- ViSN Tests, page A-42

Note
- For information about configuring online diagnostic tests see Chapter 14, “Online Diagnostics.”
- Before you enable any online diagnostics tests, enable console logging to see all warning messages.
- We recommend that when you are running disruptive tests that you only run the tests when connected through console. When disruptive tests are complete a warning message on the console recommends that you reload the system to return to normal operation: strictly follow this warning.
- While tests are running, all ports are shut down as a stress test is being performed with looping ports internally and external traffic might affect the test results. The switch must be rebooted to bring the switch to normal operation. When you issue the command to reload the switch, the system will ask you if the configuration should be saved.
- Do not save the configuration.
- If you are running the tests on other modules, after the test is initiated and complete, you must reset the module.

TestAsicSync

This test periodically verifies the status of bus and port synchronization ASICs.

</tr>
</tbody>
</table>
TestEARLInternalTables

This test detects most PFC and DFC hardware table problems by running consistency checks on the PFC and DFC hardware tables. The test runs every 5 minutes.

A failure of the test for the PFC results in one of these actions:
- Failover to the redundant supervisor engine.
- If a redundant supervisor engine is not installed, shutdown of the supervisor engine.

A failure of the test for the DFC results in one of these actions:
- Up to two resets of the DFC-equipped switching module.
- Shutdown following a third failure.

A CallHome message is generated if CallHome is configured on the system.

</tbody>
</table>

TestErrorCounterMonitor

This test monitors the errors and interrupts that occur on each module in the system by periodically polling for the error counters maintained in the module. If the errors exceed a threshold value, a syslog message is displayed with detailed information including the error-counter identifier, port number, total failures, consecutive failures, and the severity of the error counter.

</tbody>
</table>
TestIntPortLoopback

This test uses the switching module internal port to run a non-disruptive loopback test. It can be used to detect fabric channel failure and also port ASIC failure. This test is similar to TestFabricCh0Health. The test runs every 15 seconds.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

TestL3TcamMonitoring

This test verifies Layer 3 packet switching and monitors the health of both FIB and CL TCAM using the diagnostic lookup key. This test is nondisruptive and runs periodically every 15 seconds. Ten consecutive failures are treated as fatal, which cause the module to reload during runtime.

<table>
<thead>
<tr>

</tbody>
</table>
# TestLtlFpoeMemoryConsistency

This test verifies that the LTL and FPOE memories are working properly. The test runs every 15 seconds. Self-correction is applied if an error is detected. If self-correction fails, corrective action is triggered to reset the module. The module is powered-down on the third consecutive module reset. If self-correction passes, no action is taken. If too many self-corrections occur within a short period of time (more than three self-corrections in less than 300 seconds), the module is reset.

<table>

</tr>
</tbody>
</table>

# TestMacNotification

This test verifies the data and control path between DFC-equipped modules and supervisor engines. This test also ensures Layer 2 MAC address consistency across Layer 2 MAC address tables. The test runs every six seconds. Ten consecutive failures causes the module to reset during bootup or runtime (default). After three consecutive resets, the module powers down. This test runs every 15 seconds.

<table>
<thead>
<tr>

<tr>
<td>Hardware support</td>
<td>DFC-equipped modules.</td>
</tr>
</tbody>
</table>
TestPortTxMonitoring

This test periodically polls the transmit counters on each port. The test displays a syslog message and error disables the port if no activity is seen for the configured time interval and failure threshold. You configure the time interval and threshold by entering the `diagnostic monitor interval` and `diagnostic monitor threshold` commands. The test does not source any packets, but leverages the CDP protocol that transmits packets periodically. If the CDP protocol is disabled, the polling for that port is not performed. The test runs every 75 seconds, and the failure threshold is set to five by default.

<table>

</tr>
</tbody>
</table>

TestScratchRegister

This test monitors the health of application-specific integrated circuits (ASICs) by writing values into registers and reading back the values from these registers. The test runs every 30 seconds. Five consecutive failures causes a supervisor engine to switchover (or reset), if you are testing the supervisor engine, or in the module powering down when testing a module.

