius-server host 172.120.39.46 test username user1
Switch(config)# radius-server key rad123
Switch(config)# radius-server dead-criteria tries 2

Configuring the HTTP Server

To use web-based authentication, you must enable the HTTP server within the switch. You can enable
the server for either HTTP or HTTPS.

To enable the server, perform one of these tasks:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# ip http server</td>
<td>Enables the HTTP server. The web-based authentication feature uses the HTTP server to communicate with the hosts for user authentication.</td>
</tr>
<tr>
<td>Switch(config)# ip http secure-server</td>
<td>Enables HTTPS.</td>
</tr>
</tbody>
</table>

Starting with Cisco IOS Release 12.2(50)SG, you can optionally configure custom authentication proxy
web pages or specify a redirection URL for successful login, as described in the following sections:
• Customizing the Authentication Proxy Web Pages
• Specifying a Redirection URL for Successful Login
Customizing the Authentication Proxy Web Pages

With Cisco IOS Release 12.2(50)SG, you can display four substitute HTML pages to the user rather than the switch’s switch internal default HTML pages during web-based authentication.

To specify the use of your custom authentication proxy web pages, first store your custom HTML files on the switch’s internal disk or flash memory, then perform this task in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1  | Switch(config)# ip admission proxy http login page file device:login-filename | Specifies the location in the switch memory file system of the custom HTML file to use in place of the default login page. The device: is either disk or flash memory, such as disk0:.
| Step 2  | Switch(config)# ip admission proxy http success page file device:success-filename | Specifies the location of the custom HTML file to use in place of the default login success page.
| Step 3  | Switch(config)# ip admission proxy http failure page file device:fail-filename | Specifies the location of the custom HTML file to use in place of the default login failure page.
| Step 4  | Switch(config)# ip admission proxy http login expired page file device:expired-filename | Specifies the location of the custom HTML file to use in place of the default login expired page.

When configuring customized authentication proxy web pages, observe the following guidelines:

- To enable the custom web pages feature, specify all four custom HTML files. If you specify fewer than four files, the internal default HTML pages are used.
- The four custom HTML files must be present on the disk or flash of the switch. The maximum size of each HTML file is 8 KB.
- Any images on the custom pages must be located on an accessible HTTP server. An intercept ACL must be configured within the admission rule to allow access to the HTTP server.
- Any external link from a custom page requires configuration of an intercept ACL within the admission rule.
- Any name resolution required for external links or images requires configuration of an intercept ACL within the admission rule to access a valid DNS server.
- If the custom web pages feature is enabled, a configured auth-proxy-banner is not used.
- If the custom web pages feature is enabled, the redirection URL for successful login feature is not available.
- To remove the specification of a custom file, use the no form of the command.

Because the custom login page is a public web form, consider the following guidelines for this page:

- The login form must accept user input for the username and password and must POST the data as uname and pwd.
- The custom login page should follow best practices for a web form, such as page timeout, hidden password, and prevention of redundant submissions.

The following example shows how to configure custom authentication proxy web pages:

```
Switch(config)# ip admission proxy http login page file disk1:login.htm
Switch(config)# ip admission proxy http success page file disk1:success.htm
Switch(config)# ip admission proxy http fail page file disk1:fail.htm
Switch(config)# ip admission proxy http login expired page file disk1:expired.htm
```
The following example shows how to verify the configuration of custom authentication proxy web pages:

Switch# show ip admission configuration

Authentication proxy webpage
Login page : disk1:login.htm
Success page : disk1:success.htm
Fail Page : disk1:fail.htm
Login expired Page : disk1:expired.htm

Authentication global cache time is 60 minutes
Authentication global absolute time is 0 minutes
Authentication global init state time is 2 minutes
Authentication Proxy Session ratelimit is 100
Authentication Proxy Watch-list is disabled
Authentication Proxy Auditing is disabled
Max Login attempts per user is 5

Specifying a Redirection URL for Successful Login

With Cisco IOS Release 12.2(50)SG, you have the option to specify a URL to which the user is redirected upon successful authentication, effectively replacing the internal Success HTML page.

To specify a redirection URL for successful login, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# ip admission proxy http success redirect url-string</td>
<td>Specifies a URL for redirection of the user in place of the default login success page.</td>
</tr>
</tbody>
</table>

When configuring a redirection URL for successful login, consider the following guidelines:

- If the custom authentication proxy web pages feature is enabled, the redirection URL feature is disabled and is not available in the CLI. You can perform redirection in the custom login success page.
- If the redirection URL feature is enabled, a configured auth-proxy-banner is not used.
- To remove the specification of a redirection URL, use the no form of the command.

The following example shows how to configure a redirection URL for successful login:

Switch(config)# ip admission proxy http success redirect www.cisco.com

The following example shows how to verify the redirection URL for successful login:

Switch# show ip admission configuration

Authentication Proxy Banner not configured
Customizable Authentication Proxy webpage not configured
HTTP Authentication success redirect to URL: http://www.cisco.com
Authentication global cache time is 60 minutes
Authentication global absolute time is 0 minutes
Authentication global init state time is 2 minutes
Authentication Proxy Watch-list is disabled
Authentication Proxy Auditing is disabled
Max Login attempts per user is 5
Configuring the Web-Based Authentication Parameters

You can configure the maximum number of failed login attempts allowed before the client is placed in a watch list for a waiting period.

To configure the web-based authentication parameters, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch(config)# ip admission max-login-attempts number</td>
</tr>
<tr>
<td></td>
<td>Sets the maximum number of failed login attempts. The range is 1 to 2147483647 attempts; the default is 5.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch# show ip admission configuration</td>
</tr>
<tr>
<td></td>
<td>Displays the authentication proxy configuration.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch# show ip admission cache</td>
</tr>
<tr>
<td></td>
<td>Displays the list of authentication entries.</td>
</tr>
</tbody>
</table>

This example shows how to set the maximum number of failed login attempts to 10:

Switch(config)# ip admission max-login-attempts 10

Removing Web-Based Authentication Cache Entries

To delete existing session entries, perform either of these tasks:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# clear ip auth-proxy cache {*</td>
<td>host ip address})</td>
</tr>
<tr>
<td>Switch# clear ip admission cache {*</td>
<td>host ip address})</td>
</tr>
</tbody>
</table>

This example shows how to remove the web-based authentication session for the client at IP address 209.165.201.1:

Switch# clear ip auth-proxy cache 209.165.201.1

Displaying Web-Based Authentication Status

To display the web-based authentication settings for all interfaces or for specific ports, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# show authentication sessions [interface type slot/port]</td>
</tr>
<tr>
<td></td>
<td>Displays the web-based authentication settings. type = fastethernet, gigabitethernet, or tengigabitethernet (Optional) Use the interface keyword to display the web-based authentication settings for a specific interface.</td>
</tr>
</tbody>
</table>
This example shows how to view only the global web-based authentication status:

```
Switch# show authentication sessions
```

This example shows how to view the web-based authentication settings for interface Gi 3/27:

```
Switch# show authentication sessions interface gigabitethernet 3/27
```
Configuring Port Security

This chapter describes how to configure port security on the Catalyst 4500 series switch. It provides an overview of port security on the Catalyst 4500 series switch and details the configuration on various types of ports such as access, voice, trunk and private VLAN (PVLAN).

This chapter consists of these sections:

- Command List, page 38-1
- Port Security, page 38-3
- Configuring Port Security on Access Ports, page 38-7
- Configuring Port Security on PVLAN Ports, page 38-14
- Configuring Port Security on Trunk Ports, page 38-17
- Configuring Port Security on Voice Ports, page 38-22
- Displaying Port Security Settings, page 38-27
- Configuring Port Security with Other Features/Environments, page 38-31
- Guidelines and Restrictions, page 38-33

Note

For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

Command List

This table lists the commands most commonly used with Port Security.
## Chapter 38 Configuring Port Security

### Command List

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
<th>Navigation</th>
</tr>
</thead>
<tbody>
<tr>
<td>errdisable recovery cause</td>
<td>Brings a secure port out of error-disabled state</td>
<td>Violation Actions, page 38-6</td>
</tr>
<tr>
<td>psecure-violation</td>
<td>Customizes the time to recover from a specified error disable cause</td>
<td>Violation Actions, page 38-6</td>
</tr>
<tr>
<td>port-security mac-address</td>
<td>Configures all secure MAC addresses on each VLAN</td>
<td>Secure MAC Addresses, page 38-3</td>
</tr>
<tr>
<td>port-security maximum</td>
<td>Configures a maximum number of MAC addresses on an interface</td>
<td>Configuring Port Security on Access Ports, page 38-7</td>
</tr>
<tr>
<td>private-vlan association add</td>
<td>Creates an association between a secondary VLAN and a primary VLAN</td>
<td>Example of Port Security on an Isolated Private VLAN Host Port, page 38-16</td>
</tr>
<tr>
<td>private-vlan isolated</td>
<td>Designates the VLAN as a private VLAN</td>
<td>Configuring Port Security on an Isolated Private VLAN Host Port, page 38-14</td>
</tr>
<tr>
<td>private-vlan primary</td>
<td>Specifies the VLAN as the primary private VLAN</td>
<td>Configuring Port Security on an Isolated Private VLAN Host Port, page 38-14</td>
</tr>
<tr>
<td>switchport mode private-vlan host</td>
<td>Specifies that ports with valid private VLAN trunk association become active host private VLAN trunk ports</td>
<td>Configuring Port Security on an Isolated Private VLAN Host Port, page 38-14</td>
</tr>
<tr>
<td>switchport private-vlan host-association</td>
<td>Defines a host association on an isolated host port</td>
<td>Configuring Port Security on an Isolated Private VLAN Host Port, page 38-14</td>
</tr>
<tr>
<td>switchport private-vlan mapping</td>
<td>Defines a private VLAN for the promiscuous ports</td>
<td>Configuring Port Security on an Isolated Private VLAN Host Port, page 38-14</td>
</tr>
<tr>
<td>switchport port-security</td>
<td>Enables port security</td>
<td>Configuring Port Security on Access Ports, page 38-7</td>
</tr>
<tr>
<td>switchport port-security aging static</td>
<td>Configures static aging of MAC address.</td>
<td>Aging Secure MAC Addresses, page 38-5</td>
</tr>
<tr>
<td>switchport port-security aging time</td>
<td>Specifies an aging time for a port</td>
<td>Example 3: Setting the Aging Timer, page 38-11</td>
</tr>
<tr>
<td>switchport port-security limit rate invalid-source-mac</td>
<td>Sets the rate limit for bad packets</td>
<td>Example 7: Setting a Rate Limit for Bad Packets, page 38-13</td>
</tr>
<tr>
<td>switchport port-security mac-address</td>
<td>Configures a secure MAC address for an interface</td>
<td>Example 5: Configuring a Secure MAC Address, page 38-12</td>
</tr>
<tr>
<td>switchport port-security mac-address mac_address</td>
<td>Specifies the sticky MAC address for an interface</td>
<td>Configuring Port Security on Access Ports, page 38-7</td>
</tr>
<tr>
<td>switchport port-security mac-address sticky</td>
<td>Enables sticky Port Security</td>
<td>Sticky Addresses on a Port, page 38-5</td>
</tr>
<tr>
<td>no switchport port-security mac-address sticky</td>
<td>Converts a sticky secure MAC address to a dynamic MAC secure address</td>
<td>Configuring Port Security on Access Ports, page 38-7</td>
</tr>
</tbody>
</table>
Port Security enables you to restrict the number of MAC addresses (termed secure MAC addresses) on a port, allowing you to prevent access by unauthorized MAC addresses. It also allows you to configure a maximum number of secure MAC addresses on a given port (and optionally for a VLAN for trunk ports). When a secure port exceeds the maximum, a security violation is triggered, and a violation action is performed based on the violation action mode configured on the port.

If you configure the maximum number of secure MAC addresses as 1 on the port, the device attached to the secure port is assured sole access to the port.

If a secure MAC address is secured on a port, that MAC address is not allowed to enter on any other port off that VLAN. If it does, the packet is dropped unnoticed in the hardware. Other than through the interface or port counters, you do not receive a log message reflecting this fact. Be aware that this condition does not trigger a violation. Dropping these packets in the hardware is more efficient and can be done without putting additional load on the CPU.

Port Security has the following characteristics:

- It allows you to age out secure MAC addresses. Two types of aging are supported: inactivity and absolute.
- It supports a sticky feature whereby the secure MAC addresses on a port are retained through switch reboots and link flaps.
- It can be configured on various types of ports such as access, voice, trunk, and private VLAN ports.

This overview contains the following topics:

- **Secure MAC Addresses**, page 38-3
- **Maximum Number of Secure MAC Addresses**, page 38-4
- **Aging Secure MAC Addresses**, page 38-5
- **Sticky Addresses on a Port**, page 38-5
- **Violation Actions**, page 38-6

### Secure MAC Addresses

Port Security supports the following types of secure MAC addresses:

- Dynamic or Learned—Dynamic secure MAC addresses are learned when packets are received from the host on the secure port. You might want to use this type if the user’s MAC address is not fixed (laptop).
Port Security

- Static or Configured—Static secure MAC addresses are configured by the user through CLI or SNMP. You might want to use this type if your MAC address remains fixed (PC).
- Sticky—Sticky addresses are learned like dynamic secure MAC addresses, but persist through switch reboots and link flaps like static secure MAC addresses. You might want to use this type if a large number of fixed MAC addresses exist and you do not want to configure MAC addresses manually (100 PCs secured on their own ports).

If a port has reached its maximum number of secure MAC addresses and you try to configure a static secure MAC address, your configuration is rejected and an error message displays. If a port has reached its maximum number of secure MAC addresses and a new dynamic secure MAC address is added, a violation action is triggered.

You can clear dynamic secure MAC addresses with the `clear port-security` command. You can clear sticky and static secure MAC addresses one at a time with the `no` form of the `switchport port-security mac-address` command.

### Maximum Number of Secure MAC Addresses

A secure port has a default of one MAC address. You can change the default to any value between 1 and 3,072. The upper limit of 3,072 guarantees one MAC address per port and an additional 3,072 across all ports in the system.

After you have set the maximum number of secure MAC addresses on a port, you can include the secure addresses in an address table in one of the following ways:

- You can configure the secure MAC addresses with the `switchport port-security mac-address mac_address` interface configuration command.
- You can configure all secure MAC addresses on a range of VLANs with the `port-security mac-address VLAN range` configuration command for trunk ports.
- You can allow the port to dynamically configure secure MAC addresses with the MAC addresses of connected devices.
- You can configure some of the addresses and allow the rest to be dynamically configured.

**Note**
If a port’s link goes down, all dynamically secured addresses on that port are no longer secure.

- You can configure MAC addresses to be sticky. These can be dynamically learned or manually configured, stored in the address table, and added to the running configuration. After these addresses are saved in the configuration file, the interface does not need to dynamically relearn them when the switch restarts. Although you can manually configure sticky secure addresses, this action is not recommended.

**Note**
On a trunk port, a maximum number of secure MAC addresses can be configured on both the port and port VLAN. The port’s maximum value can be greater than or equal to the port VLAN maximum(s) but not less than the port VLAN maximum(s). If the port’s maximum value is less than at least one of the port VLAN’s maximum (for example, if we have max set to 3 on VLAN 10 while no “sw port max” is set (defaults to 1)), the port shuts down when dynamic adds reaches 2 on VLAN 10 (see “Guidelines and Restrictions” on page 33). The port VLAN maximum enforces the maximum allowed on a given port on a given VLAN. If the maximum is exceeded on a given VLAN but the port’s maximum is not exceeded, the port still shuts down. The entire port is shut down even if one of the VLANs on the port has actually caused the violation.
Aging Secure MAC Addresses

You might want to age secure MAC addresses when the switch may be receiving more than 3,000 MAC addresses ingress.

**Note**
Aging of sticky addresses is not supported.

By default, port security does not age out the secure MAC addresses. After learned, the MAC addresses remain on the port until either the switch reboots or the link goes down (unless the sticky feature is enabled). However, port security does allow you to configure aging based on the absolute or inactivity mode and aging interval (in minutes, from 1 to n).

- Absolute mode: ages between n and n+1
- Inactivity mode: ages between n+1 and n+2

Use this feature to remove and add PCs on a secure port without manually deleting the existing secure MAC addresses, while still limiting the number of secure addresses on a port.

Unless static aging is explicitly configured with the `switchport port-security aging static` command, static addresses are not aged even if aging is configured on the port.

**Note**
The aging increment is one minute.

Sticky Addresses on a Port

By enabling *sticky port security*, you can configure an interface to convert the dynamic MAC addresses to sticky secure MAC addresses and to add them to the running configuration. You might want to do this if you do not expect the user to move to another port, and you want to avoid statically configuring a MAC address on every port.

**Note**
If you use a different chassis, you might need another MAC address.

To enable sticky *port security*, enter the `switchport port-security mac-address sticky` command. When you enter this command, the interface converts all the dynamic secure MAC addresses, including those that were dynamically learned before sticky learning was enabled, to sticky secure MAC addresses.

The sticky secure MAC addresses do not automatically become part of the configuration file, which is the startup configuration used each time the switch restarts. If you save the running config file to the configuration file, the interface does not need to relearn these addresses when the switch restarts. If you do not save the configuration, they are lost.

If sticky *port security* is disabled, the sticky secure MAC addresses are converted to dynamic secure addresses and are removed from the running configuration.

After the maximum number of secure MAC addresses is configured, they are stored in an address table. To ensure that an attached device has sole access of the port, configure the MAC address of the attached device and set the maximum number of addresses to one, which is the default.
A security violation occurs if the maximum number of secure MAC addresses to a port has been added to the address table and a workstation whose MAC address is not in the address table attempts to access the interface.

**Violation Actions**

A security violation is triggered when the number of secure MAC addresses on the port exceeds the maximum number of secure MAC addresses allowed on the port.

---

**Note**

A secure violation is not triggered if the host secured on one port shows up on another port. The Catalyst 4500 series switch drops such packets on the new port silently in the hardware and does not overload the CPU.

You can configure the interface for one of the following violation modes, which are based on the response to the violation:

- **Restrict**—A port security violation restricts data (that is, packets are dropped in software), causes the SecurityViolation counter to increment, and causes an SNMP Notification to be generated. You might want to configure this mode in order to provide uninterrupted service/access on a secure port. The rate at which SNMP traps are generated can be controlled by the `snmp-server enable traps port-security trap-rate` command. The default value (“0”) causes an SNMP trap to be generated for every security violation.

- **Shutdown**—A port security violation causes the interface to shut down immediately. You might want to configure this mode in a highly secure environment, where you do not want unsecured MAC addresses to be denied in software and service interruption is not an issue.

- **Shutdown VLAN**—Use to set the security violation mode for each VLAN. In this mode, the offending VLAN is error disabled instead of the entire port when a violation occurs. When a secure port is in the error-disabled state, you can bring it out of this state automatically by configuring the `errdisable recovery cause psecure-violation` global configuration command or you can manually reenable it by entering the `shutdown` and `no shutdown` interface configuration commands. This is the default mode. If a port is in per-VLAN errdisable mode, you can also use `clear errdisable interface name vlan range` command to re-enable the VLAN on the port.

You can also customize the time to recover from the specified error disable cause (default is 300 seconds) by entering the `errdisable recovery interval interval command`.

---

**Invalid Packet Handling**

You might want to rate limit invalid source MAC address packets on a secure port if you anticipate that a device will send invalid packets (such as traffic generator, sniffer, and bad NICs).

The port security feature considers the following as “invalid frames”:

- Packets with a source or destination MAC address that is all zero
- Packets with a multicast or broadcast source MAC address
- Packets from an address either learned or configured on a secure interface that are observed on another secure interface in the same VLAN

You can choose to rate limit these packets. If the rate is exceeded, you can trigger a violation action for the port.
Configuring Port Security on Access Ports

These sections describe how to configure port security:

- Configuring Port Security on Access Ports, page 38-7
- Examples, page 38-10

Note
Port security can be enabled on a Layer 2 port channel interface configured in access mode. The port security configuration on an EtherChannel is kept independent of the configuration of any physical member ports.

Configuring Port Security on Access Ports

To restrict traffic through a port by limiting and identifying MAC addresses of the stations allowed to the port, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**  
Switch(config)# interface interface_id  
interface port-channel port_channel_number | Enters interface configuration mode and specifies the interface to configure.  
*Note*  
The interface can be a Layer 2 port channel logical interface. |
| **Step 2**  
Switch(config-if)# switchport mode access | Sets the interface mode.  
*Note*  
An interface in the default mode (dynamic auto) cannot be configured as a secure port. |
| **Step 3**  
Switch(config-if)# [no] switchport port-security | Enables port security on the interface.  
To return the interface to the default condition as nonsecure port, use the **no switchport port-security** command. |
| **Step 4**  
Switch(config-if)# [no] switchport port-security maximum value | (Optional) Sets the maximum number of secure MAC addresses for the interface. The range is 1 to 3072; the default is 1.  
To return the interface to the default number of secure MAC addresses, use the **no switchport port-security maximum** value. |
Chapter 38      Configuring Port Security

### Configuring Port Security on Access Ports

#### Step 5

Switch(config-if)# switchport port-security
[aging (static | time aging_time | type (absolute | inactivity)]

Sets the aging time and aging type for all secure addresses on a port.

Use this feature to remove and add PCs on a secure port without manually deleting the existing secure MAC addresses while still limiting the number of secure addresses on a port.

The **static** keyword enables aging for statically configured secure addresses on this port.

The **time aging_time** keyword specifies the aging time for this port. Valid range for aging_time is from 0 to 1440 minutes. If the time is equal to 0, aging is disabled for this port.

The **type** keyword sets the aging type as **absolute** or **inactive**.

- **absolute**—All the secure addresses on this port age out exactly after the time (minutes) specified and are removed from the secure address list.

- **inactive**—The secure addresses on this port age out only if there is no data traffic from the secure source address for the specified time period.

To disable port security aging for all secure addresses on a port, use the **no switchport port-security aging time** interface configuration command.
### Command

**Step 6**

```
Switch(config-if)# [no] switchport port-security violation (restrict | shutdown | shutdown vlan)
```

(Optional) Sets the violation mode, the action to be taken when a security violation is detected, as one of these:

- **restrict**—A port security violation restricts data and causes the SecurityViolation counter to increment and send an SNMP trap notification.
- **shutdown**—The interface is error-disabled when a security violation occurs.
- **shutdown vlan**—Use to set the security violation mode for each VLAN. In this mode, the VLAN is error-disabled instead of the entire port when a violation occurs.

**Note**  When a secure port is in the error-disabled state, you can bring it out of this state by entering the `errdisable recovery cause psecure-violation` global configuration command or you can manually reenable it by entering the `shutdown` and `no shutdown` interface configuration commands.

To return the violation mode to the default condition (shutdown mode), use the `no switchport port-security violation shutdown` command.

**Step 7**

```
Switch(config-if)# switchport port-security limit rate invalid-source-mac packets_per_sec
```

Sets the rate limit for bad packets.

Default is 10 pps.

**Step 8**

```
Switch(config-if)# [no] switchport port-security mac-address mac_address
```

(Optional) Enters a secure MAC address for the interface. Use this command to configure a secure MAC addresses. If you configure fewer secure MAC addresses than the maximum, the remaining MAC addresses are dynamically learned.

To delete a MAC address from the address table, use the `no switchport port-security mac-address mac_address` command.

**Note** This command only applies to access, PVLAN host, and PVLAN promiscuous mode. For more details on PVLAN, trunk, or regular trunk mode, refer to the “Configuring Port Security on Trunk Ports” section on page 38-17.

**Step 9**

```
Switch(config-if)# [no] switchport port-security mac-address sticky
```

(Optional) Enables sticky learning on the interface.

To disable sticky learning on an interface, use the `no switchport port-security mac-address sticky` command. The interface converts the sticky secure MAC addresses to dynamic secure addresses.
### Configuring Port Security on Access Ports

#### Note
To clear dynamically learned port security MAC addresses in the CAM table, use the `clear port-security dynamic` command. The `address` keyword enables you to clear a secure MAC addresses. The `interface` keyword enables you to clear all secure addresses on any interface (including any port channel interface). The `VLAN` keyword allows you to clear port security MACs on a per-VLAN per-port basis.

### Examples

The following examples are provided:

- Example 1: Setting Maximum Number of Secure Addresses, page 38-11
- Example 2: Setting a Violation Mode, page 38-11
- Example 3: Setting the Aging Timer, page 38-11
- Example 4: Setting the Aging Timer Type, page 38-12
- Example 5: Configuring a Secure MAC Address, page 38-12
- Example 6: Configuring Sticky Port Security, page 38-13
- Example 7: Setting a Rate Limit for Bad Packets, page 38-13
- Example 8: Clearing Dynamic Secure MAC Addresses, page 38-14

---

### Command

<table>
<thead>
<tr>
<th>Step</th>
<th>Command</th>
<th>Purpose (continued)</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>`Switch(config-if)# [no] switchport port-security mac-address mac_address sticky [vlan [voice</td>
<td>access]]`</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When you specify the <code>vlan</code> keyword, the mac-address becomes sticky in the specified VLAN.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>To delete a sticky secure MAC addresses from the address table, use the <code>no switchport port-security mac-address mac_address sticky</code> command. To convert sticky to dynamic addresses, use the <code>no switchport port-security mac-address sticky</code> command.</td>
</tr>
<tr>
<td></td>
<td></td>

---

To clear dynamically learned port security MAC addresses in the CAM table, use the `clear port-security dynamic` command. The `address` keyword enables you to clear a secure MAC addresses. The `interface` keyword enables you to clear all secure addresses on any interface (including any port channel interface). The `VLAN` keyword allows you to clear port security MACs on a per-VLAN per-port basis.
Example 1: Setting Maximum Number of Secure Addresses

This example shows how to enable port security on the Fast Ethernet interface 3/12 and how to set the maximum number of secure addresses to 5. The violation mode is the default, and no secure MAC addresses are configured.

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fastethernet 3/12
Switch(config-if)# switchport mode access
Switch(config-if)# switchport port-security
Switch(config-if)# switchport port-security maximum 5
Switch(config-if)# switchport port-security mac-address sticky
Switch(config-if)# end
Switch#
```

```
show port-security interface fastethernet 3/12
Port Security              : Enabled
Port Status                : Secure-up
Violation Mode             : Shutdown
Aging Time                 : 0 mins
Aging Type                 : Absolute
SecureStatic Address Aging : Enabled
Maximum MAC Addresses      : 5
Total MAC Addresses        : 0
Configured MAC Addresses   : 0
Sticky MAC Addresses       : 0
Last Source Address:Vlan   : 0000.0000.0000:0
Security Violation Count   : 0
```

Example 2: Setting a Violation Mode

This example shows how to set the violation mode on the Fast Ethernet interface 3/12 to restrict.

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fastethernet 3/12
Switch(config-if)# switchport port-security violation restrict
Switch(config-if)# end
Switch#
```

SNMP traps can be enabled with a rate-limit to detect port-security violations due to restrict mode. The following example shows how to enable traps for port-security with a rate of 5 traps per second:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# snmp-server enable traps port-security trap-rate 5
Switch(config)# end
Switch#
```

Example 3: Setting the Aging Timer

This example shows how to set the aging time to 2 hours (120 minutes) for the secure addresses on the Fast Ethernet interface 5/1:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fastethernet 5/1
Switch(config-if)# switchport port-security aging time 120
Switch(config-if)# end
Switch#
```
This example shows how to set the aging time to 2 minutes:

```
Switch(config-if)# switchport port-security aging time 2
```

You can verify the previous commands with the `show port-security interface` command.

### Example 4: Setting the Aging Timer Type

This example shows how to set the aging timer type to Inactivity for the secure addresses on the Fast Ethernet interface 3/5:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fastethernet 3/5
Switch(config-if)# switchport port-security aging type inactivity
Switch(config-if)# end
Switch# show port-security interface fastethernet 3/5
Port Security              : Enabled
Port Status                : Secure-up
Violation Mode             : Shutdown
Aging Time                 : 0 mins
Aging Type                 : Inactivity
SecureStatic Address Aging : Disabled
Maximum MAC Addresses      : 1
Total MAC Addresses        : 0
Configured MAC Addresses   : 0
Sticky MAC Addresses       : 0
Last Source Address:Vlan   : 0000.0000.0000:0
Security Violation Count   : 0
```

### Example 5: Configuring a Secure MAC Address

This example shows how to configure a secure MAC address on Fast Ethernet interface 5/1 and to verify the configuration:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fastethernet 5/1
Switch(config-if)# switchport mode access
Switch(config-if)# switchport port-security
Switch(config-if)# switchport port-security maximum 10
Switch(config-if)# switchport port-security mac-address 0000.0000.0003 (Static secure MAC)
Switch(config-if)# end
Switch# show port address
Secure Mac Address Table
--------------------------------------------------------
Vlan    Mac Address       Type                     Ports   Remaining Age (mins)
----    -----------       ----                     -----   -------------
1    0000.0000.0003    SecureConfigured         Fa5/1        -
--------------------------------------------------------
Total Addresses in System (excluding one mac per port) : 2
Max Addresses limit in System (excluding one mac per port) : 3072
```
Example 6: Configuring Sticky Port Security

This example shows how to configure a sticky MAC address on Fast Ethernet interface 5/1 and to verify the configuration:

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fa5/1
Switch(config-if)# switchport mode access
Switch(config-if)# switchport port-security
Switch(config-if)# switchport port-security mac-address sticky
Switch(config-if)# switchport port-security maximum 5
Switch(config-if)# end

Note

Sending traffic to the ports causes the system to configure the port with sticky secure addresses.

Switch# show port-security address
Secure Mac Address Table

<table>
<thead>
<tr>
<th>Vlan</th>
<th>Mac Address</th>

switchport port-security mac-address sticky 0000.0000.0002
switchport port-security mac-address sticky 0000.0000.0003
end

Switch#

Example 7: Setting a Rate Limit for Bad Packets

The following example shows how to configure rate limit for invalid source packets on Fast Ethernet interface 5/1:

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fastethernet 5/1
Switch(config-if)# switchport port-security limit rate invalid-source-mac 100
Switch(config-if)# end
Switch#
The following example shows how to configure rate limit for invalid source packets on Fast Ethernet interface 5/1:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fastethernet 5/1
Switch(config-if)# switchport port-security limit rate invalid-source-mac none
Switch(config-if)# end
Switch#
```

### Example 8: Clearing Dynamic Secure MAC Addresses

The following example shows how to clear a dynamic secure MAC address:

```
Switch# clear port-security dynamic address 0000.0001.0001
```

The following example shows how to clear all dynamic secure MAC addresses on Fast Ethernet interface 2/1:

```
Switch# clear port-security dynamic interface fa2/1
```

The following example shows how to clear all dynamic secure MAC addresses in the system:

```
Switch# clear port-security dynamic
```

---

**Configuring Port Security on PVLAN Ports**

You can configure port security on a private VLAN port to take advantage of private VLAN functionality as well as to limit the number of MAC addresses.

---

**Note**

This section follows the same configuration model that was presented for access ports.

These sections describe how to configure trunk port security on host and promiscuous ports:

- Configuring Port Security on an Isolated Private VLAN Host Port, page 38-14
- Example of Port Security on an Isolated Private VLAN Host Port, page 38-16
- Configuring Port Security on a Private VLAN Promiscous Port, page 38-16
- Example of Port Security on a Private VLAN Promiscous Port, page 38-17

---

**Configuring Port Security on an Isolated Private VLAN Host Port**

Figure 38-1 illustrates a typical topology for port security implemented on private VLAN host ports. In this topology, the PC connected through port a on the switch can communicate only with the router connected through the promiscuous port on the switch. The PC connected through port a cannot communicate with the PC connected through port b.
Figure 38-1 Port Security on Isolated Private VLAN Host Ports

Note
Dynamic addresses secured on an isolated private VLAN host port on private VLANs are secured on the secondary VLANs, and not primary VLANs.

To configure port security on an isolated private VLAN host port, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 Switch# configure terminal</td>
<td>Enter global configuration mode.</td>
</tr>
<tr>
<td>Step 2 Switch(config)# vlan sec_vlan_id</td>
<td>Specifies a secondary VLAN.</td>
</tr>
<tr>
<td>Step 3 Switch(config-vlan)# private-vlan isolated</td>
<td>Sets the private VLAN mode to isolated.</td>
</tr>
<tr>
<td>Step 4 Switch(config-vlan)# exit</td>
<td>Returns to global configuration mode.</td>
</tr>
<tr>
<td>Step 5 Switch(config)# vlan pri_vlan_id</td>
<td>Specifies a primary VLAN.</td>
</tr>
<tr>
<td>Step 6 Switch(config-vlan)# private-vlan primary</td>
<td>Specifies the VLAN as the primary private VLAN.</td>
</tr>
<tr>
<td>Step 7 Switch(config-vlan)# private-vlan association add sec_vlan_id</td>
<td>Creates an association between a secondary VLAN and a primary VLAN.</td>
</tr>
<tr>
<td>Step 8 Switch(config-vlan)# exit</td>
<td>Returns to global configuration mode.</td>
</tr>
<tr>
<td>Step 9 Switch(config)# interface interface_id</td>
<td>Enters interface configuration mode and specifies the physical interface to configure.</td>
</tr>
<tr>
<td>Step 10 Switch(config-if)# switchport mode private-vlan host</td>
<td>Specifies that the ports with a valid private VLAN trunk association become active host private VLAN trunk ports.</td>
</tr>
<tr>
<td>Step 11 Switch(config-if)# switchport private-vlan host-association primary_vlan secondary_vlan</td>
<td>Establishes a host association on an isolated host port.</td>
</tr>
<tr>
<td>Step 12 Switch(config-if)# [no] switchport port-security</td>
<td>Enables port security on the interface.</td>
</tr>
<tr>
<td>Step 13 Switch(config-if)# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Step 14 Switch# show port-security address interface interface_id</td>
<td>Verifies your entries.</td>
</tr>
</tbody>
</table>
Example of Port Security on an Isolated Private VLAN Host Port

The following example shows how to configure port security on an isolated private VLAN host port, Fast Ethernet interface 3/12:

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# vlan 6
Switch(config-vlan)# private-vlan isolated
Switch(config-vlan)# exit
Switch(config)# vlan 3
Switch(config-vlan)# private-vlan primary
Switch(config-vlan)# private-vlan association add 6
Switch(config-vlan)# exit
Switch(config)# interface fastethernet 3/12
Switch(config-if)# switchport mode private-vlan host
Switch(config-if)# switchport private-vlan association host 3 6
Switch(config-if)# switchport port-security
Switch(config-if)# end

Configuring Port Security on a Private VLAN Promiscous Port

To configure port security on a private VLAN promiscous port, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# vlan sec_vlan_id</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config-vlan)# private-vlan isolated</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config-vlan)# exit</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch(config)# vlan pri_vlan_id</td>
</tr>
<tr>
<td>Step 6</td>
<td>Switch(config-vlan)# private-vlan primary</td>
</tr>
<tr>
<td>Step 7</td>
<td>Switch(config-vlan)# private-vlan association add sec_vlan_id</td>
</tr>
<tr>
<td>Step 8</td>
<td>Switch(config-vlan)# exit</td>
</tr>
<tr>
<td>Step 9</td>
<td>Switch(config)# interface interface_id</td>
</tr>
<tr>
<td>Step 10</td>
<td>Switch(config-if)# switchport mode private-vlan promiscuous</td>
</tr>
<tr>
<td>Step 11</td>
<td>Switch(config-if)# switchport private-vlan mapping primary_vlan secondary_vlan</td>
</tr>
<tr>
<td>Step 12</td>
<td>Switch(config-if)# switchport port-security</td>
</tr>
<tr>
<td>Step 13</td>
<td>Switch(config-if)# end</td>
</tr>
<tr>
<td>Step 14</td>
<td>Switch# show port-security address interface interface_id</td>
</tr>
<tr>
<td></td>
<td>Switch# show port-security address</td>
</tr>
</tbody>
</table>

---

Chapter 38 Configuring Port Security
Example of Port Security on a Private VLAN Promiscuous Port

The following example shows how to configure port security on a private VLAN promiscuous port, Fast Ethernet interface 3/12:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# vlan 6
Switch(config-vlan)# private-vlan isolated
Switch(config-vlan)# exit
Switch(config)# vlan 3
Switch(config-vlan)# private-vlan primary
Switch(config-vlan)# private-vlan association add 6
Switch(config-vlan)# exit
Switch(config)# interface fastethernet 3/12
Switch(config-if)# switchport mode private-vlan promiscuous
Switch(config-if)# switchport mode private-vlan mapping 3 6
Switch(config-if)# switchport port-security
Switch(config-if)# end
```

Configuring Port Security on Trunk Ports

You might want to configure port security on trunk ports in metro aggregation to limit the number of MAC addresses per VLAN. Trunk port security extends port security to trunk ports. It restricts the allowed MAC addresses or the maximum number of MAC addresses to individual VLANs on a trunk port. Trunk port security enables service providers to block the access from a station with a different MAC address than the ones specified for that VLAN on that trunk port. Trunk port security is also supported on private VLAN trunk ports.

**Note**
Port security can be enabled on a Layer 2 port channel interface configured in mode. The port security configuration on an EtherChannel is kept independent of the configuration of any physical member ports.

These sections describe how to configure trunk port security:

- Configuring Trunk Port Security, page 38-17
- Examples of Trunk Port Security, page 38-19
- Trunk Port Security Guidelines and Restrictions, page 38-21

Configuring Trunk Port Security

Trunk port security is used when a Catalyst 4500 series switch has a dot1q or isl trunk attached to a neighborhood Layer 2 switch. This may be used, for example, in metro aggregation networks (Figure 38-2).
You can configure various port security related parameters on a per-port per-VLAN basis.

Note
The steps involved in configuring port security parameters is similar to those for access ports. In addition to those steps, the following per-port per-VLAN configuration steps are supported for trunk ports.

To configure port security related parameters on a per-VLAN per-port basis, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> Switch(config)# interface interface_id</td>
<td>Enters interface configuration mode and specifies the</td>
</tr>
<tr>
<td>interface port-channel port_channel_number</td>
<td>interface to configure.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>The interface can be a Layer 2 port channel</td>
</tr>
<tr>
<td></td>
<td>logical interface.</td>
</tr>
<tr>
<td><strong>Step 2</strong> Switch(config-if)# switchport trunk encapsulation dot1q</td>
<td>Sets the trunk encapsulation format to 802.1Q.</td>
</tr>
<tr>
<td><strong>Step 3</strong> Switch(config-if)# switchport mode trunk</td>
<td>Sets the interface mode.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>An interface in the default mode (dynamic auto)</td>
</tr>
<tr>
<td></td>
<td>cannot be configured as a secure port.</td>
</tr>
</tbody>
</table>
Chapter 38 Configuring Port Security

Configuring Port Security on Trunk Ports

Examples of Trunk Port Security

The following examples are provided:

- Example 1: Configuring a Maximum Limit of Secure MAC Addresses for all VLANs, page 38-19
- Example 2: Configuring a Maximum Limit of Secure MAC Addresses for Specific VLANs, page 38-20
- Example 3: Configuring Secure MAC Addresses in a VLAN Range, page 38-20

Example 1: Configuring a Maximum Limit of Secure MAC Addresses for all VLANs

This example shows how to configure a secure MAC-address and a maximum limit of secure MAC addresses on Gigabit Ethernet interface 1/1 for all VLANs:

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface gi1/1
Switch(config-if)# sw mode trunk
Switch(config-if)# switchport port-security
Switch(config-if)# switchport port-security maximum 3

Switch# show port-security in gi1/1 vlan
Default maximum: 3
VLAN Maximum Current
1 3 0
2 3 0
3 3 0
4 3 0
5 3 0

Command | Purpose (continued)
--- | ---
Step 4 Switch(config-if)# switchport port-security maximum value vlan | Configures a maximum number of secure mac-addresses for each VLAN on the interface that are not explicitly configured with a maximum mac-address limit. (See the “Maximum Number of Secure MAC Addresses” section on page 38-4.)
Step 5 Switch(config-if)# vlan-range range | Enters VLAN range sub-mode.
Step 6 Switch(config-if-vlan-range)# port-security maximum value | Configures a maximum number of secure MAC addresses for each VLAN.
Step 7 Switch(config-if-vlan-range)# no port-security maximum | Removes a maximum number of secure MAC addresses configuration for all the VLANs. Subsequently, the maximum value configured on the port is used for all the VLANs.
Step 8 Switch(config-if-vlan-range)# [no] port-security mac-address mac_address | Configures a secure MAC-address on a range of VLANs.
Step 9 Switch(config-if-vlan-range)# [no] port-security mac-address sticky mac_address | Configures a sticky MAC-address on a range of VLANs.
Step 10 Switch(config-if-vlan-range)# end | Returns to interface configuration mode.
Step 11 Switch(config-if)# end | Returns to privileged EXEC mode.
Chapter 38      Configuring Port Security

Configuring Port Security on Trunk Ports

Example 2: Configuring a Maximum Limit of Secure MAC Addresses for Specific VLANs

This example shows how to configure a secure MAC-address on interface gi1/1 in a specific VLAN or range of VLANs:

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface gi1/1
Switch(config-if)# sw mode trunk
Switch(config-if)# switchport port-security
Switch(config-if)# vlan-range 2-6
Switch(config-if-vlan-range)# port-security maximum 3
Switch(config-if)# exit

Switch# show port-security interface gi1/1 vlan
Default maximum: not set, using 3072
VLAN   Maximum    Current
 2      3          0
 3      3          0
 4      3          0
 5      3          0
 6      3          0

Switch#

Example 3: Configuring Secure MAC Addresses in a VLAN Range

This example shows how to configure a secure MAC-address in a VLAN on interface gi1/1:

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface gi1/1
Switch(config-if)# sw mode trunk
Switch(config-if)# switchport port-security
Switch(config-if)# switchport port-security mac-address sticky
Switch(config-if)# vlan-range 2-6
Switch(config-if-vlan-range)# port-security mac-address 1.1.1
Switch(config-if-vlan-range)# port-security mac-address sticky 1.1.2
Switch(config-if-vlan-range)# port-security mac-address sticky 1.1.3
Switch(config-if-vlan-range)# exit

Switch# show port-security interface gi1/1 address vlan 2-4

### Trunk Port Security Guidelines and Restrictions

Follow these guidelines when configuring port security related parameters on a per-port per-VLAN basis:

- A secure MAC-address cannot be configured on a VLAN that is not allowed on a regular trunk port.
- The configuration on the primary VLAN on the private VLAN trunk is not allowed. The CLI is rejected and an error message is displayed.
- If a specific VLAN on a port is not configured with a maximum value (directly or indirectly), the maximum configured for the port is used for that VLAN. In this situation, the maximum number of addresses that can be secured on this VLAN is limited to the maximum value configured on the port.

Each VLAN can be configured with a maximum count that is greater than the value configured on the port. Also, the sum of the maximum configured values for all the VLANs can exceed the maximum configured for the port. In either of these situations, the number of MAC addresses secured on each VLAN is limited to the lesser of the VLAN configuration maximum and the port configuration maximum. Also, the number of addresses secured on the port across all VLANs cannot exceed a maximum that is configured on the port.

- For private VLAN trunk ports, the VLAN on which the configuration is being performed must be in either the allowed VLAN list of the private VLAN trunk or the secondary VLAN list in the association pairs. (The CLI is rejected if this condition is not met.) The allowed VLAN list on a private VLAN trunk is intended to hold the VLAN-IDs of all the regular VLANs that are allowed on the private VLAN trunk.

- Removal of an association pair from a PVLAN trunk causes all static and sticky addresses associated with the secondary VLAN of the pair to be removed from the running configuration. Dynamic addresses associated with the secondary VLAN are deleted from the system.

Similarly, when a VLAN is removed from the list of allowed PVLAN trunks, the addresses associated with that VLAN are removed.

**Note**

For a regular or private VLAN trunk port, if the VLAN is removed from the allowed VLAN list, all the addresses associated with that VLAN are removed.
Port Mode Changes

Generally, when a port mode changes, all dynamic addresses associated with that port are removed. All static or sticky addresses and other port security parameters configured on the native VLAN are moved to the native VLAN of the port in the new mode. All the addresses on the non-native VLANs are removed.

The native VLAN refers to the following VLAN on the specified port type:

<table>
<thead>
<tr>
<th>Port Type</th>
<th>Native VLAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>access</td>
<td>access VLAN</td>
</tr>
<tr>
<td>trunk</td>
<td>native VLAN</td>
</tr>
<tr>
<td>isolated</td>
<td>secondary VLAN (from host association)</td>
</tr>
<tr>
<td>promiscuous</td>
<td>primary VLAN (from mapping)</td>
</tr>
<tr>
<td>private VLAN trunk</td>
<td>private VLAN trunk native VLAN</td>
</tr>
<tr>
<td>.1Q tunnel</td>
<td>access VLAN</td>
</tr>
</tbody>
</table>

For example, when the mode changes from access to private VLAN trunk, all the static or sticky addresses configured on the access VLAN of the access port are moved to the private VLAN native VLAN of the private VLAN trunk port. All other addresses are removed.

Similarly, when the mode changes from private VLAN trunk to access mode, all the static or sticky addresses configured on the private VLAN native VLAN are moved to the access VLAN of the access port. All other addresses are removed.

When a port is changed from trunk to private VLAN trunk, addresses associated with a VLAN on the trunk are retained if that VLAN is present in the allowed list of private VLAN trunk or the secondary VLAN of an association on the private VLAN trunk. If the VLAN is not present in either of them, the address is removed from the running configuration.

When a port is changed from private VLAN trunk to trunk, a static or sticky address is retained if the VLAN associated with the address is present in the allowed VLAN list of the trunk. If the VLAN is not present in the allowed list, the address is removed from running configuration.

Configuring Port Security on Voice Ports

You might want to configure port security in an IP Telephony environment when a port is configured with a data VLAN for a PC and a voice VLAN for a Cisco IP Phone.

These sections describe how to configure port security on voice ports:

- Configuring Port Security on Voice Ports, page 38-23
- Examples of Voice Port Security, page 38-25
- Voice Port Security Guidelines and Restrictions, page 38-27
# Configuring Port Security on Voice Ports

To configure port security on a voice port, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch(config)# interface interface_id</td>
</tr>
<tr>
<td></td>
<td>Enters interface configuration mode and specifies the physical interface to configure.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config-if)# switchport mode access</td>
</tr>
<tr>
<td></td>
<td>Sets the interface mode. <strong>Note</strong> An interface in the default mode (dynamic auto) cannot be configured as a secure port.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config-if)# [no] switchport port-security</td>
</tr>
<tr>
<td></td>
<td>Enables port security on the interface. To return the interface to the default condition as nonsecure port, use the <em>no switchport port-security</em> command.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config-if)# [no] switchport port-security violation (restrict</td>
</tr>
<tr>
<td></td>
<td>(Optional) Sets the violation mode, the action to be taken when a security violation is detected, as one of these:</td>
</tr>
<tr>
<td></td>
<td>• restrict—A port security violation restricts data and causes the SecurityViolation counter to increment and send an SNMP trap notification.</td>
</tr>
<tr>
<td></td>
<td>• shutdown—The interface is error-disabled when a security violation occurs. <strong>Note</strong> When a secure port is in the error-disabled state, you can bring it out of this state by entering the <em>errdisable recovery cause psecure-violation</em> global configuration command or you can manually reenable it by entering the <em>shutdown</em> and <em>no shutdown</em> interface configuration commands.</td>
</tr>
<tr>
<td></td>
<td>To return the violation mode to the default condition (shutdown mode), use the <em>no switchport port-security violation shutdown</em> command.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch(config-if)# switchport port-security limit rate invalid-source-mac packets_per_sec</td>
</tr>
<tr>
<td></td>
<td>Sets the rate limit for bad packets. Default is 10 pps.</td>
</tr>
</tbody>
</table>
Chapter 38      Configuring Port Security

Configuring Port Security on Voice Ports

Step 6

Switch(config-if)# [no] switchport port-security mac-address mac_address {vlan (voice | access)}

(Optional) Specifies a secure MAC address for the interface.

When you specify the vlan keyword, addresses are configured in the specified VLAN.

- **voice**—MAC address is configured in the voice VLAN.
- **access**—MAC address is configured in the access VLAN.

Use this command to configure secure MAC addresses. If you configure fewer secure MAC addresses than the maximum, the remaining MAC addresses are dynamically learned.

To delete a MAC address from the address table, use the **no switchport port-security mac-address** command.

**Note** This command only applies to access, PVLAN host, and PVLAN promiscuous mode. For more details on PVLAN, trunk, or regular trunk mode, refer to the “Configuring Port Security on Trunk Ports” section on page 38-17.

Step 7

Switch(config-if)# [no] switchport port-security mac-address sticky

(Optional) Enables sticky learning on the interface.

To disable sticky learning on an interface, use the **no switchport port-security mac-address sticky** command. The interface converts the sticky secure MAC addresses to dynamic secure addresses.

Step 8

Switch(config-if)# [no] switchport port-security mac-address mac_address sticky {vlan (voice | access)}

Specifies the sticky mac-address for the interface.

When you specify the vlan keyword, the mac-address becomes sticky in the specified VLAN.

- **voice**—MAC address becomes sticky in the voice VLAN.
- **access**—MAC address becomes sticky in the access VLAN.

To delete a sticky secure MAC addresses from the address table, use the **no switchport port-security mac-address** command. To convert sticky to dynamic addresses, use the **no switchport port-security mac-address sticky** command.

**Note** This command only applies to access, PVLAN host, and PVLAN promiscuous mode. For more details on PVLAN or trunk or regular trunk mode, refer to the “Configuring Port Security on Trunk Ports” section on page 38-17.
Chapter 38 Configuring Port Security

Configuring Port Security on Voice Ports

Note
To clear dynamically learned port security MAC addresses in the CAM table, use the `clear port-security dynamic` command. The `address` keyword enables you to clear a secure MAC addresses. The `interface` keyword enables you to clear all secure addresses on an interface (including any port channel interface). The `VLAN` keyword allows you to clear port security MACs on a per-VLAN per-port basis.

