Avoiding Network Congestion

Heterogeneous networks include different protocols used by applications, giving rise to the need to prioritize traffic in order to satisfy time-critical applications while still addressing the needs of less time-dependent applications, such as file transfer. If your network is designed to support different traffic types that share a single data path between devices in a network, implementing congestion avoidance mechanisms ensures fair treatment across the various traffic types and avoids congestion at common network bottlenecks. Congestion avoidance mechanism is achieved through packet dropping.

Random Early Detection (RED) is a commonly used congestion avoidance mechanism in a network.

Tail Drop

Tail drop treats all traffic equally and does not differentiate within a class of service. When the output queue is full and tail drop is in effect, packets are dropped until the congestion is eliminated and the queue is no longer full.

Weighted Random Early Detection (WRED)

The RED mechanism takes advantage of the congestion control mechanism of TCP. Packets are randomly dropped prior to periods of high congestion. Assuming the packet source uses TCP, it decreases its transmission

rate until all the packets reach their destination, indicating that the congestion is cleared. You can use RED as a way to cause TCP to slow down transmission of packets. TCP not only pauses, but also restarts quickly and adapts its transmission rate to the rate that the network can support.

WRED is the Cisco implementation of RED. It combines the capabilities of RED algorithm with IP Precedence or Differentiated Services Code Point (DSCP) or Class of Service (COS) values.

How WRED Works

WRED reduces the chances of tail drop by selectively dropping packets when the output interface begins to show signs of congestion. WRED drops some packets early rather than waiting until the queue is full. Thus it avoids dropping large number of packets at once and minimizes the chances of TCP global synchronization.

WRED supports multiple sub-classes of service when they are mapped to a single queue for a class. Each sub-class of service is dropped with a different probability to provide for the QoS differentiation.

Approximate Fair Drop (AFD) is an Active Queue Management (AQM) algorithm that determines the packet drop probability. The probability of dropping packets depends upon the arrival rate calculation of a flow at ingress and the current queue length.

AFD based WRED is implemented on wired network ports.

AFD based WRED emulates the preferential dropping behavior of WRED. This preferential dropping behavior is achieved by changing the weights of AFD sub-classes based on their corresponding WRED drop thresholds. Within a physical queue, traffic with larger weight incurs less drop probability than that of smaller weight.

- Each WRED enabled queue has high and low thresholds.
- A sub-class of higher priority has a larger AFD weight.
- The sub-classes are sorted in ascending order, based on lowest of WRED minThreshold.

WRED Weight Calculation

- AFD weight is calculated using minimum and maximum threshold values; it is an average of WRED high and WRED low.
- AFD weight is normalized for 1-64 range.

When a packet arrives at an interface, the following events occur:

1. Average queue length and drop probability are calculated.
2. The drop probability decides if the packet is to be dropped or not.
3. If the packet is not dropped and the queue length does not exceed the queue limit, the packet is put back to the queue.

Limitations for WRED Configuration

- Weighted Tail Drop (WTD) is enabled by default on all the queues.

- WRED can be enabled / disabled per queue. When WRED is disabled, WTD is adapted on the target queue.
- WRED is supported only in network port queues and is not supported on internal CPU queues and stack queues.
- Each WRED physical queue can support three subqueues, with unique WRED threshold pair configuration.
- Ensure that you configure bandwidth/shape in the policy-map along with WRED.
- Specify all the WRED thresholds only in percentage mode.
- Map the WRED threshold pairs by mapping class-map filter with corresponding match filters.
We recommend the class-map with match “any” filter.
- Policy-map with WRED profile is configured only on physical ports as output policy.
- Wired ports support a maximum of eight physical queues, of which you can configure WRED only on four physical queues, each with three threshold pairs. The remaining queues are configured with WTD. Policies with more than four WRED queues are rejected.
- Do not configure WRED for priority traffic.
- WRED does not support Explicit Congestion Notification (ECN) configuration in Cisco IOS XE Release 16.5.1a.

Usage Guidelines for WRED

To configure AFD based WRED feature, specify the policy map and add the class. Use the **random-detect** command to specify the method (using the dscp-based / cos-based / precedence-based arguments) that you want WRED to use to calculate the drop probability.

Note You can modify the policy on the fly. The AFD weights are automatically recalculated.

WRED can be configured for any kind of traffic like IPv4/IPv6, Multicast, and so on.