<td>Reset the malfunctioning supervisor engine or power down the module.</td>
</tr>
</tbody>
</table>
**TestSnrMonitoring**

This test monitors the SNR (signal-to-noise ratio) margin for a port, which varies between -12.7 dB to +12.7 dB. The test uses the following two threshold levels to compare SNR:

- Minor threshold at +1.0 dB
- Major threshold at 0.0 dB

When the SNR value drops below the minor threshold, the test logs a minor warning message. When the SNR value drops below the major threshold, the test logs a major warning message. Similarly, recovery messages are logged when SNR recovers the two threshold levels. The default interval for the test is 30 seconds and can be configured to as low as 10 seconds for faster monitoring. The TestSnrMonitoring is not a bootup test and cannot be run on demand.

</tbody>
</table>

**TestUnusedPortLoopback**

This test periodically verifies the data path between the supervisor engine and the network ports of a module in the runtime. In this test, a Layer 2 packet is flooded onto the VLAN associated with the test port and the inband port of the supervisor engine. The packet loops back in the test port and returns to the supervisor engine on the same VLAN. This test is similar to TestLoopback but only runs on unused (admin down) network ports and on only one unused port per port ASIC. This test substitutes the lack of a nondisruptive loopback test in current ASICs. This test runs every 60 seconds.

<table>

**TestActiveToStandbyLoopback**

This test verifies the data path between the active supervisor engine and the network ports of the standby supervisor engine. In this test, a Layer 2 packet is flooded onto a VLAN that consists of only the test port and the active supervisor engine’s inband port. The test packets are looped back in the targeted port and are flooded back onto the bus with only the active supervisor engine’s inband port listening in on the flooded VLAN.

</tbody>
</table>

TestNetflowInlineRewrite

This test verifies the NetFlow lookup operation, the ACL permit and deny functionality, and the inline rewrite capabilities of the port ASIC. The test packet will undergo a NetFlow table lookup to obtain the rewrite information. The VLAN and the source and destination MAC addresses are rewritten when the packet reaches the targeted port.

<table>
<thead>
<tr>

</tbody>
</table>
TestNonDisruptiveLoopback

This test verifies the data path between the supervisor engine and the network ports of a module. In this test, a Layer 2 packet is flooded onto VLAN that contains a group of test ports. The test port group consists of one port per port ASIC channel. Each port in the test port group nondisruptively loops back the packet and directs it back to the supervisor engine’s inband port. The ports in the test port group are tested in parallel.

TestBadBpdu

This test verifies the ability to trap or redirect packets to the switch processor. This test verifies that the Trap feature of the Layer 2 forwarding engine is working properly. When running the test on the supervisor engine, the diagnostic packet is sent from the supervisor engine’s inband port and performs a packet lookup using the supervisor engine’s Layer 2 forwarding engine. For DFC-equipped modules, the diagnostic packet is sent from the supervisor engine’s inband port through the switch fabric and looped back from one of the DFC ports. The BPDU feature is verified during the diagnostic packet lookup by the Layer 2 forwarding engine.

TestCapture

This test verifies that the capture feature of Layer 2 forwarding engine is working properly. The capture functionality is used for multicast replication. When running the test on the supervisor engine, the diagnostic packet is sent from the supervisor engine’s inband port and performs a packet lookup using the supervisor engine’s Layer 2 forwarding engine. For DFC-equipped modules, the diagnostic packet is sent from the supervisor engine’s inband port through the switch fabric and looped back from one of the DFC ports. The Capture feature is verified during the diagnostic packet lookup by the Layer 2 forwarding engine.

Appendix A  Online Diagnostic Tests

DFC Layer 2 Tests

TestConditionalLearn

This test verifies the ability to learn a Layer 2 source MAC address under specific conditions. When running the test on the supervisor engine, the diagnostic packet is sent from the supervisor engine’s inband port and performs a packet lookup using the supervisor engine Layer 2 forwarding engine. For DFC-equipped modules, the diagnostic packet is sent from the supervisor engine’s inband port through the switch fabric and looped back from one of the DFC ports. The Conditional Learn feature is verified during the diagnostic packet lookup by the Layer 2 forwarding engine.

</tbody>
</table>

TestDontLearn

This test verifies that new source MAC addresses are not populated in the MAC address table when they should not be learned. This test verifies that the “don’t learn” feature of the Layer 2 forwarding engine is working properly. For DFC-equipped modules, the diagnostic packet is sent from the supervisor engine inband port through the switch fabric and looped back from one of the ports on the DFC-enabled module. The “don’t learn” feature is verified during diagnostic packet lookup by the Layer 2 forwarding engine.