Note
Each port-security configured interface accepts one mac-address by default. With port-security port level port-security configuration takes precedence over VLAN level port-security configuration. So, to allow one mac-address each for voice and data VLAN, configure the port for a maximum of greater than or equal to two addresses.

Examples of Voice Port Security

The following examples are provided:

- Example 1: Configuring Maximum MAC Addresses for Voice and Data VLANs, page 38-25
- Example 2: Configuring Sticky MAC Addresses for Voice and Data VLANs, page 38-26

Example 1: Configuring Maximum MAC Addresses for Voice and Data VLANs

This example shows how to designate a maximum of one MAC address for a voice VLAN (for a Cisco IP Phone, let’s say) and one MAC address for the data VLAN (for a PC, let’s say) on Fast Ethernet interface 5/1 and to verify the configuration:

```
Switch(config)# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fa5/1
Switch(config-if)# switchport mode access
Switch(config-if)# switchport port-security
Switch(config-if)# switchport port-security maximum 2
Switch(config-if)# switchport port-security mac-address sticky
Switch(config-if)# switchport port-security maximum 1 vlan voice
Switch(config-if)# switchport port-security maximum 1 vlan access
Switch(config-if)# end
```

Note
Sending traffic to the ports causes the system to configure the port with sticky secure addresses.
Switch# show port-security address
Secure Mac Address Table

<table>
<thead>
<tr>
<th>Vlan</th>

  switchport port-security mac-address sticky 0000.0000.0b0b vlan voice
end

Switch#

**Voice Port Security Guidelines and Restrictions**

Port security as implemented on voice ports behaves the same as port security on access ports:

- You can configure sticky port security on voice ports. If sticky port security is enabled on a voice port, addresses secured on data and voice VLANs are secured as sticky addresses.
- You can configure maximum secure addresses per VLAN. You can set a maximum for either the data VLAN or the voice VLAN. You can also set a maximum per-port, just as with access ports.
- You can configure port security MAC addresses on a per-VLAN basis on either the data or voice VLANs.
- Prior to Cisco IOS Release 12.2(31)SG, you required three MAC addresses as the maximum parameter to support an IP Phone and a PC. With Cisco IOS Release 12.2(31)SG and later releases, the maximum parameter must be configured to two, one for the phone and one for the PC.

**Displaying Port Security Settings**

Use the `show port-security` command to display port-security settings for an interface or for the switch.
To display traffic control information, perform one or more of these tasks:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# show interface status err-disable</td>
<td>Displays interfaces that have been error-disabled along with the cause for which they were disabled.</td>
</tr>
<tr>
<td>Switch# show port-security [interface interface_id</td>
<td>Displays port security settings for the switch or for the specified interface, including the maximum allowed number of secure MAC addresses for each interface, the number of secure MAC addresses on the interface, the number of security violations that have occurred, and the violation mode. The interface can be a port channel logical interface.</td>
</tr>
<tr>
<td>interface port_channel port_channel_number]</td>
<td></td>
</tr>
<tr>
<td>Switch# show port-security [interface interface_id</td>
<td>Displays all secure MAC addresses configured on all switch interfaces or on a specified interface with aging information for each address.</td>
</tr>
<tr>
<td>interface port_channel port_channel_number] address</td>
<td></td>
</tr>
<tr>
<td>Switch# show port-security [interface interface_id</td>
<td>Displays the maximum allowed number of secure MAC addresses and the current number of secure MAC addresses on a specific VLAN-list and a specific interface.</td>
</tr>
<tr>
<td>interface port_channel port_channel_number] vlan vlan_list</td>
<td></td>
</tr>
<tr>
<td>Switch# show port-security [interface interface_id</td>
<td>Displays all secure MAC addresses configured on a specific VLAN-list and a specific interface.</td>
</tr>
<tr>
<td>interface port_channel port_channel_number] [address [vlan vlan_list]]</td>
<td></td>
</tr>
</tbody>
</table>

Examples

The following examples are provided:

- Example 1: Displaying Security Settings for the Entire Switch, page 38-28
- Example 2: Displaying Security Settings for an Interface, page 38-29
- Example 3: Displaying all Secure Addresses for the Entire Switch, page 38-29
- Example 4: Displaying a Maximum Number of MAC Addresses on an Interface, page 38-30
- Example 5: Displaying Security Settings on an Interface for a VLAN Range, page 38-30
- Example 6: Displaying Secured MAC Addresses and Aging Information on an Interface, page 38-30
- Example 7: Displaying Secured MAC Addresses for a VLAN Range on an Interface, page 38-30

Example 1: Displaying Security Settings for the Entire Switch

This example shows how to display port security settings for the entire switch:

Switch# show port-security

Total Addresses in System (excluding one mac per port) : 8
Max Addresses limit in System (excluding one mac per port): 3072

Example 4: Displaying a Maximum Number of MAC Addresses on an Interface

This example shows how to display the maximum allowed number of secure MAC addresses and the current number of secure MAC addresses on Gigabit Ethernet interface 1/1:

```
Switch# show port-security interface g1/1 vlan
Default maximum: 22
VLAN  Maximum  Current
 2     22       3
 3     22       3
 4     22       3
 5     22       1
 6     22       2
```

Example 5: Displaying Security Settings on an Interface for a VLAN Range

This example shows how to display the port security settings on Gigabit Ethernet interface 1/1 for VLANs 2 and 3:

```
Switch# show port-security interface g1/1 vlan 2-3
Default maximum: 22
VLAN  Maximum  Current
 2     22       3
 3     22       3
```

Example 6: Displaying Secured MAC Addresses and Aging Information on an Interface

This example shows how to display all secure MAC addresses configured on Gigabit Ethernet interface 1/1 with aging information for each address.

```

### Configuring Port Security with Other Features/Environments

The following topics are discussed:

- DHCP and IP Source Guard, page 38-31
- 802.1X Authentication, page 38-32
- Configuring Port Security in a Wireless Environment, page 38-32

### DHCP and IP Source Guard

You might want to configure port security with DHCP and IP Source Guard to prevent IP spoofing by unsecured MAC addresses. IP Source Guard supports two levels of IP traffic filtering:

- Source IP address filtering
- Source IP and MAC address filtering

When used in source IP and MAC address filtering, IP Source Guard uses private ACLs to filter traffic based on the source IP address, and uses port security to filter traffic based on the source MAC address. So, port security must be enabled on the access port in this mode.

When both features are enabled, the following limitations apply:

- The DHCP packet is not subject to port security dynamic learning.
- If multiple IP clients are connected to a single access port, port security cannot enforce exact binding of source IP and MAC address for each client.

Let’s say that clients reside on an access port with the following IP/MAC address:

- client1: MAC1 <---> IP1
- client2: MAC2 <---> IP2

Then, any combination of the source MAC and IP address traffic is allowed:

- MAC1 <---> IP1, valid
- MAC2 <---> IP2, valid
- MAC1 <---> IP2, invalid
- MAC2 <---> IP1, invalid
IP traffic with the correct source IP and MAC address binding is permitted and port security dynamically learns its MAC address. IP traffic with source addresses that are not in the binding are treated as invalid packets and dropped by port security. To prevent a denial of service attack, you must configure port security rate limiting for the invalid source MAC address.

### 802.1X Authentication

You might want to configure port security with 802.1X authentication to prevent MAC spoofing. 802.1X is not supported on regular or private VLAN trunks. On access ports and PVLAN host or promiscuous ports, both port security and 802.1X can be configured simultaneously. When both are configured, hosts must be 802.1X authenticated before port security can secure the MAC address of the host. Both 802.1X and port security must approve of the host or a security violation is triggered. The type of security violation depends on which feature rejects the port: if the host is allowed by 802.1X (for example, because the port is in multi-host mode) but is disallowed by port security, the port-security violation action is triggered. If the host is allowed by port security but rejected by 802.1X (for example, because the host is non-authorized on a single-host mode port) then the 802.1X security violation action is triggered.

802.1X, port-security and VVID can all be configured on the same port.

For more information on the interaction between 802.1X and Port Security, see “Using 802.1X with Port Security” on page 16.

### Configuring Port Security in a Wireless Environment

If access points are connected to a secure port, do not configure a static MAC address for your users. A MAC address might move from one access point to another and might cause security violations if both the access points are connected on the same switch.

Figure 38-3 illustrates a typical topology of port security in a wireless environment.
Guidelines and Restrictions

Follow these guidelines when configuring port security:

- After port security is configured on a port along with a "denying" PACL, the CPU will neither see any of the PACL packets denied from the given port nor learn the source MAC addresses from the denied packets. Therefore, the port security feature will not be aware of such packets.

- A secure port cannot be a destination port for the Switch Port Analyzer (SPAN).

- A secure port and a static MAC address configuration for an interface are mutually exclusive.

- When you enter a maximum secure address value for an interface, and the new value is greater than the previous value, the new value overwrites the previously configured value. If the new value is less than the previous value and the number of configured secure addresses on the interface exceeds the new value, the command is rejected.

- While configuring trunk port security on a trunk port, you do not need to account for the protocol packets (like CDP and BPDU) because they are not learned and secured.

- You cannot enable port security aging on sticky secure MAC addresses.

- To restrict MAC spoofing using port security, you must enable 802.1X authentication.

- You cannot configure port security on dynamic ports. You must change the mode to access before you enable port security.
Configuring Control Plane Policing

This chapter contains information on how to protect your Catalyst 4000 family switch using control plane policing (CoPP). The information covered in this chapter is unique to the Catalyst 4500 series switches, and it supplements the network security information and procedures in Chapter 42, “Configuring Network Security with ACLs.” This information also supplements the network security information and procedures in these publications:

- *Cisco IOS Security Configuration Guide, Cisco IOS Release 12.4*, at this URL:
- *Cisco IOS Security Command Reference, Cisco IOS Release 12.4*, at this URL:

This chapter includes the following major sections:

- About Control Plane Policing, page 39-2
- CoPP Default Configuration, page 39-3
- Configuring CoPP, page 39-3
- CoPP Configuration Guidelines and Restrictions, page 39-7
- Monitoring CoPP, page 39-7

For complete syntax and usage information for the switch commands used in this chapter, look at the *Cisco Catalyst 4500 Series Switch Command Reference* and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the *Catalyst 4500 Series Switch Cisco IOS Command Reference* and related publications at this location:

About Control Plane Policing

The control plane policing (CoPP) feature increases security on the Catalyst 4000 family switch by protecting the CPU from unnecessary or DoS traffic and giving priority to important control plane and management traffic. The Classification TCAM and QoS policers provide hardware support for CoPP. CoPP works with all supervisor engines supported by Cisco IOS Release 12.2(31)SG.

The traffic managed by the CPU is divided into three functional components or planes:

- Data plane
- Management plane
- Control plane

You can use CoPP to protect most of the CPU bound traffic and ensure routing stability, reachability and packet delivery. Most importantly, CoPP is often used to protect the CPU from the DoS attack. There is a list of pre-defined ACLs matching a selected set of Layer 2 and Layer 3 control plane packets. You can define your preferred policing parameters to each of these control packets but you cannot modify the matching criteria of these pre-defined ACLs. Following is the list of pre-defined ACLs:

<table>
<thead>
<tr>
<th>Pre-defined Named ACL</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>system-cpp-dot1x</td>
<td>MAC DA = 0180.C200.0003</td>
</tr>
<tr>
<td>system-cpp-lldp</td>
<td>MAC DA=0180.c200.000E</td>
</tr>
<tr>
<td>system-cpp-mcast-cfm</td>
<td>MAC DA=0100.0ccc.ccc0 - 0100.0ccc.ccc7</td>
</tr>
<tr>
<td>system-cpp-ucast-cfm</td>
<td>MAC DA=0100.0ccc.ccc0</td>
</tr>
<tr>
<td>system-cpp-bpdu-range</td>
<td>MAC DA = 0180.C200.0000 - 0180.C200.000F</td>
</tr>
<tr>
<td>system-cpp-cdp</td>
<td>MAC DA = 0100.0CCC.CCCC (UDLD/DTP/VTP/Pagp)</td>
</tr>
<tr>
<td>system-cpp-sstp</td>
<td>MAC DA = 0100.0CCC.CCCD</td>
</tr>
<tr>
<td>system-cpp-cgmp</td>
<td>MAC DA = 01-00-0C-DD-DD-DD</td>
</tr>
<tr>
<td>system-cpp-hsrpv2</td>
<td>IP Protocol = UDP, IPDA = 224.0.0.102</td>
</tr>
<tr>
<td>system-cpp-ospf</td>
<td>IP Protocol = OSPF, IPDA matches 224.0.0.0/24</td>
</tr>
<tr>
<td>system-cpp-igmp</td>
<td>IP Protocol = IGMP, IPDA matches 224.0.0.0/3</td>
</tr>
<tr>
<td>system-cpp-pim</td>
<td>IP Protocol = PIM, IPDA matches 224.0.0.0/24</td>
</tr>
<tr>
<td>system-cpp-all-systems-on-subnet</td>
<td>IPDA = 224.0.0.1</td>
</tr>
<tr>
<td>system-cpp-all-routers-on-subnet</td>
<td>IPDA = 224.0.0.2</td>
</tr>
<tr>
<td>system-cpp-ripv2</td>
<td>IPDA = 224.0.0.9</td>
</tr>
<tr>
<td>system-cpp-ip-mcast-linklocal</td>
<td>IP DA = 224.0.0.0/24</td>
</tr>
<tr>
<td>system-cpp-dhcp-cs</td>
<td>IP Protocol = UDP, L4SrcPort = 68, L4DstPort = 67</td>
</tr>
<tr>
<td>system-cpp-dhcp-sc</td>
<td>IP Protocol = UDP, L4SrcPort = 67, L4DstPort = 68</td>
</tr>
<tr>
<td>system-cpp-dhcp-ss</td>
<td>IP Protocol = UDP, L4SrcPort = 67, L4DstPort = 67</td>
</tr>
</tbody>
</table>

For the Data Plane and Management Plane traffic, you can define your own ACLs to match the traffic class that you want to police.
CoPP uses MQC to define traffic classification criteria and to specify the configurable policy actions for the classified traffic. MQC uses class maps to define packets for a particular traffic class. After you have classified the traffic, you can create policy maps to enforce policy actions for the identified traffic. The control-plane global configuration command allows the CoPP service policy to be directly attached to the control plane.

The only policy-map that you can attach to the control-plane is system-cpp-policy. It must contain the pre-defined class-maps in the pre-defined order at the beginning of the policy map. The best way to create the system-cpp-policy policy-map is through the global macro system-cpp.

The system-cpp-policy contains the pre-defined class maps for the control plane traffic. The names of all system defined CoPP class maps and their matching ACLs contain the prefix “system-cpp-”. By default, no action is specified for each traffic class. You can define your own class maps matching CPU bound data plane and management plane traffic. You can add your defined class maps to the system-cpp-policy policy-map.

CoPP Default Configuration

CoPP is disabled by default.

Configuring CoPP

This section includes the following tasks:

- Configure CoPP for Control Plane Traffic, page 39-3

Configure CoPP for Control Plane Traffic

To configure CoPP for Control Plane traffic, perform this task:

<table>
<thead>
<tr>
<th>Step</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# config terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# macro global apply system-cpp</td>
<td>(Optional) Creates the system-cpp-policy policy-map and attaches it to the control-plane.</td>
</tr>
</tbody>
</table>
Configuring CoPP

The following example shows how to police CDP packets:

```
Switch(config)# policy-map system-cpp-policy
Switch(config-pmap)# class {
  system-cpp-dot1x | system-cpp-bpdu-range |
  system-cpp-cdp | service | system-cpp-ssdp |
  system-cpp-cgmp | system-cpp-ospf | system-cpp-igmp | system-cpp-pim |
  system-cpp-all-systems-on-subnet |
  system-cpp-all-routers-on-subnet |
  system-cpp-ripv2 | system-cpp-hsrpv2 |
  system-cpp-ip-mcast-linklocal |
  system-cpp-dhcp-cs | system-cpp-dhcp-sc |
  system-cpp-dhcp-ss }
Switch(config-pmap-c)# policy {aggregate name} rate burst [conform-action {drop | transmit}] [{exceed-action {drop | transmit}]}
```

Associates actions to one or multiple system defined control plane traffic in the service policy map. Repeat this step if necessary.

**Step 4**

```
Switch# show policy-map system-cpp-policy
(Optional) Verifies the configuration
```

```
The following example shows how to police CDP packets:

Switch(config)# policy-map system-cpp-policy
Switch(config-pmap)# class {
  system-cpp-dot1x | system-cpp-bpdu-range |
  system-cpp-cdp | service | system-cpp-ssdp |
  system-cpp-cgmp | system-cpp-ospf |
  system-cpp-igmp | system-cpp-pim |
  system-cpp-all-systems-on-subnet |
  system-cpp-all-routers-on-subnet |
  system-cpp-ripv2 | system-cpp-hsrpv2 |
  system-cpp-ip-mcast-linklocal |
  system-cpp-dhcp-cs | system-cpp-dhcp-sc |
  system-cpp-dhcp-ss }
Switch(config-pmap-c)# policy {aggregate name} rate burst [conform-action {drop | transmit}] [{exceed-action {drop | transmit}]}
```

(Optional) Verifies the configuration

```
The following example shows how to police CDP packets:

Switch(config)# policy-map system-cpp-policy
Switch(config-pmap)# class {
  system-cpp-dot1x | system-cpp-bpdu-range |
  system-cpp-cdp | service | system-cpp-ssdp |
  system-cpp-cgmp | system-cpp-ospf |
  system-cpp-igmp | system-cpp-pim |
  system-cpp-all-systems-on-subnet |
  system-cpp-all-routers-on-subnet |
  system-cpp-ripv2 | system-cpp-hsrpv2 |
  system-cpp-ip-mcast-linklocal |
  system-cpp-dhcp-cs | system-cpp-dhcp-sc |
  system-cpp-dhcp-ss }
Switch(config-pmap-c)# policy {aggregate name} rate burst [conform-action {drop | transmit}] [{exceed-action {drop | transmit}]}
```

(Optional) Verifies the configuration

```
Configure CoPP for Data Plane and Management Plane Traffic

To configure CoPP for Data Plane and Management Plane traffic, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# config terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# macro global apply system-cpp</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config)# (ip</td>
</tr>
</tbody>
</table>

For an **ip** access list, issue
Switch(config-ext-nacl)# (permit | deny) (protocol) source (source-wildcard) destination (destination-wildcard)

For a **mac** access list, issue
Switch(config-ext-macl)# (permit | deny) source (source-wildcard) destination (destination-wildcard) [protocol-family]

OR

Switch(config)# access-list (access-list-name) (permit | deny) (type-code wild-mask | address mask)

Defines ACLs to match traffic:

- **permit** - sets the conditions under which a packet passes a named ACL
- **deny** - sets the conditions under which a packet does not pass a name ACL

**Note** You must configure ACLs in most cases to identify the important or unimportant traffic.

- **type-code** - 16-bit hexadecimal number written with a leading 0x; for example, 0x6000. Specify either a Link Service Access Point (LSAP) type code for 802-encapsulated packets or a SNAP type code for SNAP-encapsulated packets. (LSAP, sometimes called SAP, refers to the type codes found in the DSAP and SSAP fields of the 802 header.)

- **wild-mask** - 16-bit hexadecimal number whose ones bits correspond to bits in the type-code argument. The wild-mask indicates which bits in the type-code argument should be ignored when making a comparison. (A mask for a DSAP/SSAP pair should always be 0x0101 because these two bits are used for purposes other than identifying the SAP code.)

- **address** - 48-bit Token Ring address written as a dotted triple of four-digit hexadecimal numbers. This field is used for filtering by vendor code.

- **mask** - 48-bit Token Ring address written as a dotted triple of four-digit hexadecimal numbers. The ones bits in mask are the bits to be ignored in address. This field is used for filtering by vendor code.
### Configuring CoPP

The following example shows how to configure trusted hosts with source addresses 10.1.1.1 and 10.1.1.2 to forward Telnet packets to the control plane without constraint, while allowing all remaining Telnet packets to be policed at the specific rate (this example assumes the global qos is enabled and the system-cpp-policy policy-map has been created):

```
Switch# config terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# qos
Switch(config)# macro global apply system-cpp

! Allow 10.1.1.1 trusted host traffic.
Switch(config)# access-list 140 deny tcp host 10.1.1.1 any eq telnet

! Allow 10.1.1.2 trusted host traffic.
Switch(config)# access-list 140 deny tcp host 10.1.1.2 any eq telnet

! Rate limit all other Telnet traffic.
Switch(config)# access-list 140 permit tcp any any eq telnet

! Define class-map "telnet-class."
Switch(config)# class-map telnet-class
Switch(config-cmap)# match access-group 140
Switch(config-cmap)# exit

! Add the class-map "telnet-class" to "system-cpp-policy" and define ! the proper action
Switch(config)# policy-map system-cpp-policy
Switch(config-pmap)# class telnet-class
Switch(config-pmap-c)# police 80000 1000 byte conform-action transmit exceed-action drop
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit
```

### Command Purpose

<table>
<thead>
<tr>
<th>Step</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 4</td>
<td>Switch(config)# class-map (traffic-class-name)</td>
<td>Defines the packet classification criteria. Use the <code>match</code> statements to identify the traffic associated with the class.</td>
</tr>
<tr>
<td></td>
<td>Switch(config-cmap)# match access-group (access-list-number</td>
<td>name (access-list-name))</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch(config-cmap)# exit</td>
<td>Returns to global configuration mode.</td>
</tr>
<tr>
<td>Step 6</td>
<td>Switch(config)# policy-map system-cpp-policy</td>
<td>Adds the traffic classes to the CoPP policy-map. Uses the <code>police</code> statement to associate actions to the traffic class.</td>
</tr>
<tr>
<td></td>
<td>Switch(config-pmap)# class &lt;class-map-name&gt;</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Switch(config-pmap-c)# police [aggregate name] rate burst [conform-action {drop</td>
<td>transmit}] [ {[exceed-action {drop</td>
</tr>
<tr>
<td>Step 7</td>
<td>Switch(config)# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Step 8</td>
<td>Switch# show policy-map system-cpp-policy</td>
<td>Verifies your entries.</td>
</tr>
</tbody>
</table>

The following example shows how to configure trusted hosts with source addresses 10.1.1.1 and 10.1.1.2 to forward Telnet packets to the control plane without constraint, while allowing all remaining Telnet packets to be policed at the specific rate (this example assumes the global qos is enabled and the system-cpp-policy policy-map has been created):
CoPP Configuration Guidelines and Restrictions

When configuring CoPP, follow these guidelines and restrictions:

- Only ingress CoPP is supported. So only `input` keyword is supported in control-plane related CLIs.
- Use the system defined class maps for policing control plane traffic.
- System-defined class maps cannot be used in policy-maps for regular QoS.
- Use ACLs and class-maps to identify data plane and management plane traffic that are handled by CPU. User-defined class maps should be added to the `system-cpp-policy` policy-map for CoPP.
- The policy-map named `system-cpp-policy` is dedicated for CoPP.
- The default `system-cpp-policy` map does not define actions for the system-defined class maps, which means no policing.
- The only action supported in `system-cpp-policy` policy-map is `police`.
- Do not use the `log` keyword in the CoPP policy ACLs.
- Both MAC and IP ACLs can be used to define data plane and management plane traffic classes. But if a packet also matches a pre-defined ACL for the control plane traffic, the `police` action (or no police action) of the control plane class will be taken as the control plane classes appear above user-defined classes in the service policy. This is the same MQC semantic.
- The exceeding action `policed-dscp-transmit` is not supported for CoPP.

Monitoring CoPP

You can enter the `show policy-map control-plane` command for developing site-specific policies, monitoring statistics for the control plane policy, and troubleshooting CoPP. This command displays dynamic information about the actual policy applied including rate information and the number of bytes (and packets) that conformed or exceeded the configured policies both in hardware and in software.

The output of the `show policy-map control-plane` command is as follows:

```
Switch# show policy-map control-plane

Control Plane

Service-policy input: system-cpp-policy

Class-map: system-cpp-dot1x (match-all)
```

Configuring DHCP Snooping, IP Source Guard, and IPSG for Static Hosts

This chapter describes how to configure Dynamic Host Configuration Protocol (DHCP) snooping, IP Source Guard, and IPSG for Static Hosts on Catalyst 4500 series switches. It provides guidelines, procedures, and configuration examples.

This chapter consists of the following major sections:

- About DHCP Snooping, page 40-1
- Configuring DHCP Snooping, page 40-6
- Displaying DHCP Snooping Information, page 40-18
- About IP Source Guard, page 40-19
- Configuring IP Source Guard, page 40-20
- Displaying IP Source Binding Information, page 40-23

Note

For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

About DHCP Snooping

DHCP snooping is a DHCP security feature that provides security by filtering untrusted DHCP messages and by building and maintaining a DHCP snooping binding table. An untrusted message is a message that is received from outside the network or firewall and that can cause traffic attacks within your network.
About DHCP Snooping

The DHCP snooping binding table contains the MAC address, IP address, lease time, binding type, VLAN number, and interface information that corresponds to the local untrusted interfaces of a switch; it does not contain information regarding hosts interconnected with a trusted interface. An untrusted interface is an interface that is configured to receive messages from outside the network or firewall. A trusted interface is an interface that is configured to receive only messages from within the network.

DHCP snooping acts like a firewall between untrusted hosts and DHCP servers. It also gives you a way to differentiate between untrusted interfaces connected to the end-user and trusted interfaces connected to the DHCP server or another switch.

Note

In order to enable DHCP snooping on a VLAN, you must enable DHCP snooping on the switch.

You can configure DHCP snooping for switches and VLANs. When you enable DHCP snooping on a switch, the interface acts as a Layer 2 bridge, intercepting and safeguarding DHCP messages going to a Layer 2 VLAN. When you enable DHCP snooping on a VLAN, the switch acts as a Layer 2 bridge within a VLAN domain.

Topics include:

- Trusted and Untrusted Sources, page 40-2
- Overview of the DHCP Snooping Database Agent, page 40-2
- Option-82 Data Insertion, page 40-4

Trusted and Untrusted Sources

The DHCP snooping feature determines whether traffic sources are trusted or untrusted. An untrusted source may initiate traffic attacks or other hostile actions. To prevent such attacks, the DHCP snooping feature filters messages and rate-limits traffic from untrusted sources.

In an enterprise network, devices under your administrative control are trusted sources. These devices include the switches, routers and servers in your network. Any device beyond the firewall or outside your network is an untrusted source. Host ports are generally treated as untrusted sources.

In a service provider environment, any device that is not in the service provider network is an untrusted source (such as a customer switch). Host ports are untrusted sources.

In the Catalyst 4500 series switch, you indicate that a source is trusted by configuring the trust state of its connecting interface.

The default trust state of all interfaces is untrusted. You must configure DHCP server interfaces as trusted. You can also configure other interfaces as trusted if they connect to devices (such as switches or routers) inside your network. You usually do not configure host port interfaces as trusted.

Note

For DHCP snooping to function properly, all DHCP servers must be connected to the switch through trusted interfaces, as untrusted DHCP messages are forwarded only to trusted interfaces.

Overview of the DHCP Snooping Database Agent

To retain the bindings across switch reloads, you must use the DHCP snooping database agent. Without this agent, the bindings established by DHCP snooping are lost upon switch reload. Connectivity is lost as well.
The mechanism for the database agent stores the bindings in a file at a configured location. Upon reload, the switch reads the file to build the database for the bindings. The switch keeps the file current by writing to the file as the database changes.

The format of the file that contains the bindings is as follows:

```
<initial-checksum>
TYPE DHCP-SNOOPING
VERSION 1
BEGIN
<entry-1> <checksum-1>
<entry-2> <checksum-1-2>
...
<entry-n> <checksum-1-2...-n>
END
```

Each entry in the file is tagged with a checksum that is used to validate the entries whenever the file is read. The `initial-checksum` entry on the first line helps distinguish entries associated with the latest write from entries that are associated with a previous write.

This is a sample bindings file:

```
3ebe1518
TYPE DHCP-SNOOPING
VERSION 1
BEGIN
1.1.1.1 512 0001.0001.0005 3EBE2881 Gi1/1                                e5e1e733
1.1.1.1 512 0001.0001.0002 3EBE2881 Gi1/1                                4b3486ec
1.1.1.1 1536 0001.0001.0004 3EBE2881 Gi1/1                               f0e02872
1.1.1.1 1024 0001.0001.0003 3EBE2881 Gi1/1                               ac41ad9f
1.1.1.1 1 0001.0001.0001 3EBE2881 Gi1/1                                  34b3273e
END
```

Each entry holds an IP address, VLAN, MAC address, lease time (in hex), and the interface associated with a binding. At the end of each entry is a checksum that accounts for all the bytes from the start of the file through all the bytes associated with the entry. Each entry consists of 72 bytes of data, followed by a space, followed by a checksum.

Upon bootup, when the calculated checksum equals the stored checksum, a switch reads entries from the file and adds the bindings to the DHCP snooping database. When the calculated checksum does not equal the stored checksum, the entry read from the file is ignored and so are all the entries following the failed entry. The switch also ignores all those entries from the file whose lease time has expired. (This situation is possible because the lease time might indicate an expired time.) An entry from the file is also ignored if the interface referred to in the entry, no longer exists on the system or if it is a router port or a DHCP snooping-trusted interface.

When a switch learns of new bindings or when it loses some bindings, the switch writes the modified set of entries from the snooping database to the file. The writes are performed with a configurable delay to batch as many changes as possible before the actual write happens. Associated with each transfer is a timeout after which a transfer is aborted if it is not completed. These timers are referred to as the write delay and abort timeout.
### About DHCP Snooping

In residential, metropolitan Ethernet-access environments, DHCP can centrally manage the IP address assignments for a large number of subscribers. When the DHCP option-82 feature is enabled on the switch, a subscriber device is identified by the switch port through which it connects to the network (in addition to its MAC address). Multiple hosts on the subscriber LAN can be connected to the same port on the access switch and are uniquely identified.

The DHCP option-82 feature is supported only when DHCP snooping is globally enabled and on the VLANs to which subscriber devices using this feature are assigned.

Figure 40-1 is an example of a metropolitan Ethernet network in which a centralized DHCP server assigns IP addresses to subscribers connected to the switch at the access layer. Because the DHCP clients and their associated DHCP server do not reside on the same IP network or subnet, a DHCP relay agent (the Catalyst switch) is configured with a helper address to enable broadcast forwarding and to transfer DHCP messages between the clients and the server.

![DHCP Relay Agent in a Metropolitan Ethernet Network](image)

When you enable the DHCP snooping information option 82 on the switch, this sequence of events occurs:

- The host (DHCP client) generates a DHCP request and broadcasts it on the network.
- When the switch receives the DHCP request, it adds the option-82 information in the packet. By default, the remote-ID suboption is the switch MAC address, and the circuit-ID suboption is the port identifier, `vlan-mod-port`, from which the packet is received. Beginning with Cisco IOS Release 12.2(40)SG, you can configure the remote ID and circuit ID. For information on configuring these suboptions, see the “Enabling DHCP Snooping and Option 82” section on page 40-10.
- If the IP address of the relay agent is configured, the switch adds this IP address in the DHCP packet.
- The switch forwards the DHCP request that includes the option-82 field to the DHCP server.
- The DHCP server receives the packet. If the server is option-82-capable, it can use the remote ID, the circuit ID, or both to assign IP addresses and implement policies, such as restricting the number of IP addresses that can be assigned to a single remote ID or circuit ID. Then the DHCP server echoes the option-82 field in the DHCP reply.
• The DHCP server unicasts the reply to the switch if the request was relayed to the server by the switch. The switch verifies that it originally inserted the option-82 data by inspecting the remote ID and possibly the circuit ID fields. The switch removes the option-82 field and forwards the packet to the switch port that connects to the DHCP client that sent the DHCP request.

In the default suboption configuration, when the described sequence of events occurs, the values in the fields in Figure 40-2 do not change:

• Circuit-ID suboption fields
  - Suboption type
  - Length of the suboption type
  - Circuit-ID type
  - Length of the circuit-ID type

• Remote-ID suboption fields
  - Suboption type
  - Length of the suboption type
  - Remote-ID type
  - Length of the remote-ID type

Figure 40-2 shows the packet formats for the remote-ID suboption and the circuit-ID suboption when the default suboption configuration is used. For the circuit-ID suboption, the module number corresponds to the switch module number. The switch uses the packet formats when you globally enable DHCP snooping and enter the `ip dhcp snooping information option` global configuration command.
Figure 40-3 shows the packet formats for user-configured remote-ID and circuit-ID suboptions. The switch uses these packet formats when DHCP snooping is globally enabled and when the `ip dhcp snooping information option format remote-id` global configuration command and the `ip dhcp snooping vlan information option format-type circuit-id string` interface configuration command are entered.

The values for these fields in the packets change from the default values when you configure the remote-ID and circuit-ID suboptions:

- **Circuit-ID suboption fields**
  - The circuit-ID type is 1.
  - The length values are variable, depending on the length of the string that you configure.

- **Remote-ID suboption fields**
  - The remote-ID type is 1.
  - The length values are variable, depending on the length of the string that you configure.

---

**Figure 40-3  User-Configured Suboption Packet Formats**

**Circuit ID Suboption Frame Format (for user-configured string):**

```
1 byte 1 byte 1 byte 1 byte  N bytes (N = 3-63)
```

**Remote ID Suboption Frame Format (for user-configured string):**

```
1 byte 1 byte 1 byte 1 byte  N bytes (N = 1-63)
```

---

**Configuring DHCP Snooping**

When you configure DHCP snooping on your switch, you are enabling the switch to differentiate untrusted interfaces from trusted interfaces. You must enable DHCP snooping globally before using DHCP snooping on a VLAN. You can enable DHCP snooping independently from other DHCP features.

These sections describe how to configure DHCP snooping:

- **Default Configuration for DHCP Snooping, page 40-7**
- **Enabling DHCP Snooping, page 40-7**
- **Enabling DHCP Snooping on the Aggregation Switch, page 40-9**
Chapter 40  Configuring DHCP Snooping, IP Source Guard, and IPSG for Static Hosts

Enabling DHCP Snooping

For DHCP server configuration information, refer to “Configuring DHCP” in the Cisco IOS IP and IP Routing Configuration Guide at:

Default Configuration for DHCP Snooping

DHCP snooping is disabled by default. Table 40-1 shows all the default configuration values for each DHCP snooping option.

<table>
<thead>
<tr>
<th>Option</th>
<th>Default Value/State</th>
</tr>
</thead>
<tbody>
<tr>
<td>DHCP snooping</td>
<td>Disabled</td>
</tr>
<tr>
<td>DHCP snooping information option</td>
<td>Enabled</td>
</tr>
<tr>
<td>DHCP snooping information option</td>
<td>Disabled</td>
</tr>
<tr>
<td>allow-untrusted</td>
<td></td>
</tr>
<tr>
<td>DHCP snooping limit rate</td>
<td>Infinite (functions as if rate limiting were disabled)</td>
</tr>
<tr>
<td>DHCP snooping trust</td>
<td>Untrusted</td>
</tr>
<tr>
<td>DHCP snooping vlan</td>
<td>Disabled</td>
</tr>
</tbody>
</table>

If you want to change the default configuration values, see the “Enabling DHCP Snooping” section.

Enabling DHCP Snooping

When DHCP snooping is enabled globally, DHCP requests are dropped until the ports are configured. Consequently, you should probably configure this feature during a maintenance window and not during production.
To enable DHCP snooping, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch(config)# ip dhcp snooping</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# ip dhcp snooping vlan number vlan (vlan range)</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config)# errdisable recovery cause dhcp-rate-limit</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config)# errdisable detect cause dhcp-rate-limit (action shutdown vlan)</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch(config-if)# ip dhcp snooping trust</td>
</tr>
<tr>
<td>Step 6</td>
<td>Switch(config-if)# ip dhcp snooping limit rate</td>
</tr>
<tr>
<td>Step 7</td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td>Step 8</td>
<td>Switch# show ip dhcp snooping</td>
</tr>
</tbody>
</table>

1. Cisco recommends not configuring the untrusted interface rate limit to more than 100 packets per second. The recommended rate limit for each untrusted client is 15 packets per second. Normally, the rate limit applies to untrusted interfaces. If you want to set up rate limiting for trusted interfaces, keep in mind that trusted interfaces aggregate all DHCP traffic in the switch, and you must adjust the rate limit to a higher value. You should fine tune this threshold depending on the network configuration. The CPU should not receive DHCP packets at a sustained rate of more than 1,000 packets per second.

You can configure DHCP snooping for a single VLAN or a range of VLANs. To configure a single VLAN, enter a single VLAN number. To configure a range of VLANs, enter a beginning and an ending VLAN number or a dash and range of VLANs.

The number of incoming DHCP packets is rate-limited to prevent a denial-of-service attack. When the rate of incoming DHCP packets exceeds the configured limit, the switch places the port in the error-disabled state. To prevent the port from shutting down, use the errdisable detect cause dhcp-rate-limit action shutdown vlan global configuration command to shut down just the offending VLAN on the port where the violation occurred.

When a secure port is in the error-disabled state, you can bring it out of this state automatically by configuring the errdisable recovery cause dhcp-rate-limit global configuration command or you can manually reenable it by entering the shutdown and no shutdown interface configuration commands. If a port is in per-VLAN errdisable mode, you can also use clear errdisable interface name vlan range command to re-enable the VLAN on the port.

This example shows how to enable DHCP Snooping on Vlan 500 through 555:

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# ip dhcp snooping
Switch(config)# ip dhcp snooping vlan 500 555
Switch(config)# ip dhcp snooping information option format remote-id string switch123
Switch(config)# interface GigabitEthernet 5/1
Switch(config-if)# ip dhcp snooping trust
Switch(config-if)# ip dhcp snooping limit rate 100
Switch(config-if)# ip dhcp snooping vlan 555 information option format-type circuit-id string customer-555
Switch(config-if)# interface FastEthernet 2/1
Switch(config-if)# ip dhcp snooping vlan 555 information option format-type circuit-id string customer-500
Switch(config)# end
Switch# show ip dhcp snooping
Switch DHCP snooping is enabled
DHCP snooping is configured on following VLANs: 500,555
DHCP snooping is operational on following VLANs: 500,555
DHCP snooping is configured on the following L3 Interfaces:

Insertion of option 82 is enabled
  circuit-id default format: vlan-mod-port
  remote-id: switch123 (string)
Option 82 on untrusted port is not allowed Verification of hwaddr field is enabled DHCP snooping trust/rate is configured on the following Interfaces:

<table>
<thead>
<tr>
<th>Interface</th>
<th>Trusted</th>
<th>Rate limit (pps)</th>
</tr>
</thead>
<tbody>
<tr>
<td>FastEthernet5/1</td>
<td>yes</td>
<td>100</td>
</tr>
<tr>
<td>Custom circuit-ids: VLAN 555: customer-555</td>
<td></td>
<td></td>
</tr>
<tr>
<td>FastEthernet2/1</td>
<td>no</td>
<td>unlimited</td>
</tr>
<tr>
<td>Custom circuit-ids: VLAN 500: customer-500</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Switch#

The following configuration describes the DHCP snooping configuration steps if routing is defined on another Catalyst switch (for example, a Catalyst 6500 series switch):

// Trust the uplink gigabit Ethernet trunk port

interface range GigabitEthernet 1/1 – 2
switchport mode trunk
switchport trunk encapsulation dot1q
ip dhcp snooping trust

!

interface VLAN 14
ip address 10.33.234.1 255.255.254.0
ip helper-address 10.5.1.2

---

If you are enabling trunking on uplink gigabit interfaces, and the above routing configuration is defined on a Catalyst 6500 series switch, you must configure the “trust” relationship with downstream DHCP Snooping (on a Catalyst 4500 series switch) which adds Option 82. On a Catalyst 6500 series switch, this task is accomplished with `ip dhcp relay information trusted` VLAN configuration command.

---

**Enabling DHCP Snooping on the Aggregation Switch**

To enable DHCP Snooping on an aggregation switch, configure the interface connecting to a downstream switch as a snooping untrusted port. If the downstream switch (or a device such as a DSLAM in the path between the aggregation switch and the DHCP clients) adds DHCP information option 82 to the DHCP packets, the DHCP packets would be dropped on arriving on a snooping untrusted
Enabling DHCP Snooping and Option 82

To enable DHCP snooping and Option 82 on the switch, perform the following steps:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# ip dhcp snooping</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config)# ip dhcp snooping vlan vlan-range</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config)# ip dhcp snooping information option</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch(config)# ip dhcp snooping information option format remote-id [string ASCII-string</td>
</tr>
<tr>
<td></td>
<td>hostname]</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Switch(config)# ip dhcp snooping information option allow-untrusted</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>Switch(config)# interface interface-id</td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>Switch(config-if)# ip dhcp snooping vlan vlan information option format-type circuit-id string ASCII-string</td>
</tr>
</tbody>
</table>
Chapter 40 Configuring DHCP Snooping, IP Source Guard, and IPSG for Static Hosts

Configuring DHCP Snooping

To disable DHCP snooping, use the `no ip dhcp snooping` global configuration command. To disable DHCP snooping on a VLAN or range of VLANs, use the `no ip dhcp snooping vlan vlan-range` global configuration command. To disable the insertion and removal of the option-82 field, use the `no ip dhcp snooping information option` global configuration command. To configure an aggregation switch to drop incoming DHCP snooping packets with option-82 information from an edge switch, use the `no ip dhcp snooping information option allow-untrusted` global configuration command.

This example shows how to enable DHCP snooping globally and on VLAN 10 and to configure a rate limit of 100 packets per second on a port:

```
Switch(config)# ip dhcp snooping
Switch(config)# ip dhcp snooping vlan 10
Switch(config)# ip dhcp snooping information option
Switch(config)# interface gigabitethernet2/0/1
Switch(config-if)# ip dhcp snooping limit rate 100
```

Enabling DHCP Snooping on Private VLAN

DHCP snooping can be enabled on private VLANs, which provide isolation between Layer 2 ports within the same VLAN. If DHCP snooping is enabled (or disabled), the configuration is propagated to both the primary VLAN and its associated secondary VLANs. You cannot enable (or disable) DHCP snooping on a primary VLAN without reflecting this configuration change on the secondary VLANs.
Configuring DHCP snooping on a secondary VLAN is still allowed, but it does not take effect if the associated primary VLAN is already configured. If the associated primary VLAN is configured, the effective DHCP snooping mode on the secondary VLAN is derived from the corresponding primary VLAN. Manually configuring DHCP snooping on a secondary VLAN causes the switch to issue this warning message:

DHCP Snooping configuration may not take effect on secondary vlan XXX

The `show ip dhcp snooping` command displays all VLANs (both primary and secondary) that have DHCP snooping enabled.

### Configuring DHCP Snooping on Private VLAN

DHCP snooping, IPSG, and DAI are Layer 2 based security features that can be enabled and disabled on an individual VLAN, including auxiliary/voice VLAN. This means that you need to enable DHCP snooping on a voice VLAN for a Cisco IP phone to function properly.

### Configuring DHCP Snooping with an Ethernet Channel Group

When you configure DHCP snooping, you need to configure trunk interfaces that transmit DHCP packets as trusted interfaces by adding `ip dhcp snooping trust` to the physical interface configuration. However, if DHCP packets are transmitted over an ethernet channel group, you must configure `ip dhcp snooping trust` on the logical port-channel interface, for example:

```
Switch# show run int port-channel50
Building configuration...
Current configuration : 150 bytes
!
interface Port-channel50
  switchport
  switchport trunk native vlan 4092
  switchport mode trunk
  switchport nonegotiate
  ip dhcp snooping trust
end
```

### Enabling the DHCP Snooping Database Agent

To configure the database agent, perform one or more of the following tasks:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`Switch(config)# ip dhcp snooping database (url</td>
<td>write-delay seconds</td>
</tr>
<tr>
<td>`Switch(config)# no ip dhcp snooping database [write-delay</td>
<td>timeout]`</td>
</tr>
<tr>
<td><code>Switch# show ip dhcp snooping database [detail]</code></td>
<td>(Optional) Displays the current operating state of the database agent and statistics associated with the transfers.</td>
</tr>
</tbody>
</table>
Note
Because both NVRAM and bootflash have limited storage capacity, you should use TFTP or network-based files. If you use flash to store the database file, new updates (by the agent) result in the creation of new files (flash fills quickly). Moreover, because of the filesystem used on the flash, a large number of files can cause slow access. When a file is stored in a remote location accessible through TFTP, an RPR/SSO standby supervisor engine can take over the binding list when a switchover occurs.

Note
Network-based URLs (such as TFTP and FTP) require that you create an empty file at the configured URL before the switch can write the set of bindings for the first time.

Limiting the Rate of Incoming DHCP Packets

The switch CPU performs DHCP validation checks; therefore, the number of incoming DHCP packets is rate-limited to prevent a denial-of-service attack.

When the rate of incoming DHCP packets exceeds the configured limit, the switch places the port in the error-disabled state. The port remains in that state until you intervene or you enable error-disable recovery so that ports automatically emerge from this state after a specified timeout period.

Note
Unless you explicitly configure a rate limit on an interface, changing the trust state of the interface also changes its rate limit to the default value for that trust state. After you configure the rate limit, the interface retains the rate limit even when its trust state is changed. If you enter the no ip dhcp snooping limit rate interface configuration command, the interface reverts to its default rate limit.

To prevent the port from shutting down, use the errdisable detect cause dhcp-rate-limit action shutdown vlan global configuration command to shut down only the offending VLAN on the port where the violation occurred.

To limit the rate of incoming DHCP packets, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# errdisable detect cause dhcp-rate-limit [action shutdown vlan]</td>
</tr>
</tbody>
</table>
### Command Purpose

<table>
<thead>
<tr>
<th>Step 3</th>
<th>Switch(config)# interface interface-id</th>
<th>Specifies the interface to be rate-limited, and enter interface configuration mode.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 4</td>
<td>Switch(config-if)# [no] ip dhcp snooping limit rate</td>
<td>Limits the rate of incoming DHCP requests and responses on the interface. The default rate is disabled.</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch(config-if)# exit</td>
<td>Returns to global configuration mode.</td>
</tr>
<tr>
<td>Step 6</td>
<td>Switch(config)# errdisable recovery {cause dhcp-rate-limit</td>
<td>(Optional) Enables error recovery from the DHCP error-disable state. By default, recovery is disabled, and the recovery interval is 300 seconds. For <strong>interval interval</strong>, specify the time in seconds to recover from the error-disable state. The range is 30 to 86400.</td>
</tr>
<tr>
<td>Step 7</td>
<td>Switch(config)# exit</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Step 8</td>
<td>Switch# show interfaces status</td>
<td>Verifies your settings.</td>
</tr>
<tr>
<td>Step 9</td>
<td>Switch# show errdisable recovery</td>
<td>Verifies your settings.</td>
</tr>
<tr>
<td>Step 10</td>
<td>Switch# copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

To return to the default rate-limit configuration, use the **no ip dhcp-rate-limit** interface configuration command. To disable error recovery for DHCP inspection, use the **no errdisable recovery cause dhcp-rate-limit** global configuration command.