Consider the following points when you are configuring WRED with **random-detect** command:

- With dscp-based argument, WRED uses the DSCP value to calculate drop probability.
- With cos-based argument, WRED uses the COS value to calculate drop probability.
- By default, WRED uses the IP Precedence value to calculate drop probability. **precedence-based** argument is the default and it is not displayed in the CLI.

Note **show run policy-map** *policy-map* command does not display “precedence” though precedence is configured with **random-detect** command.

- The dscp-based and precedence-based arguments are mutually exclusive.

- Each of the eight physical queues can be configured with different WRED profiles.

Configuring WRED

Configuring WRED based on DSCP Values

Use the following steps to configure WRED profile based on DSCP values in packet mode:

Procedure

	Command or Action	Purpose
Step 1	class-map <i>match-criteria class-name</i> Example: device(config)# class-map match-any CS	Configures match criteria for the class map. Recommended match-criteria is match-any
Step 2	match <i>class-map-name</i> Example: device(config)#match CS	Match a class-map.
Step 3	policy-map <i>name</i> Example: device(config)#policy-map pwred	Specifies the name of the WRED profile policy to be created.
Step 4	class <i>class-name</i> Example: device(config-pmap)#class CS	Specifies the name of the Class to be associated with the policy.
Step 5	bandwidth { <i>kbps</i> remaining percentage percent percentage } Example: device(config-pmap-c)#bandwidth percent 10	Specifies the bandwidth allocated for a class belonging to a policy map.
Step 6	random-detect <i>dscp-based</i> Example: device(config-pmap-c)#random-detect dscp-based	Configures WRED to use the DSCP value when it calculates the drop probability for the packet.
Step 7	random-detect dscp <i>dscp-value percent minThreshold maxThreshold</i> Example: device(config-pmap-c)#random-detect dscp csl percent 10 20	Specifies the minimum and maximum thresholds, in percentage. Note random-detect range CLI is not supported on Cisco IOS XE Release 16.5.1a

	Command or Action	Purpose
Step 8	interface <i>interface-name</i> Example: device(config)#interface GigabitEthernet1/0/8	Enters the interface configuration mode.
Step 9	service-policy output <i>policy-map</i> Example: device(config-if)#service-policy output pwred	Attaches the policy map to an output interface.

Configuring WRED based on Class of Service (CoS) Values

Use the following steps to configure WRED profile based on Class of Service (COS) values in packet mode:

Procedure

	Command or Action	Purpose
Step 1	class-map <i>match-criteria class-name</i> Example: device(config)# class-map match-any CS	Configures match criteria for the class map. Recommended match-criteria is match-any
Step 2	match <i>class-map-name</i> Example: device(config-cmap)#match CS	Match a class-map.
Step 3	policy-map <i>name</i> Example: device(config)#policy-map pwred	Specifies the name of the WRED profile policy to be created.
Step 4	class <i>class-name</i> Example: device(config-pmap)#class CS	Specifies the name of the Class to be associated with the policy.
Step 5	bandwidth { <i>kbits</i> remaining percentage percent percentage } Example: device(config-pmap-c)#bandwidth percent 10	Specifies the bandwidth allocated for a class belonging to a policy map.
Step 6	random-detect <i>cos-based</i> Example: device(config-pmap-c)#random-detect cos-based	Configures WRED to use the CoS value when it calculates the drop probability for the packet.

	Command or Action	Purpose
Step 7	random-detect <i>cos cos-value percent minThreshold maxThreshold</i> Example: <pre>device(config-pmap-c)#random-detect cos 3 percent 10 20</pre>	Specifies the minimum and maximum thresholds, in percentage.
Step 8	interface <i>interface-name</i> Example: <pre>device(config)# interface GigabitEthernet1/0/8</pre>	Enters the interface configuration mode.
Step 9	service-policy output <i>policy-map</i> Example: <pre>device(config-if)#service-policy output pwred</pre>	Attaches the policy map to an output interface.