TestIndexLearn

This test ensures that existing MAC address table entries can be updated. This test verifies the Index Learn feature of the Layer 2 forwarding engine is working properly. When running the test on the supervisor engine, the diagnostic packet is sent from the supervisor engine’s inband port and performs a packet lookup using the supervisor engine Layer 2 forwarding engine. For DFC-equipped modules, the diagnostic packet is sent from the supervisor engine’s inband port through the switch fabric and looped back from one of the DFC ports. The Index Learn feature is verified during the diagnostic packet lookup by the Layer 2 forwarding engine.

TestNewLearn

This test verifies the Layer 2 source MAC address learning functionality of the Layer 2 forwarding engine. For supervisor engines, a diagnostic packet is sent from the supervisor engine inband port to verify that the Layer 2 forwarding engine is learning the new source MAC address from the diagnostic packet. For DFC-equipped modules, a diagnostic packet is sent from the supervisor engine inband port through the switch fabric and looped back from one of the ports on the DFC-enabled module. The Layer 2 learning functionality is verified during the diagnostic packet lookup by the Layer 2 forwarding engine.

TestPortSecurity

This test verifies the ability to redirect packets to the CPU if a secure MAC address is transmitting the packets from a different port. For the supervisor engine, a diagnostic packet is sent from the supervisor engine’s inband port and the port security feature is verified during the diagnostic packet lookup by the Layer 2 forwarding engine. For DFC-equipped modules, a diagnostic packet is sent from the supervisor engine inband port through the fabric and is looped back in one of the ports on the DFC-equipped module. The port security feature is verified during the diagnostic packet lookup by the Layer 2 forwarding engine.

TestProtocolMatchChannel

This test verifies the ability to match specific Layer 2 protocols in the Layer 2 forwarding engine. When running the test on the supervisor engine, the diagnostic packet is sent from the supervisor engine’s inband port and performs a packet lookup using the supervisor engine’s Layer 2 forwarding engine. For DFC-equipped modules, the diagnostic packet is sent from the supervisor engine’s inband port through the switch fabric and looped back from one of the DFC ports. The Match feature is verified during the diagnostic packet lookup by the Layer 2 forwarding engine.

</table>
TestStaticEntry

This test verifies the ability to populate static entries in the Layer 2 MAC address table. For DFC-equipped modules, the diagnostic packet is sent from the supervisor engine’s inband port through the switch fabric and looped back from one of the DFC ports. The Static Entry feature is verified during the diagnostic packet lookup by the Layer 2 forwarding engine.

TestTrap

This test verifies the ability to trap or redirect packets to the switch processor. This test verifies that the Trap feature of the Layer 2 forwarding engine is working properly. When running the test on the supervisor engine, the diagnostic packet is sent from the supervisor engine’s inband port and performs a packet lookup using the supervisor engine’s Layer 2 forwarding engine. For DFC-equipped modules, the diagnostic packet is sent from the supervisor engine’s inband port through the switch fabric and looped back from one of the DFC ports. The Trap feature is verified during the diagnostic packet lookup by the Layer 2 forwarding engine.

**TestAclDeny**

This test verifies that the ACL deny feature of the Layer 2 and Layer 3 forwarding engine is working properly. The test uses different ACL deny scenarios such as input, output, Layer 2 redirect, Layer 3 redirect, and Layer 3 bridges to determine whether or not the ACL deny feature is working properly.

<table>

**TestAclPermit**

This test verifies that the ACL permit functionality is working properly. An ACL entry permitting a specific diagnostics packet is installed in the ACL TCAM. The corresponding diagnostic packet is sent from the supervisor engine and looked up by the Layer 3 forwarding engine to make sure that it hits the ACL TCAM entry and gets permitted and forwarded appropriately.

TestIPv4FibShortcut

This test does the following:

- Verifies whether the IPv4 FIB forwarding of the Layer 3 forwarding engine is working properly. One diagnostic IPv4 FIB and an adjacency entry are installed, and a diagnostic packet is sent to make sure that the diagnostic packet is forwarded according to rewritten MAC and VLAN information.
- Verifies whether the FIB TCAM and adjacency devices are functional. One FIB entry is installed on each FIB TCAM device. A diagnostic packet is sent to make sure that the diagnostic packet is switched by the FIB TCAM entry installed on the TCAM device. This is not an exhaustive TCAM device test; only one entry is installed on each TCAM device.