This example shows how to set an upper limit for the number of incoming packets (100 pps) and to specify a burst interval (1 second):

```plaintext
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface g3/31
Switch(config-if)# ip dhcp-rate-limit rate 100 burst interval 1
Switch(config-if)# exit
Switch(config)# errdisable recovery cause dhcp-rate-limit
Switch(config)# exit
Switch# show interfaces status
```

<table>
<thead>
<tr>
<th>Port</th>
<th>Name</th>
<th>Status</th>
<th>Vlan</th>
<th>Duplex</th>
<th>Speed</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tel/1</td>
<td>connected</td>
<td>1</td>
<td>full</td>
<td>10G</td>
<td>10GBase-LR</td>
<td></td>
</tr>
<tr>
<td>Tel/2</td>
<td>connected</td>
<td>vl-err-dis</td>
<td>full</td>
<td>10G</td>
<td>10GBase-LR</td>
<td></td>
</tr>
</tbody>
</table>

```

Configuration Examples for the Database Agent

The following examples show how to use the above commands.

Example 1: Enabling the Database Agent

The following example shows how to configure the DHCP snooping database agent to store the bindings at a given location and to view the configuration and operating state:

Switch# configure terminal
Switch(config)# ip dhcp snooping database tftp://10.1.1.1/directory/file
Switch(config)# end
Switch# show ip dhcp snooping database detail
Agent URL : tftp://10.1.1.1/directory/file
Write delay Timer : 300 seconds
Abort Timer : 300 seconds
Agent Running : No
Delay Timer Expiry : 7 (00:00:07)
Abort Timer Expiry : Not Running
Last Succeeded Time : None
Last Failed Time : 17:14:25 UTC Sat Jul 7 2001
Last Failed Reason : Unable to access URL.

Total Attempts : 21  Startup Failures : 0
Successful Transfers : 0  Failed Transfers : 21
Successful Reads : 0  Failed Reads : 0
Successful Writes : 0  Failed Writes : 21
Media Failures : 0
First successful access: Read

Last ignored bindings counters:
Binding Collisions : 0  Expired leases : 0
Invalid interfaces : 0  Unsupported vlans : 0
Parse failures : 0
Last Ignored Time : None

Total ignored bindings counters:
Binding Collisions : 0  Expired leases : 0
Invalid interfaces : 0  Unsupported vlans : 0
Parse failures : 0

Switch#

The first three lines of output show the configured URL and related timer configuration values. The next three lines show the operating state and the amount of time left for expiry of write delay and abort timers.

Among the statistics shown in the output, startup failures indicate the number of attempts the read or create of the file has failed upon bootup.

Note
Because the location is based off in the network, you must create a temporary file on the TFTP server. You can create a temporary file on a typical UNIX workstation by creating a 0 byte file “file” in the directory “directory” that can be referenced by the TFTP server daemon. With some server implementations on UNIX workstations, the file should be provided with full (777) permissions for write access to the file.

DHCP snooping bindings are keyed on the MAC address and VLAN combination. Therefore, if an entry in the remote file has an entry for a given MAC address and VLAN set, for which the switch already has a binding, the entry from the remote file is ignored when the file is read. This condition is referred to as the binding collision.

An entry in a file may no longer be valid because the lease indicated by the entry may have expired by the time it is read. The expired leases counter indicates the number of bindings ignored because of this condition. The Invalid interfaces counter refers to the number of bindings that have been ignored when the interface referred by the entry either does not exist on the system or is a router or DHCP snooping trusted interface if it exists, when the read happened. Unsupported VLANs refers to the number of entries that have been ignored because the indicated VLAN is not supported on the system. The Parse failures counter provides the number of entries that have been ignored when the switch is unable to interpret the meaning of the entries from the file.

The switch maintains two sets of counters for these ignored bindings. One provides the counters for a read that has at least one binding ignored by at least one of these conditions. These counters are shown as the “Last ignored bindings counters.” The total ignored bindings counters provides a sum of the number of bindings that have been ignored because of all the reads since the switch bootup. These two set of counters are cleared by the clear command. Therefore, the total counter set may indicate the number of bindings that have been ignored since the last clear.

Example 2: Reading Binding Entries from a TFTP File

To manually read the entries from a TFTP file, perform this task:
This is an example of how to manually read entries from the tftp://10.1.1.1/directory/file:

Switch# show ip dhcp snooping database
Agent URL :
Write delay Timer : 300 seconds
Abort Timer : 300 seconds

Agent Running : No
Delay Timer Expiry : Not Running
Abort Timer Expiry : Not Running

Last Succeeded Time : None
Last Failed Time : None
Last Failed Reason : No failure recorded.

Total Attempts : 0 Startup Failures : 0
Successful Transfers : 0 Failed Transfers : 0
Successful Reads : 0 Failed Reads : 0
Successful Writes : 0 Failed Writes : 0
Media Failures : 0

Switch#
Switch# renew ip dhcp snoop data tftp://10.1.1.1/directory/file
Loading directory/file from 10.1.1.1 (via GigabitEthernet1/1): !
[OK - 457 bytes]
Database downloaded successfully.

Switch#
Step 1
Switch# show ip dhcp snooping database
Displays the DHCP snooping database agent statistics.

Step 2
Switch# renew ip dhcp snoop data url
Directs the switch to read the file from given URL.

Step 3
Switch# show ip dhcp snoop data
Displays the read status.

Step 4
Switch# show ip dhcp snoop bind
Verifies whether the bindings were read successfully.
### Example 3: Adding Information to the DHCP Snooping Database

To manually add a binding to the DHCP snooping database, perform this task:

1. **Step 1**
   - Switch# `show ip dhcp snooping binding`
     - Views the DHCP snooping database

2. **Step 2**
   - Switch# `ip dhcp snooping binding binding-id vlan vlan-id interface interface expiry lease-time`
     - Adds the binding using the 'ip dhcp snooping' exec command

3. **Step 3**
   - Switch# `show ip dhcp snooping binding`
     - Checks the DHCP snooping database

This example shows how to manually add a binding to the DHCP snooping database:

```
Switch# show ip dhcp snooping binding
MacAddress          IpAddress        Lease(sec)  Type           VLAN  Interface
------------------  ---------------  ----------  -------------  ----  --------------------
00:01:00:01:00:01   1.1.1.1          992         dhcp-snooping  1     GigabitEthernet1/1
Switch# ip dhcp snooping binding 1.1.1 vlan 1 1.1.1.1 interface gi1/1 expiry 1000
Switch# show ip dhcp snooping binding
MacAddress          IpAddress        Lease(sec)  Type           VLAN  Interface
------------------  ---------------  ----------  -------------  ----  --------------------
00:01:00:01:00:01   1.1.1.1          992         dhcp-snooping  1     GigabitEthernet1/1
```

### Displaying DHCP Snooping Information

You can display a DHCP snooping binding table and configuration information for all interfaces on a switch.

### Displaying a Binding Table

The DHCP snooping binding table for each switch contains binding entries that correspond to untrusted ports. The table does not contain information about hosts interconnected with a trusted port because each interconnected switch has its own DHCP snooping binding table.

This example shows how to display the DHCP snooping binding information for a switch:

```
Switch# show ip dhcp snooping binding
MacAddress          IpAddress        Lease(sec)  Type           VLAN  Interface
------------------  ---------------  ----------  -------------  ----  --------------------
00:01:00:01:00:01   1.1.1.1          992         dhcp-snooping  1     GigabitEthernet1/1
Switch#
```
Chapter 40      Configuring DHCP Snooping, IP Source Guard, and IPSG for Static Hosts

About IP Source Guard

Similar to DHCP snooping, this feature is enabled on a DHCP snooping untrusted Layer 2 port. Initially, all IP traffic on the port is blocked except for DHCP packets that are captured by the DHCP snooping process. When a client receives a valid IP address from the DHCP server, or when a static IP source binding is configured by the user, a per-port and VLAN Access Control List (PVACL) is installed on the port. This process restricts the client IP traffic to those source IP addresses configured in the binding; any IP traffic with a source IP address other than that in the IP source binding is filtered out. This filtering limits a host’s ability to attack the network by claiming a neighbor host’s IP address.

If IP Source Guard is enabled on a trunk port with a large number of VLANs that have DHCP snooping enabled, you might run out of ACL hardware resources, and some packets might be switched in software instead.

Table 40-2 describes the fields in the `show ip dhcp snooping binding` command output.

### Table 40-2  show ip dhcp snooping binding Command Output

Displaying the DHCP Snooping Configuration

This example shows how to display the DHCP snooping configuration for a switch.

```
Switch# show ip dhcp snooping
Switch DHCP snooping is enabled.
DHCP Snooping is configured on the following VLANs:
  10 30-40 100 200-220
Insertion of option 82 is enabled
Option82 on untrusted port is not allowed
Verification of hwaddr field is enabled
Interface Trusted Rate limit (pps)
   --------- ------- ----------------
  FastEthernet2/1   yes     10
  FastEthernet3/1   yes     none
  GigabitEthernet1/1 no      20
Switch#
```
Configuring IP Source Guard

To enable IP Source Guard, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch(config)# ip dhcp snooping</td>
</tr>
<tr>
<td></td>
<td>Enables DHCP snooping globally. Use the <code>no</code> keyword to disable DHCP snooping.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# ip dhcp snooping vlan number</td>
</tr>
<tr>
<td></td>
<td>Enables DHCP snooping on your VLANs.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config-if)# no ip dhcp snooping trust</td>
</tr>
<tr>
<td></td>
<td>Configures the interface as trusted or untrusted. Use the <code>no</code> keyword of to configure an interface to receive only messages from within the network.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config-if)# ip verify source vlan dhcp-snooping port-security</td>
</tr>
<tr>
<td></td>
<td>Enables IP source guard, source IP, and source MAC address filtering on the port.</td>
</tr>
</tbody>
</table>
Chapter 40  Configuring DHCP Snooping, IP Source Guard, and IPSG for Static Hosts

### Configuring IP Source Guard

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 5**  
Switch(config-if)# switchport port-security limit rate invalid-source-mac N | Enables security rate limiting for learned source MAC addresses on the port. |

**Note**  
This limit only applies to the port where IP Source Guard is enabled as filtering both IP and MAC addresses.

| **Step 6**  
Switch(config)# ip source binding mac-address Vlan vlan-id ip-address interface interface-name | Configures a static IP binding on the port. |

| **Step 7**  
Switch(config)# end | Exits configuration mode. |

| **Step 8**  
Switch# show ip verify source interface interface-name | Verifies the configuration. |

If you want to stop IP Source Guard with Static Hosts on an interface, use the following commands in interface configuration submode:

```
Switch(config-if)# no ip verify source
Switch(config-if)# no ip device tracking max
```

If the `no ip device tracking` command is entered in interface configuration submode, it is interpreted and run in the global configuration mode, causing IP device tracking to be disabled globally. For all the interfaces configured with the `ip verify source tracking [port-security]` command, disabling IP device tracking globally causes the IP Source Guard with Static Hosts feature to deny all IP traffic from those interfaces.

**Note**  
The static IP source binding can only be configured on switch port. If you issue the `ip source binding vlan interface` command on a Layer 3 port, you receive this error message:  

```
Static IP source binding can only be configured on switch port.
```

This example shows how to enable per-Layer 2-port IP source guard on VLANs 10 through 20:

```
Switch# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch(config)# ip dhcp snooping
Switch(config)# ip dhcp snooping vlan 10 20
Switch(config)# interface fa6/1
Switch(config-if)# switchport trunk encapsulation dot1q
Switch(config-if)# switchport mode trunk
Switch(config-if)# switchport trunk native vlan 10
Switch(config-if)# switchport trunk allowed vlan 11-20
Switch(config-if)# no ip dhcp snooping trust
Switch(config-if)# ip verify source vlan dhcp-snooping
Switch(config)# end
Switch# show ip verify source interface fa6/1
Interface  Filter-type  Filter-mode  IP-address  Mac-address  Vlan
---------  -----------  -----------  ----------  ----------  ------
Fa6/1      ip-mac     active       10.0.0.1          10
Fa6/1      ip-mac     active       deny-all         11-20
Switch#
```

The output shows that there is one valid DHCP binding to VLAN 10.
Configuring IP Source Guard on Private VLANs

For private VLAN ports, you must enable DHCP snooping on primary VLANs in order for IP source guard to be effective. IP source guard on a primary VLAN is automatically propagate to a secondary VLAN. Configuring a static IP source binding on a secondary VLAN is allowed, but it does not take effect. When manually configuring a static IP source binding on a secondary VLAN, you receive the following warning:

**Warning**

IP source filter may not take effect on secondary vlan where IP source binding is configured. If private vlan feature is enabled, IP source filter on primary vlan automatically propagates to all secondary vlans.

Displaying IP Source Guard Information

You can display IP Source Guard PVACL information for all interfaces on a switch using the `show ip verify source` command.

- This example shows displayed PVACLs if DHCP snooping is enabled on VLAN 10 through 20, if interface fa6/1 is configured for IP filtering, and if there is an existing IP address binding 10.0.0.1 on VLAN 10:

<table>
<thead>
<tr>
<th>Interface</th>
<th>Filter-type</th>
<th>Filter-mode</th>
<th>IP-address</th>
<th>Mac-address</th>
<th>Vlan</th>
</tr>
</thead>
<tbody>
<tr>
<td>fa6/1</td>
<td>ip</td>
<td>active</td>
<td>10.0.0.1</td>
<td></td>
<td>10</td>
</tr>
<tr>
<td>fa6/1</td>
<td>ip</td>
<td>active</td>
<td>deny-all</td>
<td></td>
<td>11-20</td>
</tr>
</tbody>
</table>

**Note**

The second entry shows that a default PVACL (deny all IP traffic) is installed on the port for those snooping-enabled VLANs that do not have a valid IP source binding.

- This example shows displayed PVACL for a trusted port:

<table>
<thead>
<tr>
<th>Interface</th>
<th>Filter-type</th>
<th>Filter-mode</th>
<th>IP-address</th>
<th>Mac-address</th>
<th>Vlan</th>
</tr>
</thead>
<tbody>
<tr>
<td>fa6/2</td>
<td>ip</td>
<td>inactive-trust-port</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- This example shows displayed PVACL for a port in a VLAN not configured for DHCP snooping:

<table>
<thead>
<tr>
<th>Interface</th>
<th>Filter-type</th>
<th>Filter-mode</th>
<th>IP-address</th>
<th>Mac-address</th>
<th>Vlan</th>
</tr>
</thead>
<tbody>
<tr>
<td>fa6/3</td>
<td>ip</td>
<td>inactive-no-snooping-vlan</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- This example shows displayed PVACLs for a port with multiple bindings configured for an IP/MAC filtering:

<table>
<thead>
<tr>
<th>Interface</th>
<th>Filter-type</th>
<th>Filter-mode</th>
<th>IP-address</th>
<th>Mac-address</th>
<th>Vlan</th>
</tr>
</thead>
<tbody>
<tr>
<td>fa6/4</td>
<td>ip-mac</td>
<td>active</td>
<td>10.0.0.2</td>
<td>aaaa.bbbb.cccc</td>
<td>10</td>
</tr>
<tr>
<td>fa6/4</td>
<td>ip-mac</td>
<td>active</td>
<td>11.0.0.1</td>
<td>aaaa.bbbb.cccd</td>
<td>11</td>
</tr>
<tr>
<td>fa6/4</td>
<td>ip-mac</td>
<td>active</td>
<td>deny-all</td>
<td>deny-all</td>
<td>12-20</td>
</tr>
</tbody>
</table>

- This example shows displayed PVACLs for a port configured for IP/MAC filtering but not for port security:

<table>
<thead>
<tr>
<th>Interface</th>
<th>Filter-type</th>
<th>Filter-mode</th>
<th>IP-address</th>
<th>Mac-address</th>
<th>Vlan</th>
</tr>
</thead>
</table>
Chapter 40      Configuring DHCP Snooping, IP Source Guard, and IPSG for Static Hosts

Displaying IP Source Binding Information

You can display all IP source bindings configured on all interfaces on a switch using the `show ip source binding` command.

```
Switch# show ip source binding
```

Table 40-3 describes the fields in the `show ip source binding` command output.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAC Address</td>
<td>Client hardware MAC address</td>
</tr>
<tr>
<td>IP Address</td>
<td>Client IP address assigned from the DHCP server</td>

Displaying IP Source Binding Information
CHAPTER 41

Configuring Dynamic ARP Inspection

This chapter describes how to configure Dynamic ARP Inspection (DAI) on the Catalyst 4500 series switch.

This chapter includes the following major sections:

- About Dynamic ARP Inspection, page 41-1
- Configuring Dynamic ARP Inspection, page 41-5

Note

For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

About Dynamic ARP Inspection

Dynamic ARP Inspection (DAI) is a security feature that validates Address Resolution Protocol (ARP) packets in a network. DAI allows a network administrator to intercept, log, and discard ARP packets with invalid MAC-IP pairs. This capability protects the network from certain “man-in-the-middle” attacks.

This section contains the following subsections:

- ARP Cache Poisoning, page 41-2
- Purpose of Dynamic ARP Inspection, page 41-2
- Interface Trust State, Security Coverage and Network Configuration, page 41-3
- Relative Priority of Static Bindings and DHCP Snooping Entries, page 41-4
- Logging of Dropped Packets, page 41-4
- Rate Limiting of ARP Packets, page 41-4
- Port Channels and Their Behavior, page 41-5
About Dynamic ARP Inspection

You can attack hosts, switches, and routers connected to your Layer 2 network by “poisoning” their ARP caches. For example, a malicious user might intercept traffic intended for other hosts on the subnet by poisoning the ARP caches of systems connected to the subnet.

Consider the following configuration:

**Figure 41-1  ARP Cache Poisoning**

Hosts HA, HB, and HC are connected to the switch on interfaces A, B and C, all of which are on the same subnet. Their IP and MAC addresses are shown in parentheses; for example, Host HA uses IP address IA and MAC address MA. When HA needs to communicate to HB at the IP Layer, HA broadcasts an ARP request for the MAC address associated with IB. As soon as HB receives the ARP request, the ARP cache on HB is populated with an ARP binding for a host with the IP address IA and a MAC address MA. When HB responds to HA, the ARP cache on HA is populated with a binding for a host with the IP address IB and a MAC address MB.

Host HC can “poison” the ARP caches of HA and HB by broadcasting forged ARP responses with bindings for a host with an IP address of IA (or IB) and a MAC address of MC. Hosts with poisoned ARP caches use the MAC address MC as the destination MAC address for traffic intended for IA or IB. This means that HC intercepts that traffic. Because HC knows the true MAC addresses associated with IA and IB, HC can forward the intercepted traffic to those hosts using the correct MAC address as the destination. HC has inserted itself into the traffic stream from HA to HB, the classic “man in the middle” attack.

**Purpose of Dynamic ARP Inspection**

To prevent ARP poisoning attacks, a switch must ensure that only valid ARP requests and responses are relayed. DAI prevents these attacks by intercepting all ARP requests and responses. Each of these intercepted packets is verified for valid MAC address to IP address bindings before the local ARP cache is updated or the packet is forwarded to the appropriate destination. Invalid ARP packets are dropped.

DAI determines the validity of an ARP packet based on valid MAC address to IP address bindings stored in a trusted database. This database is built at runtime by DHCP snooping, provided this feature is enabled on VLANs and on the switch. In addition, in order to handle hosts that use statically configured IP addresses, DAI can also validate ARP packets against user-configured ARP ACLs.

DAI can also be configured to drop ARP packets when the IP addresses in the packet are invalid or when the MAC addresses in the body of the ARP packet do not match the addresses specified in the Ethernet header.
Interface Trust State, Security Coverage and Network Configuration

DAI associates a trust state with each interface on the system. Packets arriving on trusted interfaces bypass all DAI validation checks. Those arriving on untrusted interfaces go through the DAI validation process. In a typical network configuration for DAI, all ports connected to host ports are configured as untrusted, while all ports connected to switches are configured as trusted. With this configuration, all ARP packets entering the network from a given switch pass the security check.

**Figure 41-2 Validation of ARP Packets on a DAI-Enabled VLAN**

Use the trust state configuration carefully. Configuring interfaces as untrusted when they should be trusted can result in a loss of connectivity. If we assume that both S1 and S2 (in Figure 41-2) run DAI on the VLAN ports that contains H1 and H2, and if H1 and H2 were to acquire their IP addresses from the DHCP server connected to S1, then only S1 binds the IP to MAC address of H1. Therefore, if the interface between S1 and S2 is untrusted, the ARP packets from H1 get dropped on S2. This condition would result in a loss of connectivity between H1 and H2.

Configuring interfaces to be trusted when they are actually untrusted leaves a security hole in the network. If S1 were not running DAI, then H1 can easily poison the ARP of S2 (and H2, if the inter-switch link is configured as trusted). This condition can occur even though S2 is running DAI.

DAI ensures that hosts (on untrusted interfaces) connected to a switch running DAI do not poison the ARP caches of other hosts in the network. It does not, however, ensure that hosts from other portions of the network do not poison the caches of the hosts connected to it.

To handle cases in which some switches in a VLAN run DAI and other switches do not, the interfaces connecting such switches should be configured as untrusted. To validate the bindings of packets from non-DAI switches, however, the switch running DAI should be configured with ARP ACLs. When it is not feasible to determine such bindings, switches running DAI should be isolated from non-DAI switches at Layer 3.

**Note**

Depending on the setup of the DHCP server and the network, it may not be possible to perform validation of a given ARP packet on all switches in the VLAN.
Relative Priority of Static Bindings and DHCP Snooping Entries

As mentioned previously, DAI populates its database of valid MAC address to IP address bindings through DHCP snooping. It also validates ARP packets against statically configured ARP ACLs. It is important to note that ARP ACLs have precedence over entries in the DHCP snooping database. ARP packets are first compared to user-configured ARP ACLs. If the ARP ACL denies the ARP packet, then the packet is denied even if a valid binding exists in the database populated by DHCP snooping.

Logging of Dropped Packets

When the switch drops a packet, it places an entry in the log buffer and then generates system messages on a rate-controlled basis. After the message is generated, the switch clears the entry from the log buffer. Each log entry contains flow information, such as the receiving VLAN, the port number, the source and destination IP addresses, and the source and destination MAC addresses.

You use the `ip arp inspection log-buffer` global configuration command to configure the number of entries in the buffer and the number of entries needed in the specified interval to generate system messages. You specify the type of packets that are logged by using the `ip arp inspection vlan logging` global configuration command. For configuration information, see the “Configuring the Log Buffer” section on page 41-14.

Rate Limiting of ARP Packets

DAI performs validation checks in the CPU, so the number of incoming ARP packets is rate-limited to prevent a denial of service attack. By default, the rate for untrusted interfaces is set to 15 pps second, whereas trusted interfaces have no rate limit. When the rate of incoming ARP packets exceeds the configured limit, the port is placed in the errdisable state. The port remains in that state until an administrator intervenes. With the `errdisable recovery` global configuration command, you can enable errdisable recovery so that ports emerge from this state automatically after a specified timeout period.

You use the `ip arp inspection limit` global configuration command to limit the rate of incoming ARP requests and responses on the interface. Unless a rate limit is explicitly configured on an interface, changing the trust state of the interface also changes its rate limit to the default value for that trust state; that is, 15 packets per second for untrusted interfaces and unlimited for trusted interfaces. After a rate limit is configured explicitly, the interface retains the rate limit even when its trust state is changed. At any time, the interface reverts to its default rate limit if the `no` form of the `rate limit` command is applied.

For configuration information, see the “Limiting the Rate of Incoming ARP Packets” section on page 41-16.

---

**Note**

When you enable DAI, all ARP packets are forwarded by CPU (software forwarding, the slow path). With this mechanism, whenever a packet exits through multiple ports, the CPU must create as many copies of the packet as there are egress ports. So, the number of egress ports is a multiplying factor for the CPU. Furthermore, when QoS policing is applied on egress packets that were forwarded by CPU, QoS must be applied in the CPU as well. (You cannot apply QoS in hardware on CPU generated packets because the hardware forwarding path is turned off for CPU generated packets.) Both factors can drive the CPU to a very high utilization level.
Port Channels and Their Behavior

A given physical port can join a channel only when the trust state of the physical port and of the channel match. Otherwise, the physical port remains suspended in the channel. A channel inherits its trust state from the first physical port that joined the channel. Consequently, the trust state of the first physical port need not match the trust state of the channel.

Conversely, when the trust state is changed on the channel, the new trust state is configured on all the physical ports that comprise the channel.

The rate limit check on port channels is unique. The rate of incoming packets on a physical port is checked against the port channel configuration rather than the physical ports’ configuration.

The rate limit configuration on a port channel is independent of the configuration on its physical ports. The rate limit is cumulative across all physical ports; that is, the rate of incoming packets on a port channel equals the sum of rates across all physical ports.

When you configure rate limits for ARP packets on trunks, you must account for VLAN aggregation because a high rate limit on one VLAN can cause a “denial of service” attack to other VLANs when the port is errdisabbed by software. Similarly, when a port channel is errdisabbed, a high rate limit on one physical port can cause other ports in the channel to go down.

Configuring Dynamic ARP Inspection

These sections describe how to configure dynamic ARP inspection on your switch:

- Configuring Dynamic ARP Inspection in DHCP Environments, page 41-5 (required)
- Configuring ARP ACLs for Non-DHCP Environments, page 41-11 (optional)
- Configuring the Log Buffer, page 41-14 (optional)
- Limiting the Rate of Incoming ARP Packets, page 41-16 (optional)
- Performing Validation Checks, page 41-19 (optional)

Configuring Dynamic ARP Inspection in DHCP Environments

This procedure shows how to configure dynamic ARP inspection when two switches support this feature. Host 1 is connected to Switch A, and Host 2 is connected to Switch B as shown in Figure 41-3. Both switches are running dynamic ARP inspection on VLAN 100 where the hosts are located. A DHCP server is connected to Switch A. Both hosts acquire their IP addresses from the same DHCP server. Therefore, Switch A has the bindings for Host 1, and Switch B has the bindings for Host 2.
Dynamic ARP inspection depends on the entries in the DHCP snooping binding database to verify IP-to-MAC address bindings in incoming ARP requests and ARP responses. Make sure to enable DHCP snooping to permit ARP packets that have dynamically assigned IP addresses. For configuration information, see Chapter 40, “Configuring DHCP Snooping, IP Source Guard, and IPSG for Static Hosts.”

For information on how to configure dynamic ARP inspection when only one switch supports the feature, see the “Configuring ARP ACLs for Non-DHCP Environments” section on page 41-11.

To configure dynamic ARP inspection, perform this task on both switches:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> Switch# show cdp neighbors</td>
<td>Verifies the connection between the switches.</td>
</tr>
<tr>
<td><strong>Step 2</strong> Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong> Switch(config)# [no] ip arp inspection vlan vlan-range</td>
<td>Enables dynamic ARP inspection on a per-VLAN basis. By default, dynamic ARP inspection is disabled on all VLANs. To disable dynamic ARP inspection, use the <strong>no ip arp inspection vlan vlan-range</strong> global configuration command. For <strong>vlan-range</strong>, specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094. Specify the same VLAN ID for both switches.</td>
</tr>
<tr>
<td><strong>Step 4</strong> Switch(config)# interface interface-id</td>
<td>Specifies the interface connected to the other switch, and enter interface configuration mode.</td>
</tr>
</tbody>
</table>
This example shows how to configure dynamic ARP inspection on Switch A in VLAN 100. You would perform a similar procedure on Switch B.

### On Switch A

SwitchA# `show cdp neighbors`
Capability Codes: R - Router, T - Trans Bridge, B - Source Route Bridge  
                   S - Switch, H - Host, I - IGMP, r - Repeater, P - Phone

SwitchB#
### Configuring ARP ACLs for Non-DHCP Environments

This procedure shows how to configure dynamic ARP inspection when Switch B shown in Figure 41-3 on page 41-6 does not support dynamic ARP inspection or DHCP snooping.

If you configure port 1 on Switch A as trusted, a security hole is created because both Switch A and Host 1 could be attacked by either Switch B or Host 2. To prevent this possibility, you must configure port 1 on Switch A as untrusted. To permit ARP packets from Host 2, you must set up an ARP ACL and apply it to VLAN 100. If the IP address of Host 2 is not static, such that it is impossible to apply the ACL configuration on Switch A, you must separate Switch A from Switch B at Layer 3 and use a router to route packets between them.

To configure an ARP ACL (on switch A in a non-DHCP environment), perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>Switch# configure terminal</strong></td>
</tr>
</tbody>
</table>
| **Step 2** | **Switch(config)# arp access-list acl-name** | Defines an ARP ACL, and enter ARP access-list configuration mode. By default, no ARP access lists are defined.  
**Note** At the end of the ARP access list, there is an implicit **deny ip any mac any** command. |
| **Step 3** | **Switch(config-arp-nac)# permit ip host sender-ip mac host sender-mac [log]** | Permits ARP packets from the specified host (Host 2).  
• For *sender-ip*, enter the IP address of Host 2.  
• For *sender-mac*, enter the MAC address of Host 2.  
• (Optional) Specify **log** to log a packet in the log buffer when it matches the access control entry (ACE). Matches are logged if you also configure the **matchlog** keyword in the **ip arp inspection vlan logging** global configuration command. For more information, see the “Configuring the Log Buffer” section on page 41-14. |
| **Step 4** | **Switch(config-arp-nac)# exit** | Returns to global configuration mode. |
### Command Purpose

**Step 5**

```
Switch(config)# ip arp inspection filter arp-acl-name vlan vlan-range [static]
```

Applies the ARP ACL to the VLAN. By default, no defined ARP ACLs are applied to any VLAN.

- For `arp-acl-name`, specify the name of the ACL created in Step 2.
- For `vlan-range`, specify the VLAN that the switches and hosts are in. You can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094.
- (Optional) Specify `static` to treat implicit denies in the ARP ACL as explicit denies and to drop packets that do not match any previous clauses in the ACL. DHCP bindings are not used.

If you do not specify this keyword, it means that there is no explicit deny in the ACL that denies the packet, and DHCP bindings determine whether a packet is permitted or denied if the packet does not match any clauses in the ACL.

ARP packets containing only IP-to-MAC address bindings are compared against the ACL. Packets are permitted only if the access list permits them.

**Step 6**

```
Switch(config)# interface interface-id
```

Specifies the Switch A interface that is connected to Switch B, and enter interface configuration mode.

**Step 7**

```
Switch(config-if)# no ip arp inspection trust
```

Configures the Switch A interface that is connected to Switch B as untrusted.

By default, all interfaces are untrusted.

For untrusted interfaces, the switch intercepts all ARP requests and responses. It verifies that the intercepted packets have valid IP-to-MAC address bindings before updating the local cache and before forwarding the packet to the appropriate destination.

The switch drops invalid packets and logs them in the log buffer according to the logging configuration specified with the `ip arp inspection vlan logging` global configuration command. For more information, see the “Configuring the Log Buffer” section on page 41-14.

**Step 8**

```
Switch(config-if)# end
```

Returns to privileged EXEC mode.

**Step 9**

```
Switch# show arp access-list [acl-name]
Switch# show ip arp inspection vlan vlan-range
Switch# show ip arp inspection interfaces
```

Verifies the dynamic ARP inspection configuration.

**Step 10**

```
Switch# copy running-config startup-config
```

(Optional) Saves your entries in the configuration file.
To remove the ARP ACL, use the `no arp access-list` global configuration command. To remove the ARP ACL attached to a VLAN, use the `no ip arp inspection filter arp-acl-name vlan vlan-range` global configuration command.

This example shows how to configure an ARP ACL called `host2` on Switch A, to permit ARP packets from HostB (IP address 170.1.1.2 and MAC address 2.2.2), to apply the ACL to VLAN 100, and to configure port 1 on Switch A as untrusted:

```
SwitchA# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
SwitchA(config)# arp access-list hostB
SwitchA(config-arp-nacl)# permit ip host 170.1.1.2 mac host 2.2.2 log
SwitchA(config-arp-nacl)# exit
SwitchA(config)# ip arp inspection filter hostB vlan 100 static
SwitchA(config)# interface g3/48
SwitchA(config-if)# no ip arp inspection trust
SwitchA(config-if)# end
SwitchA# show arp access-list hostB
ARP access list hostB
  permit ip host 170.1.1.2 mac host 0002.0002.0002 log

SwitchA# show ip arp inspection interfaces

Configuring the Log Buffer

When the switch drops a packet, it places an entry in the log buffer and then generates system messages on a rate-controlled basis. After the message is generated, the switch clears the entry from the log buffer. Each log entry contains flow information, such as the receiving VLAN, the port number, the source and destination IP addresses, and the source and destination MAC addresses.

A log-buffer entry can represent more than one packet. For example, if an interface receives many packets on the same VLAN with the same ARP parameters, the switch combines the packets as one entry in the log buffer and generates a single system message for the entry.

If the log buffer overflows, it means that a log event does not fit into the log buffer, and the display for the `show ip arp inspection log` privileged EXEC command is affected. No other statistics are provided for the entry.
To configure the log buffer, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>Purpose</strong></td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Configures the dynamic ARP inspection logging buffer.</td>
</tr>
<tr>
<td>Switch(config)# ip arp inspection log-buffer {entries number</td>
<td>logs number interval seconds}</td>
</tr>
<tr>
<td>The keywords have these meanings:</td>
<td></td>
</tr>
<tr>
<td>• For entries number, specify the number of entries to be logged in the buffer. The range is 0 to 1024.</td>
<td></td>
</tr>
<tr>
<td>• For logs number interval seconds, specify the number of entries to generate system messages in the specified interval.</td>
<td></td>
</tr>
<tr>
<td>For logs number, the range is 0 to 1024.</td>
<td>A 0 value means that the entry is placed in the log buffer, but a system message is not generated.</td>
</tr>
<tr>
<td>For interval seconds, the range is 0 to 86400 seconds (1 day).</td>
<td>A 0 value means that a system message is immediately generated (and the log buffer is always empty).</td>
</tr>
<tr>
<td>An interval setting of 0 overrides a log setting of 0.</td>
<td></td>
</tr>
<tr>
<td>The logs and interval settings interact. If the logs number X is greater than interval seconds Y, X divided by Y (X/Y) system messages are sent every second. Otherwise, one system message is sent every Y divided by X (Y/X) seconds.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Controls the type of packets that are logged per VLAN. By default, all denied or all dropped packets are logged. The term logged means the entry is placed in the log buffer and a system message is generated.</td>
</tr>
<tr>
<td>Switch(config)# [no] ip arp inspection vlan vlan-range logging {acl-match {matchlog</td>
<td>none}</td>
</tr>
<tr>
<td>• For vlan-range, specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094.</td>
<td></td>
</tr>
<tr>
<td>• For acl-match matchlog, log packets based on the ACE logging configuration. If you specify the matchlog keyword in this command and the log keyword in the permit or deny ARP access-list configuration command, ARP packets permitted or denied by ACEs with log keyword are logged.</td>
<td></td>
</tr>
<tr>
<td>• For acl-match none, do not log packets that match ACLs.</td>
<td></td>
</tr>
<tr>
<td>• For dhcp-bindings all, log all packets that match DHCP bindings.</td>
<td></td>
</tr>
<tr>
<td>• For dhcp-bindings none, do not log packets that match DHCP bindings.</td>
<td></td>
</tr>
<tr>
<td>• For dhcp-bindings permit, log DHCP-binding permitted packets.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Switch(config)# exit</td>
<td></td>
</tr>
</tbody>
</table>
Chapter 41      Configuring Dynamic ARP Inspection

Configuring Dynamic ARP Inspection

To return to the default log buffer settings, use the **no ip arp inspection log-buffer** global configuration command. To return to the default VLAN log settings, use the **no ip arp inspection vlan vlan-range logging {acl-match | dhcp-bindings}** global configuration command. To clear the log buffer, use the **clear ip arp inspection log** privileged EXEC command.

This example shows how to configure the number of entries for the log buffer to 1024. It also shows how to configure your Catalyst 4500 series switch so that the logs must be generated from the buffer at the rate of 100 per 10 seconds.

```
SwitchB# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
SwitchB(config)# ip arp inspection log-buffer entries 1024
SwitchB(config)# ip arp inspection log-buffer logs 100 interval 10
SwitchB(config)# end

**Limiting the Rate of Incoming ARP Packets**

The switch CPU performs dynamic ARP inspection validation checks; therefore, the number of incoming ARP packets is rate-limited to prevent a denial-of-service attack.

**Note**

Unless you explicitly configure a rate limit on an interface, changing the trust state of the interface also changes its rate limit to the default value for that trust state. After you configure the rate limit, the interface retains the rate limit even when its trust state is changed. If you enter the **no ip arp-inspection limit** interface configuration command, the interface reverts to its default rate limit.

By default, the switch places the port in the error-disabled state when the rate of incoming ARP packets exceeds the configured limit. To prevent the port from shutting down, use the **errdisable detect cause arp-inspection action shutdown vlan** global configuration command to shut down just the offending VLAN on the port where the violation occurred.

When a port is in the error-disabled state, you can bring it out of this state automatically by configuring the **errdisable recovery cause arp-inspection** global configuration command or you can manually reenable it by entering the **shutdown** and **no shutdown** interface configuration commands. If a port is in per-VLAN errdisable mode, you can also use the **clear errdisable interface name vlan range** command to re-enable the VLAN on the port.

---

**Command**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 5 Switch# show ip arp inspection log</td>
<td>Verifies your settings.</td>
</tr>
<tr>
<td>Step 6 Switch# copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>
To limit the rate of incoming ARP packets, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# errdisable detect cause arp-inspection [action shutdown vlan]</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config)# interface interface-id</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config-if)# [no] ip arp inspection limit [rate pps [burst interval seconds]]</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch(config-if)# exit</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Switch(config)# errdisable recovery [cause arp-inspection</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>Switch(config)# exit</td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>Switch# show ip arp inspection interfaces</td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>Switch# show errdisable recovery</td>
</tr>
<tr>
<td><strong>Step 10</strong></td>
<td>Switch# copy running-config startup-config</td>
</tr>
</tbody>
</table>

To return to the default rate-limit configuration, use the no ip arp inspection limit interface configuration command. To disable error recovery for dynamic ARP inspection, use the no errdisable recovery cause arp-inspection global configuration command.

This example shows how to set an upper limit for the number of incoming packets (100 pps) and to specify a burst interval (1 second):

```
SwitchB# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
SwitchB(config)# interface g3/31
SwitchB(config-if)# ip arp inspection limit rate 100 burst interval 1
SwitchB(config-if)# exit
```
SwitchB(config)# **errdisable recovery cause arp-inspection**
SwitchB(config)# **exit**
SwitchB# **show ip arp inspection interfaces**

Performing Validation Checks

Dynamic ARP inspection intercepts, logs, and discards ARP packets with invalid IP-to-MAC address bindings. You can configure the switch to perform additional checks on the destination MAC address, the sender and target IP addresses, and the source MAC address.
To perform specific checks on incoming ARP packets, perform this task.

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>Switch# configure terminal</strong></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>**Switch(config)# ip arp inspection validate[</td>
</tr>
<tr>
<td></td>
<td>The keywords have these meanings:</td>
</tr>
<tr>
<td></td>
<td>• For <strong>src-mac</strong>, check the source MAC address in the Ethernet header against the sender MAC address in the ARP body. This check is performed on both ARP requests and responses. When enabled, packets with different MAC addresses are classified as invalid and are dropped.</td>
</tr>
<tr>
<td></td>
<td>• For <strong>dst-mac</strong>, check the destination MAC address in the Ethernet header against the target MAC address in the ARP body. This check is performed for ARP responses. When enabled, packets with different MAC addresses are classified as invalid and are dropped.</td>
</tr>
<tr>
<td></td>
<td>• For <strong>ip</strong>, check the ARP body for invalid and unexpected IP addresses. Addresses include 0.0.0.0, 255.255.255.255, and all IP multicast addresses. Sender IP addresses are checked in all ARP requests and responses, and target IP addresses are checked only in ARP responses.</td>
</tr>
<tr>
<td></td>
<td>You must specify at least one of the keywords. Each command overrides the configuration of the previous command; that is, if a command enables <strong>src</strong> and <strong>dst mac</strong> validations, and a second command enables IP validation only, the <strong>src</strong> and <strong>dst mac</strong> validations are disabled as a result of the second command.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><strong>Switch(config)# exit</strong></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><strong>Switch# show ip arp inspection vlan vlan-range</strong></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><strong>Switch# copy running-config startup-config</strong></td>
</tr>
</tbody>
</table>

To disable checking, use the **no ip arp inspection validate[|src-mac| |dst-mac| |ip|]** global configuration command. To display statistics for forwarded, dropped, MAC validation failure, and IP validation failure packets, use the **show ip arp inspection statistics** privileged EXEC command.

This example shows how to configure source mac validation. Packets are dropped and an error message may be generated when the source address in the Ethernet header does not match the sender hardware address in the ARP body.

**SwitchB# configure terminal**
Enter configuration commands, one per line. End with CNTL/Z.

**SwitchB(config)# ip arp inspection validate src-mac**

**SwitchB(config)# exit**

**SwitchB# show ip arp inspection vlan 100**

Source Mac Validation : Enabled
Destination Mac Validation : Disabled
IP Address Validation : Disabled

CHAPTER 42

Configuring Network Security with ACLs

This chapter describes how to use access control lists (ACLs) to configure network security on the Catalyst 4500 series switches.

**Note**

The Catalyst 4500 series switch supports time-based ACLs.

**Note**

For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

This chapter consists of the following major sections:

- About ACLs, page 42-2
- Hardware and Software ACL Support, page 42-5
- TCAM Programming and ACLs, page 42-6
- Layer 4 Operators in ACLs, page 42-9
- Configuring Unicast MAC Address Filtering, page 42-12
- Configuring Named MAC Extended ACLs, page 42-12
- Configuring EtherType Matching, page 42-14

About ACLs

This section contains the following subsections:

- ACL Overview, page 42-2
- Supported Features That Use ACLs, page 42-3
- Router ACLs, page 42-3
- Port ACLs, page 42-4
- VLAN Maps, page 42-5

ACL Overview

An ACL is a collection of sequential permit and deny conditions that applies to packets. When a packet is received on an interface, the switch compares the fields in the packet against any applied ACLs to verify that the packet has the permissions required to be forwarded, based on the conditions specified in the access lists. It tests the packets against the conditions in an access list one-by-one. The first match determines whether the switch accepts or rejects the packets. Because the switch stops testing conditions after the first match, the order of conditions in the list is critical. If no conditions match, the switch drops the packet. If there are no restrictions, the switch forwards the packet; otherwise, the switch drops the packet.

Switches traditionally operate at Layer 2, switching traffic within a VLAN, whereas routers route traffic between VLANs at Layer 3. The Catalyst 4500 series switch can accelerate packet routing between VLANs by using Layer 3 switching. The Layer 3 switch bridges the packet, and then routes the packet internally without going to an external router. The packet is then bridged again and sent to its destination. During this process, the switch can control all packets, including packets bridged within a VLAN.

You configure access lists on a router or switch to filter traffic and provide basic security for your network. If you do not configure ACLs, all packets passing through the switch could be allowed on all parts of the network. You can use ACLs to control which hosts can access different parts of a network or to decide which types of traffic are forwarded or blocked at router interfaces. For example, you can allow e-mail traffic to be forwarded but not Telnet traffic. ACLs can be configured to block inbound traffic, outbound traffic, or both. However, on Layer 2 interfaces, you can apply ACLs only in the inbound direction.

An ACL contains an ordered list of access control entries (ACEs). Each ACE specifies permit or deny and a set of conditions the packet must satisfy in order to match the ACE. The meaning of permit or deny depends on the context in which the ACL is used.

The Catalyst 4500 series switch supports three types of ACLs:

- IPv4 ACLs, which filter IPv4 traffic, including TCP, the User Datagram Protocol (UDP), Internet Group Management Protocol (IGMP), and Internet Control Message Protocol (ICMP)
- IPv6 ACLs, which filter IPv6 traffic
- MAC ACLs, which filter non-IPv4, non-IPv6 traffic
Supported Features That Use ACLs

The switch supports two applications of ACLs to filter traffic:

- **Router ACLs** are applied to Layer 3 interfaces. They control the access of routed traffic between VLANs. All Catalyst 4500 series switches can create router ACLs, but you must have a Cisco IOS software image on your switch to apply an ACL to a Layer 3 interface and filter packets routed between VLANs.

- **Port ACLs** perform access control on traffic entering a Layer 2 interface. If there are not enough hardware CAM entries, the output port ACL is not applied to the port and a warning message is given to user. (This restriction applies to all access group modes for output port ACLs.) When there are enough CAM entries, the output port ACL might be reapplied.

    If there is any output port ACL configured on a Layer 2 port, then no VACL or router ACL can be configured on the VLANs that the Layer 2 port belongs to. Also, the reverse is true: port ACLs and VLAN-based ACLs (VACLs and router ACLs) are mutually exclusive on a Layer 2 port. This restriction applies to all access group modes. On the input direction, port ACLs, VLAN-based ACLs, and router ACLs can co-exist.

    You can apply only one IPv4 access list, one IPv6 access list, and one MAC access list to any given Layer 2 interface.

- **VLAN ACLs** or VLAN maps control the access of all packets (bridged and routed). You can use VLAN maps to filter traffic between devices in the same VLAN. You do not need the enhanced image to create or apply VLAN maps. VLAN maps are configured to control access based on Layer 3 addresses for IP. MAC addresses using Ethernet ACEs control the access of unsupported protocols. After you apply a VLAN map to a VLAN, all packets (routed or bridged) entering the VLAN are checked against that map. Packets can either enter the VLAN through a switch port or through a routed port after being routed.

    You can use both router ACLs and VLAN maps on the same switch.

**Router ACLs**

You can apply one access-list of each supported type to an interface.

Multiple features can use one ACL for a given interface, and one feature can use multiple ACLs. When a single router ACL is used by multiple features, it is examined multiple times. The access list type determines the input to the matching operation:

- Standard IP access lists use source addresses for matching operations.

- Extended IP access lists use source and destination addresses and optional protocol type information for matching operations.

The switch examines ACLs associated with features configured on a given interface and a direction. As packets enter the switch on an interface, ACLs associated with all inbound features configured on that interface are examined. After packets are routed and before they are forwarded to the next hop, all ACLs associated with outbound features configured on the egress interface are examined.

ACLs permit or deny packet forwarding based on how the packet matches the entries in the ACL. For example, you can use access lists to allow one host to access a part of a network, but prevent another host from accessing the same part. In Figure 42-1, ACLs applied at the router input allow Host A to access the Human Resources network, but prevent Host B from accessing the same network.
About ACLs

Figure 42-1  Using ACLs to Control Traffic to a Network

Host A

Host B

Catalyst 4500 series switch

Human
Resources
network

Research &
Development
network

× = ACL denying traffic from Host B
and permitting traffic from Host A

⇒ = Packet

Port ACLs

You can also apply ACLs to Layer 2 interfaces on a switch. Port ACLs are supported on physical interfaces and EtherChannel interfaces.

The following access lists are supported on Layer 2 interfaces:

- Standard IP access lists using source addresses
- Extended IP access lists using source and destination addresses and optional protocol type information
- IPv6 access lists using source and destination addresses and optional protocol type information
- MAC extended access lists using source and destination MAC addresses and optional protocol type information

As with router ACLs, the switch examines ACLs associated with features configured on a given interface and permits or denies packet forwarding based on how the packet matches the entries in the ACL. In the example in Figure 42-1, if all workstations were in the same VLAN, ACLs applied at the Layer 2 input would allow Host A to access the Human Resources network, but prevent Host B from accessing the same network.

When you apply a port ACL to a trunk port, the ACL filters traffic on all VLANs present on the trunk port. When you apply a port ACL to a port with voice VLAN, the ACL filters traffic on both data and voice VLANs.

With port ACLs, you can filter IPv4 traffic by using IPv4 access lists, IPv6 traffic by using IPv6 access lists, and non-IP traffic by using MAC access lists. You can filter IPv4, IPv6, and MAC access lists on the same Layer 2 interface by applying IPv4, IPv6, and MAC access lists to the interface.
Chapter 42 Configuring Network Security with ACLs

Hardware and Software ACL Support

You cannot apply more than one access list of a given type to a Layer 2 interface. If an access list of a given type is already configured on a Layer 2 interface and you apply a new access list of that type to the interface, the new ACL replaces the previously configured one.

VLAN Maps

VLAN maps can control the access of all traffic in a VLAN. You can apply VLAN maps on the switch to all packets that are routed into or out of a VLAN or are bridged within a VLAN. Unlike router ACLs, VLAN maps are not defined by direction (input or output).

You can configure VLAN maps to match Layer 3 addresses for IPv4 traffic. Access of all non-IPv4, non-IPv6 protocols is controlled with a MAC address and an Ethertype using MAC ACLs in VLAN maps. (IP traffic is not controlled by MAC ACLs in VLAN maps.) You can enforce VLAN maps only on packets going through the switch; you cannot enforce VLAN maps on traffic between hosts on a hub or on another switch connected to this switch.

With VLAN maps, forwarding packets is permitted or denied, based on the action specified in the map. Figure 42-2 illustrates how a VLAN map is applied to deny a specific type of traffic from Host A in VLAN 10 from being forwarded.

Hardware and Software ACL Support

This section describes how to determine whether ACLs are processed in hardware or in software:

- Flows that match a deny statement in standard and extended ACLs are dropped in hardware if ICMP unreachable messages are disabled.
- Flows that match a permit statement in standard ACLs are processed in hardware.
- The following ACL types are not supported in software:
  - Standard Xerox Network Systems (XNS) Protocol access list
  - Extended XNS access list
  - DECnet access list
  - Protocol type-code access list
  - Standard Internet Packet Exchange (IPX) access list
TCAM Programming and ACLs

You apply three types of hardware resources when you program ACLs and ACL-based features on the Supervisor Engine 7: mapping table entries (MTEs), profiles, and TCAM value/mask entries. If any of these resources are exhausted, packets are sent to the CPU for software-based processing.

Note
Supervisor Engine 7 automatically manages the available resources.

If you exhaust resources on the Supervisor Engine 7-E, you should try reducing the complexity of your configuration.

Note
When an interface is in down state, TCAMs are not consumed for RACLs, but are for PACLs.

Troubleshooting High CPU Due to ACLs

Packets that match entries in fully programmed ACLs are processed in hardware.

Packets that match entries in partially programmed ACLs are processed in software using the CPU. This may cause high CPU utilization and packets to be dropped. To determine whether packets are being dropped due to high CPU utilization, reference the following:

Selecting Mode of Capturing Control Packets

In some deployments, you might want to bridge control packets in hardware rather than globally capture and forward them in software (at the expense of the CPU). The per-VLAN capture mode feature allows a Catalyst 4500 series switch to capture control packets only on selected VLANs and bridge traffic in hardware on all other VLANs.

When you employ per-VLAN capture mode on your switch, it partially disables the global TCAM capture entries internally and attaches feature-specific capture ACLs on those VLANs that are enabled for snooping or routing features. (All IP capture entries, CGMP, and other non-IP entries are still captured through global TCAM.) Because this feature controls specific control packets, they are captured only on the VLANs on which the internal ACLs are installed. On all other VLANs, the control traffic is bridged in hardware rather than forwarded to CPU.

The per-VLAN capture mode allows you to apply user-defined ACLs and QoS policers (in hardware) on control packets. Furthermore, you can subject the aggregate control traffic ingressing the CPU to Control Plane Policing.

When you use per-VLAN capture mode, the following four protocol groups are selectable per VLAN. Observe the breakdown of protocols intercepted by each group.

- IGMP Snooping - Cgmp, Ospf, Igmp, RipV2, Pim, 224.0.0.1, 224.0.0.2, 224.0.0.*
- DHCP Snooping - Client to Server, Server to Client, Server to Server
- Unicast Routing - Ospf, Rip v2, 224.0.0.1, 224.0.0.2, 224.0.0.*
- Multicast Routing - Ospf, Rip v2, Igmp, Pim, 224.0.0.1, 224.0.0.2, 224.0.0.*

Because some of the groups have multiple overlapping ACEs (for example, 224.0.0.* is present in all the groups except for DHCP Snooping), turning on a certain group will also trigger the interception of some protocols from other groups.

Following are the programming triggers for the four protocol groups per VLAN:

- IGMP Snooping should be enabled globally on a given VLAN.
- DHCP Snooping should be enabled globally on a given VLAN.
- Unicast Routing should be enabled and SVI (or a Layer 3 physical) interface should be up and configured with an IP protocol address. This is because interfaces immediately become part of the routing process once the SVI interface comes up and the protocol family address is configured.
- Multicast Routing should be enabled and one of the multicast routing protocols should be configured on the interface (IGMP, PIMv1, PIMv2, MBGP, MOSPF, DVMRP, and IGMP snooping).

Caveats and Restriction

Before configuring per-VLAN capture mode, you should examine your configuration to ensure that only the necessary features are enabled on the desired VLANs.

The following caveats and restrictions apply to per-VLAN capture mode:

- Enabling per-VLAN capture mode consumes additional entries in the ACL/feature TCAM.
  The number of available TCAM entries depends on the type of supervisor engine. The entry/mask count further limits the utilization of the ACL/feature TCAM.
• Certain configurations can exhaust TCAM resource earlier in per-VLAN capture mode than in global capture mode (such as, IP Source Guard is enabled on several interfaces, or on a user configured PACL).

• In per-VLAN capture mode, you can configure ACLs to permit or deny control traffic on a VLAN or port.

Because security ACLs are terminated by an implicit deny, you must ensure that the ACLs are configured to permit the control packets necessary for the feature (protocol) to operate. However, this rule does not differ from the default behavior.

Configuration

To select the mode of capturing control packets, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# conf terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# [no] access-list hardware capture mode [vlan</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config)# end</td>
</tr>
</tbody>
</table>

This example shows how to configure a Catalyst 4500 series switch to capture control packets only on VLANs where features are enabled:

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# access-list hardware capture mode vlan
Switch(config)# end
Switch#

This example shows how to configure a Catalyst 4500 series switch to capture control packets globally across all VLANs (using static ACL, the default mode):

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# access-list hardware capture mode global
Switch(config)# end
Switch#

When the capture mode changes from global to VLAN, the static CAM entries are invalidated. This creates a window during which control packets may pass through a Catalyst 4500 series switch without being intercepted to the CPU. This temporary situation is restored when the new per-VLAN capture entries are programmed in the hardware.

When you configure per-VLAN capture mode, you should examine the show commands for individual features to verify the appropriate behavior. In per-VLAN capture mode, the invalidated static CAM entries will appear as inactive in the output of the show platform hardware acl input entries static command. For example, the hit count for inactive entries will remain frozen because those entries are invalidated and applied per VLAN where the feature is enabled:
Layer 4 Operators in ACLs

The following sections describe guidelines and restrictions for configuring ACLs that include Layer 4 port operations:

- Restrictions for Layer 4 Operations, page 42-9
- Configuration Guidelines for Layer 4 Operations, page 42-10
- How ACL Processing Impacts CPU, page 42-11

Restrictions for Layer 4 Operations

You can specify these operator types, each of which uses one Layer 4 operation in the hardware:

- `gt` (greater than)
- `lt` (less than)
- `neq` (not equal)
- `range` (inclusive range)

For Supervisor Engine 7-E, the limits on the number of Layer 4 operations differ for each type of ACL, and can also vary based on other factors: whether an ACL is applied to incoming or outgoing traffic, whether the ACL is a security ACL or is used as a match condition for a QoS policy, and whether IPv6 ACLs are being programmed using the compressed flowlabel format.

The IPv6 compressed flowlabel format uses the Layer 2 Address Table to compress a portion of the IPv6 source address of each ACE in the ACL. The extra space freed in the flowlabel can then be used to support more Layer 4 operations. For this compression to be used, the IPv6 ACL cannot contain any ACEs which mask in only a portion of the bottom 48 bits of the source IPv6 address.

Generally, you will receive at most the following number of Layer 4 operations on the same ACL:

<table>
<thead>
<tr>
<th>Direction</th>
<th>Protocol</th>
<th>Type</th>
<th>Operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Input</td>
<td>IPv4</td>
<td>Security</td>
<td>16</td>
</tr>
<tr>
<td>Input</td>
<td>IPv6 Compressed</td>
<td>Security</td>
<td>16</td>
</tr>
<tr>
<td>Input</td>
<td>IPv6 Uncompressed</td>
<td>Security</td>
<td>7</td>
</tr>
<tr>
<td>Input</td>
<td>IPv4</td>
<td>QoS</td>
<td>5</td>
</tr>
<tr>
<td>Input</td>
<td>IPv6 Compressed</td>
<td>QoS</td>
<td>12</td>
</tr>
<tr>
<td>Input</td>
<td>IPv6 Uncompressed</td>
<td>QoS</td>
<td>8</td>
</tr>
<tr>
<td>Output</td>
<td>IPv4</td>
<td>Security</td>
<td>17</td>
</tr>
</tbody>
</table>

Note: The IPv6 compressed flowlabel format uses the Layer 2 Address Table to compress a portion of the IPv6 source address of each ACE in the ACL. The extra space freed in the flowlabel can then be used to support more Layer 4 operations. For this compression to be used, the IPv6 ACL cannot contain any ACEs which mask in only a portion of the bottom 48 bits of the source IPv6 address.
Layer 4 Operators in ACLs

<table>
<thead>
<tr>
<th>Output</th>
<th>IPv6 Compressed</th>
<th>Security</th>
<th>17</th>
</tr>
</thead>
<tbody>
<tr>
<td>Output</td>
<td>IPv6 Uncompressed</td>
<td>Security</td>
<td>8</td>
</tr>
<tr>
<td>Output</td>
<td>IPv4</td>
<td>QoS</td>
<td>5</td>
</tr>
<tr>
<td>Output</td>
<td>IPv6 Compressed</td>
<td>QoS</td>
<td>12</td>
</tr>
<tr>
<td>Output</td>
<td>IPv6 Uncompressed</td>
<td>QoS</td>
<td>8</td>
</tr>
</tbody>
</table>

Note: Cases where up to 16 Operations are supported; the 17th will trigger an expansion.

If you exceed the number of available Layer 4 operations, each new operation might cause the affected ACE to be translated into multiple ACEs in the hardware. If this translation fails, packets are sent to the CPU for software processing.

Configuration Guidelines for Layer 4 Operations

Observe the following guidelines when using Layer 4 operators:

- Layer 4 operations are considered different if the operator or operand differ. For example, the following ACL contains three different Layer 4 operations because $gt\ 10$ and $gt\ 11$ are considered two different Layer 4 operations:

  ```
  ... \text{gt}\ 10\ \text{permit} \\
  ... \text{lt}\ 9\ \text{deny} \\
  ... \text{gt}\ 11\ \text{deny}
  ```

Note: The $eq$ operator can be used an unlimited number of times because $eq$ does not use a Layer 4 operation in hardware.

- Layer 4 operations are considered different if the same operator/operand couple applies once to a source port and once to a destination port, as in the following example:

  ```
  ... \text{Src}\ \text{gt}\ 10\ \text{....} \\
  ... \text{Dst}\ \text{gt}\ 10
  ```

A more detailed example follows:

```
access-list\ 101 \\
... \text{(dst port)}\ \text{gt}\ 10\ \text{permit} \\
... \text{(dst port)}\ \text{lt}\ 9\ \text{deny} \\
... \text{(dst port)}\ \text{gt}\ 11\ \text{deny} \\
... \text{(dst port)}\ \text{neq}\ 6\ \text{permit} \\
... \text{(src port)}\ \text{neq}\ 6\ \text{deny} \\
... \text{(dst port)}\ \text{gt}\ 10\ \text{deny}
```

```
access-list\ 102 \\
... \text{(dst port)}\ \text{gt}\ 20\ \text{deny} \\
... \text{(src port)}\ \text{lt}\ 9\ \text{deny} \\
... \text{(src port)}\ \text{range}\ 11\ 13\ \text{deny} \\
... \text{(dst port)}\ \text{neq}\ 6\ \text{permit}
```

Access lists 101 and 102 use the following Layer 4 operations:

- Access list 101 Layer 4 operations: 5
  - $gt\ 10\ \text{permit}$ and $gt\ 10\ \text{deny}$ both use the same operation because they are identical and both operate on the destination port.

- Access list 102 Layer 4 operations: 4
Layer 4 Operators in ACLs

- Total Layer 4 operations: 8 (due to sharing between the two access lists)
  - `neq 6 permit` is shared between the two ACLs because they are identical and both operate on the same destination port.
- A description of the Layer 4 operations usage is as follows:
  - Layer 4 operation 1 stores `gt 10 permit` and `gt 10 deny` from ACL 101
  - Layer 4 operation 2 stores `lt 9 deny` from ACL 101
  - Layer 4 operation 3 stores `gt 11 deny` from ACL 101
  - Layer 4 operation 4 stores `neg 6 permit` from ACL 101 and 102
  - Layer 4 operation 5 stores `neg 6 deny` from ACL 101
  - Layer 4 operation 6 stores `gt 20 deny` from ACL 102
  - Layer 4 operation 7 stores `lt 9 deny` from ACL 102
  - Layer 4 operation 8 stores `range 11 13 deny` from ACL 102

How ACL Processing Impacts CPU

ACL processing can impact the CPU in two ways:

- For some packets, when the hardware runs out of resources, the software must perform the ACL matches:
  - For Supervisor Engine 7-E, the TCP flag combinations "rst ack", "syn fin rst", "urg" and "psh" are processed in hardware. "rst ack" is equivalent to the keyword `established`. Other TCP flag combinations are supported in software.
  - For Supervisor Engine 7-E, refer to the “Restrictions for Layer 4 Operations” section on page 42-9.

Examples:

The following access lists are processed completely in hardware:

```
access-list 104 permit tcp any any established
access-list 105 permit tcp any any rst ack
access-list 107 permit tcp any synfin rst
```

Access lists 104 and 105 are identical; established is shorthand for `rst` and `ack`.

Access list 101, below, is processed completely in software:

```
access-list 101 permit tcp any any syn
```

Because four source and two destination operations exist, access list 106, below, is processed in hardware:

```
access-list 106 permit tcp any range 100 120 any range 120 140
access-list 106 permit tcp any range 140 160 any range 180 200
access-list 106 permit tcp any range 200 220
access-list 106 deny tcp any range 220 240
```

In the following code, the Layer 4 operations for the third ACE trigger an attempt to translate dst lt 1023 into multiple ACEs in hardware, because three source and three destination operations exist. If the translation attempt fails, the third ACE is processed in software.

```
access-list 102 permit tcp any lt 80 any gt 100
access-list 102 permit tcp any range 100 120 any range 120 1024
access-list 102 permit tcp any gt 1024 any lt 1023
```
Similarly, for access list 103, below, the third ACE triggers an attempt to translate dst gt 1023 into multiple ACEs in hardware. If the attempt fails, the third ACE is processed in software. Although the operations for source and destination ports look similar, they are considered different Layer 4 operations.)

access-list 103 permit tcp any lt 80 any lt 80
access-list 103 permit tcp any range 100 120 any range 100 120
access-list 103 permit tcp any gt 1024 any gt 1023

**Note**
Remember that source port lt 80 and destination port lt 80 are considered different operations.

- Some packets must be sent to the CPU for accounting purposes, but the action is still performed by the hardware. For example, if a packet must be logged, a copy is sent to the CPU for logging, but the forwarding (or dropping) is performed in the hardware. Although logging slows the CPU, it does not affect the forwarding rate. This sequence of events would happen under the following conditions:
  - When a log keyword is used
  - When an output ACL denies a packet
  - When an input ACL denies a packet, and on the interface where the ACL is applied, ip unreachable is enabled (ip unreachable is enabled by default on all the interfaces)

### Configuring Unicast MAC Address Filtering

To block all unicast traffic to or from a MAC address in a specified VLAN, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# mac-address-table static mac_address vlan vlan_ID drop</td>
<td>Blocks all traffic to or from the configured unicast MAC address in the specified VLAN. To clear MAC address-based blocking, use the no form of this command without the drop keyword.</td>
</tr>
</tbody>
</table>

This example shows how to block all unicast traffic to or from MAC address 0050.3e8d.6400 in VLAN 12:

Router# configure terminal
Router(config)# mac-address-table static 0050.3e8d.6400 vlan 12 drop

### Configuring Named MAC Extended ACLs

You can filter non-IPv4, non-IPv6 traffic on a VLAN and on a physical Layer 2 port by using MAC addresses and named MAC extended ACLs. The procedure is similar to that of configuring other extended named ACLs. You can use a number to name the access list, but MAC access list numbers from 700 to 799 are not supported.
Named MAC extended ACLs cannot be applied to Layer 3 interfaces.

For more information about the supported non-IP protocols in the `mac access-list extended` command, refer to the *Catalyst 4500 Series Switch Cisco IOS Command Reference*.

To create a named MAC extended ACL, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# [no] mac access-list extended name</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config-ext-macl)# (deny</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config-ext-macl)# end</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch# show access-lists [number</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Switch(config)# copy running-config startup-config</td>
</tr>
</tbody>
</table>

This example shows how to create and display an access list named `mac1`, denying only EtherType DECEnet Phase IV traffic, but permitting all other types of traffic:

```
Switch(config)# mac access-list extended mac1
Switch(config-ext-macl)# deny any any decnet-iv (old) protocol-family decnet (new)
Switch(config-ext-macl)# permit any any
Switch(config-ext-macl)# end
Switch# show access-lists
Extended MAC access list mac1
  deny any any decnet-iv (old) protocol-family decnet (new)
  permit any any
```

The following example shows how to enable or disable hardware statistics while configuring ACEs in the access list:

```
Switch# config t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# mac access-list extended mac1
Switch(config-ext-nacl)# hardware statistics
Switch(config-ext-nacl)# end
```
Configuring EtherType Matching

You can classify non-IPv4 and non-IPv6 traffic based on the EtherType value using the existing MAC access list commands. When you classify non-IPv4 and non-IPv6 traffic by EtherType, you can apply security ACLs and QoS policies to traffic that carry the same EtherType.

EtherType matching allows you to classify tagged and untagged IP packets based on the EtherType value. Tagged packets present a potential operation problem:

- While single-tagged packets are supported on the access and trunk ports, double-tagged packets are not.
- Single and double-tagged packets are not supported if the port mode is dot1qtunnel.

For more information about the `mac access-list extended` command, refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference.

To create a named MAC extended ACL, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# [no] mac access-list extended name</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config-ext-macl)# {deny</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config-ext-macl)# end</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch# show access-lists [number</td>
</tr>
<tr>
<td>Step 6</td>
<td>Switch(config)# copy running-config startup-config</td>
</tr>
</tbody>
</table>

This example shows how to create and display an access list named `matching`, permitting the 0x8863 and 0x8040 EtherType values:

```
Switch(config)# mac access-list extended matching
Switch(config-ext-macl)# permit any any 0x8863
Switch(config-ext-macl)# permit any any 0x8040
Switch(config-ext-macl)# end
Switch #
```
Configuring Named IPv6 ACLs

Supervisor 7-E also supports hardware-based IPv6 ACLs to filter unicast, multicast, and broadcast IPv6 traffic on a Layer 3 interface.

To create a named IPv6 ACLs, perform this task:

<table>
<thead>
<tr>
<th>Step</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>2</td>
<td>Switch(config)# ipv6 access-list name</td>
<td>Defines an IPv6 access list using a name. Use the no form of the command to delete the IPv6 ACL. You can also delete individual ACEs from IPv6 access-list.</td>
</tr>
<tr>
<td>3</td>
<td>Switch(config-ipv6-acl)# {deny</td>
<td>permit} {any</td>
</tr>
<tr>
<td>4</td>
<td>Switch(config-ipv6-acl)# hardware statistics</td>
<td>(Optional) Enables hardware statistics for the IPv6 ACL.</td>
</tr>
<tr>
<td>5</td>
<td>Switch(config-ipv6-acl)# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>6</td>
<td>Switch# show ipv6 access-list</td>
<td>Displays the IPv6 access list configuration.</td>
</tr>
</tbody>
</table>

The following example shows how to create and display an IPv6 access list named v6test, denying only one IPv6 traffic with one particular source/destination address, but permitting all other types of IPv6 traffic:

```
Switch(config)# ipv6 access-list v6test
Switch(config-ipv6-acl)# deny ipv6 host 2020::10 host 2040::10
Switch(config-ipv6-acl)# permit any any
Switch(config-ipv6-acl)# end
Switch# show ipv6 access-list
IPv6 access list v6test
  deny ipv6 host 2020::10 host 2040::10 sequence 10
  permit ipv6 any any sequence 20
```

To enable hardware statistics, enter the following commands while configuring ACEs in the access list:

```
Switch(config)# ipv6 access-list v6test
Switch(config-ipv6-acl)# hardware statistics
Switch(config-ipv6-acl)# end
```

**Note**: Hardware statistics is disabled by default.
Applying IPv6 ACLs to a Layer 2 Interface

To apply an IPv6 ACL to a Layer 2 interface, perform the following task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# interface interface-type slot/interface</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config-if)# ipv6 traffic-filter ipv6-acl (in</td>
</tr>
</tbody>
</table>

**Note**
IPv6 ACLs are supported on Layer 3 interfaces and on Layer 2 ports using the `ipv6 traffic-filter` command.

The following example applies the extended-named IPv6 ACL `simple-ipv6-acl` to SVI 300 routed ingress traffic:

Switch# configure terminal
Switch(config)# interface vlan 300
Switch(config-if)# ipv6 traffic-filter simple-ipv6-acl in

**Note**
Output IPv6 ACLs with Ace to match on the ICMP option fail on a switch.

The following conditions may cause a RACL to malfunction (There is no workaround.):

- ACL are applied on the output direction of the interface.
- IPv6 ACL contain Ace to match on the ICMP option fields (ICMP Type or ICMP Code).

Here are two examples of such non-functioning RACL:

IPv6 access list a1
  permit icmp any any nd-ns sequence 10
  deny ipv6 any any sequence 20

IPv6 access list a2
  permit icmp 2020::/96 any nd-ns sequence 10
  deny ipv6 any any sequence 20

Applying IPv6 ACLs to a Layer 3 Interface

To apply an IPv6 ACL to a Layer 3 interface, perform the following task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
</tbody>
</table>
### Configuring VLAN Maps

This section contains the following subsections:

- VLAN Map Configuration Guidelines, page 42-18
- Creating and Deleting VLAN Maps, page 42-19
- Applying a VLAN Map to a VLAN, page 42-21
- Using VLAN Maps in Your Network, page 42-22

This section describes how to configure VLAN maps, which is the only way to control filtering within a VLAN. VLAN maps have no direction. To filter traffic in a specific direction by using a VLAN map, you need to include an ACL with specific source or destination addresses. If there is a match clause for that type of packet (IP or MAC) in the VLAN map, the default action is to drop the packet if the packet does not match any of the entries within the map. If there is no match clause for that type of packet, the default is to forward the packet.
To create a VLAN map and apply it to one or more VLANs, perform this task:

**Step 1** Create the standard or extended IP ACLs or named MAC extended ACLs that you want to apply to the VLAN.

**Step 2** Enter the `vlan access-map` global configuration command to create a VLAN ACL map entry.

**Step 3** In access map configuration mode, you have the optional to enter an **action** (forward [the default] or drop) and enter the `match` command to specify an IP packet or a non-IP packet and to match the packet against one or more ACLs (standard or extended). If a match clause is not specified, the action is applied to all packets. The match clause can be used to match against multiple ACLs. If a packet matches any of the specified ACLs, the action is applied.

**Note** If the VLAN map has a match clause for the type of packet (IP or MAC) and the packet does not match the type, the default is to drop the packet. If there is no match clause in the VLAN map for that type of packet, and no action specified, the packet is forwarded.

**Step 4** Use the `vlan filter` global configuration command to apply a VLAN map to one or more VLANs.

**Note** You cannot apply a VLAN map to a VLAN on a switch that has ACLs applied to Layer 2 interfaces (port ACLs).

### VLAN Map Configuration Guidelines

Keep the following guidelines in mind when configuring VLAN maps:

- VLAN maps do not filter IPv4 ARP packets.
- VLAN maps do not filter IPv6 packets.
- If there is no router ACL configured to deny traffic on a routed VLAN interface (input or output), and no VLAN map configured, all traffic is permitted.
- Each VLAN map consists of a series of entries. The order of entries in a VLAN map is important. A packet that comes into the switch is tested against the first entry in the VLAN map. If it matches, the action specified for that part of the VLAN map is taken. If there is no match, the packet is tested against the next entry in the map.
- If the VLAN map has at least one match clause for the type of packet (IP or MAC) and the packet does not match any of these match clauses, the default is to drop the packet. If there is no match clause for that type of packet in the VLAN map, the default is to forward the packet.
- The system might take longer to boot if you have configured a very large number of ACLs.
Creating and Deleting VLAN Maps

Each VLAN map consists of an ordered series of entries. To create, add to, or delete a VLAN map entry, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# vlan access-map name [number]</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config-access-map)# action {drop</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config-access-map)# match {ip</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch(config-access-map)# end</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Switch(config)# show running-config</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>Switch(config)# copy running-config startup-config</td>
</tr>
</tbody>
</table>

You can use the `no vlan access-map name` global configuration command to delete a map. You can use the `no vlan access-map name number` global configuration command to delete a single sequence entry from within the map. You can use the `no action` access-map configuration command to enforce the default action, which is to forward.

VLAN maps do not use the specific `permit` or `deny` keywords. To deny a packet by using VLAN maps, create an ACL that would match the packet, and then set the action to drop. A permit in the ACL is the same as a match. A deny in the ACL means no match.

Examples of ACLs and VLAN Maps

These examples show how to create ACLs and VLAN maps in three different situations.

Example 1

This example shows how to create an ACL and a VLAN map to deny a packet. In the first map, any packets that match the ip1 ACL (TCP packets) would be dropped. You first create the ip1 ACL to permit any TCP packet and no other packets. Because there is a match clause for IP packets in the VLAN map, the default action is to drop any IP packet that does not match any of the match clauses.
Chapter 42  Configuring Network Security with ACLs

Configuring VLAN Maps

Example 2

In this example, the VLAN map is configured to drop IP packets and to forward MAC packets by default. By applying standard ACL 101 and the extended named access lists igmp-match and tcp-match, the VLAN map is configured to do the following:

- Forward all UDP packets
- Drop all IGMP packets
- Forward all TCP packets
- Drop all other IP packets
- Forward all non-IP packets

Example 3

In this example, the VLAN map is configured to drop MAC packets and forward IP packets by default. By applying MAC extended access lists, good-hosts and good-protocols, the VLAN map is configured to do the following:

- Forward MAC packets from hosts 0000.0c00.0111 and 0000.0c00.0211.
- Forward MAC packets of DECnet or VINES (Virtual Integrated Network Service) protocol-family.
Chapter 42 Configuring Network Security with ACLs

Configuring VLAN Maps

Example 4

In this example, the VLAN map is configured to drop all packets (IP and non-IP). By applying access lists tcp-match and good-hosts, the VLAN map is configured to do the following:

- Forward all TCP packets
- Forward MAC packets from hosts 0000.0c00.0111 and 0000.0c00.0211
- Drop all other IP packets
- Drop all other MAC packets

Applying a VLAN Map to a VLAN

To apply a VLAN map to one or more VLANs, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# vlan filter mapname vlan-list list</td>
</tr>
<tr>
<td></td>
<td>Applies the VLAN map to one or more VLAN IDs.</td>
</tr>
<tr>
<td></td>
<td>The list can be a single VLAN ID (22), a consecutive list (10-22), or a string of VLAN IDs (12, 22, 30). Spaces around comma, and dash, are optional.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config)# show running-config</td>
</tr>
<tr>
<td></td>
<td>Displays the access list configuration.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config)# copy running-config startup-config</td>
</tr>
<tr>
<td></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>
You cannot apply a VLAN map to a VLAN on a switch that has ACLs applied to Layer 2 interfaces (port ACLs).

This example shows how to apply VLAN map 1 to VLANs 20 through 22:

```
Switch(config)# vlan filter map 1 vlan-list 20-22
```

## Using VLAN Maps in Your Network

Figure 42-3 shows a typical wiring closet configuration. Host X and Host Y are in different VLANs, connected to wiring closet switches A and C. Traffic moving from Host X to Host Y is routed by Switch B. Access to traffic moving from Host X to Host Y can be controlled at the entry point of Switch A. In the following configuration, the switch can support a VLAN map and a QoS classification ACL.

**Figure 42-3 Wiring Closet Configuration**

For example, if you do not want HTTP traffic to be switched from Host X to Host Y, you could apply a VLAN map on Switch A to drop all HTTP traffic moving from Host X (IP address 10.1.1.32) to Host Y (IP address 10.1.1.34) at Switch A and not bridge the traffic to Switch B. To configure this scenario, you would do the following:

First, define an IP access list http to permit (match) any TCP traffic on the HTTP port, as follows:

```
Switch(config)# ip access-list extended http
Switch(config-ext-nacl)# permit tcp host 10.1.1.32 host 10.1.1.34 eq www
Switch(config-ext-nacl)# exit
```
Next, create a VLAN access map named map2 so that traffic that matches the http access list is dropped and all other IP traffic is forwarded, as follows:

```plaintext
Switch(config)# vlan access-map map2 10
Switch(config-access-map)# match ip address http
Switch(config-access-map)# action drop
Switch(config-access-map)# exit
```

```plaintext
Switch(config)# ip access-list extended match_all
Switch(config-ext-nacl)# permit ip any any
Switch(config-ext-nacl)# exit
Switch(config)# vlan access-map map2 20
Switch(config-access-map)# match ip address match_all
Switch(config-access-map)# action forward
```

Then, apply the VLAN access map named map2 to VLAN 1, as follows:

```plaintext
Switch(config)# vlan filter map2 vlan 1
```

### Denying Access to a Server on Another VLAN

Figure 42-4 shows how to restrict access to a server on another VLAN. In this example, server 10.1.1.100 in VLAN 10 has the following access restrictions:

- Hosts in subnet 10.1.2.0/8 in VLAN 20 should not have access.
- Hosts 10.1.1.4 and 10.1.1.8 in VLAN 10 should not have access.

This procedure configures ACLs with VLAN maps to deny access to a server on another VLAN. The VLAN map SERVER1_ACL denies access to hosts in subnet 10.1.2.0/8, host 10.1.1.4, and host 10.1.1.8. Then it permits all other IP traffic. In Step 3, VLAN map SERVER1 is applied to VLAN 10.

To configure this scenario, you could perform the following steps:

**Step 1** Define the IP ACL to match and permit the correct packets.

```plaintext
Switch(config)# ip access-list extended SERVER1_ACL
Switch(config-ext-nacl)# permit ip 10.1.2.0 0.0.0.255 host 10.1.1.100
Switch(config-ext-nacl)# permit ip host 10.1.1.4 host 10.1.1.100
Switch(config-ext-nacl)# permit ip host 10.1.1.8 host 10.1.1.100
Switch(config-ext-nacl)# exit
```
## Displaying VLAN Access Map Information

To display information about VLAN access maps or VLAN filters, perform one of these commands:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# <code>show vlan access-map [mapname]</code></td>
<td>Shows information about all VLAN access-maps or the specified access map.</td>
</tr>
<tr>
<td>Switch# <code>show vlan filter [access-map name / vlan vlan-id]</code></td>
<td>Shows information about all VLAN filters or about a specified VLAN or VLAN access map.</td>
</tr>
</tbody>
</table>

This is a sample output of the `show vlan access-map` command:

```
Switch# show vlan access-map
Vlan access-map 'map_1' 10
    Match clauses:
        ip address: ip1
    Action:
        drop
Vlan access-map 'map_1' 20
    Match clauses:
        mac address: mac1
    Action:
        forward
Vlan access-map 'map_1' 30
    Match clauses:
    Action:
        drop
```

### Note
Sequence 30 does not have a match clause. All packets (IP as well as non-IP) are matched against it and dropped.

This is a sample output of the `show vlan filter` command:

```
Switch# show vlan filter
VLAN Map map_1 is filtering VLANs:
    20-22
```
Using VLAN Maps with Router ACLs

If the VLAN map has a match clause for a packet type (IP or MAC) and the packet does not match the type, the default is to drop the packet. If there is no match clause in the VLAN map, and no action is specified, the packet is forwarded if it does not match any VLAN map entry.

Note

You cannot combine VLAN maps or input router ACLs with port ACLs on a switch.

Guidelines for Using Router ACLs and VLAN Maps on the Same VLAN

Because the switch hardware performs one lookup for each direction (input and output), you must merge a router ACL and a VLAN map when they are configured on the same VLAN. Merging the router ACL with the VLAN map can significantly increase the number of ACEs.

When possible, try to write the ACL so that all entries have a single action except for the final, default action. You should write the ACL using one of these two forms:

    permit...
    permit...
    permit...
    deny ip any any

or

    deny...
    deny...
    deny...
    permit ip any any

To define multiple permit or deny actions in an ACL, group each action type together to reduce the number of entries.

If you need to specify the full-flow mode and the ACL contains both IP ACEs and TCP/UDP/ICMP ACEs with Layer 4 information, put the Layer 4 ACEs at the end of the list. Doing this gives priority to the filtering of traffic based on IP addresses.

Examples of Router ACLs and VLAN Maps Applied to VLANs

These examples show how router ACLs and VLAN maps are applied on a VLAN to control the access of switched, bridged, routed, and multicast packets. Although the following illustrations show packets being forwarded to their destination, each time a packet crosses a line indicating a VLAN map or an ACL, the packet could be dropped rather than forwarded.

ACLs and Switched Packets

Figure 42-5 shows how an ACL processes packets that are switched within a VLAN. Packets switched within the VLAN are not processed by router ACLs.
Using VLAN Maps with Router ACLs

Figure 42-5 Applying ACLs on Switched Packets

ACLs and Routed Packets

Figure 42-6 shows how ACLs are applied on routed packets. For routed packets, the ACLs are applied in this order:

1. VLAN map for input VLAN
2. Input router ACL
3. Output router ACL
4. VLAN map for output VLAN
Configuring PACLs

This section describes how to configure PACLs, which are used to control filtering on Layer 2 interfaces. PACLs can filter traffic to or from Layer 2 interfaces based on Layer 3 information, Layer 4 head information or non-IP Layer 2 information.

This section contains the following topics:

- Creating a PACL, page 42-27
- PACL Configuration Guidelines, page 42-28
- Configuring IPv6, IP, and MAC ACLs on a Layer 2 Interface, page 42-28
- Using PACL with Access-Group Mode, page 42-29
- Configuring Access-group Mode on Layer 2 Interface, page 42-30
- Applying ACLs to a Layer 2 Interface, page 42-30
- Displaying an ACL Configuration on a Layer 2 Interface, page 42-31

Creating a PACL

To create a PACL and apply it to one or more interfaces, perform this task:

**Step 1** Create the standard or extended IPv4 ACLs, named IPv6 ACLs, or named MAC extended ACLs that you want to apply to the interface.

**Step 2** Use the `ip access-group ipv6 traffic-filter` or `mac access-group interface` command to apply an IPv4 ACL, IPv6 ACL, or MAC ACL to one or more Layer 2 interfaces.
PACL Configuration Guidelines

Consider the following guidelines when configuring PACLS:

- There can be at most one IPv4 access list, one IPv6 access list, and one MAC access list applied to the same Layer 2 interface per direction.
- The IPv4 access list filters only IPv4 packets; the IPv6 access list filters only IPv6 packets, and the MAC access list filters only non-IPv4, non-IPv6 packets.
- The number of ACLs and ACEs that can be configured as part of a PACL are bounded by the hardware resources on the switch. Those hardware resources are shared by various ACL features (for example, RACL, VACL) that are configured on the system. If there are insufficient hardware resources to program PACL in hardware, the actions for input and output PACLs differ:
  - For input PACLs, some packets are sent to CPU for software forwarding.
  - For output PACLs, the PACL is disabled on the port.
- These restrictions pertain to output PACLs only:
  - If there are insufficient hardware resources to program the PACL, the output PACL is not applied to the port, and you receive a warning message.
  - If an output PACL is configured on a Layer 2 port, then neither a VACL nor a Router ACL can be configured on the VLANs to which the Layer 2 port belongs.
    If any VACL or Router ACL is configured on the VLANs to which the Layer 2 port belongs, the output PACL cannot be configured on the Layer 2 port. That is, PACLs and VLAN-based ACLs (VACL and Router ACL) are mutually exclusive on Layer 2 ports.
- The input IP ACL logging option is supported, although logging is not supported for output IP ACLs, and MAC ACLs.
- The access group mode can change the way PACLs interact with other ACLs. To maintain consistent behavior across Cisco platforms, use the default access group mode.

Configuring IPv6, IP, and MAC ACLs on a Layer 2 Interface

Only IPv4, IPv6, and MAC ACLs can be applied to Layer 2 physical interfaces. Standard (numbered, named) and Extended (numbered, named) IP ACLs, Named IPv6 ACLs and Extended Named MAC ACLs are also supported.

To apply IPv6 ACLs on a Layer 2 interface, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Switch(config)# interface interface</td>
<td>Enters interface config mode.</td>
</tr>
<tr>
<td>Switch(config-if)# [no] ipv6 traffic-filter ipv6AclName [in</td>
<td>out]</td>
</tr>
<tr>
<td>Switch(config)# show running-config</td>
<td>Displays the access list configuration.</td>
</tr>
</tbody>
</table>

The following example shows how to apply IPv6 ACLs on interface Gi3/1:

```
Switch(config)# interface Gi3/1
Switch(config-if)# ipv6 traffic-filter ipv6AclName in
Switch(config-if)# end
```
To apply IP or MAC ACLs on a Layer 2 interface, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# interface interface</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config-if)# [no] {ip</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config)# show running-config</td>
</tr>
</tbody>
</table>

The following example shows how to configure the Extended Named IP ACL simple-ip-acl to permit all TCP traffic and implicitly deny all other IP traffic:

Switch(config)# interface Gi3/1
Switch(config-if)# ip access-list extended simple-ip-acl
Switch(config-ext-nacl)# permit tcp any any
Switch(config-ext-nacl)# end

The following example shows how to configure the Extended Named MACL simple-mac-acl to permit source host 000.000.011 to any destination host:

Switch(config)# interface Gi3/1
Switch(config-if)# mac access-list extended simple-mac-acl
Switch(config-ext-macl)# permit host 000.000.011 any
Switch(config-ext-macl)# end

### Using PACL with Access-Group Mode

You can use the access group mode to change the way PACLs interact with other ACLs. For example, if a Layer 2 interface belongs to VLAN100, VACL (VLAN filter) V1 is applied on VLAN100, and PACL P1 is applied on the Layer 2 interface. In this situation, you must specify how P1 and V1 impact the traffic with the Layer 2 interface on VLAN100. In a per-interface fashion, the **access-group mode** command can be used to specify one of the desired behaviors that are defined below.

The following modes are defined:

- **prefer port mode**— If PACL is configured on a Layer 2 interface, then PACL takes effect and overwrites the effect of other ACLs (Router ACL and VACL). If no PACL feature is configured on the Layer 2 interface, other features applicable to the interface are merged and applied on the interface. This is the default access group mode.

- **prefer vlan mode**— VLAN-based ACL features take effect on the port provided they have been applied on the port and no PACLs are in effect. If no VLAN-based ACL features are applicable to the Layer 2 interface, then the PACL feature already on the interface is applied.

- **merge mode**— Merges applicable ACL features before they are programmed into the hardware.

### Note

Because output PACLs are mutually exclusive with VACL and Router ACLs, the access group mode does not change the behavior of output traffic filtering.
Configuring Access-group Mode on Layer 2 Interface

To configure an access mode on a Layer 2 interface, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# interface interface</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config-if)# [no] access-group mode (prefer {port</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config)# show running-config</td>
</tr>
</tbody>
</table>

This example shows how to merge and apply features other than PACL on the interface:

Switch# configure terminal
Switch(config)# interface fast 6/1
Switch(config-if)# access-group mode prefer port

This example shows how to merge applicable ACL features before they are programmed into hardware:

Switch# configure terminal
Switch(config)# interface fast 6/1
Switch(config-if)# access-group mode merge

Applying ACLs to a Layer 2 Interface

To apply IP and MAC ACLs to a Layer 2 interface, perform one of these tasks:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config-if)# ip access-group ip-acl {in</td>
<td>out}</td>
</tr>
<tr>
<td>Switch(config-if)# mac access-group mac-acl {in</td>
<td>out}</td>
</tr>
</tbody>
</table>

**Note**

Supervisor Engines III and Supervisor Engine IV running on a Catalyst 4500 series switch support both input and output PACLs on an interface.

This example applies the extended named IP ACL simple-ip-acl to interface FastEthernet 6/1 ingress traffic:

Switch# configure terminal
Switch(config)# interface fast 6/1
Switch(config-if)# ip access-group simple-ip-acl in

This example applies the extended named MAC ACL simple-mac-acl to interface FastEthernet 6/1 egress traffic:

Switch# configure terminal
Switch(config)# interface fast 6/1
Switch(config-if)# mac access-group simple-mac-acl out
Displaying an ACL Configuration on a Layer 2 Interface

To display information about an ACL configuration on Layer 2 interfaces, perform one of these tasks:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Switch# show ip interface [interface-name]</code></td>
<td>Shows the IP access group configuration on the interface.</td>
</tr>
<tr>
<td><code>Switch# show mac access-group interface [interface-name]</code></td>
<td>Shows the MAC access group configuration on the interface.</td>
</tr>
<tr>
<td><code>Switch# show access-group mode interface [interface-name]</code></td>
<td>Shows the access group mode configuration on the interface.</td>
</tr>
</tbody>
</table>

This example shows that the IP access group `simple-ip-acl` is configured on the inbound direction of interface fa6/1:

```
Switch# show ip interface fast 6/1
FastEthernet6/1 is up, line protocol is up
  Inbound access list is simple-ip-acl
  Outgoing access list is not set
```

This example shows that MAC access group `simple-mac-acl` is configured on the inbound direction of interface fa6/1:

```
Switch# show mac access-group interface fast 6/1
Interface FastEthernet6/1:
  Inbound access-list is simple-mac-acl
  Outbound access-list is not set
```

This example shows that access group `merge` is configured on interface fa6/1:

```
Switch# show access-group mode interface fast 6/1
Interface FastEthernet6/1:
  Access group mode is: merge
```

Using PACL with VLAN Maps and Router ACLs

For output PACLs, there is no interaction with VACL or output Router ACLs. (See the restrictions listed in the “PACL Configuration Guidelines” section on page 42-28.) For input PACLs, however, the interaction with Router ACLs and VACLs depends on the interface access group mode as shown in Table 42-1.

<table>
<thead>
<tr>
<th>Table 42-1 Interaction Between PACLs, VACLs and Router ACLs</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ACL Type(s)</strong></td>
</tr>
<tr>
<td>1. Input Router ACL</td>
</tr>
<tr>
<td>2. VACL</td>
</tr>
<tr>
<td>3. VACL + Input Router ACL</td>
</tr>
</tbody>
</table>
Each ACL Type listed in Table 42-1 is synonymous with a different scenario, as explained in the following discussion.

Scenario 1: Host A is connected to an interface in VLAN 20, which has an SVI configured. The interface has input PACL configured, and the SVI has input Router ACL configured as shown in Figure 42-7:

**Figure 42-7 Scenario 1: PACL Interaction with an Input Router ACL**

![Diagram: PACL Interaction with an Input Router ACL](image)

If the interface access group mode is prefer port, then only the input PACL is applied on the ingress traffic from Host A. If the mode is prefer vlan, then only the input Router ACL is applied to ingress traffic from Host A that requires routing. If the mode is merge, then the input PACL is first applied to the ingress traffic from Host A, and the input Router ACL is applied on the traffic that requires routing.

Scenario 2: Host A is connected to an interface in VLAN 10, which has a VACL (VLAN Map) configured and an input PACL configured as shown in Figure 42-8.
If the interface access group mode is prefer port, then only the input PACL is applied on the ingress traffic from Host A. If the mode is prefer vlan, then only the VACL is applied to the ingress traffic from Host A. If the mode is merge, the input PACL is first applied to the ingress traffic from Host A, and the VACL is applied on the traffic.

Scenario 3: Host A is connected to an interface in VLAN 10, which has a VACL and an SVI configured. The SVI has an input Router ACL configured and the interface has an input PACL configured, as shown in Figure 42-9.
If the interface access group mode is prefer port, then only the input PACL is applied on the ingress traffic from Host A. If the mode is prefer vlan, then the merged results of the VACL and the input Router ACL are applied to the ingress traffic from Host A. If the mode is merge, the input PACL is first applied to the ingress traffic from Host A, the VACL is applied on the traffic and finally, and the input Router ACL is applied to the traffic that needs routing. (that is, the merged results of the input PACL, VACL, and input Router ACL are applied to the traffic).
Support for IPv6

This chapter lists the IP version 6 (IPv6) features supported on the Catalyst 4500 series switches. The IPv6 for Cisco IOS software feature documentation provides implementation and command reference information for IPv6 features supported in the Cisco IOS software. Not all IPv6 features are supported on the Catalyst 4500 series switches. We strongly recommend that you read this entire chapter before reading the other IPv6 for Cisco IOS software feature documentation.

Finding Feature Information

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to http://tools.cisco.com/ITDIT/CFN/. An account on Cisco.com is not required.

The Cisco IOS IPv6 Configuration Guide is located at the following website:

The Cisco IOS IPv6 Command Reference is located at the following website:

Note

For complete syntax and usage information for the commands used in this chapter, see the Cisco IOS documentation referenced in the procedures.

This chapter consists of these sections:

- About IPv6, page 43-1
- IPv6 Default States, page 43-7

About IPv6

IPv6 provides services such as end-to-end security, quality of service (QoS), and globally unique addresses. The IPv6 address space reduces the need for private addresses and Network Address Translation (NAT) processing by border routers at network edges.

For information about how Cisco Systems implements IPv6, go to this URL:

This section describes the features that are supported for IPv6:
About IPv6

- IPv6 Addressing and Basic Connectivity, page 43-2
- DHCP, page 43-3
- Security, page 43-3
- QoS, page 43-3
- Management, page 43-4
- Multicast, page 43-4
- Static Routes, page 43-4
- First-Hop Redundancy Protocols, page 43-5
- Unicast Routing, page 43-5
- Tunneling, page 43-6

**IPv6 Addressing and Basic Connectivity**

The switch supports only IPv6 unicast addresses. It does not support site-local unicast addresses or multicast addresses.

The IPv6 128-bit addresses are represented as a series of eight 16-bit hexadecimal fields separated by colons in the format: \[n:n:n:n:n:n:n:n\]. It is an example of an IPv6 address:

\[2031:0000:130F:0000:0000:09C0:080F:130B\]

The leading zeros in each field are optional, implementation is easier without them. It is the same address without leading zeros:

\[2031:0:130F:0:0:9C0:80F:130B\]

You can also use two colons (\[::\]) to represent successive hexadecimal fields of zeros, but you can use this short version only once in each address:

\[2031:0:130F::09C0:080F:130B\]

The switch supports the following features:

- IPv6 address types: Anycast
- IPv6 default router preferences
- IPv6 MTU path discovery
- Neighbor discovery duplicate address detection
- Cisco Discovery Protocol — IPv6 address family support for neighbor information
- ICMPv6 redirect
- ICMP rate limiting
- DNS lookups over an IPv6 transport
- uRPF
- ICMPv6
- AAAA DNS lookups over an IPv4 transport

You can find information about these features at this location:

DHCP

The following DHCP features are supported for IPv6 on the Catalyst 4500 series switch:

- Relay agent
- Relay agent notification for prefix delegation
- Reload persistent interface ID option
- Ethernet remote ID option

You can find information about these features at this location:

Security

The following security features are supported for IPv6 on the Catalyst 4500 series switch:

- Secure Shell (SSH) support over IPv6
- Traffic filters
- standard access control lists (ACL)
- extended access control lists
- ACL accounting
- ACL addressing
- ACL DSCP
- ACL flags
- ACL flows
- ACL fragments
- ACL ICMP codes
- ACL logging
- ACL protocols

You can find information about these features at this location:

QoS

The following QoS features are supported for IPv6 on the Catalyst 4500 series switch:

- MQC packet classification
- MQC traffic shaping and sharing
- MQC traffic policing
- MQC packing marking and remarking

You can find information about these features at this location:
Management

The following management features are supported for IPv6 on the Catalyst 4500 series switch:

- Ping
- Syslog
- SNMP
- HTTP(s)

You can find information about these features at this location:

Multicast

Traditional IP communication allows a host to send packets to a single host (unicast transmission) or to all hosts (broadcast transmission). IPv6 multicast, allows a host to send a single data stream to a subset of all hosts (group transmission) simultaneously.

The following multicast features are supported for IPv6 on the Catalyst 4500 series switch:

- Multicast Listener Discovery (MLD) protocol, versions 1 and 2
  You can find information about IPv6 MLD Snooping at this location:
- PIM Sparse Mode (PIM-SM) (EntServices only)
- PIM Source Specific Multicast (PIM-SSM)
- MLD access group
- PIM embedded Rendezvous Point (RP) support
- Static multicast routing (mroute)
- Bootstrap routers (BSR)
- MLD snooping (EntServices and IP Base)

You can find information about these features at this location:

Static Routes

Networking devices forward packets using route information that is either manually configured or dynamically learned using a routing protocol. Static routes are manually configured and define an explicit path between two networking devices. Unlike a dynamic routing protocol, static routes are not automatically updated and must be manually reconfigured if the network topology changes. The benefits of using static routes include security and resource efficiency. Static routes use less bandwidth than dynamic routing protocols and no CPU cycles are used to calculate and communicate routes. The main disadvantage to using static routes is the lack of automatic reconfiguration if the network topology changes.
Static routes can be redistributed into dynamic routing protocols but routes generated by dynamic routing protocols cannot be redistributed into the static routing table. No algorithm exists to prevent the configuration of routing loops that use static routes.

Static routes are useful for smaller networks with only one path to an outside network and to provide security for a larger network for certain types of traffic or links to other networks that need more control. In general, most networks use dynamic routing protocols to communicate between networking devices but may have one or two static routes configured for special cases.

You can find more information regarding static routes at:

First-Hop Redundancy Protocols

IPv6 routing protocols ensure router-to-router resilience and failover. However, in situations in which the path between a host and the first-hop router fails, or the first-hop router itself fails, First-Hop Redundancy Protocols (FHRPs) ensure host-to-router resilience and failover.

The Hot Standby Router Protocol (HSRP) protects data traffic in case of a gateway failure.

You can find more information about First-Hop Redundancy Protocols at:

Unicast Routing

These sections describe the IPv6 unicast routing protocol features supported by the switch:

- RIP, page 43-5
- OSPF, page 43-5
- EIGRP, page 43-6
- Multiprotocol BGP, page 43-6

RIP

Routing Information Protocol (RIP) for IPv6 is a distance-vector protocol that uses hop count as a routing metric. It includes support for IPv6 addresses and prefixes and the all-RIP routers multicast group address FF02::9 as the destination address for RIP update messages.

You can find more about RIP at this location:

OSPF

The switch running the IP services feature set supports Open Shortest Path First (OSPF) for IPv6, a link-state protocol for IP.

You can find more information about OSPF at this location:
Chapter 43      Support for IPv6

About IPv6

EIGRP

The switch running the IP-services feature set supports Enhanced Interior Gateway Routing Protocol (EIGRP) for IPv6. It is configured on the interfaces on which it runs and does not require a global IPv6 address.

Before running, an instance of EIGRP IPv6 requires an implicit or explicit router ID. An implicit router ID is derived from a local IPv4 address, so any IPv4 node always has an available router ID. However, EIGRP IPv6 might be running in a network with only IPv6 nodes and therefore might not have an available IPv4 router ID.

You can find more information about EIGRP at this location:

Multiprotocol BGP

Multiprotocol Border Gateway Protocol (BGP) is an Exterior Gateway Protocol (EGP) used mainly to connect separate routing domains that contain independent routing policies (autonomous systems). Connecting to a service provider for access to the Internet is a common use for BGP. BGP can also be used within an autonomous system, which is referred to as internal BGP (iBGP). Multiprotocol BGP is an enhanced BGP that carries routing information for multiple network layer protocol address families, for example, IPv6 address family and for IP multicast routes. All BGP commands and routing policy capabilities can be used with multiprotocol BGP.

You can find more information about multiprotocol BGP at this location:

Tunneling

The following tunneling features are supported for IPv6 on the Catalyst 4500 series switch:

- Automatic 6to4
- ISATAP
- Configured tunnels

Note: Tunneling is not supported in hardware but is supported in software.

You can find information about these features at this location:
IPv6 Default States

Table 43-1 shows the default states of IPv6 configuration.

<table>
<thead>
<tr>

Port Unicast and Multicast Flood Blocking

This chapter describes how to configure multicast and unicast flood blocking on the Catalyst 4000 family switch. This chapter contains these topics:

- About Flood Blocking, page 44-1
- Configuring Port Blocking, page 44-1

**Note**
For complete syntax and usage information for the switch commands used in this chapter, look at the *Cisco Catalyst 4500 Series Switch Command Reference* and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the *Catalyst 4500 Series Switch Cisco IOS Command Reference* and related publications at this location:

**About Flood Blocking**

Occasionally, unknown unicast or multicast traffic is flooded to a switch port because a MAC address has timed out or has not been learned by the switch. (This condition is especially undesirable for a private VLAN isolated port.) To guarantee that no unicast and multicast traffic is flooded to the port, use the `switchport block unicast` and `switchport block multicast` commands to enable flood blocking on the switch.

**Note**
The flood blocking feature is supported on all switched ports (including PVLAN ports) and is applied to all VLANs on which the port is forwarding.

**Configuring Port Blocking**

By default, a switch floods packets with unknown destination MAC addresses to all ports. If unknown unicast and multicast traffic is forwarded to a switch port, there might be security issues. To prevent forwarding such traffic, you can configure a port to block unknown unicast or multicast packets.
Configuring Port Blocking

Note
Blocking of unicast or multicast traffic is not automatically enabled on a switch port; you must explicitly configure it.

Chapter 44  Port Unicast and Multicast Flood Blocking

Blocking Flooded Traffic on an Interface

Note
The interface can be a physical interface (for example, GigabitEthernet 1/1) or an EtherChannel group (such as port-channel 5). When you block multicast or unicast traffic for a port channel, it is blocked on all ports in the port channel group.

Note
Starting with Cisco IOS Release 12.2(52)SG, only IPV4 and IPv6 unknown multicast traffic flooding is blocked; Layer 2 unknown multicast flooding is not. This behavior stems from a fix for the following problem: when you configure blocking of unknown multicast flooding on a port, broadcast traffic to the port is also blocked.

To disable the flooding of multicast and unicast packets to an interface, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# interface interface-id</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config-if)# switchport block multicast</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config-if)# switchport block unicast</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td>Step 6</td>
<td>Switch# show interface interface-id switchport</td>
</tr>
<tr>
<td>Step 7</td>
<td>Switch# copy running-config startup-config</td>
</tr>
</tbody>
</table>

This example shows how to block unicast and multicast flooding on a GigabitEthernet interface 1/1 and how to verify the configuration:

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface gigabitethernet1/1
Switch(config-if)# switchport block multicast
Switch(config-if)# switchport block unicast
Switch(config-if)# end
Switch# show interface gigabitethernet1/1 switchport
Name: Gi1/3
Switchport: Enabled

<output truncated>
Port Protected: On
Unknown Unicast Traffic: Not Allowed
Unknown Multicast Traffic: Not Allowed

Broadcast Suppression Level: 100
Multicast Suppression Level: 100
Unicast Suppression Level: 100

Resuming Normal Forwarding on a Port

To resume normal forwarding on a port, perform this task:

<table>
<thead>
<tr>
<th>Step</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# interface interface-id</td>
<td>Enters interface configuration mode and enter the type and number of the switchport interface (GigabitEthernet1/1).</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config-if)# no switchport block multicast</td>
<td>Enables unknown multicast flooding to the port.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config-if)# no switchport block unicast</td>
<td>Enables unknown unicast flooding to the port.</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch(config)# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Step 6</td>
<td>Switch# show interface interface-id switchport</td>
<td>Verifies your entry.</td>
</tr>
<tr>
<td>Step 7</td>
<td>Switch# copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>
Configuring Storm Control

This chapter describes how to configure port-based traffic control on the Catalyst 4500 series switch. This chapter consists of these sections:

- **About Storm Control**, page 45-1
- **Enabling Broadcast Storm Control**, page 45-3
- **Enabling Multicast Storm Control**, page 45-4
- **Disabling Broadcast Storm Control**, page 45-5
- **Disabling Multicast Storm Control**, page 45-6
- **Displaying Storm Control**, page 45-6

---

**Note**

For complete syntax and usage information for the switch commands used in this chapter, look at the *Cisco Catalyst 4500 Series Switch Command Reference* and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the *Catalyst 4500 Series Switch Cisco IOS Command Reference* and related publications at this location:

**About Storm Control**

This section contains the following subsections:

- **Hardware-based Storm Control Implementation**, page 45-2
- **Software-based Storm Control Implementation**, page 45-2

Storm control prevents LAN interfaces from being disrupted by a broadcast storm. A broadcast storm occurs when broadcast packets flood the subnet, creating excessive traffic and degrading network performance. Errors in the protocol-stack implementation or in the network configuration can cause a broadcast storm.
Chapter 45      Configuring Storm Control

About Storm Control

Note

Storm control and Multicast storm control are supported in hardware on all ports on Supervisor Engine 7-E.

Hardware-based Storm Control Implementation

Broadcast suppression uses filtering that measures broadcast activity in a subnet over a one-second interval and compares the measurement with a predefined threshold. If the threshold is reached, further broadcast activity is suppressed for the duration of the interval. Broadcast suppression is disabled by default.

Figure 45-1 shows the broadcast traffic patterns on a LAN interface over a given interval. In this example, broadcast suppression occurs between times T1 and T2 and between T4 and T5. During those intervals, the amount of broadcast traffic exceeded the configured threshold.

Figure 45-1 Storm Control Example - Hardware-based Implementation

The broadcast suppression threshold numbers and the time interval combination make the broadcast suppression algorithm work with different levels of granularity. A higher threshold allows more broadcast packets to pass through.

Broadcast suppression on the Catalyst 4500 series switches (including Supervisor Engine 7-E) is implemented in hardware. The suppression circuitry monitors packets passing from a LAN interface to the switching bus. If the packet destination address is broadcast, then the broadcast suppression circuitry tracks the current count of broadcasts within the one-second interval, and when a threshold is reached, it filters out subsequent broadcast packets.

Because hardware broadcast suppression uses a bandwidth-based method to measure broadcast activity, the most significant implementation factor is setting the percentage of total available bandwidth that can be used by broadcast traffic. Because packets do not arrive at uniform intervals, the one-second interval during which broadcast activity is measured can affect the behavior of broadcast suppression.

Software-based Storm Control Implementation

When storm control is enabled on an interface, the switch monitors packets received on the interface and determines whether the packets are broadcast. The switch monitors the number of broadcast packets received within a one-second time interval. When the interface threshold is met, all incoming data traffic
on the interface is dropped. This threshold is specified as a percentage of total available bandwidth that can be used by broadcast traffic. If the lower threshold is specified, all data traffic is forwarded as soon as the incoming traffic falls below that threshold.

## Enabling Broadcast Storm Control

To enable storm control, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# interface interface-id</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config-if)# storm-control broadcast level [high level] [lower level]</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config-if)# storm-control action {shutdown</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch(config-if)# exit</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>Switch# show storm-control [interface] broadcast</td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>Switch# copy running-config startup-config</td>
</tr>
</tbody>
</table>

The following example shows how to enable storm control on interface.

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fa3/1
Switch(config-if)# storm-control broadcast level 50
Switch(config-if)# end

Switch# show storm-control
Interface  Filter  State  Broadcast  Multicast  Level
----------  -------  ------  ----------  ---------  ----
Fa3/1      Forwarding  Enabled  Disabled  50.00%

Switch# show int fa2/1 capabilities
FastEthernet2/1
  Model: WS-X4148-RJ45V-RJ-45
Enabling Multicast Storm Control

Supervisor Engine 7-E supports per-interface multicast suppression.

This allows the user to subject incoming multicast and broadcast traffic on an interface to suppression.

Note
Multicast and broadcast suppression share a common threshold per interface. Multicast suppression takes effect only if broadcast suppression is enabled. Disabling broadcast suppression on an interface also disables multicast suppression.

To enable multicast suppression, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# interface interface-id</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config-if)# storm-control broadcast include multicast</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config-if)# exit</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td>Step 6</td>
<td>Switch# show storm-control</td>
</tr>
</tbody>
</table>
The following example shows how to enable multicast suppression on ports that have broadcast suppression already enabled:

Switch# configure terminal  
Enter configuration commands, one per line. End with CNTRL/Z.  
Switch(config)# int fa3/1  
Switch(config-if)# storm-control broadcast include multicast  
Switch(config-if)# end  
Switch#  
Switch# show storm-control  

<table>
<thead>
<tr>
<th>Interface</th>
<th>Filter</th>
<th>State</th>
<th>Broadcast</th>
<th>Multicast</th>
<th>Level</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fa3/1</td>
<td>Forwarding</td>
<td>Enabled</td>
<td>Enabled</td>
<td>Enabled</td>
<td>50.00%</td>
</tr>
</tbody>
</table>

Disabling Broadcast Storm Control

To disable storm control, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 2 Switch(config)# interface interface-id</td>
<td>Enters interface configuration mode and enter the port to configure.</td>
</tr>
<tr>
<td>Step 3 Switch(config-if)# no storm-control broadcast level</td>
<td>Disables port storm control.</td>
</tr>
<tr>
<td>Step 4 Switch(config-if)# no storm-control action {shutdown</td>
<td>trap}]</td>
</tr>
<tr>
<td>Step 5 Switch(config-if)# exit</td>
<td>Returns to configuration mode.</td>
</tr>
<tr>
<td>Step 6 Switch(config)# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Step 7 Switch# show storm-control broadcast</td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td>Step 8 Switch# copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

The following example shows how to disable storm control on interface.

Switch# configure terminal  
Enter configuration commands, one per line. End with CNTRL/Z.  
Switch(config)# int fa3/1  
Switch(config-if)# no storm-control broadcast level  
Switch(config-if)# end
Disabling Multicast Storm Control

To disable multicast suppression, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong> Switch(config)# [no] storm-control broadcast include multicast</td>
<td>Enables/disables multicast suppression.</td>
</tr>
<tr>
<td><strong>Step 3</strong> Switch(config-if)# no storm-control broadcast level</td>
<td>Disables port storm control (broadcast and multicast).</td>
</tr>
<tr>
<td><strong>Step 4</strong> Switch(config-if)# end</td>
<td>Returns to configuration mode.</td>
</tr>
<tr>
<td><strong>Step 5</strong> Switch(config)# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
</tbody>
</table>

Displaying Storm Control

**Note**

Use the `show interface capabilities` command to determine the mode in which storm control is supported on an interface.

The following example shows an interface that supports broadcast suppression in software (sw).