Configuring WRED based on IP Precedence Values

Use the following steps to configure WRED profile based on IP precedence values in packet mode:

Procedure

	Command or Action	Purpose
Step 1	class-map <i>match-criteria class-name</i> Example: <pre>device(config)# class-map match-any CS</pre>	Configures match criteria for the class map. Recommended match-criteria is match-any
Step 2	match <i>class-map-name</i> Example: <pre>device(config)#match CS</pre>	Match a class-map.
Step 3	policy-map <i>name</i> Example: <pre>device(config)#policy-map pwred</pre>	Specifies the name of the WRED profile policy to be created.
Step 4	class <i>class-name</i> Example: <pre>device(config-pmap)#class CS</pre>	Specifies the name of the Class to be associated with the policy.
Step 5	bandwidth <i>{kpbs remaining percentage percent percentage}</i> Example: <pre>device(config-pmap-c)#bandwidth percent 10</pre>	Specifies the bandwidth allocated for a class belonging to a policy map.

	Command or Action	Purpose
Step 6	random-detect <i>precedence-based</i> Example: device(config-pmap-c)#random-detect precedence-based	Configures WRED to use the IP precedence value when it calculates the drop probability for the packet.
Step 7	random-detect precedence <i>precedence-value percent minThreshold maxThreshold</i> Example: device(config-pmap-c)#random-detect precedence 3 percent 10 20	Specifies the minimum and maximum thresholds, in percentage.
Step 8	interface <i>interface-name</i> Example: device(config)#interface GigabitEthernet1/0/8	Enters the interface configuration mode.
Step 9	service-policy output <i>policy-map</i> Example: device(config-if)#service-policy output pwred	Attaches the policy map to an output interface.

WRED Configuration Example

The following example enables WRED to use DSCP profile for class CS. It configures three sub-classes cs1, cs2, and cs3 with their WRED minimum and maximum thresholds and finally applies the policy to GigabitEthernet interface 8:

```
Device(config)# class-map match-any CS
Device(config-cmap)#match dscp cs1
Device(config-cmap)# match dscp cs2
Device(config-cmap)# match dscp cs3
Device(config-cmap)#policy-map PWRED
Device(config-pmap)#class CS
Device(config-pmap-c)# bandwidth percent 10
Device(config-pmap-c)# random-detect dscp-based
Device(config-pmap-c)# random-detect dscp cs1 percent 10 20
Device(config-pmap-c)# random-detect dscp cs2 percent 20 30
Device(config-pmap-c)# random-detect dscp cs3 percent 34 44
Device(config-pmap-c)# exit
Device(config-pmap)# exit
Device(config)# interface GigabitEthernet1/0/8
Device(config-if)# service-policy output PWRED
```

Support for WRED with Hierarchical QoS (HQoS)

Hierarchical QoS allows you to specify QoS behavior at multiple policy levels, which provides a high degree of granularity in traffic management.

For HQoS, WRED is allowed only on the child policy and not on the parent policy. You can have the shaping or bandwidth configured on the parent policy and WRED on the child.

The following example configures the parent policy **pwred-parent** with traffic shaped on the basis of 10 percent of the bandwidth, that applies to its child, **pwred-child** configured for DSCP-based WRED.

```
policy-map pwred-child
  class cwred
    bandwidth percent 10
    random-detect dscp-based
    random-detect dscp 1 percent 10 20
    random-detect dscp 10 percent 20 30

policy-map pwred-parent
  class class-default
  shape average percent 10
  service-policy pwred-child
```

The following show command verifies the HQoS WRED configuration:

```
device# show policy-map pwred-parent
  policy Map pwred-parent
    class class-default
      average Rate Traffic Shaping
      cir 30%
      service-policy pwred-child
  policy-map pwred-child
    class cwred
      bandwidth percent 10
      random-detect dscp-based
      random-detect dscp 1 percent 10 20
      random-detect dscp 10 percent 20 30
  policy-map pwred-parent
```

Verifying WRED Configuration

Use the following show commands to verify WRED Configuration:

Procedure

Step 1 **show policy-map** *policy-map-name*

Displays the WRED and threshold labels.

Example:

```
Device# show policy-map PWRED
  Policy Map PWRED
    Class CS
      bandwidth 10 (%)
      percent-based wred

      dscp      min-threshold  max-threshold
      -----
      cs1 (8)    10             20
      cs2 (16)   20             30
      cs3 (24)   34             44
      default (0) -
```

Step 2 **show policy-map interface** *interface-name*

Displays WRED AFD Weights, WRED Enq(in Packets and Bytes), WRED Drops(in Packets and Bytes), Configured DSCP labels against the Threshold pairs.