</tbody>
</table>

TestL3Capture2

This test verifies that the Layer 3 capture (capture 2) feature of the Layer 3 forwarding engine is working properly. This capture feature is used for ACL logging and VACL logging. One diagnostic FIB and an adjacency entry with a capture 2 bit set is installed, and a diagnostic packet is sent to make sure that the diagnostic packet is forwarded according to the capture bit information.

<table>
<thead>
<tr>

</tbody>
</table>
TestMPLSFibShortcut

This test does the following:

- Verifies that the MPLS forwarding of the Layer 3 forwarding engine is working properly. One diagnostic MPLS FIB and an adjacency entry is installed, and a diagnostic MPLS packet is sent to make sure that the diagnostic packet is forwarded according to the MPLS label from the adjacency entry.
- Verifies the EoMPLS forwarding of the Layer 3 forwarding engine. One diagnostic EoMPLS Layer 2 FIB and an adjacency entry are installed and a diagnostic Layer 2 packet is sent to the forwarding engine to make sure it is forwarded accordingly with the MPLS labels and the encapsulated Layer 2 packet.

TestMPLSFibShortcut

This test does the following:

- Verifies that the MPLS forwarding of the Layer 3 forwarding engine is working properly. One diagnostic MPLS FIB and an adjacency entry is installed, and a diagnostic MPLS packet is sent to make sure that the diagnostic packet is forwarded according to the MPLS label from the adjacency entry.
- Verifies the EoMPLS forwarding of the Layer 3 forwarding engine. One diagnostic EoMPLS Layer 2 FIB and an adjacency entry are installed and a diagnostic Layer 2 packet is sent to the forwarding engine to make sure it is forwarded accordingly with the MPLS labels and the encapsulated Layer 2 packet.

<tr>
<td>Hardware support:</td>
<td>Supervisor engines and DFC-equipped modules.</td>
</tr>
</tbody>
</table>

TestL3VlanMet

This test verifies that the multicast functionality of the replication engine is working properly. The replication engine is configured to perform multicast replication of a diagnostic packet onto two different VLANs. After the diagnostic packet is sent out from the supervisor engine’s inband port, the test verifies that two packets are received back in the inband port on the two VLANs configured in the replication engine.

<table>
<thead>
<tr>
<th>Attribute</th>

</tr>
</tbody>
</table>

TestFabricFlowControlStatus

This test reads the switch fabric ASIC registers to detect flow-control status for each fabric channel. Flow-control events are logged into the diagnostic events queue. By default, this test is disabled as a health-monitoring test, and when enabled, this test runs every 15 seconds. This test reports per-slot or per-channel rate reduction, current fabric channel utilization, peak fabric-channel utilization, and SP CPU utilization in both ingress and egress directions.

<table>

</tbody>
</table>
TestFabricInternalSnake

This test is supported for a supervisor engine and module with a fabric switching ASIC. This test is executed by firmware INIT sequence code during bootup time when the firmware initializes the entire fabric ASIC.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disruptive or Nondisruptive:</td>
<td>Disruptive.</td>
</tr>
<tr>
<td>Recommendation:</td>
<td>After the supervisor engine is online, this test is supported to run by on-demand diagnostics for chassis-standby supervisor engine but not for chassis-active supervisor engine. For modules with a fabric switching ASIC, this test is supported only for bootup diagnostic.</td>
</tr>
<tr>
<td>Default:</td>
<td>Off.</td>
</tr>
<tr>
<td>Initial Release:</td>
<td>12.2(50)SY.</td>
</tr>
<tr>
<td>Corrective action:</td>
<td>If the test fails, firmware INIT sequence fails and the supervisor engine or module under test is power reset.</td>
</tr>
<tr>
<td>Hardware support:</td>
<td>Supervisor engines and fabric-enabled module.</td>
</tr>
</tbody>
</table>