```
Switch# show int fa2/1 capabilities
FastEthernet2/1
    Model: WS-X4148-RJ45V-RJ-45
    Type: 10/100BaseTX
    Speed: 10,100,auto
    Duplex: half,full,auto
    Auto-MDIX: no
    Trunk encap. type: 802.1Q
    Trunk mode: on,off,desirable,negotiate
    Channel: yes
    Broadcast suppression: percentage(0-100), hw
    Multicast suppression: percentage(0-100), hw
    Flowcontrol: rx-(none), tx-(none)
    VLAN Membership: static, dynamic
    Fast Start: yes
    CoS rewrite: yes
    ToS rewrite: yes
    Inline power: yes (Cisco Voice Protocol)
    SPAN: source/destination
    UDLL: yes
    Link Debounce: no
    Link Debounce Time: no
    Port Security: yes
    Dotlx: yes
    Maximum MTU: 1552 bytes (Baby Giants)
    Multiple Media Types: no
    Diagnostic Monitoring: N/A
```
### Chapter 45: Configuring Storm Control

#### Displaying Storm Control

**Note**

Use the `show interfaces counters storm-control` command to display a count of discarded packets.

```
Switch# show interfaces counters storm-control
Port | Broadcast | Multicast | Level    | TotalSuppressedPackets
-----|-----------|-----------|----------|------------------------
Fa2/1| Enabled   | Disabled  | 10.00%   | 46516510               
Gi3/1| Enabled   | Enabled   | 50.00%   | 0                      
```

The following example shows the output of the `show storm-control` command:

```
Switch# show storm-control
Interface | Filter State   | Broadcast | Multicast | Level
----------|----------------|-----------|-----------|-------
Gi4/4      | Forwarding     | 2.00%     | 2.00%     | N/A   
Switch
```

**Note**

In the previous example, “current” represents the percentage of traffic suppressed at a given instant, and the value is N/A for ports that perform suppression in hardware.

```
Switch# show storm-control
Interface | Filter State   | Broadcast | Multicast | Level
----------|----------------|-----------|-----------|-------
Fa2/1      | Blocking       | Enabled   | Disabled  | 10.00%
Gi3/1      | Link Down      | Enabled   | Enabled   | 50.00%
```
Configuring SPAN and RSPAN

This chapter describes how to configure the Switched Port Analyzer (SPAN) and Remote SPAN (RSPAN) on the Catalyst 4500 series switches. SPAN selects network traffic for analysis by a network analyzer, such as a SwitchProbe device or other Remote Monitoring (RMON) probe.

This chapter consists of the following sections:

- About SPAN and RSPAN, page 46-2
- Configuring SPAN, page 46-7
- CPU Port Sniffing, page 46-10
- Encapsulation Configuration, page 46-12
- Ingress Packets, page 46-12
- Access List Filtering, page 46-13
- Packet Type Filtering, page 46-14
- Configuration Example, page 46-15
- Configuring RSPAN, page 46-16
- Displaying SPAN and RSPAN Status, page 46-24

For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

About SPAN and RSPAN

This sections includes the following subsections:

- SPAN and RSPAN Concepts and Terminology, page 46-3
- SPAN and RSPAN Session Limits, page 46-6
- Default SPAN and RSPAN Configuration, page 46-6

SPAN mirrors traffic from one or more source interfaces on any VLAN or from one or more VLANs to a destination interface for analysis. In Figure 46-1, all traffic on Ethernet interface 5 (the source interface) is mirrored to Ethernet interface 10. A network analyzer on Ethernet interface 10 receives all network traffic from Ethernet interface 5 without being physically attached to it.

For SPAN configuration, the source interfaces and the destination interface must be on the same switch. SPAN does not affect the switching of network traffic on source interfaces; copies of the packets received or transmitted by the source interfaces are sent to the destination interface.

RSPAN extends SPAN by enabling remote monitoring of multiple switches across your network. The traffic for each RSPAN session is carried over a user-specified RSPAN VLAN that is dedicated for that RSPAN session in all participating switches. The SPAN traffic from the sources is copied onto the RSPAN VLAN and then forwarded over trunk ports that are carrying the RSPAN VLAN to any RSPAN destination sessions monitoring the RSPAN VLAN, as shown in Figure 46-2.
SPAN and RSPAN do not affect the switching of network traffic on source ports or source VLANs; a copy of the packets received or sent by the sources is sent to the destination. Except for traffic that is required for the SPAN or RSPAN session, by default, destination ports do not receive or forward traffic. Use the SPAN or RSPAN destination port to forward transmitted traffic from a network security device. For example, if you connect a Cisco Intrusion Detection System (IDS) sensor appliance to a destination port, the IDS device can send TCP reset packets to close down the TCP session of a suspected attacker.

### SPAN and RSPAN Concepts and Terminology

This section describes concepts and terminology associated with SPAN and RSPAN configuration and includes the following subsections:

- SPAN Session, page 46-3
- Traffic Types, page 46-3
- Source Port, page 46-4
- Destination Port, page 46-5
- VLAN-Based SPAN, page 46-5
- SPAN Traffic, page 46-6

### SPAN Session

A local SPAN session associates a destination port with source ports. You can monitor incoming or outgoing traffic on a series or range of ports and source VLANs. An RSPAN session associates source ports and source VLANs across your network with an RSPAN VLAN. The destination source is the RSPAN VLAN.

You configure SPAN sessions by using parameters that specify the source of network traffic to monitor. You can configure multiple SPAN or RSPAN sessions with separate or overlapping sets of SPAN sources. Both switched and routed ports can be configured as SPAN sources or destination ports.

An RSPAN source session associates SPAN source ports or VLANs with a destination RSPAN VLAN. An RSPAN destination session associates an RSPAN VLAN with a destination port.

SPAN sessions do not interfere with the normal operation of the switch; however, an oversubscribed SPAN destination (for example, a 10-Mbps port monitoring a 100-Mbps port) results in dropped or lost packets.

You can configure SPAN sessions on disabled ports; however, a SPAN session does not become active unless you enable the destination port and at least one source port or VLAN for that session.

A SPAN session remains inactive after system startup until the destination port is operational.

### Traffic Types

SPAN sessions include these traffic types:

- **Receive (Rx) SPAN**—The goal of receive (or ingress) SPAN is to monitor as much as possible all packets received by the source interface or VLAN before any modification or processing is performed by the switch. A copy of each packet received by the source is sent to the destination port for that SPAN session. You can monitor a series or range of ingress ports or VLANs in a SPAN session.
About SPAN and RSPAN

On tagged packets (Inter-Switch Link [ISL] or IEEE 802.1Q), the tagging is removed at the ingress port. At the destination port, if tagging is enabled, the packets appear with the ISL or 802.1Q headers. If no tagging is specified, packets appear in the native format.

Packets that are modified because of routing are copied without modification for Rx SPAN; that is, the original packet is copied. Packets that are modified because of quality of service (QoS)—for example, modified Differentiated Services Code Point (DSCP)—are copied without modification for Rx SPAN.

Some features that can cause a packet to be dropped during receive processing have no effect on SPAN; the destination port receives a copy of the packet even if the actual incoming packet is dropped. These features include IP standard and extended input access control lists (ACLs), IP standard and extended output ACLs for unicast and ingress QoS policing, VLAN maps, ingress QoS policing, and policy-based routing. Switch congestion that causes packets to be dropped also has no effect on SPAN.

Transmit (Tx) SPAN—The goal of transmit (or egress) SPAN is to monitor as much as possible all packets sent by the source interface after the switch performs all modification and processing. After the packet is modified, the source sends a copy of each packet to the destination port for that SPAN session. You can monitor a range of egress ports in a SPAN session.

Packets that are modified because of routing—for example, with a time-to-live (TTL) or MAC-address modification—are duplicated at the destination port. On packets that are modified because of QoS, the modified packet might not have the same DSCP (IP packet) or CoS (non-IP packet) as the SPAN source.

Some features that can cause a packet to be dropped during transmit processing might also affect the duplicated copy for SPAN. These features include VLAN maps, IP standard and extended output ACLs on multicast packets, and egress QoS policing. In the case of output ACLs, if the SPAN source drops the packet, the SPAN destination would also drop the packet. In the case of egress QoS policing, if the SPAN source drops the packet, the SPAN destination might not drop it. If the source port is oversubscribed, the destination ports have different dropping behavior.

Both—In a SPAN session, you can monitor a single port series or a range of ports for both received and sent packets.

Source Port

A source port (also called a monitored port) is a switched or routed port that you monitor for network traffic analysis. In a single local SPAN session or RSPAN source session, you can monitor source port traffic, such as received (Rx), transmitted (Tx), or bidirectional (both). The switch supports any number of source ports (up to the maximum number of available ports on the switch) and any number of source VLANs.

A source port has these characteristics:

- It can be any port type (for example, EtherChannel, Fast Ethernet, Gigabit Ethernet, and so forth).
- It can be monitored in multiple SPAN sessions.
- It cannot be a destination port.
- Each source port can be configured with a direction (ingress, egress, or both) to monitor. For EtherChannel sources, the monitored direction would apply to all physical ports in the group.
- Source ports can be in the same or different VLANs.
- For VLAN SPAN sources, all active ports in the source VLAN are included as source ports.
You can configure a trunk port as a source port. By default, all VLANs active on the trunk are monitored. You can limit SPAN traffic monitoring on trunk source ports to specific VLANs by using VLAN filtering. Only switched traffic in the selected VLANs is sent to the destination port. This feature affects only traffic forwarded to the destination SPAN port and does not affect the switching of normal traffic. This feature is not allowed in sessions with VLAN sources.

### Destination Port

Each local SPAN session or RSPAN destination session must have a destination port (also called a *monitoring port*) that receives a copy of traffic from the source ports and VLANs.

A destination port has these characteristics:

- A destination port must reside on the same switch as the source port (for a local SPAN session).
- A destination port can be any Ethernet physical port.
- A destination port can participate in only one SPAN session at a time. (A destination port in one SPAN session cannot be a destination port for a second SPAN session.)
- A destination port cannot be a source port.
- A destination port cannot be an EtherChannel group.
- A destination port can be a physical port that is assigned to an EtherChannel group, even if the EtherChannel group has been specified as a SPAN source. The port is removed from the group while it is configured as a SPAN destination port.
- The port does not transmit any traffic except that traffic required for the SPAN session unless learning is enabled. If learning is enabled, the port also transmits traffic directed to hosts that have been learned on the destination port.
- If ingress traffic forwarding is enabled for a network security device, the destination port forwards traffic at Layer 2.
- A destination port does not participate in spanning tree while the SPAN session is active.
- When it is a destination port, it does not participate in any of the Layer 2 protocols (STP, VTP, CDP, DTP, PagP).
- A destination port that belongs to a source VLAN of any SPAN session is excluded from the source list and is not monitored.
- A destination port receives copies of sent and received traffic for all monitored source ports. If a destination port is oversubscribed, it could become congested and result in packet drops at the destination port. This congestion does not affect traffic forwarding on the source ports.

### VLAN-Based SPAN

VLAN-based SPAN (VSPAN) is the monitoring of the network traffic in one or more VLANs.

Use these guidelines for VSPAN sessions:

- Traffic on RSPAN VLANs is not monitored by VLAN-based SPAN sessions.
- Only traffic on the monitored VLAN is sent to the destination port.
- If a destination port belongs to a source VLAN, it is excluded from the source list and is not monitored.
- If ports are added to or removed from the source VLANs, the traffic on the source VLAN received by those ports is added to or removed from the sources being monitored.
About SPAN and RSPAN

- VLAN pruning and the VLAN allowed list have no effect on SPAN monitoring.
- VSPAN monitors only traffic that enters the switch, not traffic that is routed between VLANs. For example, if a VLAN is being Rx-monitored, and the multilayer switch routes traffic from another VLAN to the monitored VLAN, that traffic is not monitored and is not received on the SPAN destination port.
- You cannot use filter VLANs in the same session with VLAN sources.
- You can monitor only Ethernet VLANs.

SPAN Traffic

Use the local SPAN to monitor all network traffic, including multicast and bridge protocol data unit (BPDU) packets, Cisco Discovery Protocol (CDP), VLAN Trunk Protocol (VTP), Dynamic Trunking Protocol (DTP), Spanning Tree Protocol (STP), and Port Aggregation Protocol (PAgP) packets. You cannot use RSPAN to monitor Layer 2 protocols. (See the “RSPAN Configuration Guidelines” section on page 46-16 for more information.)

In some SPAN configurations, multiple copies of the same source packet are sent to the SPAN destination port. For example, a bidirectional (both Rx and Tx) SPAN session is configured for the sources a1 Rx monitor and the a2 Rx and Tx monitor to destination port d1. If a packet enters the switch through a1 and is switched to a2, both incoming and outgoing packets are sent to destination port d1. Both packets are the same (unless a Layer-3 rewrite occurs, in which case the packets are different because of the added Layer 3 information).

SPAN and RSPAN Session Limits

You can configure a maximum of sixteen SPAN/RSPAN sessions (eight concurrent sessions with ingress-only sources and eight concurrent sessions with egress-only sources). Bidirectional sources count as both ingress and egress. RSPAN destination sessions count as a session containing an ingress source.

Default SPAN and RSPAN Configuration

Table 46-1 shows the default SPAN and RSPAN configuration.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>

<tr>
<td>Ingress forwarding (destination port)</td>
<td>Disabled.</td>
</tr>
<tr>
<td>Host learning (destination port)</td>
<td>Disabled.</td>
</tr>
</tbody>
</table>
Configuring SPAN

The following sections describe how to configure SPAN:

- SPAN Configuration Guidelines and Restrictions, page 46-7
- Configuring SPAN Sources, page 46-8
- Configuring SPAN Destinations, page 46-9
- Monitoring Source VLANs on a Trunk Interface, page 46-9
- Configuration Scenario, page 46-10
- Verifying a SPAN Configuration, page 46-10

Note

Entering SPAN configuration commands does not clear previously configured SPAN parameters. You must enter the **no monitor session** command to clear configured SPAN parameters.

SPAN Configuration Guidelines and Restrictions

Follow these guidelines and restrictions when configuring SPAN:

- You must use a network analyzer to monitor interfaces.
- You cannot mix source VLANs and filter VLANs within a SPAN session. You can have source VLANs or filter VLANs, but not both at the same time.
- EtherChannel interfaces can be SPAN source interfaces; they cannot be SPAN destination interfaces.
- When you specify source interfaces and do not specify a traffic type (Tx, Rx, or both), “both” is used by default. To change from both to either “tx” or “rx,” unconfigure the corresponding other type “rx” or “tx” with the **no monitor session {session_number} {source {interface interface_list | {vlan vlan_IDs | cpu [queue queue_ids] } {rx | tx}}** command.
- If you specify multiple SPAN source interfaces, the interfaces can belong to different VLANs.
- You must enter the **no monitor session number** command with no other parameters to clear the SPAN session number.
- The **no monitor** command clears all SPAN sessions.
- SPAN destinations never participate in any spanning tree instance. SPAN includes BPDUs in the monitored traffic, so any BPDUs seen on the SPAN destination are from the SPAN source.
- SPAN is limited to one destination port per session.
- When you create a SPAN session, the packet filter is set to good by default and you see another configuration line automatically:

  `monitor session number filter packet-type good rx`
Configuring SPAN Sources

To configure the source for a SPAN session, perform this task:

```
Command Description
Switch(config)# [no] monitor session (session_number) source (interface <interface_list> | (vlan vlan_IDs | cpu [queue queue_ids] ) {rx | tx | both} Specifies the SPAN session number (1 through 16), the source interfaces (FastEthernet or GigabitEthernet), VLANs (1 through 4094), whether traffic received or sent from the CPU is copied to the session destination, and the traffic direction to be monitored.
For session_number, specifies the session number identified with this session (1 through 16).
For interface-list, specifies the source port to monitor. Valid interfaces include physical interfaces and port-channel logical interfaces (port-channel port-channel-number).
For vlan_IDs, specifies the source VLAN.
For queue_ids, specifies the queue(s) involved.
(Optional) Specifies a series or range of interfaces. Enter a space after the comma; enter a space before and after the hyphen.
(Optional) Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the source interface sends both transmitted (Tx) and received (Rx) traffic. Only received traffic can be monitored on additional source ports.
• Rx—Monitor received traffic.
• Tx—Monitor transmitted traffic.
• both—Monitor both received and transmitted traffic (bidirectional).
Queues may be identified either by number or by name. Queue names may subsume multiple numbered queues for convenience.
Use the no keyword to restore the defaults.
```

This example shows how to configure SPAN session 1 to monitor bidirectional traffic from source interface Fast Ethernet 5/1:

```
Switch(config)# monitor session 1 source interface fastethernet 5/1
```

This example shows how to configure sources with differing directions within a SPAN session:

```
Switch(config)# monitor session 1 source interface fa2/3 rx
Switch(config)# monitor session 1 source interface fa2/2 tx
```

Configuring SPAN Destinations

To configure the destination for a SPAN session, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# [no] monitor session &lt;session_number&gt; destination interface &lt;interface&gt; [encapsulation dot1q] [ingress [vlan vlan_IDs] [learning]]</td>
<td>Specifies the SPAN session number (1 through 16) and the destination interfaces or VLANs. For &lt;session_number&gt;, specifies the session number identified with this session (1 through 16). For &lt;interface&gt;, specifies the destination interface. For vlan_IDs, specifies the destination VLAN. Use the no keyword to restore the defaults.</td>
</tr>
</tbody>
</table>

Note

SPAN is limited to one destination port per session.

This example shows how to configure interface Fast Ethernet 5/48 as the destination for SPAN session 1:

```
Switch(config)# monitor session 1 destination interface fastethernet 5/48
```

Monitoring Source VLANs on a Trunk Interface

To monitor specific VLANs when the SPAN source is a trunk interface, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# [no] monitor session &lt;session_number&gt; filter (vlan vlan_IDs {,</td>
<td>- })</td>
</tr>
</tbody>
</table>

This example shows how to monitor VLANs 1 through 5 and VLAN 9 when the SPAN source is a trunk interface:

```
Switch(config)# monitor session 2 filter vlan 1 - 5 , 9
```
Configuration Scenario

This example shows how to use the commands described in this chapter to completely configure and unconfigure a span session. Assume that you want to monitor bidirectional traffic from source interfaces Fast Ethernet 4/10, 4/11 and 4/12. Interface 4/10 is configured as a trunk interface carrying VLANs 1 through 4094. Interface Fast Ethernet 4/11 is configured as an access port in VLAN 57 and interface Fast Ethernet 4/12 is configured as an access port in VLAN 58. You want to monitor only traffic in VLAN 57 in that session. Using Fast Ethernet 4/15 as your destination interface, you would enter the following commands:

Switch(config)# monitor session 1 source interface fastethernet 4/10 - 12
Switch(config)# monitor session 1 filter vlan 57
Switch(config)# monitor session 1 destination interface fastethernet 4/15

You are now monitoring traffic from interface Fast Ethernet 4/10 that is on VLAN 57 out of interface FastEthernet 4/15. To disable the span session enter the following command:

Switch(config)# no monitor session 1

Verifying a SPAN Configuration

This example shows how to verify the configuration of SPAN session 2:

Switch# show monitor session 2
Session 2
---------
Source Ports:
  RX Only:       Fa5/12
  TX Only:       None
  Both:          None
Source VLANs:
  RX Only:       None
  TX Only:       None
  Both:          None
Destination Ports: Fa5/45
Filter VLANs:      1-5,9
Switch#

CPU Port Sniffing

When configuring a SPAN session, you can specify the CPU (or a subset of CPU queues) as a SPAN source. Queues may be specified either by number or by name. When such a source is specified, traffic going to the CPU through one of the specified queues is mirrored and sent out of the SPAN destination port in the session. This traffic includes both control packets and regular data packets that are sent to or from the CPU (due to software forwarding).

You can mix the CPU source with either regular port sources or VLAN sources.
To configure CPU source sniffing, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| `Switch(config)# [no] monitor session {session_number} {source (interface interface_list | (vlan vlan_IDs | cpu | {queue queue_ids})} [rx | tx | both]` | Specifies that the CPU causes traffic received by or sent from the CPU to be copied to the destination of the session. The `queue` identifier optionally allows sniffing-only traffic (received) on the specified CPU queue(s).

For `session_number`, specifies the session number identified with this SPAN session (1 through 16).

For `interface-list`, specifies the source port to monitor. Valid interfaces include physical interfaces and port-channel logical interfaces (`port-channel port-channel-number`).

For `vlan_IDs`, specifies the source VLAN.

For `queue_ids`, specifies the queue(s) involved.

(Optional) `[ , | - ]` Specifies a series or range of interfaces. Enter a space after the comma; enter a space before and after the hyphen.

(Optional) Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the source interface sends both transmitted (Tx) and received (Rx) traffic. Only received traffic can be monitored on additional source ports.

- **Rx**—Monitor received traffic.
- **Tx**—Monitor transmitted traffic.
- **both**—Monitor both received and transmitted traffic (bidirectional).

Queues may be identified either by number or by name. Queue names may subsume multiple numbered queues for convenience.

Use the `no` keyword to restore the defaults.

This example shows how to configure a CPU source to sniff all packets received by the CPU:

`Switch# configure terminal`  
Enter configuration commands, one per line. End with CNTL/Z.

`Switch(config)# monitor session 1 source cpu rx`  

This example shows how to use queue names and queue number ranges for the CPU as a SPAN source:

`Switch(config)# monitor session 2 source cpu queue control-packet rx`  

`Switch(config)# monitor session 3 source cpu queue 10 rx`
Encapsulation Configuration

When configuring a SPAN destination port, you can explicitly enable the encapsulation option. Packets exiting the port are tagged with 802.1q encapsulation. The encapsulation mode also controls how tagged packets are handled when the ingress packet option is enabled.

The replicate encapsulation type (in which packets are transmitted from the destination port using whatever encapsulation applied to the original packet) is not supported. If no encapsulation mode is specified, the port default is untagged. To view the task of configuring encapsulation, see the command table below.

Ingress Packets

When ingress is enabled, the SPAN destination port accepts incoming packets (potentially tagged depending on the encapsulation option) and switches them normally. When configuring a SPAN destination port, you can specify whether the ingress feature is enabled and what VLAN to use to switch untagged ingress packets. Although the port is STP forwarding, it does not participate in the STP, so use caution when configuring this feature lest a spanning-tree loop be introduced in the network. When both ingress and a trunk encapsulation are specified on a SPAN destination port, the port goes forwarding in all active VLANs. Configuring a non-existent VLAN as an ingress VLAN is not allowed.

By default, host learning is disabled on SPAN destination ports with ingress enabled. The port is also removed from VLAN floodsets, so regular traffic is not switched out of the destination port. If learning is enabled, however, then traffic for hosts learned on the destination port is switched out the destination port. A host connected to SPAN destination port will not receive broadcast ARP request and so will not respond. It is also possible to configure static host entries (including a static ARP entry and a static entry in the MAC-address table) on SPAN destination ports.

This configuration does not work if the SPAN session does not have a source configured; the session is half configured with only the SPAN destination port.

To configure ingress packets and encapsulation, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# [no] monitor session &lt;session_number&gt; destination interface &lt;interface&gt; [encapsulation dot1q] [ingress [vlan vlan_IDs] [learning]]</td>
<td>Specifies the configuration of the ingress packet and the encapsulation of the destination port.</td>
</tr>
<tr>
<td>For session_number, specifies the session number identified with this SPAN session (1 through 16).</td>
<td></td>
</tr>
<tr>
<td>For interface, specifies the destination interface.</td>
<td></td>
</tr>
<tr>
<td>For vlan_IDs, specifies the destination VLAN. Use the no keyword to restore the defaults.</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to configure a destination port with 802.1q encapsulation and ingress packets using native VLAN 7:
Switch(config)# monitor session 1 destination interface fastethernet 5/48
encapsulation dot1q ingress vlan 7

With this configuration, traffic from SPAN sources associated with session 1 would be copied out of
interface Fast Ethernet 5/48, with 802.1q encapsulation. Incoming traffic would be accepted and
switched, with untagged packets being classified into VLAN 7.

Access List Filtering

When configuring a SPAN session, you can apply access list filtering. Access list filtering applies to all
packets passing through a SPAN destination port that might be sniffed in the egress or ingress direction.
Access list filters are allowed on local SPAN sessions only. If the SPAN destination is an RSPAN
VLAN, the access list filter is rejected.

ACL Configuration Guidelines

You can configure ACLs on a SPAN session. Use these guidelines for ACL/SPAN sessions:

• If an ACL is associated with a SPAN session, the rules associated with that ACL are applied against
  all packets exiting the SPAN destination interface. Rules pertaining to other VACLs or RACLs
  previously associated with the SPAN destination interface are not applied.
• Only one ACL can be associated with a SPAN session.
• When no ACLs are applied to packets exiting a SPAN destination interface, all traffic is permitted
  regardless of the PACLS, VACLs, or RACLs that have been previously applied to the destination
  interface or VLAN to which the SPAN destination interface belongs.
• If an ACL is removed from a SPAN session, all traffic is permitted once again.
• If SPAN configuration is removed from the SPAN session, all rules associated with the SPAN
  destination interface are applied once again.
• If a SPAN destination port is configured as a trunk port and the VLANs to which it belongs have
  ACLs associated with them, the traffic is not subjected to the VACLs.
• ACL configuration applies normally to the RSPAN VLAN and to trunk ports carrying the RSPAN
  VLAN. This configuration enables the user to apply VACLs on RSPAN VLANs. If a user attempts
  to configure an ACL on a SPAN session with the destination port as an RSPAN VLAN, the
  configuration is rejected.
• If CAM resources are exhausted and packets are passed to the CPU for lookup, any output port
  ACLs associated with a SPAN session are not applied.
• If a named IP ACL is configured on a SPAN session before an ACL is created, the configuration is
  accepted, and the software creates an empty ACL with no ACEs. (An empty ACL permits all
  packets.) Subsequently, the rules can be added to the ACL.
• The ACLs associated with a SPAN session are applied on the destination interface on output.
• No policing is allowed on traffic exiting SPAN ports.
• Only IP ACLs are supported on SPAN sessions.
Chapter 46      Configuring SPAN and RSPAN

Configuring Access List Filtering

To configure access list filtering, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# monitor session {session_number} filter {ip access-group [name</td>
<td>id ]</td>
</tr>
</tbody>
</table>

**Note**

IP access lists must be created in configuration mode as described in the chapter “Configuring Network Security with ACLs.”

This example shows how to configure IP access group 10 on a SPAN session and verify that an access list has been configured:

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# monitor session 1 source interface fa6/1 both
Switch(config)# monitor session 1 destination interface fa6/2
Switch(config)# monitor session 1 filter vlan 1
Switch(config)# monitor session 1 filter ip access-group 10
Switch(config)# exit
Switch# show monitor

Session 1
--------
Type : Local Session
Source Ports :
Both : Fa6/1
Destination Ports : Fa6/2
Encapsulation : Native
Ingress : Disabled
Learning : Disabled
Filter VLANs : 1
IP Access-group : 10

Packet Type Filtering

When configuring a SPAN session, you can specify packet filter parameters similar to VLAN filters. When specified, the packet filters indicate types of packets that may be sniffed. If no packet filters are specified, packets of all types may be sniffed. Different types of packet filters may be specified for ingress and egress traffic.
Chapter 46  Configuring SPAN and RSPAN

Configuration Example

There are two categories of packet filtering: packet-based (good, error) or address-based (unicast/multicast/broadcast). Packet-based filters can only be applied in the ingress direction. Packets are classified as broadcast, multicast, or unicast by the hardware based on the destination address.

**Note**

When filters of both types are configured, only packets that pass both filters are spanned. For example, if you set both “error” and “multicast,” only multicast packets with errors are spanned.

To configure packet type filtering, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# {no} monitor session {session_number} filter {vlan vlan_IDs [ ,</td>
<td>- ]</td>
</tr>
<tr>
<td></td>
<td>For <strong>session_number</strong>, specifies the session number identified with this SPAN session (1 through 6).</td>
</tr>
<tr>
<td></td>
<td>For <strong>vlan_IDs</strong>, specifies the VLAN.</td>
</tr>
<tr>
<td></td>
<td>You can specify both Rx and Tx type filters, as well as specify multiple type filters at the same time (such as <strong>good</strong> and <strong>unicast</strong> to only sniff non-error unicast frames). As with VLAN filters, if no type or filter is specified, then the session sniffs all packet types.</td>
</tr>
<tr>
<td></td>
<td>Use the <strong>no</strong> keyword to restore the defaults.</td>
</tr>
</tbody>
</table>

This example shows how to configure a session to accept only unicast packets in the ingress direction:

```
Switch(config)# monitor session 1 filter address-type unicast rx
```

**Configuration Example**

The following is an example of SPAN configuration using some of the SPAN enhancements.

In the example below, you configure a session to sniff unicast traffic arriving on interface Gi1/1. The traffic is mirrored out of interface Gi1/2 with dot1q encapsulation. Ingress traffic is permitted.

```
Switch# configure terminal
Enter configuration commands, one per line.  End with CNTRL/Z.
Switch(config)# monitor session 1 source interface gi1/1 rx
Switch(config)# monitor session 1 destination interface gi1/2 encapsulation dot1q ingress
Switch(config)# monitor session 1 filter address-type unicast rx
Switch(config)# exit
Switch# show monitor

Session 1
--------
Type : Local Session
Source Ports :
   RX Only  : Gi1/1
Destination Ports : Gi1/2
   Encapsulation : DOT1q
   Ingress : Enabled
   Learning : Disabled
Filter Addr Type :
   RX Only  : Unicast
```
Configuring RSPAN

This section describes how to configure RSPAN on your switch and it contains this configuration information:

- RSPAN Configuration Guidelines, page 46-16
- Creating an RSPAN Session, page 46-17
- Creating an RSPAN Destination Session, page 46-18
- Creating an RSPAN Destination Session and Enabling Ingress Traffic, page 46-19
- Removing Ports from an RSPAN Session, page 46-21
- Specifying VLANs to Monitor, page 46-22
- Specifying VLANs to Filter, page 46-23

RSPAN Configuration Guidelines

Follow these guidelines when configuring RSPAN:

Note

Since RSPAN VLANs have special properties, you should reserve a few VLANs across your network for use as RSPAN VLANs; do not assign access ports to these VLANs.

Note

You can apply an output access control list (ACL) to RSPAN traffic to selectively filter or monitor specific packets. Specify these ACLs on the RSPAN VLAN in the RSPAN source switches.

- RSPAN sessions can coexist with SPAN sessions within the limits described in the “SPAN and RSPAN Session Limits” section on page 46-6.
- For RSPAN configuration, you can distribute the source ports and the destination ports across multiple switches in your network.
- RSPAN does not support BPDU packet monitoring or other Layer 2 switch protocols.
- The RSPAN VLAN is configured only on trunk ports and not on access ports. To avoid unwanted traffic in RSPAN VLANs, make sure that all participating switches support the VLAN remote-span feature. Access ports on the RSPAN VLAN are silently disabled.
- You should create an RSPAN VLAN before configuring an RSPAN source or destination session.
- If you enable VTP and VTP pruning, RSPAN traffic is pruned in the trunks to prevent the unwanted flooding of RSPAN traffic across the network for VLAN-IDs that are lower than 1005.
- Because RSPAN traffic is carried across a network on an RSPAN VLAN, the original VLAN association of the mirrored packets is lost. Therefore, RSPAN can only support forwarding of traffic from an IDS device onto a single user-specified VLAN.
Creating an RSPAN Session

First create an RSPAN VLAN that does not exist for the RSPAN session in any of the switches that participate in RSPAN. With VTP enabled in the network, you can create the RSPAN VLAN in one switch, and then VTP propagates it to the other switches in the VTP domain for VLAN-IDs that are lower than 1005.

Use VTP pruning to get efficient flow of RSPAN traffic, or manually delete the RSPAN VLAN from all trunks that do not need to carry the RSPAN traffic.

To start an RSPAN source session and to specify the source (monitored) ports and the destination RSPAN VLAN, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch## configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# no monitor session {session_number</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config)# vlan (remote_vlan_ID)</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config-vlan)# remote-span</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch(config-vlan)# exit</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Switch(config)# [no] monitor session {session_number} {source {interface &lt;interface_list&gt;</td>
</tr>
<tr>
<td>• Rx—Monitor received traffic.</td>
<td></td>
</tr>
<tr>
<td>• Tx—Monitor transmitted traffic.</td>
<td></td>
</tr>
<tr>
<td>• both—Monitor both received and transmitted traffic (bidirectional).</td>
<td></td>
</tr>
</tbody>
</table>
Chapter 46  Configuring SPAN and RSPAN

Configuring RSPAN

This example shows how to clear any existing RSPAN configuration for session 1, configure RSPAN session 1 to monitor multiple source interfaces, and configure the destination RSPAN VLAN.

```
Switch# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch(config)# no monitor session 1
Switch(config)# monitor session 1 source interface fastEthernet3/10 tx
Switch(config)# monitor session 1 source interface fastEthernet3/2 rx
Switch(config)# monitor session 1 source interface fastEthernet3/3 rx
Switch(config)# monitor session 1 source interface port-channel 102 rx
Switch(config)# monitor session 1 destination remote vlan 901
Switch(config)# end
```

Creating an RSPAN Destination Session

To create an RSPAN destination session and to specify the source RSPAN VLAN and the destination port, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 7</strong></td>
<td>Specifies the RSPAN session and the destination remote VLAN. For <em>session_number</em>, specifies the session number identified with this RSPAN session (1 through 16). For <em>vlan-ID</em>, specifies the RSPAN VLAN to carry the monitored traffic to the destination port.</td>
</tr>
<tr>
<td>Switch(config)# monitor session <em>session_number</em> destination remote vlan <em>vlan-ID</em></td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Switch(config)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td>Switch# show monitor [session <em>session_number</em>]</td>
<td></td>
</tr>
<tr>
<td><strong>Step 10</strong></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
<tr>
<td>Switch# copy running-config startup-config</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to clear any existing RSPAN configuration for session 1, configure RSPAN session 1 to monitor multiple source interfaces, and configure the destination RSPAN VLAN.

```
Switch# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch(config)# no monitor session 1
Switch(config)# monitor session 1 source interface fastEthernet3/10 tx
Switch(config)# monitor session 1 source interface fastEthernet3/2 rx
Switch(config)# monitor session 1 source interface fastEthernet3/3 rx
Switch(config)# monitor session 1 source interface port-channel 102 rx
Switch(config)# monitor session 1 destination remote vlan 901
Switch(config)# end
```

```
Creating an RSPAN Destination Session

To create an RSPAN destination session and to specify the source RSPAN VLAN and the destination port, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Switch# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Specifies the RSPAN session and the source RSPAN VLAN. For <em>session_number</em>, specifies the session number identified with this RSPAN session (1 through 16). For <em>vlan-ID</em>, specifies the source RSPAN VLAN to monitor.</td>
</tr>
<tr>
<td>Switch(config)# monitor session <em>session_number</em> source remote vlan <em>vlan-ID</em></td>
<td></td>
</tr>
</tbody>
</table>
Chapter 46 Configuring SPAN and RSPAN

Configuring RSPAN

This example shows how to configure VLAN 901 as the source remote VLAN and port 5 as the destination interface:

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# monitor session 1 source remote vlan 901
Switch(config)# monitor session 1 destination interface gigabitEthernet1/2
Switch(config)# end

Creating an RSPAN Destination Session and Enabling Ingress Traffic

To create an RSPAN destination session, to specify the source RSPAN VLAN, and to enable ingress traffic on the destination port for a network security device (such as a Cisco IDS [Intrusion Detection System] sensor appliance), perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# monitor session {session_number} source vlan vlan_IDs</td>
</tr>
</tbody>
</table>
### Configuring RSPAN

#### Step 3

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# monitor session session_number destination interface interface-id [encapsulation dot1q] ingress vlan vlan_id] [learning]</td>
<td>Specifies the RSPAN session, the destination port, the packet encapsulation, and the ingress VLAN. For session_number, specifies the session number identified with this RSPAN session (1 through 16). For interface-id, specifies the destination port. Valid interfaces include physical interfaces. (Optional) Specifies the encapsulation of the packets transmitted on the RSPAN destination port. If no encapsulation is specified, all transmitted packets are sent in native format (untagged). • Enter encapsulation dot1q to send native VLAN packets untagged, and all other VLAN tx packets tagged dot1q. (Optional) Specifies whether forwarding is enabled for ingress traffic on the RSPAN destination port. • For native (untagged) and dot1q encapsulation, specify ingress vlan vlan_id to enable ingress forwarding with vlan_id as the native VLAN; vlan_id is also used as the native VLAN for transmitted packets. • Specify learning to enable learning when ingress is enabled.</td>
</tr>
</tbody>
</table>

#### Step 4

| Switch(config)# end | Returns to privileged EXEC mode. |

#### Step 5

| Switch# show monitor [session session_number] | Verifies your entries. |

#### Step 6

| Switch# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

This example shows how to configure VLAN 901 as the source remote VLAN and how to configure the destination port for ingress traffic on VLAN 5 by using a security device that supports 802.1Q encapsulation:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# monitor session 1 source remote vlan 901
Switch(config)# monitor session 1 destination interface gigabitEthernet1/2 ingress vlan 5
Switch(config)# end
```
Removing Ports from an RSPAN Session

To remove a port as an RSPAN source for a session, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# [no] monitor session (session_number) {source (interface interface_list</td>
</tr>
<tr>
<td></td>
<td>Specifies the characteristics of the RSPAN source port (monitored port) to remove.</td>
</tr>
<tr>
<td></td>
<td>For session_number, specifies the session number identified with this RSPAN session (1 through 16).</td>
</tr>
<tr>
<td></td>
<td>For interface-list, specifies the source port to no longer monitor. Valid interfaces include physical interfaces and port-channel logical interfaces (port-channel port-channel-number).</td>
</tr>
<tr>
<td></td>
<td>For vlan_IDs, specifies the source vlan or vlans to monitor. Valid VLANs are in the range from 1 to 4094.</td>
</tr>
<tr>
<td></td>
<td>For queue_ids, specifies either a set of CPU queue numerical identifiers from 1 to 32, or a named queue.</td>
</tr>
<tr>
<td></td>
<td>(Optional) [,</td>
</tr>
<tr>
<td></td>
<td>(Optional) Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the source interface sends both transmitted (Tx) and received (Rx) traffic. Only received traffic can be monitored on additional source ports.</td>
</tr>
<tr>
<td></td>
<td>• Rx—Monitor received traffic.</td>
</tr>
<tr>
<td></td>
<td>• Tx—Monitor transmitted traffic.</td>
</tr>
<tr>
<td></td>
<td>• both—Monitor both received and transmitted traffic (bidirectional).</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch# show monitor [session session_number]</td>
</tr>
<tr>
<td></td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch# copy running-config startup-config</td>
</tr>
<tr>
<td></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

This example shows how to remove port 1 as an RSPAN source for RSPAN session 1:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTRL/Z.
Switch(config)# no monitor session 1 source interface gigabitEthernet1/1
Switch(config)# end
```

This example shows how to disable received traffic monitoring on port 1, which was configured for bidirectional monitoring:

```
Switch(config)# no monitor session 1 source interface gigabitEthernet1/1 rx
```

The monitoring of traffic received on port 1 is disabled, but traffic transmitted from this port continues to be monitored.
### Specifying VLANs to Monitor

VLAN monitoring is similar to port monitoring. To specify VLANs to monitor, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# no monitor session (session_number</td>
</tr>
<tr>
<td></td>
<td>Clears any existing SPAN configuration for the session.</td>
</tr>
<tr>
<td></td>
<td>For session_number, specifies the session number identified with this RSPAN session (1 through 16).</td>
</tr>
<tr>
<td></td>
<td>Specify all to remove all SPAN sessions, local to remove all local sessions, or remote to remove all remote SPAN sessions.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config)# [no] monitor session (session_number</td>
</tr>
<tr>
<td></td>
<td>Specifies the RSPAN session and the source VLANs (monitored VLANs). You can monitor only received (rx) traffic on VLANs.</td>
</tr>
<tr>
<td></td>
<td>For session_number, specifies the session number identified with this RSPAN session (1 through 16).</td>
</tr>
<tr>
<td></td>
<td>For interface-list, specifies the source port to no longer monitor. Valid interfaces include physical interfaces and port-channel logical interfaces (port-channel port-channel-number).</td>
</tr>
<tr>
<td></td>
<td>For vlan-IDs, the range is 1 to 4094; do not enter leading zeros.</td>
</tr>
<tr>
<td></td>
<td>For queue_ids, specifies the source queue.</td>
</tr>
<tr>
<td></td>
<td>(Optional) [,</td>
</tr>
<tr>
<td></td>
<td>(Optional) Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the source interface sends both transmitted (Tx) and received (Rx) traffic. Only received traffic can be monitored on additional source ports.</td>
</tr>
<tr>
<td></td>
<td>• Rx—Monitor received traffic.</td>
</tr>
<tr>
<td></td>
<td>• Tx—Monitor transmitted traffic.</td>
</tr>
<tr>
<td></td>
<td>• both—Monitor both received and transmitted traffic (bidirectional).</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config)# monitor session session_number destination remote vlan vlan-id</td>
</tr>
<tr>
<td></td>
<td>Specifies the RSPAN session, the destination remote VLAN.</td>
</tr>
<tr>
<td></td>
<td>For session_number, specifies the session number identified with this RSPAN session (1 through 16).</td>
</tr>
<tr>
<td></td>
<td>For vlan-id, specifies the RSPAN VLAN to carry the monitored traffic to the destination port.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Switch# show monitor [session session_number]</td>
</tr>
<tr>
<td></td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>Switch# copy running-config startup-config</td>
</tr>
<tr>
<td></td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

To remove one or more source VLANs from the RSPAN session, use the **no monitor session session_number source vlan vlan-id rx** global configuration command.
This example shows how to clear any existing configuration on RSPAN session 2, configure RSPAN session 2 to monitor received traffic on all ports belonging to VLANs 1 through 3, and send it to destination remote VLAN 902. The configuration is then modified to also monitor received traffic on all ports belonging to VLAN 10.