Note Use this command only after you initiate the traffic. **show policy-map interface** is updated with WRED configuration only after a traffic is sent.

Example:

```
Device#show policy-map interface Te 3/0/1
TenGigabitEthernet3/0/1
```

```
Service-policy output: PWRED
```

```
Class-map: CS (match-any)
  0 packets
  Match: dscp cs1 (8)
  Match: dscp cs2 (16)
  Match: dscp cs3 (24)
  Queueing
```

```
(total drops) 27374016
(bytes output) 33459200081
bandwidth 10% (1000000 kbps)
```

```
AFD WRED STATS BEGIN

  0 packets
  Match: any
```

```
(total drops) 0
(bytes output) 192
```

Best Practices for WRED Configuration

• Support for three WRED configuration pairs

Each WRED Physical Queue (AFD Queue) can support three WRED configuration pairs, with unique WRED threshold pair configuration.

```
Policy-map P1
  Class CS
    Random-detect dscp-based
    Random-detect dscp CS1 percent 10 20 // WRED pair 1
    Random-detect dscp CS2 percent 20 30 // WRED pair 2
    Random-detect dscp CS3 percent 30 40 // WRED pair 3
  Class-map match-any CS
    match cs1
    match cs2
    match cs3
```

• Appending WRED configuration pairs

You can add overlapping threshold pairs into the WRED configuration pairs.

```
Policy-map P1
  Class CS
    Random-detect dscp-based
    Random-detect dscp CS1 percent 10 20 // WRED pair 1
    Random-detect dscp CS2 percent 20 30 // WRED pair 2
    Random-detect dscp CS3 percent 30 40 // WRED pair 3
    Random-detect dscp CS4 percent 30 40 ==> belongs to WRED pair 3
    Random-detect dscp CS5 percent 20 30 ==> belongs to WRED pair 2
  Class-map match-any CS
    match cs1
    match cs2
    match cs3
    match cs4 >>
    match cs5 >>
```

• Default WRED pairs

If less than three WRED pairs are configured, any class-map filter participating WRED gets assigned to the third default WRED pair with maximum threshold (100, 100).

```
Policy-map P1
  Class CS
    Random-detect dscp-based
    Random-detect dscp CS1 percent 10 20 // WRED pair 1
    Random-detect dscp CS2 percent 20 30 // WRED pair 2
  Class-map match-any CS
    match CS1
    match CS2
    match CS3
    match CS4
```

In this case, classes CS3 and CS4 are mapped to WRED pair 3 with threshold (100, 100).

• Rejection of Mismatched Configuration

If you configure random-detect without matching filters in a class-map, the policy installation is rejected.

```
Class-map match-any CS
  match CS1
  match CS2
  match CS5
```

```

Policy-map P1
  Class CS
    Shape average percent 10
    Random-detect dscp-based
    Random-detect dscp CS1 percent 10 20 // WRED pair 1
    Random-detect dscp CS2 percent 20 30 // WRED pair 2
    Random-detect dscp CS3 percent 30 40 // WRED pair 3 ==> Mismatched sub-class.

```

When this policy is applied to the interface on the egress side, the policy fails during installation as the class-map values are incorrect:

```

device(config)# int Fo1/0/5
device(config-if)# service-policy output P1
device(config-if)#
*Feb 20 17:33:16.964: %IOSXE-5-PLATFORM: Switch 1 R0/0: fed: WRED POLICY INSTALL
FAILURE.Invalid WRED filter mark: 24 in class-map: CS
*Feb 20 17:33:16.965: %FED_QOS_ERRMSG-3-LABEL_2_QUEUE_MAPPING_HW_ERROR: Switch 1 R0/0:
fed: Failed to detach queue-map for FortyGigabitEthernet1/0/5: code 2

```

Feature Information for Weighted Random Early Detection

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use the Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Feature Name	Releases	Feature Information
Support for Weighted Random Early Detection mechanism.	Cisco IOS XE Everest 16.5.1a	<p>WRED is a mechanism to avoid congestion in networks. WRED reduces the chances of tail drop by selectively dropping packets when the output interface begins to show signs of congestion, thus avoiding large number of packet drops at once. You can configure WRED to act based on any of the following values:</p> <ul style="list-style-type: none"> - Differentiated Service Code Point - IP Precedence - Class of Service