TestFabricVlanLoopback

This test verifies the data path between the inband port of the module under test and the local fabric port responsible for switching traffic from and to the inband port through the per queue VLAN loopback feature provided by the hardware. When the test packet from the inband port arrives at the input queue of the local fabric port with matching VLAN to the pre-programmed VLAN loopback register, the test packet transverses the fabric, loopbacks to the output queue of the same fabric port, and forwards the test packet back to the inband port.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disruptive or Nondisruptive:</td>
<td>Nondisruptive.</td>
</tr>
<tr>
<td>Recommendation:</td>
<td>Test runs automatically on bootup. On-demand is also supported. Use this test to verify the data path between the local fabric channel and the inband port or use for debugging.</td>
</tr>
<tr>
<td>Default:</td>
<td>Off.</td>
</tr>
<tr>
<td>Initial Release:</td>
<td>12.2(50)SY.</td>
</tr>
<tr>
<td>Corrective action:</td>
<td>None. See the system message guide for more information.</td>
</tr>
<tr>
<td>Hardware support:</td>
<td>Supervisor engines and DFC-equipped modules.</td>
</tr>
</tbody>
</table>
**TestSynchedFabChannel**

This test periodically checks the fabric synchronization status for both the module and the fabric. This test is available only for fabric-enabled modules. This test is not a packet-switching test so it does not involve the data path. This test sends an SCP control message to the module and fabric to query the synchronization status.

<table>
<thead>
<tr>

<td>All fabric-enabled modules.</td>
</tr>
</tbody>
</table>

**Exhaustive Memory Tests**

- TestAclQosTcam, page A-36
- TestAsicMemory, page A-36
- TestEarlMemOnBootup, page A-37

**Note**

Because the supervisor engine must be rebooted after running memory tests, run memory tests on the other modules before running them on the supervisor engine. For more information about running on-demand online diagnostic tests see the “Configuring On-Demand Online Diagnostics” section on page 14-3.
TestAclQosTcam

This test tests all the bits and checks the location of both ACL and QoS TCAMs on the PFC.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disruptive or Nondisruptive</td>

</tr>
</tbody>
</table>

Stress Tests

- TestEobcStressPing, page A-38
- TestTrafficStress, page A-39

TestEobcStressPing

This test stresses a module’s EOBC link with the supervisor engine. The test is started when the supervisor engine initiates a number of sweep-ping processes (the default is one). The sweep-ping process pings the module with 20,000 SCP-ping packets. The test passes if all 20,000 packets respond before each packet-ping timeout, which is two seconds. If unsuccessful, the test allows five retries to account for traffic bursts on the EOBC bus during the test.

<table>
<thead>
<tr>
<th>Attribute</th>

ViSN Tests

- TestRslHm, page A-42
- TestVSAactiveToStandbyLoopback, page A-43
- TestVslBridgeLink, page A-43
- TestVslLocalLoopback, page A-44
- TestVslStatus, page A-44

TestRslHm

This test monitors the data and control links between the remote switch and core switches. A diagnostic packet is sent from the supervisor engine inband port on the remote switch to the supervisor engine inband port on the core switch and is pinged back along the reverse data path. This tests each RSL link between the remote switch and both active and standby core switches.

<table>

<td>VSL-capable modules.</td>
</tr>
</tbody>
</table>
**TestVSActiveToStandbyLoopback**

This test is the only GOLD test that tests the full data path across the virtual switch links. This test selects an uplink port in the standby virtual switch supervisor engine as the loopback point and sends the VLAN flood packet from the active virtual switch supervisor engine inband port to the system. Due to the configuration of the FPOE and LTL VLAN flood region for all VSL modules and VSL interfaces in the active and standby virtual switch, the packet goes across VSL and arrives at the uplink port of the standby virtual switch supervisor engines, and loopbacks from there. The packet comes back to the inband port of the active supervisor engine due to the preconfiguration of FPOE and LTL in the standby and active virtual switches. In case of a test failure, the error check is executed for SP CPU, fabric flow control, and other errors in both active and standby virtual switches.

**TestVslBridgeLink**

This test provides diagnostic coverage for VSL-capable modules and the supervisor engine during module bootup. The data path of this test picks only one port corresponding to the local and remote bridge inband port as the loopback points. A diagnostic packet is sent from the inband port of the supervisor engine to the loopback points on the VSL module, and the packet traverses the bridge link between two fabric data path complexes to verify the hardware bridge link functionality.

TestVslLocalLoopback

This test verifies the hardware functionality of each port on the VSL module before the VSL link interface is up. The data path of this test is constrained with the VSL module. A diagnostic packet is sent from the local inband port of the VSL module to each port to run a loopback test. This test is run only during module bootup.

TestVslStatus

This test reports the status change detected by the VSLP protocol. When any link problem is detected by the VSLP protocol, the status of the link is changed and the result is updated accordingly. This test also triggers the loopback test to check the hardware status requested by the VSLP protocol.