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# no monitor session 2
Switch(config)# monitor session 2 source vlan 1 - 3 rx
Switch(config)# monitor session 2 destination remote vlan 902
Switch(config)# monitor session 2 source vlan 10 rx
Switch(config)# end

Specifying VLANs to Filter

To limit RSPAN source traffic to specific VLANs, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# no monitor session (session_number</td>
</tr>
<tr>
<td></td>
<td>Clears any existing SPAN configuration for the session.</td>
</tr>
<tr>
<td></td>
<td>For session_number, specifies the session number identified with this RSPAN session (1 through 16).</td>
</tr>
<tr>
<td></td>
<td>Specify all to remove all SPAN sessions, local to remove all local sessions, or remote to remove all remote SPAN sessions.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config)# [no] monitor session (session_number) (source {interface interface_list</td>
</tr>
<tr>
<td></td>
<td>Specifies the characteristics of the source port (monitored port) and RSPAN session.</td>
</tr>
<tr>
<td></td>
<td>For session_number, specifies the session number identified with this RSPAN session (1 through 16).</td>
</tr>
<tr>
<td></td>
<td>For interface-list, specifies the source port to monitor. The interface specified must already be configured as a trunk port.</td>
</tr>
<tr>
<td></td>
<td>For vlan-IDs, the range is 1 to 4094; do not enter leading zeros.</td>
</tr>
<tr>
<td></td>
<td>For queue_ids, specifies the source queue.</td>
</tr>
<tr>
<td></td>
<td>(Optional) [</td>
</tr>
<tr>
<td></td>
<td>(Optional) Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the source interface sends both transmitted (Tx) and received (Rx) traffic. Only received traffic can be monitored on additional source ports.</td>
</tr>
<tr>
<td></td>
<td>• Rx—Monitor received traffic.</td>
</tr>
<tr>
<td></td>
<td>• Tx—Monitor transmitted traffic.</td>
</tr>
<tr>
<td></td>
<td>• both—Monitor both received and transmitted traffic (bidirectional).</td>
</tr>
</tbody>
</table>
Chapter 46      Configuring SPAN and RSPAN

Displaying SPAN and RSPAN Status

To display the status of the current SPAN or RSPAN configuration, use the show monitor privileged EXEC command.

This example displays the output for the show monitor command for SPAN source session 1:

```
Switch# show monitor session 1
Session 1
--------
Type: Local Source Session
Source Ports:
  RX Only:  Fa3/13
  TX Only:  None
  Both:     None

Source VLANs:
  RX Only:  None
  TX Only:  None
```

To monitor all VLANs on the trunk port, use the no monitor session session_number filter vlan vlan-id [ , | - ] global configuration command.

This example shows how to clear any existing configuration on RSPAN session 2, configure RSPAN session 2 to monitor traffic received on trunk port 4, and send traffic for only VLANs 1 through 5 and 9 to destination remote VLAN 902.

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# no monitor session 2
Switch(config)# monitor session 2 source interface gigabitethernet1/1 rx
Switch(config)# monitor session 2 filter vlan 1 - 5 , 9
Switch(config)# monitor session 2 destination remote vlan 902
Switch(config)# end
```

Step 4

```
Switch(config)# monitor session session_number filter vlan vlan-id [, | - ]
```

Limits the RSPAN source traffic to specific VLANs.
For session_number, specifies the session number identified with this RSPAN session (1 through 16).
For vlan-id, the range is 1 to 4094; do not enter leading zeros.
(Optional) Use a comma (,) to specify a series of VLANs or use a hyphen (-) to specify a range of VLANs. Enter a space after the comma; enter a space before and after the hyphen.

Step 5

```
Switch(config)# monitor session session_number destination remote vlan vlan-id
```

Specifies the RSPAN session, the destination remote VLAN.
For session_number, specifies the session number identified with this RSPAN session (1 through 16).
For vlan-id, specifies the RSPAN VLAN to carry the monitored traffic to the destination port.

Step 6

```
Switch(config)# end
```

Returns to privileged EXEC mode.

Step 7

```
Switch# show monitor [session session_number]
```

Verifies your entries.

Step 8

```
Switch# copy running-config startup-config
```

(Optional) Saves your entries in the configuration file.
Both: None
Source RSPAN VLAN: None
Destination Ports: None
   Encapsulation: DOT1Q
       Ingress: Enabled, default VLAN=5
Filter VLANs: None
Dest RSPAN VLAN: None
   Ingress: Enabled, default VLAN=2

Configuring System Message Logging

This chapter describes how to configure system message logging on the Catalyst 4500 series switch. This chapter consists of these sections:

- About System Message Logging, page 47-1
- Configuring System Message Logging, page 47-2
- Displaying the Logging Configuration, page 47-12

For complete syntax and usage information for the commands used in this chapter, see the Cisco IOS Configuration Fundamentals Command Reference

and related publications at this location:

About System Message Logging

By default, a switch sends the output from system messages and debug privileged EXEC commands to a logging process. The logging process controls the distribution of logging messages to various destinations, such as the logging buffer, terminal lines, or a UNIX syslog server, depending on your configuration. The process also sends messages to the console.

The syslog format is compatible with 4.3 BSD UNIX.

When the logging process is disabled, messages are sent only to the console. The messages are sent as they are generated, so message and debug output are interspersed with prompts or output from other commands. Messages are displayed on the console after the process that generated them has finished.

You can set the severity level of the messages to control the type of messages displayed on the consoles and each of the destinations. You can time-stamp log messages or set the syslog source address to enhance real-time debugging and management. For information on possible messages, see the system message guide for this release.
You can access logged system messages by using the switch command-line interface (CLI) or by saving them to a properly configured syslog server. The switch software saves syslog messages in an internal buffer on the switch. If the switch fails, the log is lost unless you had saved it to flash memory.

You can remotely monitor system messages by viewing the logs on a syslog server or by accessing the switch through Telnet or through the console port.

## Configuring System Message Logging

These sections describe how to configure system message logging:

- System Log Message Format, page 47-2
- Default System Message Logging Configuration, page 47-3
- Disabling Message Logging, page 47-4 (optional)
- Setting the Message Display Destination Device, page 47-5 (optional)
- Synchronizing Log Messages, page 47-6 (optional)
- Enabling and Disabling Timestamps on Log Messages, page 47-7 (optional)
- Enabling and Disabling Sequence Numbers in Log Messages (Optional), page 47-7 (optional)
- Defining the Message Severity Level (Optional), page 47-8 (optional)
- Limiting Syslog Messages Sent to the History Table and to SNMP (Optional), page 47-9 (optional)
- Configuring UNIX Syslog Servers, page 47-10 (optional)

## System Log Message Format

System log messages can contain up to 80 characters and a percent sign (%), which follows the optional sequence number or time-stamp information, if configured. Messages are displayed in this format:

```
seq no:timestamp: %facility-severity-MNEMONIC:description
```

The part of the message preceding the percent sign depends on the setting of the `service sequence-numbers`, `service timestamps log datetime`, `service timestamps log datetime [localtime] [msec] [show-timezone]`, or `service timestamps log uptime` global configuration command.

Table 47-1 describes the elements of syslog messages.
Chapter 47  Configuring System Message Logging

Configuring System Message Logging

This example shows a partial switch system message:

```
00:00:46: %LINK-3-UPDOWN: Interface Port-channel1, changed state to up
00:00:47: %LINK-3-UPDOWN: Interface GigabitEthernet1/0/1, changed state to up
00:00:47: %LINK-3-UPDOWN: Interface GigabitEthernet1/0/2, changed state to up
00:00:48: %LINEPROTO-5-UPDOWN: Line protocol on Interface Vlan1, changed state to down
00:00:48: %LINEPROTO-5-UPDOWN: Line protocol on Interface GigabitEthernet1/0/1, changed state to down 2
*Mar 1 18:46:11: %SYS-5-CONFIG_I: Configured from console by vty2 (10.34.195.36)
18:47:02: %SYS-5-CONFIG_I: Configured from console by vty2 (10.34.195.36)
*Mar 1 18:48:50.483 UTC: %SYS-5-CONFIG_I: Configured from console by vty2 (10.34.195.36)
```

Default System Message Logging Configuration

Table 47-2 shows the default system message logging configuration.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>System message logging to the console</td>
<td>Enabled.</td>
</tr>
<tr>
<td>Console severity</td>
<td>Debugging (and numerically lower levels; see Table 47-3 on page 47-9).</td>
</tr>
<tr>
<td>Logging file configuration</td>
<td>No filename specified.</td>
</tr>
<tr>
<td>Logging buffer size</td>
<td>4096 bytes.</td>
</tr>
<tr>
<td>Logging history size</td>
<td>1 message.</td>
</tr>
<tr>
<td>Timestamps</td>
<td>Disabled.</td>
</tr>
</tbody>
</table>

This example shows a partial switch system message:

```
00:00:46: %LINK-3-UPDOWN: Interface Port-channel1, changed state to up
00:00:47: %LINK-3-UPDOWN: Interface GigabitEthernet1/0/1, changed state to up
00:00:47: %LINK-3-UPDOWN: Interface GigabitEthernet1/0/2, changed state to up
00:00:48: %LINEPROTO-5-UPDOWN: Line protocol on Interface Vlan1, changed state to down
00:00:48: %LINEPROTO-5-UPDOWN: Line protocol on Interface GigabitEthernet1/0/1, changed state to down 2
*Mar 1 18:46:11: %SYS-5-CONFIG_I: Configured from console by vty2 (10.34.195.36)
18:47:02: %SYS-5-CONFIG_I: Configured from console by vty2 (10.34.195.36)
*Mar 1 18:48:50.483 UTC: %SYS-5-CONFIG_I: Configured from console by vty2 (10.34.195.36)
```
Disabling Message Logging

Message logging is enabled by default. It must be enabled to send messages to any destination other than the console. When enabled, log messages are sent to a logging process, which logs messages to designated locations asynchronously to the processes that generated the messages.

To disable message logging, perform this task:

<table>
<thead>
<tr>
<th>Step</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>2</td>
<td>Switch(config)# no logging on</td>
<td>Disables message logging.</td>
</tr>
<tr>
<td>3</td>
<td>Switch(config)# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>4</td>
<td>Switch# show running-config or show logging</td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td>5</td>
<td>Switch# copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

Disabling the logging process can slow down the switch because a process must wait until the messages are written to the console before continuing. When the logging process is disabled, messages are displayed on the console as soon as they are produced, often appearing in the middle of command output.

The `logging synchronous` global configuration command also affects the display of messages to the console. When this command is enabled, messages appear only after you press Return. For more information, see the “Synchronizing Log Messages” section on page 47-6.

To re-enable message logging after it has been disabled, use the `logging on` global configuration command.

---

Table 47-2 Default System Message Logging Configuration (continued)

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Synchronous logging</td>
<td>Disabled.</td>
</tr>
<tr>
<td>Logging server</td>
<td>Disabled.</td>
</tr>
<tr>
<td>Syslog server IP address</td>
<td>None configured.</td>
</tr>
<tr>
<td>Server facility</td>
<td>Local7 (see Table 47-4 on page 47-12).</td>
</tr>
<tr>
<td>Server severity</td>
<td>Informational (and numerically lower levels; see Table 47-3 on page 47-9).</td>
</tr>
</tbody>
</table>
### Setting the Message Display Destination Device

If message logging is enabled, you can send messages to specific locations in addition to the console.

To specify the locations that receive messages, perform this task, beginning in privileged EXEC mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>Switch# configure terminal</strong> Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><strong>Switch(config)# logging buffered [size]</strong> Logs messages to an internal buffer on the switch. The default buffer size is 4096. The range is 4096 to 2147483647 bytes. If the switch, the log file is lost unless you previously saved it to flash memory. See Step 4. <strong>Note</strong> Do not make the buffer size too large because the switch could run out of memory for other tasks. Use the <code>show memory</code> privileged EXEC command to view the free processor memory on the switch. However, this value is the maximum available, and the buffer size should <strong>not</strong> be set to this amount.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><strong>Switch(config)# logging host</strong> Logs messages to a UNIX syslog server host. For <code>host</code>, specify the name or IP address of the host to be used as the syslog server. To build a list of syslog servers that receive logging messages, enter this command more than once. For complete syslog server configuration steps, see the “Configuring UNIX Syslog Servers” section on page 47-10.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><strong>Switch(config)# end</strong> Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><strong>Switch# terminal monitor</strong> Logs messages to a nonconsole terminal during the current session. Terminal parameter-setting commands are set locally and do not remain in effect after the session has ended. You must perform this step for each session to see the debugging messages.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td><strong>Switch# show running-config</strong> Verifies your entries.</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td><strong>Switch# copy running-config startup-config</strong> (Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

The `logging buffered` global configuration command copies logging messages to an internal buffer. The buffer is circular, so newer messages overwrite older messages after the buffer is full. To display the messages that are logged in the buffer, use the `show logging` privileged EXEC command. The first message displayed is the oldest message in the buffer. To clear the contents of the buffer, use the `clear logging` privileged EXEC command.

To disable logging to the console, use the `no logging console` global configuration command. To disable logging to a file, use the `no logging file [severity-level-number | type]` global configuration command.
## Synchronizing Log Messages

You can synchronize unsolicited messages and `debug` privileged EXEC command output with solicited device output and prompts for a specific console port line or virtual terminal line. You can identify the types of messages to be output asynchronously based on the level of severity. You can also configure the maximum number of buffers for storing asynchronous messages for the terminal after which messages are dropped.

When synchronous logging of unsolicited messages and `debug` command output is enabled, unsolicited device output appears on the console or printed after solicited device output appears or printed. Unsolicited messages and `debug` command output appears on the console after the prompt for user input is returned. Therefore, unsolicited messages and `debug` command output are not interspersed with solicited device output and prompts. After the unsolicited messages are displayed, the console again displays the user prompt.

To configure synchronous logging, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> Switch# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
</tbody>
</table>
| **Step 2** Switch(config)# line [console | vty] line-number [ending-line-number] | Specifies the line to be configured for synchronous logging of messages.  
  * Use the `console` keyword for configurations that occur through the switch console port.  
  * Use the `line vty line-number` command to specify which vty lines are to have synchronous logging enabled. You use a vty connection for configurations that occur through a Telnet session. The range of line numbers is from 0 to 15.  
You can change the setting of all 16 vty lines at once by entering:  
`line vty 0 15`  
Or you can change the setting of the single vty line being used for your current connection. For example, to change the setting for vty line 2, enter:  
`line vty 2`  
When you enter this command, the mode changes to line configuration. |
| **Step 3** Switch(config)# logging synchronous [level [severity-level | all] | limit number-of-buffers] | Enables synchronous logging of messages.  
  * (Optional) For `level severity-level`, specify the message severity level. Messages with a severity level equal to or higher than this value are printed asynchronously. Low numbers mean greater severity and high numbers mean lesser severity. The default is 2.  
  * (Optional) Specifying `level all` means that all messages are printed asynchronously regardless of the severity level.  
  * (Optional) For `limit number-of-buffers`, specify the number of buffers to be queued for the terminal after which new messages are dropped. The range is 0 to 2147483647. The default is 20. |
| **Step 4** Switch(config)# end | Returns to privileged EXEC mode. |
To disable synchronization of unsolicited messages and debug output, use the `no logging synchronous [level severity-level | all] [limit number-of-buffers]` line configuration command.

### Enabling and Disabling Timestamps on Log Messages

**Note**

By default, log messages are not time-stamped.

To enable time-stamping of log messages, perform this task:

1. **Step 1**
   - Switch# configure terminal
   - Enters global configuration mode.

2. **Step 2**
   - Switch(config)# service timestamps log uptime
   - Enables log time-stamps.
   - The first command enables time-stamps on log messages, showing the time since the system was rebooted.
   - The second command enables time-stamps on log messages. Depending on the options selected, the timestamp can include the date, time in milliseconds relative to the local time zone, and the time zone name.

3. **Step 3**
   - Switch(config)# end
   - Returns to privileged EXEC mode.

4. **Step 4**
   - Switch# show running-config
   - Verifies your entries.

5. **Step 5**
   - Switch# copy running-config startup-config
   - (Optional) Saves your entries in the configuration file.

To disable time-stamps for both debug and log messages, use the `no service timestamps` global configuration command.

This example shows part of a logging display with the `service timestamps log datetime` global configuration command enabled:

```
*Mar  1 18:46:11: %SYS-5-CONFIG_I: Configured from console by vty2 (10.34.195.36)
```

This example shows part of a logging display with the `service timestamps log uptime` global configuration command enabled:

```
00:00:46: %LINK-3-UPDOWN: Interface Port-channel1, changed state to up
```

### Enabling and Disabling Sequence Numbers in Log Messages (Optional)

Because more than one log message can have the same timestamp, you can display messages with sequence numbers so that you can unambiguously refer to a single message. By default, sequence numbers in log messages are not displayed.
To enable sequence numbers in log messages, perform this task, which is optional.

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# service sequence-numbers Enables sequence numbers.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config)# end Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch# show running-config Verifies your entries.</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch# copy running-config startup-config (Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

To disable sequence numbers, use the no service sequence-numbers global configuration command.

This example shows part of a logging display with sequence numbers enabled:

```
000019: %SYS-5-CONFIG_I: Configured from console by vty2 (10.34.195.36)
```

### Defining the Message Severity Level (Optional)

You can limit messages displayed to the selected device by specifying the severity level of the message, which are described in Table 47-3.

To define the message severity level, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# logging console level Limits messages logged to the console. By default, the console receives debugging messages and numerically lower levels (see Table 47-3 on page 47-9).</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config)# logging monitor level Limits messages logged to the terminal lines. By default, the terminal receives debugging messages and numerically lower levels (see Table 47-3 on page 47-9).</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(config)# logging trap level Limits messages logged to the syslog servers. By default, syslog servers receive informational messages and numerically lower levels (see Table 47-3 on page 47-9). For complete syslog server configuration steps, see the “Configuring UNIX Syslog Servers” section on page 47-10.</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch(config)# end Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Step 6</td>
<td>Switch# show running-config or Switch# show logging Verifies your entries.</td>
</tr>
<tr>
<td>Step 7</td>
<td>Switch# copy running-config startup-config (Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

**Note** Specifying a *level* causes messages at that level and numerically lower levels to be displayed at the destination.
To disable logging to the console, use the `no logging console` global configuration command. To disable logging to a terminal other than the console, use the `no logging monitor` global configuration command. To disable logging to syslog servers, use the `no logging trap` global configuration command.

Table 47-3 describes the `level` keywords. It also lists the corresponding UNIX syslog definitions from the most severe level to the least severe level.

### Table 47-3 Message Logging Level Keywords

<table>
<thead>
<tr>
<th>Level Keyword</th>
<th>Level</th>
<th>Description</th>
<th>Syslog Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>emergencies</td>
<td>0</td>
<td>System unstable</td>
<td>LOG_EMERG</td>
</tr>
<tr>
<td>alerts</td>
<td>1</td>
<td>Immediate action needed</td>
<td>LOG_ALERT</td>
</tr>
<tr>
<td>critical</td>
<td>2</td>
<td>Critical conditions</td>
<td>LOG_CRIT</td>
</tr>
<tr>
<td>errors</td>
<td>3</td>
<td>Error conditions</td>
<td>LOG_ERR</td>
</tr>
<tr>
<td>warnings</td>
<td>4</td>
<td>Warning conditions</td>
<td>LOG_WARNING</td>
</tr>
<tr>
<td>notifications</td>
<td>5</td>
<td>Normal but significant condition</td>
<td>LOG_NOTICE</td>
</tr>
<tr>
<td>informational</td>
<td>6</td>
<td>Informational messages only</td>
<td>LOG_INFO</td>
</tr>
<tr>
<td>debugging</td>
<td>7</td>
<td>Debugging messages</td>
<td>LOG_DEBUG</td>
</tr>
</tbody>
</table>

The software generates four other categories of messages:

- Error messages about software or hardware malfunctions, displayed at levels `warnings` through `emergencies`. These types of messages mean that the functionality of the switch is affected. For information on how to recover from these malfunctions, see the system message guide for this release.
- Output from the `debug` commands, displayed at the `debugging` level. Debug commands are typically used only by the Technical Assistance Center.
- Interface up or down transitions and system restart messages, displayed at the `notifications` level. This message is only for information; switch functionality is not affected.
- Reload requests and low-process stack messages, displayed at the `informational` level. This message is only for information; switch functionality is not affected.

## Limiting Syslog Messages Sent to the History Table and to SNMP (Optional)

If you enabled syslog message traps to be sent to an SNMP network management station by using the `snmp-server enable trap` global configuration command, you can change the level of messages sent and stored in the switch history table. You also can change the number of messages that are stored in the history table.

Messages are stored in the history table because SNMP traps are not guaranteed to reach their destination. By default, one message of the level `warning` and numerically lower levels (see Table 47-3 on page 47-9) are stored in the history table even if syslog traps are not enabled.
Configuring System Message Logging

To change the level and history table size defaults, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>Switch# configure terminal</code> Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td><code>Switch(config)# logging history level 1</code> Changes the default level of syslog messages stored in the history file and sent to the SNMP server. See Table 47-3 on page 47-9 for a list of level keywords. By default, warnings, errors, critical, alerts, and emergencies messages are sent.</td>
</tr>
<tr>
<td>Step 3</td>
<td><code>Switch(config)# logging history size number</code> Specifies the number of syslog messages that can be stored in the history table. The default is to store one message. The range is 0 to 500 messages.</td>
</tr>
<tr>
<td>Step 4</td>
<td><code>Switch(config)# end</code> Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Step 5</td>
<td><code>Switch# show running-config</code> Verifies your entries.</td>
</tr>
<tr>
<td>Step 6</td>
<td><code>Switch# copy running-config startup-config</code> (Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

1. Table 47-3 lists the level keywords and severity level. For SNMP usage, the severity level values increase by 1. For example, emergencies equal 1, not 0, and critical equals 3, not 2.

When the history table is full (it contains the maximum number of message entries specified with the `logging history size` global configuration command), the oldest message entry is deleted from the table to allow the new message entry to be stored.

To return the logging of syslog messages to the default level, use the `no logging history` global configuration command. To return the number of messages in the history table to the default value, use the `no logging history size` global configuration command.

### Configuring UNIX Syslog Servers

The next sections describe how to configure the UNIX server syslog daemon and how to define the UNIX system logging facility.

### Logging Messages to a UNIX Syslog Daemon

Before you can send system log messages to a UNIX syslog server, you must configure the syslog daemon on a UNIX server. This procedure is optional.

**Note** Some recent versions of UNIX syslog daemons no longer accept by default syslog packets from the network. If this is the case with your system, use the UNIX `man syslogd` command to decide what options must be added to or removed from the syslog command line to enable logging of remote syslog messages.
Log in as root, and perform these steps:

**Step 1**  Add a line such as the following to the file `/etc/syslog.conf`:
```
local7.debug /usr/adm/logs/cisco.log
```

The `local7` keyword specifies the logging facility to be used; see Table 47-4 on page 47-12 for information on the facilities. The `debug` keyword specifies the syslog level; see Table 47-3 on page 47-9 for information on the severity levels. The syslog daemon sends messages at this level or at a more severe level to the file specified in the next field. The file must already exist, and the syslog daemon must have permission to write to it.

**Step 2**  Create the log file by entering these commands at the UNIX shell prompt:
```
$ touch /var/log/cisco.log
$ chmod 666 /var/log/cisco.log
```

**Step 3**  Ensure that the syslog daemon reads the new changes:
```
$ kill -HUP `cat /etc/syslog.pid`
```

For more information, see the `man syslog.conf` and `man syslogd` commands on your UNIX system.

### Configuring the UNIX System Logging Facility

When sending system log messages to an external device, you can cause the switch to identify its messages as originating from any of the UNIX syslog facilities.

To configure UNIX system facility message logging, perform this task, which is optional.

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** 
Switch# `configure terminal` | Enters global configuration mode. |
| **Step 2** 
Switch(config)# `logging host` | Logs messages to a UNIX syslog server host by entering its IP address. To build a list of syslog servers that receive logging messages, enter this command more than once. |
| **Step 3** 
Switch(config)# `logging trap level` | Limits messages logged to the syslog servers. Be default, syslog servers receive informational messages and lower. See Table 47-3 on page 47-9 for `level` keywords. |
| **Step 4** 
Switch(config)# `logging facility facility-type` | Configures the syslog facility. See Table 47-4 on page 47-12 for `facility-type` keywords. The default is `local7`. |
| **Step 5** 
Switch(config)# `end` | Returns to privileged EXEC mode. |
| **Step 6** 
Switch# `show running-config` | Verifies your entries. |
| **Step 7** 
Switch# `copy running-config startup-config` | (Optional) Saves your entries in the configuration file. |
To remove a syslog server, use the `no logging host` global configuration command, and specify the syslog server IP address. To disable logging to syslog servers, enter the `no logging trap` global configuration command.

Table 47-4 lists the UNIX system facilities supported by the software. For more information about these facilities, consult the operator’s manual for your UNIX operating system.

### Displaying the Logging Configuration

To display the logging configuration and the contents of the log buffer, use the `show logging` privileged EXEC command. For information about the fields in this display, see the *Cisco IOS Configuration Fundamentals Command Reference, Release 12.3*. 
Chapter 48

Configuring Onboard Failure Logging (OBFL)

- Prerequisites for OBFL, page 48-1
- Restrictions for OBFL, page 48-2
- Information About OBFL, page 48-2
- Default Settings for OBFL, page 48-9
- Enabling OBFL, page 48-9
- Configuration Examples for OBFL, page 48-10

Note
For complete syntax and usage information for the commands used in this chapter, see these publications:

Note
For complete syntax and usage information for the switch commands used in this chapter, first look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Series Switch Command Reference, it will be found in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

Prerequisites for OBFL

None.
Restrictions for OBFL

They include:

- **Software Restrictions**—If a device (router or switch) intends to use linear flash memory as its OBFL storage media, Cisco IOS software must reserve a minimum of two physical sectors (or physical blocks) for the OBFL feature. Because an erase operation for a linear flash device is done on per-sector (or per-block) basis, one extra physical sector is needed. Otherwise, the minimum amount of space reserved for the OBFL feature on any device must be at least 8 KB.

- **Firmware Restrictions**—If a line card or port adapter runs an operating system or firmware that is different from the Cisco IOS operating system, the line card or port adapter must provide device driver level support or an interprocess communications (IPC) layer that allows the OBFL file system to communicate to the line card or port adapter. This requirement is enforced to allow OBFL data to be recorded on a storage device attached to the line card or port adapter.

- **Hardware Restrictions**—To support the OBFL feature, a device must have at least 8 KB of nonvolatile memory space reserved for OBFL data logging.

Information About OBFL

- **Overview of OBFL**, page 48-2
- **Information about Data Collected by OBFL**, page 48-2

Overview of OBFL

The Onboard Failure Logging (OBFL) feature collects data such as operating temperatures, hardware uptime, interrupts, and other important events and messages from system hardware installed in a Cisco router or switch. The data is stored in nonvolatile memory and helps technical personnel diagnose hardware problems.

Information about Data Collected by OBFL

- **OBFL Data Overview**, page 48-2
- **Temperature**, page 48-3
- **Operational Uptime**, page 48-4
- **Interrupts**, page 48-7
- **Message Logging**, page 48-8

OBFL Data Overview

The OBFL feature records operating temperatures, hardware uptime, interrupts, and other important events and messages that can assist with diagnosing problems with hardware cards (or modules) installed in a Cisco router or switch. Data is logged to files stored in nonvolatile memory. When the onboard hardware is started up, a first record is made for each area monitored and becomes a base value for subsequent records. The OBFL feature provides a circular updating scheme for collecting continuous records and archiving older (historical) records, ensuring accurate data about the system. Data is
recorded in one of two formats: continuous information that displays a snapshot of measurements and samples in a continuous file, and summary information that provides details about the data being collected. The data is displayed using the `show logging onboard` command. The message “No historical data to display” is seen when historical data is not available.

**Temperature**

Temperatures surrounding hardware modules can exceed recommended safe operating ranges and cause system problems such as packet drops. Higher than recommended operating temperatures can also accelerate component degradation and affect device reliability. Monitoring temperatures is important for maintaining environmental control and system reliability. Once a temperature sample is logged, the sample becomes the base value for the next record. From that point on, temperatures are recorded either when there are changes from the previous record or if the maximum storage time is exceeded. Temperatures are measured and recorded in degrees Celsius.

**Temperature Example**

```
Switch# sh logging onboard temperature

Switch#

To interpret this data:

- Number of sensors is the total number of temperature sensors that will be recorded. A column for each sensor is displayed with temperatures listed under the number of each sensor, as available.
- Sampling frequency is the time between measurements.
- Maximum time of storage determines the maximum amount of time, in minutes, that can pass when the temperature remains unchanged and the data is not saved to storage media. After this time, a temperature record will be saved even if the temperature has not changed.
- The Sensor column lists the name of the sensor.
- The ID column lists an assigned identifier for the sensor.
- Maximum Temperature 0C shows the highest recorded temperature per sensor.
- Temp indicates a recorded temperature in degrees Celsius in the historical record. Columns following show the total time each sensor has recorded that temperature.
- Sensor ID is an assigned number, so that temperatures for the same sensor can be stored together.

### Operational Uptime

The operational uptime tracking begins when the module is powered on, and information is retained for the life of the module.
### Operational Uptime Example

Switch# `sh logging onboard uptime detail`

Chapter 48 Configuring Onboard Failure Logging (OBFL)

Information About OBFL

Switch#

The operational uptime application tracks the following events:

- Date and time the customer first powered on a component.
- Total uptime and downtime for the component in years, weeks, days, hours, and minutes.
- Total number of component resets.
- Total number of slot (module) changes.
- Current reset timestamp to include the date and time.
- Current slot (module) number of the component.
- Current uptime in years, weeks, days, hours, and minutes.
## Interrupts

Interrupts are generated by system components that require attention from the CPU such as ASICs and NMIs. Interrupts are generally related to hardware limit conditions or errors that need to be corrected. The continuous format records each time a component is interrupted, and this record is stored and used as base information for subsequent records. Each time the list is saved, a timestamp is added. Time differences from the previous interrupt are counted, so that technical personnel can gain a complete record of the component’s operational history when an error occurs.

### Interrupts Example

```text
Switch# sh logging onboard interrupt detail

```

To interpret this data:
- Name is a description of the component including its position in the device.
- ID is an assigned field for data storage.
- Offset is the register offset from a component register’s base address.
- Bit is the interrupt bit number recorded from the component’s internal register.
- The timestamp shows the date and time that an interrupt occurred down to the millisecond.
Message Logging

The OBFL feature logs standard system messages. Instead of displaying the message to a terminal, the message is written to and stored in a file, so the message can be accessed and read at a later time. System messages range from level 1 alerts to level 7 debug messages, and these levels can be specified in the `hw module logging onboard` command.

**Error Message Log Example**

Switch# `sh logging onboard message det`

```
ERROR MESSAGE SUMMARY INFORMATION

Facility-Sev-Name | Count | Persistence Flag
MM/DD/YYYY HH:MM:SS

%CAT4K-3-DIAGNOSTICS_PASSED : 22 LAST
11/24/2010 15:46:20 module passed diagnostics
%CAT4K-2-DIAGNOSTIC_STATUS : 22 LAST
```

```
ERROR MESSAGE CONTINUOUS INFORMATION

MM/DD/YYYY HH:MM:SS Facility-Sev-Name

12/15/2010 11:32:39 %CAT4K-3-DIAGNOSTICS_PASSED : module passed diagnostics

12/15/2010 14:35:51 %CAT4K-2-DIAGNOSTIC_STATUS : diagnostic Packet memory Skipped
```

Switch#

To interpret this data:

- A timestamp shows the date and time the message was logged.
- Facility-Sev-Name is a coded naming scheme for a system message, as follows:
  - The Facility code consists of two or more uppercase letters that indicate the hardware device (facility) to which the message refers.
  - Sev is a single-digit code from 1 to 7 that reflects the severity of the message.
  - Name is one or two code names separated by a hyphen that describe the part of the system from where the message is coming.
- The error message follows the Facility-Sev-Name codes. For more information about system messages, see the *Cisco IOS System and Error Messages* guide.
- Count indicates the number of instances of this message that is allowed in the history file. Once that number of instances has been recorded, the oldest instance will be removed from the history file to make room for new ones.
Default Settings for OBFL

The OBFL feature is enabled by default. Because of the valuable information this feature offers technical personnel, it should not be disabled.

Enabling OBFL

To enable OBFL, perform this task:

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>Router&gt; enable</td>
<td>Enables privileged EXEC mode (enter your password if prompted).</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td>Router# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td></td>
</tr>
<tr>
<td>Router(config)# hw-module module module-number logging onboard [message level {1-7}]</td>
<td>Enables OBFL on the specified hardware module.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td></td>
</tr>
<tr>
<td>Router(config)# end</td>
<td>Ends global configuration mode.</td>
</tr>
</tbody>
</table>

Note: By default, all system messages sent to a device are logged by the OBFL feature. You can define a specific message level (only level 1 messages, as an example) to be logged using the `message level` keywords.
Chapter 48      Configuring Onboard Failure Logging (OBFL)

Configuration Examples for OBFL

The important OBFL feature is the information that is displayed by the `show logging onboard module` privileged EXEC command. This section provides the following examples of how to enable and display OBFL records.

- **Enabling OBFL Message Logging: Example**
- **OBFL Message Log: Example**
- **OBFL Component Uptime Report: Example**
- **OBFL Report for a Specific Time: Example**

### Enabling OBFL Message Logging: Example

The following example shows how to configure OBFL message logging at level 3:

```
Router(config)# hw-module module 1 logging onboard message level 3
```

### OBFL Message Log: Example

The following example shows how to display the system messages that are being logged for module 2:

```
Switch# show logging onboard module 2 message continuous
```

```
ERROR MESSAGE CONTINUOUS INFORMATION

Switch#
CHAPTER 49

Configuring SNMP

This chapter describes how to configure the Simple Network Management Protocol (SNMP) on the Catalyst 4500 series switch.

This chapter consists of these sections:
- About SNMP, page 49-1
- Configuring SNMP, page 49-5
- Displaying SNMP Status, page 49-17

Note

For complete syntax and usage information for the commands used in this chapter, see the Cisco IOS Configuration Fundamentals Command Reference

and related publications at this location:

About SNMP

SNMP is an application-layer protocol that provides a message format for communication between managers and agents. The SNMP system consists of an SNMP manager, an SNMP agent, and a MIB. The SNMP manager can be part of a network management system (NMS) such as CiscoWorks. The agent and MIB reside on the switch. To configure SNMP on the switch, you define the relationship between the manager and the agent.

The SNMP agent contains MIB variables whose values the SNMP manager can request or change. A manager can get a value from an agent or store a value into the agent. The agent gathers data from the MIB, the repository for information about device parameters and network data. The agent can also respond to a manager’s requests to get or set data.

An agent can send unsolicited traps to the manager. Traps are messages alerting the SNMP manager to a condition on the network. Traps can mean improper user authentication, restarts, link status (up or down), MAC address tracking, closing of a Transmission Control Protocol (TCP) connection, loss of connection to a neighbor, or other significant events.
This section includes information about these topics:

- **SNMP Versions**, page 49-2
- **SNMP Manager Functions**, page 49-3
- **SNMP Agent Functions**, page 49-4
- **SNMP Community Strings**, page 49-4
- **Using SNMP to Access MIB Variables**, page 49-4
- **SNMP Notifications**, page 49-5

### SNMP Versions

The Catalyst 4500 series switch supports these SNMP versions:

- **SNMPv1**—The Simple Network Management Protocol, a Full Internet Standard, defined in RFC 1157.
- **SNMPv2C** replaces the Party-based Administrative and Security Framework of SNMPv2Classic with the community-string-based Administrative Framework of SNMPv2C while retaining the bulk retrieval and improved error handling of SNMPv2Classic. It has these features:
  - **SNMPv2**—Version 2 of the Simple Network Management Protocol, a Draft Internet Standard, defined in RFCs 1902 through 1907.
  - **SNMPv2C**—The community-string-based Administrative Framework for SNMPv2, an Experimental Internet Protocol defined in RFC 1901.
- **SNMPv3**—Version 3 of the SNMP is an interoperable standards-based protocol defined in RFCs 2273 to 2275. SNMPv3 provides secure access to devices by authenticating and encrypting packets over the network and includes these security features:
  - Message integrity—ensuring that a packet was not tampered with in transit
  - Authentication—determining that the message is from a valid source
  - Encryption—mixing the contents of a package to prevent it from being read by an unauthorized source.

**Note**

To select encryption, enter the `priv` keyword. This keyword is available only when the crypto (encrypted) software image is installed.

Both SNMPv1 and SNMPv2C use a community-based form of security. The community of managers able to access the agent’s MIB is defined by an IP address access control list and password.

SNMPv2C includes a bulk retrieval mechanism and more detailed error message reporting to management stations. The bulk retrieval mechanism retrieves tables and large quantities of information, minimizing the number of round-trips required. The SNMPv2C improved error-handling includes expanded error codes that distinguish different kinds of error conditions; these conditions are reported through a single error code in SNMPv1. Error return codes in SNMPv2C report the error type.

SNMPv3 provides for both security models and security levels. A security model is an authentication strategy set up for a user and the group within which the user resides. A security level is the permitted level of security within a security model. A combination of the security level and the security model determine which security mechanism is used when handling an SNMP packet. Available security models are SNMPv1, SNMPv2C, and SNMPv3.
The following table identifies the characteristics of the different combinations of security models and levels.

<table>
<thead>
<tr>
<th>Model</th>
<th>Level</th>
<th>Authentication</th>
<th>Encryption</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>SNMPv1</td>
<td>noAuthNoPriv</td>
<td>Community string</td>
<td>No</td>
<td>Uses a community string match for authentication.</td>
</tr>
<tr>
<td>SNMPv2C</td>
<td>noAuthNoPriv</td>
<td>Community string</td>
<td>No</td>
<td>Uses a community string match for authentication.</td>
</tr>
<tr>
<td>SNMPv3</td>
<td>noAuthNoPriv</td>
<td>Username</td>
<td>No</td>
<td>Uses a username match for authentication.</td>
</tr>
<tr>
<td>SNMPv3</td>
<td>authNoPriv</td>
<td>MD5 or SHA</td>
<td>No</td>
<td>Provides authentication based on the HMAC-MD5 or HMAC-SHA algorithms.</td>
</tr>
<tr>
<td>SNMPv3</td>
<td>authPriv</td>
<td>MD5 or SHA</td>
<td>DES</td>
<td>Provides authentication based on the HMAC-MD5 or HMAC-SHA algorithms. Provides DES 56-bit encryption in addition to authentication based on the CBC-DES (DES-56) standard.</td>
</tr>
</tbody>
</table>

You must configure the SNMP agent to use the SNMP version supported by the management station. Because an agent can communicate with multiple managers, you can configure the software to support communications using SNMPv1, and SNMPv2C, and SNMPv3 protocols.

**SNMP Manager Functions**

The SNMP manager uses information in the MIB to perform the operations described in Table 49-1.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>get-request</td>
<td>Retrieves a value from a specific variable.</td>
</tr>
<tr>
<td>get-next-request</td>
<td>Retrieves a value from a variable within a table.¹</td>
</tr>
<tr>
<td>get-bulk-request²</td>
<td>Retrieves large blocks of data, such as multiple rows in a table, that would otherwise require the transmission of many small blocks of data.</td>
</tr>
<tr>
<td>get-response</td>
<td>Replies to a get-request, get-next-request, and set-request sent by an NMS.</td>
</tr>
<tr>
<td>set-request</td>
<td>Stores a value in a specific variable.</td>
</tr>
<tr>
<td>trap</td>
<td>An unsolicited message sent by an SNMP agent to an SNMP manager when some event has occurred.</td>
</tr>
</tbody>
</table>

¹. With this operation, an SNMP manager does not need to know the exact variable name. A sequential search is performed to find the needed variable from within a table.

². The `get-bulk` command only works with SNMPv2 or later.
SNMP Agent Functions

The SNMP agent responds to SNMP manager requests as follows:

- **Get a MIB variable**—The SNMP agent begins this function in response to a request from the NMS. The agent retrieves the value of the requested MIB variable and responds to the NMS with that value.

- **Set a MIB variable**—The SNMP agent begins this function in response to a message from the NMS. The SNMP agent changes the value of the MIB variable to the value requested by the NMS.

The SNMP agent also sends unsolicited trap messages to notify an NMS that a significant event has occurred on the agent. Examples of trap conditions include, but are not limited to, when a port or module goes up or down, when spanning-tree topology changes occur, and when authentication failures occur.

SNMP Community Strings

SNMP community strings authenticate access to MIB objects and function as embedded passwords. In order for the NMS to access the switch, the community string definitions on the NMS must match at least one of the three community string definitions on the switch.

A community string can have one of these attributes:

- **Read-only (RO)**—Gives read access to authorized management stations to all objects in the MIB except the community strings, but does not allow write access
- **Read-write (RW)**—Gives read and write access to authorized management stations to all objects in the MIB, but does not allow access to the community strings
- **Read-write-all**—Gives read and write access to authorized management stations to all objects in the MIB, including the community strings

Using SNMP to Access MIB Variables

An example of an NMS is the CiscoWorks network management software. CiscoWorks 2000 software uses the switch MIB variables to set device variables and to poll devices on the network for specific information. The results of a poll can be displayed as a graph and analyzed to troubleshoot internetworking problems, increase network performance, verify the configuration of devices, monitor traffic loads, and more.

As shown in Figure 49-1, the SNMP agent gathers data from the MIB. The agent can send traps, or notification of certain events, to the SNMP manager, which receives and processes the traps. Traps alert the SNMP manager to a condition on the network such as improper user authentication, restarts, link status (up or down), MAC address tracking, and so forth. The SNMP agent also responds to MIB-related queries sent by the SNMP manager in get-request, get-next-request, and set-request format.

![Figure 49-1](image-url)
SNMP Notifications

SNMP allows the switch to send notifications to SNMP managers when particular events occur. SNMP
notifications can be sent as traps or inform requests. In command syntax, unless there is an option in the
command to select either traps or informs, the keyword traps refers to either traps or informs, or both.
Use the snmp-server host command to specify whether to send SNMP notifications as traps or informs.

Note

SNMPv1 does not support informs.

Traps are unreliable because the receiver does not send an acknowledgment when it receives a trap, and
the sender cannot determine if the trap was received. When an SNMP manager receives an inform
request, it acknowledges the message with an SNMP response protocol data unit (PDU). If the sender
does not receive a response, the inform request can be sent again. Because they can be re-sent, informs
are more likely than traps to reach their intended destination.

The characteristics that make informs more reliable than traps also consume more resources in the switch
and in the network. Unlike a trap, which is discarded as soon as it is sent, an inform request is held in
memory until a response is received or the request times out. Traps are sent only once, but an inform
might be re-sent or retried several times. The retries increase traffic and contribute to a higher overhead
on the network. Therefore, traps and informs require a trade-off between reliability and resources. If it
is important that the SNMP manager receive every notification, use inform requests. If traffic on the
network or memory in the switch is a concern and notification is not required, use traps.

Configuring SNMP

This section describes how to configure SNMP on your switch. It contains this configuration
information:

- Default SNMP Configuration, page 49-5
- SNMP Configuration Guidelines, page 49-6
- Disabling the SNMP Agent, page 49-7
- Configuring Community Strings, page 49-7
- Configuring SNMP Groups and Users, page 49-9
- Configuring SNMP Notifications, page 49-11
- Setting the Agent Contact and Location Information, page 49-15
- Limiting TFTP Servers Used Through SNMP, page 49-15
- SNMP Examples, page 49-16

Default SNMP Configuration

Table 49-2 shows the default SNMP configuration.
Configuring SNMP

An SNMP group is a table that maps SNMP users to SNMP views. An SNMP user is a member of an SNMP group. An SNMP host is the recipient of an SNMP trap operation. An SNMP engine ID is a name for the local or remote SNMP engine.

When configuring SNMP, follow these guidelines:

- When configuring an SNMP group, do not specify a notify view. The `snmp-server host` global configuration command autogenerates a notify view for the user and then adds it to the group associated with that user. Modifying the group's notify view affects all users associated with that group. For information about when you should configure notify views, see the Cisco IOS Configuration Fundamentals Command Reference, Release 12.2.

- To configure a remote user, specify the IP address or port number for the remote SNMP agent of the device where the user resides.

- Before you configure remote users for a particular agent, configure the SNMP engine ID, using the `snmp-server engineID` global configuration with the `remote` option. The remote agent's SNMP engine ID and user password are used to compute the authentication and privacy digests. If you do not configure the remote engine ID first, the configuration command fails.

- When configuring SNMP informs, you need to configure the SNMP engine ID for the remote agent in the SNMP database before you can send proxy requests or informs to it.

- If a local user is not associated with a remote host, the switch does not send informs for the auth (authNoPriv) and the priv (authPriv) authentication levels.

- Changing the value of the SNMP engine ID has important side effects. A user's password (entered on the command line) is converted to an MD5 or SHA security digest based on the password and the local engine ID. The command-line password is then destroyed, as required by RFC 2274. Because of this deletion, if the value of the engine ID changes, the security digests of SNMPv3 users become invalid, and you need to reconfigure SNMP users by using the `snmp-server user` global configuration command. Similar restrictions require the reconfiguration of community strings when the engine ID changes.

### Table 49-2 Default SNMP Configuration

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>SNMP agent</td>
<td>Enabled</td>
</tr>
<tr>
<td>SNMP trap receiver</td>
<td>None configured</td>
</tr>
<tr>
<td>SNMP traps</td>
<td>None enabled except the trap for TCP connections (tty), and licensing.</td>
</tr>
<tr>
<td>SNMP version</td>
<td>If no <code>version</code> keyword is present, the default is Version 1.</td>
</tr>
<tr>
<td>SNMPv3 authentication</td>
<td>If no keyword is entered, the default is the <code>noauth</code> (noAuthNoPriv) security level.</td>
</tr>
<tr>
<td>SNMP notification type</td>
<td>If no type is specified, all notifications are sent.</td>
</tr>
</tbody>
</table>
Disabling the SNMP Agent

To disable the SNMP agent, perform this task:

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Switch# configure terminal</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# no snmp-server</td>
<td>Disables the SNMP agent operation.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config)# end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch# show running-config</td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch# copy running-config startup-config</td>
<td>(Optional) Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>

The `no snmp-server` global configuration command disables all running versions (Version 1, Version 2C, and Version 3) on the device. No specific IOS command exists to enable SNMP. The first `snmp-server` global configuration command that you enter enables all versions of SNMP.

Configuring Community Strings

You use the SNMP community string to define the relationship between the SNMP manager and the agent. The community string acts like a password to permit access to the agent on the switch. Optionally, you can specify one or more of these characteristics associated with the string:

- An access list of IP addresses of the SNMP managers that are permitted to use the community string to gain access to the agent
- A MIB view, which defines the subset of all MIB objects accessible to the given community
- Read and write or read-only permission for the MIB objects accessible to the community
To configure a community string on the switch, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# [no] snmp-server community string [view view-name] [ro</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config)# access-list access-list-number {deny / permit} source [source-wildcard]</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch# show running-config</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Switch# copy running-config startup-config</td>
</tr>
</tbody>
</table>

**Note** To disable access for an SNMP community, set the community string for that community to the null string (do not enter a value for the community string).
The `snmp-server enable informs` command is not supported. To enable the sending of SNMP inform notifications, use the `snmp-server enable traps` command combined with the `snmp-server host host-addr informs` command.

This example shows how to assign the string `comaccess` to SNMP, to allow read-only access, and to specify that IP access list 4 can use the community string to gain access to the switch SNMP agent:

```
Switch(config)# snmp-server community comaccess ro 4
```

## Configuring SNMP Groups and Users

You can specify an identification name (engine ID) for the local or remote SNMP server engine on the switch. You can configure an SNMP server group that maps SNMP users to SNMP views, and you can add new users to the SNMP group.

To configure SNMP on the switch, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>Purpose</strong></td>
</tr>
<tr>
<td><code>Switch# configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><strong>Purpose</strong></td>
</tr>
<tr>
<td>`Switch(config)# snmp-server engineID [local engine-id-string</td>
<td>remote ip-address [udp-port port-number] engineid-string]`</td>
</tr>
<tr>
<td>• The <em>engineid-string</em> is a 24-character string with the name of the copy of SNMP. You need not specify the entire 24-character engine ID if it has trailing zeros. Specify only the portion of the engine ID up to the point where only zeros remain in the value. For example, to configure an engine ID of 123400000000000000000000, you can enter this: <code>snmp-server engineID local 1234</code></td>
<td></td>
</tr>
<tr>
<td>• If you select <code>remote</code>, specify the <em>ip-address</em> of the device that contains the remote copy of SNMP and the optional UDP port on the remote device. The default is 162.</td>
<td></td>
</tr>
</tbody>
</table>
### Configuring SNMP

**Step 3**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Switch(config)# snmp-server group</code> <code>groupname</code> `{v1</td>
<td>v2c</td>
</tr>
</tbody>
</table>

- For `groupname`, specify the name of the group.
- Specify a security model:
  - `v1` is the least secure of the possible security models.
  - `v2c` is the second least secure model. It allows transmission of informs and integers twice the normal width.
  - `v3`, the most secure, requires you to select an authentication level:
    - `auth`—Enables the Message Digest 5 (MD5) and the Secure Hash Algorithm (SHA) packet authentication.
    - `noauth`—The noAuthNoPriv security level. This is the default if no keyword is specified.
    - `priv`—Enables Data Encryption Standard (DES) packet encryption (also called `privacy`).

**Note**
The `priv` keyword is available only when the crypto software image is installed.

- (Optional) Enter `read readview` with a string (not to exceed 64 characters) that is the name of the view in which you can only view the contents of the agent.
- (Optional) Enter `write writeview` with a string (not to exceed 64 characters) that is the name of the view in which you enter data and configure the contents of the agent.
- (Optional) Enter `notify notifyview` with a string (not to exceed 64 characters) that is the name of the view in which you specify a notify, inform, or trap.
- (Optional) Enter `access access-list` with a string (not to exceed 64 characters) that is the name of the access list.
Chapter 49  Configuring SNMP

Configuring SNMP

Configuring SNMP Notifications

A trap manager is a management station that receives and processes traps. Traps are system alerts that the switch generates when certain events occur. By default, no trap manager is defined, and no traps are sent. Switches running IOS Cisco IOS Release 12.2(31)SG and later releases can have an unlimited number of trap managers.

Many commands use the word traps in the command syntax. Unless there is an option in the command to select either traps or informs, the keyword traps refers to either traps, informs, or both. Use the snmp-server host command to specify whether to send SNMP notifications as traps or informs.

Table 49-3 describes the supported switch traps (notification types). You can enable any or all of these traps and configure a trap manager to receive them.

### Table 49-3: Supported Switch Traps

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 4</strong></td>
<td>Configures a new user to an SNMP group.</td>
</tr>
</tbody>
</table>
| `Switch(config)# snmp-server user username groupname [remote host [udp-port port]] [v1 / v2c | v3 [auth {md5 | sha} auth-password]} [encrypted] [access access-list]` | - The `username` is the name of the user on the host that connects to the agent.  
- The `groupname` is the name of the group to which the user is associated.  
- (Optional) Enter `remote` to specify a remote SNMP entity to which the user belongs and the hostname or IP address of that entity with the optional UDP port number. The default is 162.  
- Enter the SNMP version number (`v1`, `v2c`, or `v3`). If you enter `v3`, you have these additional options:  
  - `auth` is an authentication level setting session, which can be either the HMAC-MD5-96 or the HMAC-SHA-96 authentication level, and requires a password string (not to exceed 64 characters).  
  - `encrypted` specifies that the password appears in encrypted format.  
- (Optional) Enter `access access-list` with a string (not to exceed 64 characters) that is the name of the access list. |
| **Step 5** | Returns to privileged EXEC mode. |
| `Switch(config)# end` | |
| **Step 6** | Verifies your entries. |
| `Switch# show running-config` | |
| **Step 7** | (Optional) Saves your entries in the configuration file. |
| `Switch# copy running-config startup-config` | |
## Table 49-3  Switch Notification Types

<table>
<thead>
<tr>
<th>Notification Type Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>auth-framework</td>
<td>Enables SNMP CISCO-AUTH-FRAMEWORK-MIB traps.</td>
</tr>
<tr>
<td>bgp</td>
<td>Generates BGP state change traps.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong>  This option is only available when the enhanced multilayer image is installed.</td>
</tr>
<tr>
<td>bridge</td>
<td>Generates STP bridge MIB traps.</td>
</tr>
<tr>
<td>bulkstat</td>
<td>Enables Data-Collection-MIB Collection notifications</td>
</tr>
<tr>
<td>call-home</td>
<td>Enables SNMP CISCO-CALLHOME-MIB traps.</td>
</tr>
<tr>
<td>cef</td>
<td>Enables SNMP CEF traps.</td>
</tr>
<tr>
<td>config</td>
<td>Generates a trap for SNMP configuration changes.</td>

<tr>
<td>memory</td>
<td>Enables MEMORY traps.</td>
</tr>
<tr>
<td>msdp</td>
<td>Generates a trap for Multicast Source Discovery Protocol (MSDP) changes.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong>  This option is only available when the enhanced multilayer image is installed.</td>
</tr>
</tbody>
</table>
Configuring SNMP

You can use the `snmp-server host` global configuration command to a specific host to receive the notification types listed in Table 49-3.

To configure the switch to send traps or informs to a host, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# snmp-server engineID remote ip-address engineid-string</td>
</tr>
</tbody>
</table>
## Configuring SNMP

### Step 3
```
Switch(config)# snmp-server user username groupname remote host [udp-port port] {v1 | v2c | v3 [auth [md5 | sha] auth-password] [encrypted] [access access-list]
```
Configures an SNMP user to be associated with the remote host created in Step 2.

**Note** You cannot configure a remote user for an address without first configuring the engine ID for the remote host. If you try to configure the user before configuring the remote engine ID, you receive an error message, and the command is not executed.

### Step 4
```
Switch(config)# snmp-server host host-addr [traps | informs] [version {1 / 2c | 3 [auth | noauth | priv]}] community-string [udp-port port] [notification-type]
```
Specifies the recipient of an SNMP trap operation.

- For host-addr, specify the name or Internet address of the host (the targeted recipient).
- (Optional) Enter traps (the default) to send SNMP traps to the host.
- (Optional) Enter informs to send SNMP informs to the host.
- (Optional) Specify the SNMP version (1, 2c, or 3). SNMPv1 does not support informs.
- (Optional) For Version 3, select authentication level auth, noauth, or priv.

**Note** The priv keyword is available only when the crypto software image is installed.

- For community-string, enter the password-like community string sent with the notification operation.
- (Optional) For udp-port port, enter the remote device UDP port.
- (Optional) For notification-type, use the keywords listed in Table 49-3 on page 49-12. If no type is specified, all notifications are sent.

### Step 5
```
Switch(config)# snmp-server enable traps notification-types
```
Enables the switch to send traps or informs and specify the type of notifications to be sent. For a list of notification types, see Table 49-3 on page 49-12, or enter this: `snmp-server enable traps ?`

To enable multiple types of traps, you must enter a separate `snmp-server enable traps` command for each trap type.

### Step 6
```
Switch(config)# snmp-server trap-source interface-id
```
(Optional) Specifies the source interface, which provides the IP address for the trap message. This command also sets the source IP address for informs.

### Step 7
```
Switch(config)# snmp-server queue-length length
```
(Optional) Establishes the message queue length for each trap host. The range is 1 to 5000; the default is 1000.

### Step 8
```
Switch(config)# snmp-server trap-timeout seconds
```
(Optional) Defines how often to resend trap messages. The range is 1 to 1000; the default is 30 seconds.

### Step 9
```
Switch(config)# end
```
Returns to privileged EXEC mode.

### Step 10
```
Switch# show running-config
```
Verifies your entries.

### Step 11
```
Switch# copy running-config startup-config
```
(Optional) Saves your entries in the configuration file.

---

### Table

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 3</td>
<td>Configures an SNMP user to be associated with the remote host created in Step 2.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Specifies the recipient of an SNMP trap operation.</td>
</tr>
<tr>
<td>Step 5</td>
<td>Enables the switch to send traps or informs and specify the type of notifications to be sent.</td>
</tr>
<tr>
<td>Step 6</td>
<td>Specifies the source interface, which provides the IP address for the trap message.</td>
</tr>
<tr>
<td>Step 7</td>
<td>Establishes the message queue length for each trap host.</td>
</tr>
<tr>
<td>Step 8</td>
<td>Defines how often to resend trap messages.</td>
</tr>
<tr>
<td>Step 9</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Step 10</td>
<td>Verifies your entries.</td>
</tr>
<tr>
<td>Step 11</td>
<td>Saves your entries in the configuration file.</td>
</tr>
</tbody>
</table>
The `snmp-server host` command specifies which hosts receive the notifications. The `snmp-server enable trap` command globally enables the mechanism for the specified notification (for traps and informs). To enable a host to receive an inform, you must configure an `snmp-server host informs` command for the host and globally enable informs by using the `snmp-server enable traps` command.

To remove the specified host from receiving traps, use the `no snmp-server host host` global configuration command. The `no snmp-server host` command with no keywords disables traps, but not informs, to the host. To disable informs, use the `no snmp-server host informs` global configuration command. To disable a specific trap type, use the `no snmp-server enable traps notification-types` global configuration command.

### Setting the Agent Contact and Location Information

To set the system contact and location of the SNMP agent so that these descriptions can be accessed through the configuration file, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# snmp-server contact text</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(config)# snmp-server location text</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(config)# end</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Switch# show running-config</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Switch# copy running-config startup-config</td>
</tr>
</tbody>
</table>

### Limiting TFTP Servers Used Through SNMP

To limit the TFTP servers used for saving and loading configuration files through SNMP to the servers specified in an access list, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# snmp-server tftp-server-list access-list-number</td>
</tr>
</tbody>
</table>
### SNMP Examples

This example shows how to enable all versions of SNMP. The configuration permits any SNMP manager to access all objects with read-only permissions using the community string `public`. This configuration does not cause the switch to send any traps.

```plaintext
Switch(config)# snmp-server community public
```

This example shows how to permit any SNMP manager to access all objects with read-only permissions using the community string `public`. The switch also sends VTP traps to the hosts 192.180.1.111 and 192.180.1.33 using SNMPv1 and to the host 192.180.1.27 using SNMPv2C. The community string `public` is sent with the traps.

```plaintext
Switch(config)# snmp-server community public
Switch(config)# snmp-server enable traps vtp
Switch(config)# snmp-server host 192.180.1.27 version 2c public
Switch(config)# snmp-server host 192.180.1.111 version 1 public
Switch(config)# snmp-server host 192.180.1.33 public
```

This example shows how to allow read-only access for all objects to members of access list 4 that use the `comaccess` community string. No other SNMP managers have access to any objects. SNMP Authentication Failure traps are sent by SNMPv2C to the host `cisco.com` using the community string `public`.

```plaintext
Switch(config)# snmp-server community comaccess ro 4
Switch(config)# snmp-server enable traps snmp authentication
Switch(config)# snmp-server host cisco.com version 2c public
```

This example shows how to send Entity MIB traps to the host `cisco.com`. The community string is restricted. The first line enables the switch to send Entity MIB traps in addition to any traps previously enabled. The second line specifies the destination of these traps and overwrites any previous `snmp-server host` commands for the host `cisco.com`.

```plaintext
Switch(config)# snmp-server community comaccess ro 4
Switch(config)# snmp-server enable traps snmp authentication
Switch(config)# snmp-server host cisco.com version 2c public
```
Switch(config)# snmp-server enable traps entity
Switch(config)# snmp-server host cisco.com restricted entity

This example shows how to enable the switch to send all traps to the host myhost.cisco.com using the community string public:
Switch(config)# snmp-server enable traps
Switch(config)# snmp-server host myhost.cisco.com public

This example shows how to associate a user with a remote host and to send auth (authNoPriv) authentication-level informs when the user enters global configuration mode:
Switch(config)# snmp-server engineID remote 192.180.1.27 00000063000100a1c0b4011b
Switch(config)# snmp-server group authgroup v3 auth
Switch(config)# snmp-server user authuser authgroup remote 192.180.1.27 v3 auth md5 mypassword
Switch(config)# snmp-server user authuser authgroup v3 auth md5 mypassword
Switch(config)# snmp-server host 192.180.1.27 informs version 3 auth authuser config
Switch(config)# snmp-server enable traps
Switch(config)# snmp-server inform retries 0

## Displaying SNMP Status

To display SNMP input and output statistics, including the number of illegal community string entries, errors, and requested variables, use the `show snmp` privileged EXEC command. You can also use the other privileged EXEC commands in Table 49-4 to display SNMP information. For information about the fields in the output displays, see the *Cisco IOS Configuration Fundamentals Command Reference, Release 12.4*.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show snmp</code></td>
<td>Displays SNMP statistics.</td>
</tr>
<tr>
<td><code>show snmp chassis</code></td>
<td>Displays chassis-id.</td>
</tr>
<tr>
<td><code>show snmp community</code></td>
<td>Displays SNMP community string and access pri.</td>
</tr>
<tr>
<td><code>show snmp contact</code></td>
<td>Displays SNMP contacts.</td>
</tr>
<tr>
<td><code>show snmp context</code></td>
<td>Displays contexts.</td>
</tr>
<tr>
<td><code>show snmp engineID</code></td>
<td>Displays information on the local SNMP engine and all remote engines that have been configured on the device.</td>
</tr>
<tr>
<td><code>show snmp group</code></td>
<td>Displays information on each SNMP group on the network.</td>
</tr>
<tr>
<td><code>show snmp host</code></td>
<td>Displays information on each SNMP hosts configured.</td>
</tr>
<tr>
<td><code>show snmp location</code></td>
<td>Displays information on location configured.</td>
</tr>
<tr>
<td><code>show snmp mib</code></td>
<td>Displays information on mib objects present.</td>
</tr>
<tr>
<td><code>show snmp pending</code></td>
<td>Displays information on pending SNMP requests.</td>
</tr>
<tr>
<td><code>show snmp sessions</code></td>
<td>Displays information on the current SNMP sessions.</td>
</tr>
<tr>
<td><code>show snmp user</code></td>
<td>Displays information on each SNMP user name in the SNMP users table.</td>
</tr>
<tr>
<td><code>show snmp view</code></td>
<td>Displays information on SNMP views.</td>
</tr>
</tbody>
</table>
Configuring Cisco IOS IP SLAs Operations

This chapter describes how to use Cisco IOS IP Service Level Agreements (SLAs) on the switch. Cisco IP SLAs is a part of Cisco IOS software that allows Cisco customers to analyze IP service levels for IP applications and services by using active traffic monitoring—the generation of traffic in a continuous, reliable, and predictable manner—for measuring network performance. With Cisco IOS IP SLAs, service provider customers can measure and provide service level agreements, and enterprise customers can verify service levels, verify outsourced service level agreements, and understand network performance. Cisco IOS IP SLAs can perform network assessments, verify quality of service (QoS), ease the deployment of new services, and assist with network troubleshooting. Unless otherwise noted, the term *switch* refers to a standalone switch and to a switch stack.

**Note**

Switches running the IP base image support only IP SLAs responder functionality and must be configured with another device that supports full IP SLAs functionality, for example, a switch.

For more information about IP SLAs, see the *Cisco IOS IP SLAs Configuration Guide, Release 12.4T* at this URL: http://www.cisco.com/en/US/docs/ios/ipsla/configuration/guide/12_4t/sla_12_4t_book.html

This chapter consists of these sections:

- Command Table, page 50-2
- About Cisco IOS IP SLAs, page 50-2
- Configuring IP SLAs Operations, page 50-7
- Monitoring IP SLAs Operations, page 50-13

**Note**

Refer to *Cisco IOS XE IP SLAs Features in Cisco IOS XE 3.1.0 SG*, page 50-14 for new software available in Cisco IOS XE 3.1.0.SG but not documented in this chapter. There you will find links to the items in the Cisco IOS library.
About Cisco IOS IP SLAs

Cisco IOS IP SLAs sends data across the network to measure performance between multiple network locations or across multiple network paths. It simulates network data and IP services and collects network performance information in real time. Cisco IOS IP SLAs generates and analyzes traffic either between Cisco IOS devices or from a Cisco IOS device to a remote IP device such as a network application server. Measurements provided by the various Cisco IOS IP SLAs operations can be used for troubleshooting, for problem analysis, and for designing network topologies.

Depending on the specific Cisco IOS IP SLAs operation, various network performance statistics are monitored within the Cisco device and stored in both command-line interface (CLI) and Simple Network Management Protocol (SNMP) MIBs. IP SLAs packets have configurable IP and application layer
options such as source and destination IP address, User Datagram Protocol (UDP)/TCP port numbers, a type of service (ToS) byte (including Differentiated Services Code Point [DSCP] and IP Prefix bits), Virtual Private Network (VPN) routing/forwarding instance (VRF), and URL web address.

Because Cisco IP SLAs is Layer 2 transport independent, you can configure end-to-end operations over disparate networks to best reflect the metrics that an end user is likely to experience. IP SLAs collects a unique subset of these performance metrics:

- Delay (both round-trip and one-way)
- Jitter (directional)
- Packet loss (directional)
- Packet sequencing (packet ordering)
- Path (per hop)
- Connectivity (directional)
- Server or website download time

Because Cisco IOS IP SLAs is SNMP-accessible, it can also be used by performance-monitoring applications like CiscoWorks Internetwork Performance Monitor (IPM) and other third-party Cisco partner performance management products. You can find more details about network management products that use Cisco IOS IP SLAs at this URL: [http://www.cisco.com/go/ipsla](http://www.cisco.com/go/ipsla)

Using IP SLAs can provide these benefits:

- Service-level agreement monitoring, measurement, and verification.
- Network performance monitoring
  - Measures the jitter, latency, or packet loss in the network.
  - Provides continuous, reliable, and predictable measurements.
- IP service network health assessment to verify that the existing QoS is sufficient for new IP services.
- Edge-to-edge network availability monitoring for proactive verification and connectivity testing of network resources (for example, shows the network availability of an NFS server used to store business critical data from a remote site).
- Troubleshooting of network operation by providing consistent, reliable measurement that immediately identifies problems and saves troubleshooting time.

This section includes this information about IP SLAs functionality:

- Using Cisco IOS IP SLAs to Measure Network Performance, page 50-3
- IP SLAs Responder and IP SLAs Control Protocol, page 50-4
- Response Time Computation for IP SLAs, page 50-5
- IP SLAs Operation Scheduling, page 50-6
- IP SLAs Operation Threshold Monitoring, page 50-6

### Using Cisco IOS IP SLAs to Measure Network Performance

Use IP SLAs to monitor the performance between any area in the network—core, distribution, and edge—without deploying a physical probe. It uses generated traffic to measure network performance between two networking devices. Figure 50-1 shows how IP SLAs begins when the source device sends a generated packet to the destination device. After the destination device receives the packet, depending
on the type of IP SLAs operation, it responds with time-stamp information for the source to make the calculation on performance metrics. An IP SLAs operation performs a network measurement from the source device to a destination in the network using a specific protocol such as UDP.

Figure 50-1  Cisco IOS IP SLAs Operation

To implement IP SLAs network performance measurement, you need to perform these tasks:

1. Enable the IP SLAs responder, if required.
2. Configure the required IP SLAs operation type.
3. Configure any options available for the specified operation type.
4. Configure threshold conditions, if required.
5. Schedule the operation to run, then let the operation run for a period of time to gather statistics.
6. Display and interpret the results of the operation using the Cisco IOS CLI or a network management system (NMS) system with SNMP.

For more information about IP SLAs operations, see the operation-specific chapters in the *Cisco IOS IP SLAs Configuration Guide, Release 12.4T* at this URL:

The switch does not support Voice over IP (VoIP) service levels using the gatekeeper registration delay operations measurements. Before configuring any IP SLAs application, use the `show ip sla application` privileged EXEC command to verify that the operation type is supported on your software image.

**IP SLAs Responder and IP SLAs Control Protocol**

The IP SLAs responder is a component embedded in the destination Cisco device that allows the system to anticipate and respond to IP SLAs request packets. The responder provides accurate measurements without the need for dedicated probes. The responder uses the Cisco IOS IP SLAs Control Protocol to provide a mechanism through which it can be notified on which port it should listen and respond. Only a Cisco IOS device can be a source for a destination IP SLAs Responder.
The IP SLAs responder can be a Cisco IOS Layer 2, responder-configurable switch, such as a Catalyst 4500 running the IP base image. The responder does not need to support full IP SLAs functionality.

Figure 50-1 shows where the Cisco IOS IP SLAs responder fits in the IP network. The responder listens on a specific port for control protocol messages sent by an IP SLAs operation. Upon receipt of the control message, it enables the specified UDP or TCP port for the specified duration. During this time, the responder accepts the requests and responds to them. It disables the port after it responds to the IP SLAs packet, or when the specified time expires. MD5 authentication for control messages is available for added security.

You do not need to enable the responder on the destination device for all IP SLAs operations. For example, a responder is not required for services that are already provided by the destination router (such as Telnet or HTTP). You cannot configure the IP SLAs responder on non-Cisco devices and Cisco IOS IP SLAs can send operational packets only to services native to those devices.

**Response Time Computation for IP SLAs**

Switches and routers can take tens of milliseconds to process incoming packets due to other high priority processes. This delay affects the response times because the test-packet reply might be in a queue while waiting to be processed. In this situation, the response times would not accurately represent true network delays. IP SLAs minimizes these processing delays on the source device as well as on the target device (if the responder is being used) to determine true round-trip times. IP SLAs test packets use time stamping to minimize the processing delays.

When the IP SLAs responder is enabled, it allows the target device to take time stamps when the packet arrives on the interface at interrupt level and again just as it is leaving, eliminating the processing time. This time stamping is made with a granularity of sub-milliseconds (ms).

Figure 50-2 demonstrates how the responder works. Four time stamps are taken to make the calculation for round-trip time. At the target router, with the responder functionality enabled, time stamp 2 (TS2) is subtracted from time stamp 3 (TS3) to produce the time spent processing the test packet as represented by delta. This delta value is then subtracted from the overall round-trip time. Notice that the same principle is applied by IP SLAs on the source router where the incoming time stamp 4 (TS4) is also taken at the interrupt level to allow for greater accuracy.

An additional benefit of the two time stamps at the target device is the ability to track one-way delay, jitter, and directional packet loss. Because much network behavior is asynchronous, it is critical to have these statistics. However, to capture one-way delay measurements, you must configure both the source router and target router with Network Time Protocol (NTP) so that the source and target are synchronized to the same clock source. One-way jitter measurements do not require clock synchronization.
IP SLAs Operation Scheduling

For more details about the IP SLAs multioperations scheduling functionality, see the “IP SLAs—Multiple Operation Scheduling” chapter of the Cisco IOS IP SLAs Configuration Guide at this URL:

When you configure an IP SLAs operation, you must schedule the operation to begin capturing statistics and collecting error information. You can schedule an operation to start immediately or to start at a certain month, day, and hour. Use the pending option to set the operation to start at a later time. The pending option is an internal state of the operation that is visible through SNMP. The pending state is also used when an operation is a reaction (threshold) operation waiting to be triggered. You can schedule a single IP SLAs operation or a group of operations at one time.

You can schedule several IP SLAs operations by using a single command through the Cisco IOS CLI or the CISCO RTTMON-MIB. Scheduling the operations to run at evenly distributed times allows you to control the amount of IP SLAs monitoring traffic. This distribution of IP SLAs operations helps minimize the CPU utilization and thus improves network scalability.

IP SLAs Operation Threshold Monitoring

For details on using thresholds with Cisco IOS IP SLAs operations, see the “IP SLAs—Proactive Threshold Monitoring” chapter of the Cisco IOS IP SLAs Configuration Guide at this URL:

To support successful service level agreement monitoring, you must have mechanisms that notify you immediately of any possible violation. IP SLAs can send SNMP traps that are triggered by events such as these:

• Connection loss
• Timeout
• Round-trip time threshold
• Average jitter threshold
• One-way packet loss
• One-way jitter
• One-way mean opinion score (MOS)
• One-way latency

An IP SLAs threshold violation can also trigger another IP SLAs operation for further analysis. For example, the frequency could be increased or an ICMP path echo or ICMP path jitter operation could be initiated for troubleshooting.

Determining the type of threshold and the level to set can be complex, and depends on the type of IP service being used in the network.
Configuring IP SLAs Operations

Note

This section does not include configuration information for all available operations as the configuration information details are included in the Cisco IOS IP SLAs Configuration Guide. It does include several operations as examples, including configuring the responder, configuring UDP jitter operation, which requires a responder, and configuring ICMP echo operation, which does not require a responder. A switch running the IP base image supports only IP SLAs responder functionality. The switch must be running the IP services image for full IP SLAs functionality.

For details about configuring other operations, see the Cisco IOS IP SLAs Configuration Guide at this URL:

This section includes this information:

- Default Configuration, page 50-7
- Configuration Guidelines, page 50-7
- Configuring the IP SLAs Responder, page 50-8
- Analyzing IP Service Levels by Using the UDP Jitter Operation, page 50-9
- Analyzing IP Service Levels by Using the ICMP Echo Operation, page 50-11

Default Configuration

No IP SLAs operations are configured.

Configuration Guidelines

For detailed descriptions and configuration procedures, see the Cisco IOS IP SLAs Configuration Guide, Release 12.4T at this URL:

Note that not all of the IP SLAs commands or operations described in this guide are supported on the switch. The switch supports IP service level analysis by using UDP jitter, UDP echo, HTTP, TCP connect, ICMP echo, ICMP path echo, ICMP path jitter, FTP, DNS, and DHCP, as well as multiple operation scheduling and proactive threshold monitoring. It does not support VoIP service levels using the gatekeeper registration delay operations measurements.

Before configuring any IP SLAs application, use the show ip sla application privileged EXEC command to verify that the operation type is supported on your software image.

This is an example of the output from the command:

```
Switch# show ip sla application
IP SLAs
Version: 2.2.0 Round Trip Time MIB, Infrastructure Engine-II
Time of last change in whole IP SLAs: 22:17:39.117 UTC Fri Jun
Estimated system max number of entries: 15801

Estimated number of configurable operations: 15801
Number of Entries configured : 0
Number of active Entries     : 0
Number of pending Entries    : 0
```
Number of inactive Entries : 0

Supported Operation Types
Type of Operation to Perform: 802.1agEcho
Type of Operation to Perform: 802.1agJitter
Type of Operation to Perform: dhcp
Type of Operation to Perform: dns
Type of Operation to Perform: echo
Type of Operation to Perform: ftp
Type of Operation to Perform: http
Type of Operation to Perform: jitter
Type of Operation to Perform: pathEcho
Type of Operation to Perform: pathJitter
Type of Operation to Perform: tcpConnect
Type of Operation to Perform: udpEcho

IP SLAs low memory water mark: 21741224

Configuring the IP SLAs Responder

The IP SLAs responder is available only on Cisco IOS software-based devices, including some Layer 2 switches that do not support full IP SLAs functionality, such as the Cisco ME 2400 switch.

To configure the IP SLAs responder on the target device (the operational target), follow these steps:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>configure terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>ip sla responder [tcp-connect</td>
</tr>
<tr>
<td></td>
<td>udp-echo] ipaddress ip-address port port-number</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>end</td>
</tr>
<tr>
<td>Step 4</td>
<td>show ip sla responder</td>
</tr>
<tr>
<td>Step 5</td>
<td>copy running-config startup-config</td>
</tr>
</tbody>
</table>

To disable the IP SLAs responder, enter the no ip sla responder global configuration command. This example shows how to configure the device as a responder for the UDP jitter IP SLAs operation in the next procedure:

Switch(config)# ip sla responder udp-echo 172.29.139.134 5000
Analyzing IP Service Levels by Using the UDP Jitter Operation

Jitter means interpacket delay variance. When multiple packets are sent consecutively 10 ms apart from source to destination, if the network is behaving correctly, the destination should receive them 10 ms apart. But if there are delays in the network (like queuing, arriving through alternate routes, and so on) the arrival delay between packets might be more than or less than 10 ms with a positive jitter value meaning that the packets arrived more than 10 ms apart. If the packets arrive 12 ms apart, positive jitter is 2 ms; if the packets arrive 8 ms apart, negative jitter is 2 ms. For delay-sensitive networks, positive jitter values are undesirable, and a jitter value of 0 is ideal.

In addition to monitoring jitter, the IP SLAs UDP jitter operation can be used as a multipurpose data gathering operation. The packets IP SLAs generates carry packet sending and receiving sequence information and sending and receiving time stamps from the source and the operational target. Based on these, UDP jitter operations measure this data:

- Per-direction jitter (source to destination and destination to source)
- Per-direction packet-loss
- Per-direction delay (one-way delay)
- Round-trip delay (average round-trip time)

Because the paths for the sending and receiving of data can be different (asymmetric), use the per-direction data to more readily identify where congestion or other problems are occurring in the network.

The UDP jitter operation generates synthetic (simulated) UDP traffic and sends a number of UDP packets, each of a specified size, sent a specified number of milliseconds apart, from a source router to a target router, at a given frequency. By default, ten packet-frames, each with a payload size of 10 bytes are generated every 10 ms, and the operation is repeated every 60 seconds. You can configure each of these parameters to best simulate the IP service you want to provide.

Note

The IP SLA precision microsecond feature does not provide microsecond accuracy; it provides only microsecond granularity of the timestamps.

To provide accurate one-way delay (latency) measurements, time synchronization, such as that provided by NTP, is required between the source and the target device. Time synchronization is not required for the one-way jitter and packet loss measurements. If the time is not synchronized between the source and target devices, one-way jitter and packet loss data is returned, but values of 0 are returned for the one-way delay measurements provided by the UDP jitter operation.

Note

Before you configure a UDP jitter operation on the source device, you must enable the IP SLAs responder on the target device (the operational target).

To configure UDP jitter operation on the source device, follow these steps:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 2 ip sla operation-number</td>
<td>Creates an IP SLAs operation, and enter IP SLAs configuration mode.</td>
</tr>
</tbody>
</table>
### Step 3
```
udp-jitter
   (destination-ip-address | destination-hostname)
   destination-port [source-ip (ip-address | hostname)]
   [source-port port-number]
   [control {enable | disable}]
   [num-packets number-of-packets] [interval interpacket-interval]
```

Configures the IP SLAs operation as a UDP jitter operation, and enter UDP jitter configuration mode.

- **destination-ip-address | destination-hostname**—Specify the destination IP address or hostname.
- **destination-port**—Specify the destination port number in the range from 1 to 65535.
- **source-ip**—Specify the source IP address or hostname. When a source IP address or hostname is not specified, IP SLAs chooses the IP address nearest to the destination.
- **source-port port-number**—Specify the source port number in the range from 1 to 65535. When a port number is not specified, IP SLAs chooses an available port.
- **control**—Enable or disable sending of IP SLAs control messages to the IP SLAs responder. By default, IP SLAs control messages are sent to the destination device to establish a connection with the IP SLAs responder.
- **num-packets number-of-packets**—Enter the number of packets to be generated. The range is 1 to 6000; the default is 10.
- **interval interpacket-interval**—Enter the interval between sending packets in milliseconds. The range is 1 to 6000; the default value is 20 ms.

### Step 4
```
frequency seconds
```

(Optional) Sets the rate at which a specified IP SLAs operation repeats. The range is from 1 to 604800 seconds; the default is 60 seconds.

### Step 5
```
exit
```

Exits UDP jitter configuration mode, and return to global configuration mode.

### Step 6
```
ip sla monitor schedule
   operation-number [life {forever | seconds}]
   [start-time [hh:mm:ss] [month day | day month] | pending | now | after hh:mm:ss] [ageout seconds] [recurring]
```

Configures the scheduling parameters for an individual IP SLAs operation.

- **operation-number**—Enter the RTR entry number.
- **life**—Set the operation to run indefinitely (forever) or for a specific number of seconds. The range is from 0 to 2147483647. The default is 3600 seconds (1 hour).
- **start-time**—Enter the time for the operation to begin collecting information:
  - To start at a specific time, enter the hour, minute, second (in 24-hour notation), and day of the month. If no month is entered, the default is the current month.
  - Enter **pending** to select no information collection until a start time is selected.
  - Enter **now** to start the operation immediately.
  - Enter **after hh:mm:ss** to show that the operation should start after the entered time has elapsed.
- **ageout seconds**—Enter the number of seconds to keep the operation in memory when it is not actively collecting information. The range is 0 to 2073600 seconds, the default is 0 seconds (never ages out).
- **recurring**—Set the operation to automatically run every day.
To disable the IP SLAs operation, enter the `no ip sla operation-number` global configuration command.

This example shows how to configure a UDP jitter IP SLAs operation:

```
Switch(config)# ip sla 10
Switch(config-ip-sla)# udp-jitter 172.29.139.134 5000
Switch(config-ip-sla-jitter)# frequency 30
Switch(config-ip-sla-jitter)# exit
Switch(config)# ip sla schedule 5 start-time now life forever
Switch(config)# end
Switch(config)# show ip sla configuration 10
```

To disable the IP SLAs operation, enter the `no ip sla operation-number` global configuration command.

This example shows how to configure a UDP jitter IP SLAs operation:

```
Switch(config)# ip sla 10
Switch(config-ip-sla)# udp-jitter 172.29.139.134 5000
Switch(config-ip-sla-jitter)# frequency 30
Switch(config-ip-sla-jitter)# exit
Switch(config)# ip sla schedule 5 start-time now life forever
Switch(config)# end
Switch(config)# show ip sla configuration 10
```

Analyzing IP Service Levels by Using the ICMP Echo Operation

The ICMP echo operation measures end-to-end response time between a Cisco device and any devices using IP. Response time is computed by measuring the time taken between sending an ICMP echo request message to the destination and receiving an ICMP echo reply. Many customers use IP SLAs ICMP-based operations, in-house ping testing, or ping-based dedicated probes for response time measurements between the source IP SLAs device and the destination IP device. The IP SLAs ICMP echo operation conforms to the same specifications as ICMP ping testing, and the two methods result in the same response times.
Note
This operation does not require the IP SLAs responder to be enabled.

To configure an ICMP echo operation on the source device, follow these steps:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>configure terminal</strong></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><strong>ip sla operation-number</strong></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><strong>icmp-echo</strong></td>
</tr>
<tr>
<td></td>
<td>(destination-ip-address</td>
</tr>
<tr>
<td></td>
<td>(source-ip {ip-address</td>
</tr>
<tr>
<td></td>
<td>[source-interface</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><strong>frequency seconds</strong></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><strong>exit</strong></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td><strong>ip sla schedule</strong></td>
</tr>
<tr>
<td></td>
<td>operation-number [life</td>
</tr>
<tr>
<td></td>
<td>(forever</td>
</tr>
<tr>
<td></td>
<td>[start-time {hh:mm:ss}</td>
</tr>
<tr>
<td></td>
<td>(month day</td>
</tr>
<tr>
<td></td>
<td>pending</td>
</tr>
<tr>
<td></td>
<td>[recurring]</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td><strong>end</strong></td>
</tr>
</tbody>
</table>
To disable the IP SLAs operation, enter the `no ip sla operation-number` global configuration command. This example shows how to configure an ICMP echo IP SLAs operation:

```
Switch(config)# ip sla 12
Switch(config-ip-sla)# icmp-echo 172.29.139.134
Switch(config-ip-sla-echo)# frequency 30
Switch(config-ip-sla-echo)# exit
Switch(config)# ip sla schedule 5 start-time now life forever
Switch(config)# end
Switch# show ip sla configuration 22
```

Cisco IOS XE IP SLAs Features in Cisco IOS XE 3.1.0 SG

The following IP SLAs features are Supervisor Engine 7-E specific features

**IP SLAs - DHCP Operation**

**IP SLAs - Distribution of Statistics**

**IP SLAs - DNS Operation**

**IP SLAs - FTP Operation**

IP SLAs - HTTP Operation

IP SLAs - ICMP Echo Operation

IP SLAs - ICMP Path Echo Operation

IP SLAs - MPLS VPN Awareness

IP SLAs - Multi Operation Scheduler

IP SLAs - One Way Measurement

IP SLAs - Path Jitter Operation

IP SLAs - Reaction Threshold

IP SLAs - Scheduler

IP SLAs - TCP Connect Operation

IP SLAs - UDP Echo Operation

IP SLAs - UDP Jitter Operation

IP SLAs Random Scheduler
IPv6 - IP SLAs (UDP Jitter, UDP Echo, ICMP Echo, TCP Connect)

The following IP SLAs features are NOT K10-specific features

IP SLAs - History Statistics

IP SLAs - LSP Health Monitor

IP SLAs - LSP Health Monitor with LSP Discovery

IP SLAs - Probe Enhancements

IP SLAs - SNA LU2 Echo

IP SLAs - SNMP Support

IP SLAs for MPLS Pseudo Wire (PWE3) via VCCV

IP SLAs Responder

Configuring RMON

This chapter describes how to configure Remote Network Monitoring (RMON) on your Catalyst 4500 series switch. RMON is a standard monitoring specification that defines a set of statistics and functions that can be exchanged between RMON-compliant console systems and network probes. RMON provides you with comprehensive network-fault diagnosis, planning, and performance-tuning information.

Note

For complete syntax and usage information for the commands used in this chapter, see the Cisco IOS Configuration Fundamentals Command Reference

and related publications at this location:

This chapter consists of these sections:

- About RMON, page 51-1
- Configuring RMON, page 51-3
- Displaying RMON Status, page 51-6

About RMON

RMON is an Internet Engineering Task Force (IETF) standard monitoring specification that allows various network agents and console systems to exchange network monitoring data. You can use the RMON feature with the Simple Network Management Protocol (SNMP) agent in the switch to monitor all the traffic flowing among switches on all connected LAN segments.
The switch supports these RMON groups (defined in RFC 1757):

- Statistics (RMON group 1)—Collects Ethernet, Fast Ethernet, and Gigabit Ethernet statistics on an interface.
- History (RMON group 2)—Collects a history group of statistics on Ethernet, Fast Ethernet, and Gigabit Ethernet interfaces for a specified polling interval.
• Alarm (RMON group 3)—Monitors a specific MIB object for a specified interval, triggers an alarm at a specified value (rising threshold), and resets the alarm at another value (falling threshold). Alarms can be used with events; the alarm triggers an event, which can generate a log entry or an SNMP trap.
• Event (RMON group 9)—Determines the action to take when an event is triggered by an alarm. The action can be to generate a log entry or an SNMP trap.

Because switches supported by Cisco IOS Release 12.2(31)SG use hardware counters for RMON data processing, the monitoring is more efficient, and little processing power is required.

Configuring RMON

This section describes how to configure RMON on your switch. It contains this configuration information:
• Default RMON Configuration, page 51-3
• Configuring RMON Alarms and Events, page 51-3
• Configuring RMON Collection on an Interface, page 51-5

Default RMON Configuration

RMON is disabled by default; no alarms or events are configured.

Only RMON 1 is supported on the switch.

Configuring RMON Alarms and Events

You can configure your switch for RMON by using the command-line interface (CLI) or an SNMP-compatible network management station. We recommend that you use a generic RMON console application on the network management station (NMS) to take advantage of RMON’s network management capabilities. You must also configure SNMP on the switch to access RMON MIB objects. For more information, see Chapter 49, “Configuring SNMP.”
To enable RMON alarms and events, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>rmon alarm number variable interval absolute</td>
</tr>
<tr>
<td></td>
<td>absolute</td>
</tr>
<tr>
<td></td>
<td>delta</td>
</tr>
<tr>
<td></td>
<td>rising-threshold value event-number</td>
</tr>
<tr>
<td></td>
<td>falling-threshold value event-number</td>
</tr>
<tr>
<td></td>
<td>owner string</td>
</tr>
<tr>
<td></td>
<td>number variable interval absolute</td>
</tr>
<tr>
<td></td>
<td>delta</td>
</tr>
<tr>
<td></td>
<td>rising-threshold value event-number</td>
</tr>
<tr>
<td></td>
<td>falling-threshold value event-number</td>
</tr>
<tr>
<td></td>
<td>owner string</td>
</tr>
<tr>
<td></td>
<td>value</td>
</tr>
<tr>
<td></td>
<td>(Optional) For <strong>event-number</strong>, specify the event number to trigger when the rising or falling threshold exceeds its limit.</td>
</tr>
<tr>
<td></td>
<td>(Optional) For <strong>owner string</strong>, specify the owner of the alarm.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>rmon event number description string log owner string trap community</td>
</tr>
<tr>
<td></td>
<td>number description string log owner string trap community</td>
</tr>
<tr>
<td></td>
<td>(Optional) For <strong>description string</strong>, specify a description of the event.</td>
</tr>
<tr>
<td></td>
<td>(Optional) Use the <strong>log</strong> keyword to generate an RMON log entry when the event is triggered.</td>
</tr>
<tr>
<td></td>
<td>(Optional) For <strong>owner string</strong>, specify the owner of this event.</td>
</tr>
<tr>
<td></td>
<td>(Optional) For <strong>community</strong>, enter the SNMP community string used for this trap.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>end</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>show running-config</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>copy running-config startup-config</td>
</tr>
</tbody>
</table>
To disable an alarm, use the `no rmon alarm number` global configuration command on each alarm you configured. You cannot disable at once all the alarms that you configured. To disable an event, use the `no rmon event number` global configuration command. To learn more about alarms and events and how they interact with each other, see RFC 1757.

You can set an alarm on any MIB object. The following example configures RMON alarm number 10 by using the `rmon alarm` command. The alarm monitors the MIB variable `ifEntry.20.1` once every 20 seconds until the alarm is disabled and checks the change in the variable’s rise or fall. If the `ifEntry.20.1` value shows a MIB counter increase of 15 or more, such as from 100000 to 100015, the alarm is triggered. The alarm in turn triggers event number 1, which is configured with the `rmon event` command. Possible events can include a log entry or an SNMP trap. If the `ifEntry.20.1` value changes by 0, the alarm is reset and can be triggered again.

```
Switch(config)# rmon alarm 10 ifEntry.20.1 20 delta rising-threshold 15 1
falling-threshold 0 owner jjohnson
```

The following example creates RMON event number 1 by using the `rmon event` command. The event is defined as `High ifOutErrors` and generates a log entry when the event is triggered by the alarm. The user `jjones` owns the row that is created in the event table by this command. This example also generates an SNMP trap when the event is triggered.

```
Switch(config)# rmon event 1 log trap eventtrap description "High ifOutErrors" owner jjones
```

### Configuring RMON Collection on an Interface

You must first configure RMON alarms and events to display collection information.

To collect group history statistics on an interface, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong> interface Interface-id</td>
<td>Specifies the interface on which to collect history, and enter interface configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong> rmon collection history index [buckets bucket-number] [interval seconds] [owner ownername]</td>
<td>Enables history collection for the specified number of buckets and time period.</td>
</tr>
<tr>
<td></td>
<td>• For index, identify the RMON group of statistics. The range is 1 to 65535.</td>
</tr>
<tr>
<td></td>
<td>• (Optional) For buckets bucket-number, specify the maximum number of buckets desired for the RMON collection history group of statistics. The range is 1 to 65535. The default is 50 buckets.</td>
</tr>
<tr>
<td></td>
<td>• (Optional) For interval seconds, specify the number of seconds in each polling cycle.</td>
</tr>
<tr>
<td></td>
<td>• (Optional) For owner ownername, enter the name of the owner of the RMON group of statistics.</td>
</tr>
<tr>
<td><strong>Step 4</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 5</strong> show running-config</td>
<td>Verifies your entries.</td>
</tr>
</tbody>
</table>
Chapter 51 Configuring RMON

Displaying RMON Status

To display the RMON status, use one or more of the privileged EXEC commands in Table 51-1:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show rmon</td>
<td>Displays general RMON statistics.</td>
</tr>
<tr>
<td>show rmon alarms</td>
<td>Displays the RMON alarm table.</td>
</tr>
<tr>
<td>show rmon events</td>
<td>Displays the RMON event table.</td>
</tr>
<tr>
<td>show rmon history</td>
<td>Displays the RMON history table.</td>
</tr>
<tr>
<td>show rmon statistics</td>
<td>Displays the RMON statistics table.</td>
</tr>
</tbody>
</table>

Table 51-1 Commands for Displaying RMON Status
Configuring Call Home

This chapter describes how to configure the Call Home feature in Catalyst 4500 Series Switch.

Note

For complete syntax and usage information for the switch commands used in this chapter, refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

This chapter includes the following sections:

- About Call Home, page 52-1
- Obtaining Smart Call Home, page 52-2
- Configuring Call Home, page 52-3
- Configuring Contact Information, page 52-4
- Configuring Destination Profiles, page 52-5
- Subscribing to Alert Groups, page 52-6
- Configuring General E-Mail Options, page 52-9
- Enabling Call Home, page 52-10
- Disabling Call Home, page 52-10
- Testing Call Home Communications, page 52-10
- Configuring and Enabling Smart Call Home, page 52-13
- Displaying Call Home Configuration Information, page 52-14
- Default Settings, page 52-18
- Alert Group Trigger Events and Commands, page 52-18
- Message Contents, page 52-21

About Call Home

Call Home provides e-mail-based and web-based notification of critical system events. A versatile range of message formats are available for optimal compatibility with pager services, standard e-mail, or XML-based automated parsing applications. Common uses of this feature may include direct paging of
About Call Home

a network support engineer, e-mail notification to a Network Operations Center, XML delivery to a support website, and utilization of Cisco Smart Call Home services for direct case generation with the Cisco Systems Technical Assistance Center (TAC).

The Call Home feature can deliver alert messages containing information on configuration, diagnostics, environmental conditions, inventory, and syslog events.

The Call Home feature can deliver alerts to multiple recipients, referred to as Call Home destination profiles, each with configurable message formats and content categories. A predefined destination profile is provided for sending alerts to the Cisco TAC (callhome@cisco.com), and you also can define your own destination profiles.

Flexible message delivery and format options make it easy to integrate specific support requirements.

The Call Home feature offers the following advantages:

- Multiple message-format options:
  - Short Text—Suitable for pagers or printed reports.
  - Plain Text—Full formatted message information suitable for human reading.
  - XML—Matching readable format using Extensible Markup Language (XML) and Adaptive Markup Language (AML) document type definitions (DTDs). The XML format enables communication with the Cisco TAC.
- Multiple concurrent message destinations.
- Multiple message categories including configuration, diagnostics, environmental conditions, inventory, and syslog events.
- Filtering of messages by severity and pattern matching.
- Scheduling of periodic message sending.

Obtaining Smart Call Home

If you have a service contract directly with Cisco Systems, you can register your devices for the Smart Call Home service. Smart Call Home provides fast resolution of system problems by analyzing Call Home messages sent from your devices and providing background information and recommendations. For issues that can be identified as known, particularly GOLD diagnostics failures, Automatic Service Requests will be generated with the Cisco TAC.

Smart Call Home offers the following features:

- Boot-up diagnostics alerts for linecards & supervisor in the chassis.
- Analysis of Call Home messages from your device, and where appropriate Automatic Service Request generation, routed to the appropriate TAC team, including detailed diagnostic information to speed problem resolution.
- Secure message transport directly from your device or through a downloadable Transport Gateway (TG) aggregation point. You can use a TG aggregation point in cases requiring support for multiple devices or in cases where security requirements mandate that your devices may not be connected directly to the Internet.
- Web-based access to Call Home messages and recommendations, inventory and configuration information for all Call Home devices. Provides access to associated field notices, Security Advisories, and End-of-Life information.
Configuring Call Home

You need to register the following items:

- The SMARTnet contract number for your switch
- Your e-mail address
- Your Cisco.com ID

For detailed information on Smart Call Home, refer to the Smart Call Home page at this URL:

Configuring Call Home

How you configure Call Home depends on how you intend to use the feature. Consider the following information before you configure Call Home:

- At least one destination profile (predefined or user-defined) must be configured. The destination profile(s) used depends on whether the receiving entity is a pager, e-mail, or automated service such as Cisco Smart Call Home.
  - If the destination profile uses e-mail message delivery, you must specify a Simple Mail Transfer Protocol (SMTP) server.
  - If the destination profile uses secure HTTP (HTTPS) message transport, you must configure a trustpoint certificate authority (CA).
- The contact e-mail, phone, and street address information should be configured so that the receiver can determine the origin of messages received.
- The switch must have IP connectivity to an e-mail server or the destination HTTP server using the `ip domain name` command.
- If Cisco Smart Call Home is used, an active service contract must cover the device being configured.

**Note**

No version of the `call-home` command will remove the config setting.

To configure Call Home, follow these steps:

1. Configure your site’s contact information.
2. Configure destination profiles for each of your intended recipients.
3. Subscribe each destination profile to one or more alert groups, and set alert options.
4. Configure e-mail settings or HTTPS settings (including CA certificate), depending on the transport method.
5. Enable the Call Home feature.
6. Test Call Home messages.

**Tip**

From the Smart Call Home web application, you can download a basic configuration script to assist you in the configuration of the Call Home feature for use with Smart Call Home and the Cisco TAC. The script will also assist in configuring the trustpoint CA for secure communications with the Smart Call
Home service. The script, provided on an as-is basis, can be downloaded from this URL:

Configuring Contact Information

Each switch must include a contact e-mail address. You can optionally include a phone number, street address, contract ID, customer ID, and site ID.

To assign the contact information, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>Switch# configure terminal</strong></td>
</tr>
<tr>
<td></td>
<td>Enters configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><strong>Switch(config)# call-home</strong></td>
</tr>
<tr>
<td></td>
<td>Enters the Call Home configuration submode.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>No version of this command will remove the settings.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><strong>Switch(cfg-call-home)# contact-email-addr email-address</strong></td>
</tr>
<tr>
<td></td>
<td>Assigns the customer’s e-mail address. Enter up to 200 characters in e-mail address format with no spaces.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><strong>Switch(cfg-call-home)# phone-number +phone-number</strong></td>
</tr>
<tr>
<td></td>
<td>(Optional) Assigns the customer’s phone number.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>The number must begin with a plus (+) prefix, and may contain only dashes (-) and numbers. Enter up to 16 characters. If you include spaces, you must enclose your entry in quotes (“ “).</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><strong>Switch(cfg-call-home)# street-address street-address</strong></td>
</tr>
<tr>
<td></td>
<td>(Optional) Assigns the customer’s street address where RMA equipment can be shipped. Enter up to 200 characters. If you include spaces, you must enclose your entry in quotes (“ “).</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td><strong>Switch(cfg-call-home)# customer-id text</strong></td>
</tr>
<tr>
<td></td>
<td>(Optional) Identifies the customer ID. Enter up to 64 characters. If you include spaces, you must enclose your entry in quotes (“ “).</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td><strong>Switch(cfg-call-home)# site-id text</strong></td>
</tr>
<tr>
<td></td>
<td>(Optional) Identifies the customer site ID. Enter up to 200 characters. If you include spaces, you must enclose your entry in quotes (“ “).</td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td><strong>Switch(cfg-call-home)# contract-id text</strong></td>
</tr>
<tr>
<td></td>
<td>(Optional) Identifies the customer’s contract ID for the switch. Enter up to 64 characters. If you include spaces, you must enclose your entry in quotes (“ “).</td>
</tr>
</tbody>
</table>

This example shows the configuration of contact information:

```
Switch# configure terminal
```
Enter configuration commands, one per line. End with CNTL/Z.

Switch(config)# call-home
Switch(cfg-call-home)# contact-email-addr username@example.com
Switch(cfg-call-home)# phone-number +1-800-555-4567
Switch(cfg-call-home)# street-address "1234 Picaboo Street, Any city, Any state, 12345"
Switch(cfg-call-home)# customer-id Customer1234
Switch(cfg-call-home)# site-id Site1ManhattanNY
Switch(cfg-call-home)# contract-id Company1234
Switch(cfg-call-home)# exit
Switch(config)#

Configuring Destination Profiles

A destination profile contains the required delivery information for an alert notification. At least one destination profile is required. You can configure multiple destination profiles of one or more types.

You can use the predefined destination profile or define a desired profile. If you define a new destination profile, you must assign a profile name.

Note

If you use the Cisco Smart Call Home service, the destination profile must use the XML message format.

You can configure the following attributes for a destination profile:

- Profile name—A string that uniquely identifies each user-defined destination profile. The profile name is limited to 31 characters and is not case-sensitive. You cannot use all as a profile name.
- Transport method—The transport mechanism, either e-mail or HTTP (including HTTPS), for delivery of alerts.
  - For user-defined destination profiles, e-mail is the default, and you can enable either or both transport mechanisms. If you disable both methods, e-mail will be enabled.
  - For the predefined Cisco TAC profile, you can enable either transport mechanism, but not both.
- Destination address—The actual address related to the transport method to which the alert should be sent.
- Message formatting—The message format used for sending the alert.
  - For user-defined destination profiles, the format options are long-text, short-text, or XML. The default is XML.
  - For the predefined Cisco TAC profile, only XML is allowed.
- Message size—The maximum destination message size. The valid range is 50 to 3,145,728 bytes and the default is 3,145,728 bytes.

To create and configure a destination profile, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# call-home</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Switch(cfg-call-home)# profile name</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Switch(cfg-call-home-profile)# (no) destination transport-method (email</td>
</tr>
</tbody>
</table>
### Configuring Call Home

#### Copying a Destination Profile

To create a new destination profile by copying an existing profile, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 5</td>
<td>Switch(config-call-home-profile)# destination address {email email-address</td>
</tr>
<tr>
<td></td>
<td>Configures the destination e-mail address or URL to which Call Home messages will be sent.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> When entering a destination URL, include either http:// or https://, depending on whether the server is a secure server. If the destination is a secure server, you must also configure a trustpoint CA.</td>
</tr>
<tr>
<td>Step 6</td>
<td>Switch(config-call-home-profile)# destination preferred-msg-format {long-text</td>
</tr>
<tr>
<td></td>
<td>(Optional) Configures a preferred message format. The default is XML.</td>
</tr>
<tr>
<td>Step 7</td>
<td>Switch(config-call-home-profile)# destination message-size-limit bytes</td>
</tr>
<tr>
<td></td>
<td>(Optional) Configures a maximum destination message size for the destination profile.</td>
</tr>
<tr>
<td>Step 8</td>
<td>Switch(config-call-home-profile)# active</td>
</tr>
<tr>
<td></td>
<td>Enables the destination profile. By default, the profile is enabled when it is created.</td>
</tr>
<tr>
<td>Step 9</td>
<td>Switch(config-call-home-profile)# exit</td>
</tr>
<tr>
<td></td>
<td>Exits the Call Home destination profile configuration submode and returns to the Call Home configuration submode.</td>
</tr>
<tr>
<td>Step 10</td>
<td>Switch(config-call-home)# end</td>
</tr>
<tr>
<td></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Step 11</td>
<td>Switch# show call-home profile {name</td>
</tr>
<tr>
<td></td>
<td>Displays the destination profile configuration for a specified profile or all configured profiles.</td>
</tr>
</tbody>
</table>

#### Command Purpose

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td></td>
<td>Enters configuration mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# call-home</td>
</tr>
<tr>
<td></td>
<td>Enters the Call Home configuration submode.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(config)# copy profile source-profile target-profile</td>
</tr>
<tr>
<td></td>
<td>Creates a new destination profile with the same configuration settings as the existing destination profile.</td>
</tr>
</tbody>
</table>

### Subscribing to Alert Groups

An alert group is a predefined subset of Call Home alerts supported on the switch. Different types of Call Home alerts are grouped into different alert groups depending on their type. These alert groups are available:

- Configuration
- Diagnostic
- Environment
- Inventory
- Syslog

The triggering events for each alert group are listed in the “Alert Group Trigger Events and Commands” section on page 52-18, and the contents of the alert group messages are listed in the “Message Contents” section on page 52-21.
You can select one or more alert groups to be received by a destination profile.

**Note**

A Call Home alert is only sent to destination profiles that have subscribed to the alert group containing that Call Home alert. In addition, the alert group must be enabled.

To subscribe a destination profile to an alert group, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Switch# <strong>configure terminal</strong> Enters configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Switch(config)# <strong>call-home</strong> Enters Call Home configuration submode.</td>
</tr>
</tbody>
</table>
| **Step 3** | Switch(cfg-call-home)# **alert-group**
(all|configuration|diagnostic|
environment|inventory|syslog) Enables the specified alert group. Use the keyword all to enable all alert groups. By default, all alert groups are enabled. |
| **Step 4** | Switch(cfg-call-home)# **profile name** Enters the Call Home destination profile configuration submode for the specified destination profile. |
| **Step 5** | Switch(cfg-call-home-profile)# **subscribe-to-alert-group configuration**
(periodic (daily \( hh:mm \) | monthly date \( hh:mm \) |
weekly \( day \ hh:mm \)) Subscribes this destination profile to the Configuration alert group. The Configuration alert group can be configured for periodic notification, as described in the “ Configuring Periodic Notification” section on page 52-8. |
| **Step 6** | Switch(cfg-call-home-profile)# **subscribe-to-alert-group diagnostic**
(severity catastrophic|disaster|
fatal|critical|major|minor|warning|
notification|normal|debugging) Subscribes this destination profile to the Diagnostic alert group. The Diagnostic alert group can be configured to filter messages based on severity, as described in the “ Configuring Message Severity Threshold” section on page 52-8. |
| **Step 7** | Switch(cfg-call-home-profile)# **subscribe-to-alert-group environment**
(severity catastrophic|disaster|
fatal|critical|major|minor|warning|
notification|normal|debugging) Subscribes this destination profile to the Environment alert group. The Environment alert group can be configured to filter messages based on severity, as described in the “ Configuring Message Severity Threshold” section on page 52-8. |
| **Step 8** | Switch(cfg-call-home-profile)# **subscribe-to-alert-group inventory**
(periodic (daily \( hh:mm \) | monthly date \( hh:mm \) |
weekly \( day \ hh:mm \)) Subscribes this destination profile to the Inventory alert group. The Inventory alert group can be configured for periodic notification, as described in the “ Configuring Periodic Notification” section on page 52-8. |
Configuring Call Home

Configuring Periodic Notification

When you subscribe a destination profile to either the Configuration or the Inventory alert group, you can choose to receive the alert group messages asynchronously or periodically at a specified time. The sending period can be one of the following:

- Daily—Specify the time of day to send, using an hour:minute format `hh:mm`, with a 24-hour clock (for example, 14:30).
- Weekly—Specify the day of the week and time of day in the format `day hh:mm`, where the day of the week is spelled out (for example, `monday`).
- Monthly—Specify the numeric date, from 1 to 31, and the time of day, in the format `date hh:mm`.

Configuring Message Severity Threshold

When you subscribe a destination profile to the Diagnostic, Environment, or Syslog alert group, you can set a threshold for sending alert group messages based on the message’s level of severity. Any message with a value lower than the threshold is not sent to the destination.

The severity threshold is configured using the keywords in Table 52-1, and ranges from catastrophic (level 9, highest level of urgency) to debugging (level 0, lowest level of urgency). If no severity threshold is configured, the default is normal (level 1).

Note Call Home severity levels differ from the system message logging severity levels.

<table>
<thead>
<tr>
<th>Level</th>
<th>Keyword</th>
<th>Syslog Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>9</td>
<td>catastrophic</td>
<td>N/A</td>
<td>Network-wide catastrophic failure</td>
</tr>
<tr>
<td>8</td>
<td>disaster</td>
<td>N/A</td>
<td>Significant network impact</td>
</tr>
<tr>
<td>7</td>
<td>fatal</td>
<td>Emergency (0)</td>
<td>System unusable</td>
</tr>
<tr>
<td>6</td>
<td>critical</td>
<td>Alert (1)</td>
<td>Critical conditions, immediate attention needed</td>
</tr>
<tr>
<td>5</td>
<td>major</td>
<td>Critical (2)</td>
<td>Major conditions</td>
</tr>
<tr>
<td>4</td>
<td>minor</td>
<td>Error (3)</td>
<td>Minor conditions</td>
</tr>
<tr>
<td>3</td>
<td>warning</td>
<td>Warning (4)</td>
<td>Warning conditions</td>
</tr>
</tbody>
</table>

Step 9

Switch(config-call-home-profile)#
subscribe-to-alert-group syslog
[severity catastrophic|disaster|
fatal|critical|major|minor|warning|notification|normal|debugging]
[pattern string]

Subscribes this destination profile to the Syslog alert group. The Syslog alert group can be configured to filter messages based on severity, as described in the “Configuring Message Severity Threshold” section on page 52-8. You can specify a pattern to be matched in the syslog message. If the pattern contains spaces, you must enclose it in quotes (“”).

Step 10

Switch(config-call-home-profile)# exit

Exits the Call Home destination profile configuration submode.
Table 52-1  Severity and Syslog Level Mapping (continued)

<table>
<thead>
<tr>
<th>Level</th>
<th>Keyword</th>
<th>Syslog Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>notification</td>
<td>Notice (5)</td>
<td>Basic notification and informational messages; possibly independently insignificant</td>
</tr>
<tr>
<td>1</td>
<td>normal</td>
<td>Information (6)</td>
<td>Normal event signifying return to normal state</td>
</tr>
<tr>
<td>0</td>
<td>debugging</td>
<td>Debug (7)</td>
<td>Debugging messages</td>
</tr>
</tbody>
</table>

Configuring Syslog Pattern Matching

When you subscribe a destination profile to the Syslog alert group, you can optionally specify a text pattern to be matched within each syslog message. If you configure a pattern, a Syslog alert group message will be sent only if it contains the specified pattern and meets the severity threshold. If the pattern contains spaces, you must enclose it in quotes (“”) when configuring it. You can specify up to five patterns for each destination profile.

Configuring General E-Mail Options

To use the e-mail message transport, you must configure at least one Simple Mail Transfer Protocol (SMTP) e-mail server address. You can configure the from and reply-to e-mail addresses, and you can specify up to four backup e-mail servers. You can also set a rate limit on e-mail or HTTP messages.

To configure general e-mail options, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch# configure terminal</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch(config)# call-home</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch(cfg-call-home)# mail-server (ipv4-address</td>
</tr>
<tr>
<td></td>
<td>name) priority number</td>
</tr>
<tr>
<td>Step 4</td>
<td>Switch(cfg-call-home)# sender from email-address</td>
</tr>
<tr>
<td>Step 5</td>
<td>Switch(cfg-call-home)# sender reply-to email-address</td>
</tr>
<tr>
<td>Step 6</td>
<td>Switch(cfg-call-home)# rate-limit number</td>
</tr>
<tr>
<td>Step 7</td>
<td>Switch(cfg-call-home)# vrf vrf-name</td>
</tr>
</tbody>
</table>
The following notes apply when configuring general e-mail options:

- Backup e-mail servers can be defined by repeating the `mail-server` command using different priority numbers.
- The `mail-server priority number` parameter can be configured from 1 to 100. The server with the highest priority (lowest priority number) will be tried first.

This example shows the configuration of general e-mail parameters, including a primary and secondary e-mail server:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# call-home
Switch(cfg-call-home)# mail-server smtp.example.com priority 1
Switch(cfg-call-home)# mail-server 192.168.0.1 priority 2
Switch(cfg-call-home)# sender from username@example.com
Switch(cfg-call-home)# sender reply-to username@example.com
Switch(cfg-call-home)# exit
```

### Enabling Call Home

To enable or disable the Call Home feature, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1: Switch# configure terminal</td>
<td>Enters configuration mode.</td>
</tr>
<tr>
<td>Step 2: Switch(config)# service call-home</td>
<td>Enables the Call Home feature.</td>
</tr>
</tbody>
</table>

### Disabling Call Home

To disable the Call Home feature, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1: Switch# configure terminal</td>
<td>Enters configuration mode.</td>
</tr>
<tr>
<td>Step 2: Switch(config)# no service call-home</td>
<td>Enables the Call Home feature.</td>
</tr>
</tbody>
</table>

### Testing Call Home Communications

You can test Call Home communications by sending messages manually using two command types:

- To send a user-defined Call Home test message, use the `call-home test` command.
- To send a specific alert group message, use the `call-home send` command.
## Sending a Call Home Test Message Manually

To manually send a Call Home test message, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
Switch# `call-home test ["test-message"] profile name` | Sends a test message to the specified destination profile. The user-defined test message text is optional, but must be enclosed in quotes (" ") if it contains spaces. If no user-defined message is configured, a default message will be sent. |

This example shows how to manually send a Call Home test message:

```
Switch# call-home test "test of the day" profile Ciscotac1
```

## Sending a Call Home Alert Group Message Manually

To manually trigger a Call Home alert group message, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
Switch# `call-home send alert-group configuration [profile name]` | Sends a configuration alert group message to one destination profile if specified, or to all subscribed destination profiles. |

Switch# `call-home send alert-group diagnostic (module number | slot/subslot | slot/bay) [profile name]` | Sends a diagnostic alert group message to the configured destination profile if specified, or to all subscribed destination profiles. You must specify the module or port whose diagnostic information should be sent. |

Switch# `call-home send alert-group inventory [profile name]` | Sends an inventory alert group message to one destination profile if specified, or to all subscribed destination profiles. |

When manually sending Call Home alert group messages, note the following guidelines:

- You can only manually send the configuration, diagnostic, and inventory alert groups.
- When you manually trigger a configuration, diagnostic, or inventory alert group message and you specify a destination profile name, a message is sent to the destination profile regardless of the profile’s active status, subscription status, or severity setting.
- When you manually trigger a configuration or inventory alert group message and do not specify a destination profile name, a message is sent to all active profiles that have either a normal or periodic subscription to the specified alert group.
- When you manually trigger a diagnostic alert group message and do not specify a destination profile name, the command will cause the following actions:
  - For any active profile that subscribes to diagnostic events with a severity level of less than minor, a message is sent regardless of whether the module or interface has observed a diagnostic event.
For any active profile that subscribes to diagnostic events with a severity level of minor or higher, a message is sent only if the specified module or interface has observed a diagnostic event of at least the subscribed severity level; otherwise, no diagnostic message is sent to the destination profile.

This example shows how to send the configuration alert-group message to the destination profile:

```
Switch# call-home send alert-group configuration
```

This example shows how to send the diagnostic alert-group message to the destination profile for a specific module, slot/subslot, or slot/bay number.

```
Switch# call-home send alert-group diagnostic module 3 5/2
```

This example shows how to send the diagnostic alert-group message to all destination profiles for a specific module, slot/subslot, or slot/bay number.

```
Switch# call-home send alert-group diagnostic module 3 5/2 profile Ciscotacl
```

This example shows how to send the inventory call-home message:

```
Switch# call-home send alert-group inventory
```

### Sending a Request for an Analysis and Report

You can use the `call-home request` command to submit information about your system to Cisco in order to receive helpful information specific to your system. You can request a variety of reports, including security alerts, known bugs, best practices, and command references.

To submit a request for report and analysis information from the Cisco Output Interpreter tool, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>step 1</td>
<td></td>
</tr>
<tr>
<td>Switch# call-home request output-analysis &quot;show-command&quot; [profile name] [ccoid user-id]</td>
<td>Sends the output of the specified <code>show</code> command for analysis. The <code>show</code> command must be contained in quotes (&quot;&quot;&quot;).</td>
</tr>
<tr>
<td>Switch# call-home request {config-sanity</td>
<td>bugs-list</td>
</tr>
</tbody>
</table>

When manually sending a Call Home report and analysis request, note the following guidelines:

- If you specify a `profile name` value, the request is sent to the profile. If you do not specify a profile name, the request is sent to the Cisco TAC profile. The recipient profile does not need to be enabled for the Call Home request. The profile should specify the e-mail address where the transport gateway is configured so that the request message can be forwarded to the Cisco TAC and the user can receive the reply from the Smart Call Home service.
- The `ccoid user-id` value is the registered identifier of the Smart Call Home user. If you specify a user-id, the response is sent to the e-mail address of the registered user. If do not specify a user-id, the response is sent to the contact e-mail address of the device.
Based on the keyword specifying the type of report requested, the following information is returned:

- **config-sanity**—Information on best practices as related to the current running configuration
- **bugs-list**—Known bugs in the running version and in the currently applied features
- **command-reference**—Reference links to all commands in the running configuration
- **product-advisory**—Product Security Incident Response Team (PSIRT) notices, End of Life (EOL) or End of Sales (EOS) notices, or field notices (FN) that may affect devices in your network

This example shows a request for analysis of a user-specified `show` command:

```
Switch# call-home request output-analysis "show diagnostic result module all" profile TG
```

### Sending the Output of a Command

You can use the `call-home send` command to execute a CLI command and e-mail the command output to Cisco or to an e-mail address that you specify.

To execute a CLI command and e-mail the command output, perform this task:

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Switch# call-home send &quot;command&quot; [email email-addr] [service-number SR]</td>
<td>Executes the specified CLI command and e-mails the output.</td>
</tr>
</tbody>
</table>

When sending the output of a command, note the following guidelines:

- The specified CLI command can be any run command, including commands for all modules. The command must be contained in quotes (""").
- If an e-mail address is specified, the command output will be sent to that address. If no e-mail address is specified, the output will be sent to the Cisco TAC (attach@cisco.com). The e-mail will be sent in long text format with the service number, if specified, in the subject line.
- The service number is required only if no e-mail address is specified, or if a Cisco TAC e-mail address is specified.

This example shows how to send the output of a CLI command to a user-specified e-mail address:

```
Switch# call-home send "show diagnostic result module all" email support@example.com
```

### Configuring and Enabling Smart Call Home

For application and configuration information of the Cisco Smart Call Home service, see the “FastStart” section of the *Smart Call Home User Guide* at this location:

http://www.cisco.com/go/smartcall/

The user guide includes configuration examples for sending Smart Call Home messages directly from your device or through a transport gateway (TG) aggregation point. You can use a TG aggregation point in cases requiring support for multiple devices or in cases where security requirements mandate that your devices may not be connected directly to the Internet.

Because the Smart Call Home service uses HTTPS as the transport method, you must also configure its CA as a trustpoint, as described in the *Smart Call Home User Guide*. 
Displaying Call Home Configuration Information

To display the configured Call Home information, perform these tasks:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# <code>show call-home</code></td>
<td>Displays the Call Home configuration in summary.</td>
</tr>
<tr>
<td>Switch# <code>show call-home detail</code></td>
<td>Displays the Call Home configuration in detail.</td>
</tr>
<tr>
<td>Switch# <code>show call-home alert-group</code></td>
<td>Displays the available alert groups and their status.</td>
</tr>
<tr>
<td>Switch# <code>show call-home mail-server status</code></td>
<td>Checks and displays the availability of the configured e-mail server(s).</td>
</tr>
<tr>
<td>Switch# `show call-home profile {all</td>
<td>name}`</td>
</tr>
<tr>
<td>Switch# <code>show call-home statistics</code></td>
<td>Displays the statistics of Call Home events.</td>
</tr>
</tbody>
</table>

Examples 52-1 to 52-7 show the results when using different options of the `show call-home` command.

**Example 52-1  Configured Call Home Information**

```text
Switch# `show call-home`  
Current call home settings:  
call home feature : disable  
call home message's from address: switch@example.com  
call home message's reply-to address: support@example.com

</table>

Alert Group Trigger Events and Commands

Call Home trigger events are grouped into alert groups, with each alert group assigned CLI commands to execute when an event occurs. The CLI command output is included in the transmitted message. Table 52-3 lists the trigger events included in each alert group, including the severity level of each event and the executed CLI commands for the alert group.
### Table 52-3 Call Home Alert Groups, Events, and Actions

Message Contents

The following tables display the content formats of alert group messages:

- **Table 52-4** describes the content fields of a short text message.
- **Table 52-5** describes the content fields that are common to all long text and XML messages. The fields specific to a particular alert group message are inserted at a point between the common fields. The insertion point is identified in the table.
- **Table 52-6** describes the inserted content fields for reactive messages (system failures that require a TAC case) and proactive messages (issues that might result in degraded system performance).
- **Table 52-7** describes the inserted content fields for an inventory message.

Table 52-4 Format for a Short Text Message

Performing Diagnostics

You can use diagnostics to test and verify the functionality of the hardware components of your system (chassis, supervisor engines, modules, and ASICs) while your Catalyst 4500 series switch is connected to a live network. Diagnostics consists of packet-switching tests that test hardware components and verify the data path and control signals.

Online diagnostics are categorized as bootup, on-demand, schedule, or health-monitoring diagnostics. Bootup diagnostics run during bootup; on-demand diagnostics run from the CLI; scheduled diagnostics run at user-designated intervals or specified times when the switch is connected to a live network; and health-monitoring runs in the background.

This chapter consists of these sections:

- Configuring Online Diagnostics, page 53-1
- Performing Diagnostics, page 53-2
- Power-On Self-Test Diagnostics, page 53-9

Note

For complete syntax and usage information for the switch commands used in this chapter, refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

Configuring Online Diagnostics

These sections describe how to configure online diagnostics:

- Configuring On-Demand Online Diagnostics, page 53-1
- Scheduling Online Diagnostics, page 53-2

Configuring On-Demand Online Diagnostics

You can run on-demand online diagnostic tests from the CLI. You can set the execution action to either stop or continue the test when a failure is detected, or to stop the test after a specific number of failures occur with the failure count setting. The iteration setting allows you to configure a test to run multiple times.
To schedule online diagnostics, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# `diagnostic ondemand (iteration iteration_count)</td>
<td>(action-on-error {continue</td>
</tr>
</tbody>
</table>

This example shows how to set the on-demand testing iteration count:

Switch# `diagnostic ondemand iterations 3`  
Switch#

This example shows how to set the execution action when an error is detected:

Switch# `diagnostic ondemand action-on-fAilure continue 2`  
Switch#

### Scheduling Online Diagnostics

You can schedule online diagnostics to run at a designated time of day or on a daily, weekly, or monthly basis. You can schedule tests to run only once or to repeat at an interval. Use the no form of this command to remove the scheduling.

To configure online diagnostics, perform this task:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch(config)# `diagnostic schedule module number test (test_id</td>
<td>test_id_range</td>
</tr>
</tbody>
</table>

This example shows how to schedule diagnostic testing on a specific date and time for a specific port on module 6:

Switch(config)# `diagnostic schedule module 6 test 2 port 3 on may 23 2009 23:32`  
Switch(config)#

This example shows how to schedule diagnostic testing to occur daily:

Switch(config)# `diagnostic schedule module 6 test 2 port 3 daily 12:34`  
Switch(config)#

This example shows how to schedule diagnostic testing to occur weekly:

Switch(config)# `diagnostic schedule module 6 test 2 port 3 weekly friday 09:23`  
Switch(config)#

### Performing Diagnostics

After you configure online diagnostics, you can start or stop diagnostic tests or display the test results. You can also see which tests are configured and what diagnostic tests have already run.
These sections describe how to run online diagnostic tests after they have been configured:

- Starting and Stopping Online Diagnostic Tests, page 53-3
- Displaying Online Diagnostic Tests and Test Results, page 53-4
- Line card Online Diagnostics, page 53-7
- Troubleshooting with Online Diagnostics, page 53-7

**Note**

Before you enable any online diagnostics tests, enable the logging console or monitor to observe all warning messages.

**Note**

When running disruptive tests, only run them when you are connected through the console. When disruptive tests complete, a warning message on the console will recommend that you reload the system to return to normal operation. Strictly follow this warning.

### Starting and Stopping Online Diagnostic Tests

After you configure diagnostic tests, you can use the `start` and `stop` keywords to begin or end a test.

To start or stop an online diagnostic command, perform one of these tasks:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch# `diagnostic start module number test (test_id</td>
<td>Starts a diagnostic test on a port or range of ports on the specified module.</td>
</tr>
<tr>
<td>test_id_range</td>
<td>minimal</td>
</tr>
<tr>
<td>Switch# <code>diagnostic stop module number</code></td>
<td>Stops a diagnostic test on the specified module.</td>
</tr>
</tbody>
</table>

This example shows how to start a diagnostic test on module 6:

```
Switch# `diagnostic start module 6 test 2`
Diagnostic[module 6]: Running test(s) 2 Run interface level cable diags
Diagnostic[module 6]: Running test(s) 2 may disrupt normal system operation
Do you want to continue? [no]: yes
Switch# *
```

This example shows how to stop a diagnostic test on module 6:

```
Switch# `diagnostic stop module 6`
Diagnostic[module 6]: Diagnostic is not active.
```

The message indicates no active diagnostic on module 6.
Displaying Online Diagnostic Tests and Test Results

You can display the configured online diagnostic tests and check the results of the tests with the `show diagnostic` command.

To display the configured diagnostic tests, perform this task:

```
Switch# show diagnostic content module 6
module 6:
Diagnostics test suite attributes:
M/C/* - Minimal bootup level test / Complete bootup level test / NA
B/* - Basic ondemand test / NA
P/V/* - Per port test / Per device test / NA
D/N/* - Disruptive test / Non-disruptive test / NA
S/* - Only applicable to standby unit / NA
X/* - Not a health monitoring test / NA
F/* - Fixed monitoring interval test / NA
E/* - Always enabled monitoring test / NA
A/I - Monitoring is active / Monitoring is inactive

cable-tdr/* - Interface cable diags / NA

Test Interval Thre-
ID Test Name Attributes day hh:mm:ss.ms shold
==== ============== =========== =============== ========= =====
1) linecard-online-diag ------------> M**D****I** not configured n/a
2) online-diag-tdr -----------------> **PD****Icable- not configured n/a
```

This example shows how to display the test description for a given test on a module:

```
Switch# show diagnostic description module 6 test 1
linecard-online-diag:
Linecard online-diagnostics run after the system boots up but before it starts passing traffic. Each linecard port is placed in loopback, and a few packets are injected into the switching fabric from the cpu to the port. If the packets are successfully received by the cpu, the port passes the test. Sometimes one port
```
or a group of ports sharing common components fail. The linecard is then placed in partial faulty mode. If no ports can loop back traffic, the board is placed in faulty state.

Switch#

This example shows how to display the online diagnostic results for module 6:

**Line card Online Diagnostics**

A line card online diagnostic test verifies that all ports on a line card are working correctly. The test can detect whether the path to the front panel port on the line card is broken. The test cannot indicate where along the path that the problem occurred.

*Note*

This test is run only for line cards that have stub chips.

Line card online diagnostics runs only once, when the line cards boot. This situation can happen when you insert a line card or power up a chassis.

Line card online diagnostics are performed by sending a packet from the CPU to every port on the line card. Because this packet is marked loopback, the CPU expects to see this packet return from the port. The packet first traverses the ASICs on the supervisor engine card, then travels via the chassis backplane and the stub chip on the line cards to the PHYs. The PHY sends it back down the same path.

*Note*

The packet does not reach or exit the front panel port.

**Troubleshooting with Online Diagnostics**

A faulty line card occurs if any of the following conditions occurs.

- All ports fail
- All ports on a stub chip fail
- Only one port fails

For all of these situations, the output of the `show mod` command would display the status of the line card as faulty:

Switch# `show mod`
Chassis Type : WS-C4507R
Power consumed by backplane : 40 Watts

To troubleshoot a faulty line card, do the following:

**Step 1** Enter the command `show diagnostic result module 3`.

If a faulty line card was inserted in the chassis, it will fail the diagnostics and the output will be similar to the following:

Current bootup diagnostic level: minimal

module 3:  SerialNo : JAB093305RP

Overall Diagnostic Result for module 3 : MAJOR ERROR
Diagnostic level at card bootup: minimal

Test results: (. = Pass, F = Fail, U = Untested)

1) linecard-online-diag ------------> F

Switch#

Issue an RMA for the line card, contact TAC, and skip steps 2 and 3.

The output may display the following:

module 3:

Overall diagnostic result: PASS

Test results: (. = Pass, F = Fail, U = Untested)

1) linecard-online-diag ------------> .

The message indicates that the line card passed online diagnostics either when it was inserted into the chassis the last time or when the switch was powered up (as reported by the "."). You need to obtain additional information to determine the cause.
Step 2 Insert a different supervisor engine card and reinsert the line card.
If the linecard passes the test, it suggests that the supervisor engine card is defective.
Issue an RMA for the supervisor engine, contact TAC, and skip step 3.
Because online diagnostics does not run on the supervisor engine card, you cannot use the
#show diagnostic module 1 command to test whether the supervisor engine card is faulty.

Step 3 Reinsert the linecard in a different chassis.
If the linecard passes the test, the problem is associated with the chassis.
Issue an RMA for the chassis and contact TAC.

Power-On Self-Test Diagnostics

The following topics are discussed:
• Overview, page 53-9
• Sample POST Results, page 53-10
• Power-On Self-Test Results for Supervisor Engine V-10GE, page 53-14
• Troubleshooting the Test Failures, page 53-20

Overview

All Catalyst 4500 series switches have power-on self-test (POST) diagnostics that run whenever a
supervisor engine boots. POST tests the basic hardware functionality for the supervisor switching
engine, its associated packet memory and other on-board hardware components. The results of the POST
impacts how the switch boots, because the health of the supervisor engine is critical to the operation of
the switch. The switch might boot in a marginal or faulty state.
POST is currently supported on the following supervisor engines:
• WS-X4014
• WS-X4515
• WS-X4516
• WS-X4516-10GE
• WS-X4013+
• WS-X4013+TS
• WS-X4013+10GE
• WS-C4948G
• WS-C4948G-10GE
• ME-4924-10GE
• WS-X45-SUP6-E
• WS-X45-SUP6L-E
The POST results are indicated with a period (.) or a Pass for Pass, an F for a Fail and a U for Untested.
Note

A supervisor engine runs POST during boot up (insertion or power on). In a redundant topology, both supervisor engines run POST individually. Switchovers are allowed only after both supervisor engines have booted. During a switchover, the standby supervisor engine does not run POST again because it has already booted.

Sample POST Results

For all the supervisor engines, POST performs CPU, traffic, system, system memory, and feature tests. For CPU tests, POST verifies appropriate activity of the supervisor SEEPROM, temperature sensor, and Ethernet end-of-band channel (EOBC), when used.

The following example illustrates the output of a CPU subsystem test on all supervisor engines except the WS-X4013+TS:

```
[...]
Cpu Subsystem Tests ...
[...]
```

The following example illustrates the output of a CPU subsystem test on a WS-X4013+TS supervisor engine.

```
[...]
Cpu Subsystem Tests ...
seeprom: . temperature_sensor: .
[...]
```

For traffic tests, POST sends packets from the CPU to the switch. These packets loop several times within the switch core and validate the switching, the Layer 2 and the Layer 3 functionality. To isolate the hardware failures accurately, the loop back is done both inside and outside the switch ports.

The following example illustrates the output of a Layer 2 traffic test at the switch ports on the supervisor engines WS-X4516, WS-X4516-10GE, WS-X4013+10GE, WS-C4948G-10GE:

```
Port Traffic: L2 Serdes Loopback ...
 0: . 1: . 2: . 3: . 4: . 5: . 6: . 7: . 8: . 9: . 10: . 11: .
```

The following example illustrates the output of a Layer 2 traffic test at the switch ports on the supervisor engines WS-X4013+TS, WS-X4515, WS-X4013+, WS-X4014, WS-C4948G:

```
Port Traffic: L2 Serdes Loopback ...
 0: . 1: . 2: . 3: . 4: . 5: . 6: . 7: . 8: . 9: . 10: . 11: .
```

POST also performs tests on the packet and system memory of the switch. These are numbered dynamically in ascending order starting with 1 and represent different memories.

The following example illustrates the output from a system memory test:

```
Switch Subsystem Memory ...
 1: . 2: . 3: . 4: . 5: . 6: . 7: . 8: . 9: . 10: . 11: . 12: .
```
POST also tests the NetFlow services card (Supervisor Engine IV and Supervisor Engine V) and the NetFlow services feature (Supervisor Engine V -10GE). Failures from these tests are treated as marginal, as they do not impact functionality of the switch (except for the unavailability of the NetFlow features):

Netflow Services Feature ...

Note Supervisor Engine VI-E retains most of the previous supervisor engines’ POST features including the CPU subsystem tests, Layer 3 and Layer 2 traffic tests, and memory tests. Redundant ports on redundant systems are not tested. All POST diagnostics are local to the supervisor engine running the tests.

The following example shows the output for a WS-X4516 supervisor engine:

Power-On Self-Test Results for Supervisor Engine V-10GE

For the Supervisor Engine V-10GE (WS-X4516-10GE), POST tests extra redundancy features on the
10-Gigabit ports.

The following topics are discussed:

- POST on the Active Supervisor Engine, page 53-14
- Sample POST Results on an Active Supervisor Engine, page 53-15
- POST on a Standby Supervisor Engine, page 53-17
- Sample Display of the POST on a Standby Supervisor Engine, page 53-17

POST on the Active Supervisor Engine

The active supervisor engine tests the remote redundant 10-Gigabit ports on the standby supervisor
engine if it is present when the active supervisor engine is booting. The status of the port is displayed as
“Remote TenGigabit Port Status.” If no standby supervisor engine is present, the remote port status is
always displayed as Untested. This situation persists even after a new standby supervisor engine is
inserted. The remaining tests are conducted using only the Gigabit ports’ configuration.

After the active supervisor engine has completed the bootup diagnostics, if the standby supervisor
engine is now removed, the remote port status is changed to Untested in the overall diagnostic results.
Sample POST Results on an Active Supervisor Engine

Netflow Services Feature ...
POST on a Standby Supervisor Engine

Ports 62 and 63 of the supervisor engine always remain Untested (U). Because the standby supervisor engine never tests the remote 10-Gigabit port on the active supervisor engine, the remote 10-Gigabit port status on the standby supervisor engine is always Untested. The supervisor engine performs the remaining tests using the Gigabit ports’ configuration.

Note

On a redundant chassis, concurrent POST is supported on supervisor engines that are already inserted. However, if a second supervisor engine is inserted while the first one is loading, you might boot the first supervisor engine in a faulty IOS state (POST will abort and some of the POST’s tests will be bypassed). This situation only happens during concurrent bootup of the supervisor engines. You should not insert any additional supervisor engines in the empty supervisor engine slot while an already seated supervisor engine is running POST. The POST sequence is completed when the “Exiting to ios...” message is displayed.

Switch#

Note To ensure that the maximum number of ports are tested, ensure that both supervisor engines are present on power-up.

Troubleshooting the Test Failures

A failure of any of the POST tests reflects a problem with the hardware on the supervisor engine. Cisco IOS boots the supervisor engine with limited functionality, allowing the user to evaluate and display the diagnostic test results. To determine the failure cause, do one of the following:

- Evaluate whether the hardware failure is persistent by power cycling the supervisor engine to rerun the POST tests.
- Remove and reinsert the supervisor engine into the chassis to ensure that the seating is correct.

Please call the Cisco Systems customer support team for more information.

Note On a redundant chassis, concurrent POST is supported on supervisor engines that are already inserted. However, if a second supervisor engine is inserted while the first one is loading, you might boot the first supervisor engine in a faulty Cisco IOS state (POST will abort, and some of the POST’s tests will be bypassed). This situation only happens during concurrent bootup of the supervisor engines. You should not insert any additional supervisor engines in the empty supervisor engine slot while an already seated supervisor engine is running POST. The POST sequence is completed when the “Exiting to ios...” message is displayed.
ROM Monitor

This appendix describes the Cisco Catalyst 4500 switch ROM monitor (also called the bootloader program). The ROM monitor firmware runs when the switch is powered up or reset. The firmware helps to initialize the hardware and boot the operating system software. Use the ROM monitor to perform certain configuration tasks, such as recovering a lost password, booting an IOS image on the on-board flash/ removable storage media/management port, and upgrading the Rommon image itself. If there is no Cisco IOS software image loaded on the switch, the ROM monitor runs the switch.

This appendix contains the following sections:

- Entering the ROM Monitor, page 54-1
- ROM Monitor Commands, page 54-2
- Command Descriptions, page 54-2
- Configuration Register, page 54-3
- Exiting the ROM Monitor, page 54-5
- Digital Signing, page 54-6

Note

For complete syntax and usage information for the switch commands used in this chapter, refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

Entering the ROM Monitor

To use the ROM monitor, you must be using a terminal or PC that is connected to the switch over the console port. Refer to the installation chapter in the Cisco Catalyst 4500 Switch Hardware Installation Guide that came with the switch to connect the router to a PC or terminal.

Perform these steps to configure the switch to boot up in ROM monitor mode the next time it is rebooted.

<table>
<thead>
<tr>
<th>Command</th>
<th>Task</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enters privileged EXEC mode.</td>
</tr>
<tr>
<td>Step 2 configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 3 config-reg 0x0</td>
<td>Resets the configuration register.</td>
</tr>
</tbody>
</table>
ROM Monitor Commands

Enter `?` or `help` at the ROM monitor prompt to display a list of available commands and options, as follows (commands are case sensitive):

```
rommon 1 >?
   alias       set and display aliases command
   boot        boot up an external process
   clear       clear configurations, use `clear help` for more info
   confreg     configuration register utility
   dev         list the device table with physical device information
   dir         list filesystem information
   gdb         break into GDB debugger
   help        monitor builtin command help
   history     monitor command history
   macstats    print management port MAC statistics counters
   meminfo     main memory information
   ping        ping utility to determine network connectivity
   repeat      repeat a monitor command
   reset       system reset
   set         show/set environment vars, use `set help` for more info
   sprom       serial eprom operations
   unalias     unset an alias
   unset       unset a monitor variable
   version     display Rom Monitor version information
rommon 2 >
```

Command Descriptions

Table 54-1 describes the most commonly used ROM monitor commands.
The virtual configuration register is in nonvolatile RAM (NVRAM) and has the same functionality as other Cisco switches/routers. You can view or modify the virtual configuration register from either the ROM monitor or the operating system software. Within ROM monitor, you can change the configuration register by allowing the ROM monitor to prompt you for the setting of each bit.

Entering the `confreg` command without an argument displays the contents of the virtual configuration register and a prompt to alter the contents by describing the meaning of each bit. The new virtual configuration register value is written into NVRAM but does not take effect until you reset or reboot the switch.

The configuration register can be used to control the following things:

- Baud rate of the console part

Configuration Summary :
=> console baud: 38400
=> autoboot from: commands specified in 'BOOT' environment variable

do you wish to save this configuration? y/n [n]:  y
You must reset or power cycle for new configuration to take effect
```

```
rommon 2 >
```

### Debug Commands

The following ROM monitor commands can be useful during debugging:

• **meminfo**—displays the size main memory and the size of NVRAM; for example:

```
rommon 1 > meminfo
Main memory size: 2048 MB.
NVRAM size: 512KB
rommon 2 >
```

• **ping**—verifies network connectivity of the management interface port, as follows:

```
rommon 3 > ping 172.25.60.31
```
Exiting the ROM Monitor

You must configure the boot characteristics of the configuration register to boot a Cisco IOS image from flash memory upon startup or reloading. You can either boot the first file from internal flash memory or form an image specified in the 'BOOT' IOS environment variable (which is set when you enter the IOS `boot system filename` command).

The following example shows how to modify the configuration register and cause the switch to boot the first Cisco IOS image stored in flash memory:

```
rommon 1 > confreg

Configuration Summary :
=> console baud: 9600

do you wish to change the configuration? y/n [n]:  y
enable "diagnostic mode"? y/n [n]:  n
enable "use net in IP bcast address"? y/n [n]:
enable "load rom after netboot fails"? y/n [n]:
enable "use all zero broadcast"? y/n [n]:
enable "break/abort has effect"? y/n [n]:
enable "ignore system conf info"? y/n [n]:
change console baud rate? y/n [n]:
change the boot characteristics? y/n [n]:  y
```

Digital Signing

All bootable images (Rommon, Rommon upgrade utilities, IOS, offline diags, etc) are cryptographically signed to guard against tampering as per the FIPS 140-3 standard. When an image is booted, this signature is inspected. If the signature is valid, the image is allowed to boot. Otherwise, a suitable error message is displayed and the image is not allowed to boot. The most common reason for signatures to fail verification is due to image corruption caused by FTP'ing an image in ASCII mode or e-mailing the image (some e-mail clients have been known to alter the contents of binary files). Other reasons include a corrupted image and an image that has intentionally been tampered with or counterfeited.

An example of booting an image with a successful signature verification looks like this:

```
rommon 2 > boot bootflash:cat4500e-universalk9.SSA.03.00.00.1.63.150.1.XO.bin
loading image
Checking digital signature
bootflash:/cat4500e-universal.SSA.03.00.00.1.63.150.1.XO.bin: Digitally Signed Release Software with key version A
```

An example of booting an image with a failed signature verification looks like this:

```
rommon 2 > boot bootflash:cat4500e-universalk9.SSA.03.00.00.1.63.150.1.XO.bin
loading image
Checking digital signature
Verification FAILED for image
bootflash:/cat4500e-universal.SSA.03.00.00.1.63.150.1.XO.bin, REASON: [reason string]
```

For more detailed information on Digital Signing, refer to the following URLs:

**Configuration Fundamentals Configuration Guide, Cisco IOS XE Release 3S**

**Cisco IOS Configuration Fundamentals Command Reference**

Configuring MIB Support

This chapter describes how to configure SNMP and MIB support for the Catalyst 4500 series switch. It includes the following sections:

- Determining MIB Support for Cisco IOS Releases, page 55-1
- Using Cisco IOS MIB Tools, page 55-2
- Downloading and Compiling MIBs, page 55-2
- Enabling SNMP Support, page 55-4

For complete syntax and usage information for the switch commands used in this chapter, look at the Cisco Catalyst 4500 Series Switch Command Reference and related publications at this location:

If the command is not found in the Catalyst 4500 Command Reference, it is located in the larger Cisco IOS library. Refer to the Catalyst 4500 Series Switch Cisco IOS Command Reference and related publications at this location:

Determining MIB Support for Cisco IOS Releases

Follow these steps to determine which MIBs are included in the Cisco IOS release running on the Catalyst 4500 series switch:

**Step 1** Go to the Cisco MIBs Support page:

**Step 2** Under Cisco LAN Switches, select a **Cisco 4000 IOS** to display a list of MIBs supported on the Cisco 4500 switches.

**Step 3** Scroll through the list to find the release you are interested in.
Using Cisco IOS MIB Tools

This section describes how to access the Cisco MIB tools page. The MIB Locator finds MIBs in Cisco IOS software releases. You can find general MIB information, instructions about how to use the SNMP Object Navigator which translates SNMP object identifiers (OIDs) into SNMP names, and how to load Cisco MIBs.

Follow these steps to access the Cisco IOS MIB tools site:

---

**Step 1**
Go to the Cisco Products and Services page:
http://tools.cisco.com/ITDIT/MIBS/servlet/index

**Step 2**
Click **Cisco IOS MIB Locator** to launch the application. The locator application allows you to find a MIB in the following three ways.

From the Cisco IOS MIB Locator page, you can:

a. Click the drop-down menu and select the desired Cisco IOS software release.

b. From the Platform Family menu, select **CAT4500-SUP7-E**.

c. From the Feature Set menu, select from the following:
   - UNIVERSAL SSH, UNIVERSAL W/O CRYPTO, UNIVERSAL LITE SSH, UNIVERSAL LITE W/O CRYPTO

**Step 3**
From the MIB Locator page, you can search by image name. For example, enter the following and click the **Submit** button:

`cat4500e-ipbasek9-mz.122-53.SG2.bin`

**Step 4**
From the MIB Locator page, you can search for the MIB from the list of MIBs in the menu. You can select one, or for multiple selections, hold down the **CTRL** key, then click the **Submit** button.

---

**Note**
After you make a selection, follow the links and instructions.

---

**Downloading and Compiling MIBs**

The following sections provide information about how to download and compile MIBs for the Catalyst 4500 series switch:

- Considerations for Working with MIBs
- Downloading MIBs
- Compiling MIBs

**Considerations for Working with MIBs**

While working with MIBs, consider the following:

- Mismatches on Datatype Definitions
Mismatches on datatype definitions might cause compiler errors or warning messages. Although Cisco MIB datatype definitions are not mismatched, some standard RFC MIBs do mismatch. For example:

MIB A defines: SomeDatatype ::= INTEGER(0..100)
MIB B defines: SomeDatatype ::= INTEGER(1..50)

This example is considered to be a trivial error and the MIB loads successfully with a warning message.

The next example is considered as a nontrivial error (even though the two definitions are essentially equivalent), and the MIB is not successfully parsed.

MIB A defines: SomeDatatype ::= DisplayString
MIB B defines: SomeDatatype ::= OCTET STRING (SIZE(0..255))

If your MIB compiler treats these as errors, or you want to delete the warning messages, edit one of the MIBs that define this same datatype so that the definitions match.

Many MIBs import definitions from other MIBs. If your management application requires MIBs to be loaded, and you experience problems with undefined objects, you might want to load the following MIBs in this order:

SNMPv2-SMI.my
SNMPv2-TC.my
SNMPv2-MIB.my
RFC1213-MIB.my
IF-MIB.my
CISCO-SMI.my
CISCO-PRODUCTS-MIB.my
CISCO-TC.my

For a list of SNMP OIDs assigned to MIB objects, go to the following URL and click on SNMP Object Navigator and follow the links:

http://tools.cisco.com/ITDIT/MIBS/servlet/index

Note: You must have a Cisco CCO name and password to access the MIB Locator.

For information about how to download and compile Cisco MIBs, go to the following URL:

Downloading MIBs

Follow these steps to download the MIBs onto your system if they are not already there:

Step 1: Review the considerations in the previous section (“Considerations for Working with MIBs”).

Step 2: Go to one of the following Cisco URLs. If the MIB you want to download is not there, try the other URL; otherwise, go to one of the URLs in Step 5.
ftp://ftp.cisco.com/pub/mibs/v1

Step 3: Click the link for a MIB to download that MIB to your system.
Enabling SNMP Support

The following procedure summarizes how to configure the Catalyst 4500 series switch for SNMP support.

For detailed information about SNMP commands, see the following Cisco documents:

- *Cisco IOS Release 12.3 Configuration Fundamentals and Network Management Configuration Guide*, “Monitoring the Router and Network” section, available at the following URL:

- *Cisco IOS Release 12.3 Configuration Fundamentals and Network Management Command Reference*, Part 3: System Management Commands, “Router and Network Configuration Commands” section, available at the following URL:

To configure the Catalyst 4500 series switch for SNMP support, follow these steps:

**Step 1** Set up your basic SNMP configuration through the command line interface (CLI) on the router. Note that these basic configuration commands are issued for SNMP version 2c. For SNMP version 3, you must also set up SNMP users and groups. (See the preceding list of documents for command and setup information.)

a. Define SNMP read-only and read-write communities:
   
   ```
   Router (config)# snmp-server community Read_Only_Community_Name ro
   Router (config)# snmp-server community Read_Write_Community_Name rw
   ```

b. Configure SNMP views (to limit the range of objects accessible to different SNMP user groups):
   
   ```
   Router (config)# snmp-server view view_name oid-tree {included | excluded}
   ```

**Step 2** Identify (by IP address) the host to receive SNMP notifications from the router:

   ```
   Router (config)# snmp-server host host
   ```

**Step 3** Configure the router to generate notifications. You can use keywords to limit the number and types of messages generated.

   ```
   Router (config)# snmp-server enable traps [notification-type] [notification-option]
   ```

Compiling MIBs

If you plan to integrate the Catalyst 4500 series switch with an SNMP-based management application, then you must also compile the MIBs for that platform. For example, if you are running HP OpenView on a UNIX operating system, you must compile Catalyst 4500 series switch MIBs with the HP OpenView Network Management System (NMS). For instructions, see the NMS documentation.
Step 4  Optional. Configure the router to generate SNMP notifications released to field replaceable units (FRUs):

```
Router (config)# snmp-server enable traps fru-ctrl
```

Step 5  Optional. Configure the router to generate SNMP notifications related to environmental monitoring:

```
Router (config)# snmp-server enable traps envmon
```
