IN NO EVENT SHALL CISCO OR ITS SUPPLIERS BE LIABLE FOR ANY INDIRECT, SPECIAL, CONSEQUENTIAL, OR INCIDENTAL DAMAGES, INCLUDING, WITHOUT LIMITATION, LOST PROFITS OR LOSS OR DAMAGE TO DATA ARISING OUT OF THE USE OR INABILITY TO USE THIS MANUAL, EVEN IF CISCO OR ITS SUPPLIERS HAVE BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

Any Internet Protocol (IP) addresses and phone numbers used in this document are not intended to be actual addresses and phone numbers. Any examples, command display output, network topology diagrams, and other figures included in the document are shown for illustrative purposes only. Any use of actual IP addresses or phone numbers in illustrative content is unintentional and coincidental.

All printed copies and duplicate soft copies of this document are considered uncontrolled. See the current online version for the latest version.

Cisco has more than 200 offices worldwide. Addresses and phone numbers are listed on the Cisco website at www.cisco.com/go/offices.

The documentation set for this product strives to use bias-free language. For purposes of this documentation set, bias-free is defined as language that does not imply discrimination based on age, disability, gender, racial identity, ethnic identity, sexual orientation, socioeconomic status, and intersectionality. Exceptions may be present in the documentation due to language that is hardcoded in the user interfaces of the product software, language used based on standards documentation, or language that is used by a referenced third-party product.

CHAPTER 1	Controlling Switch Access with Passwords and Privilege Levels 1
	Restrictions for Controlling Switch Access with Passwords and Privileges 1
	Restrictions and Guidelines for Reversible Password Types 1
	Restrictions and Guidelines for Irreversible Password Types 1
	Information About Controlling Switch Access with Passwords and Privileges
	Preventing Unauthorized Access 2
	Default Password and Privilege Level Configuration 3
	Additional Password Security 3
	Password Recovery 4
	Terminal Line Telnet Configuration 4
	Username and Password Pairs 4
	Privilege Levels 5
	AES Password Encryption and Master Encryption Keys 5
	How to Configure Switch Access with Passwords and Privileges 6
	Setting or Changing a Static Enable Password 6
	Protecting Enable and Enable Secret Passwords with Encryption 7
	Disabling Password Recovery 11
	Setting a Telnet Password for a Terminal Line 12
	Configuring Username and Password Pairs 13
	Setting the Privilege Level for a Command 14
	Changing the Default Privilege Level for Lines 15
	Logging in to and Exiting a Privilege Level 16
	Configuring an Encrypted Preshared Key 17
	Monitoring Switch Access with Passwords and Privileges 18

CHAPTER

CHAPTER

	Configuration Examples for Switch Access with Passwords and Privilege Leve	els
	Example: Setting or Changing a Static Enable Password 18	
	Example: Protecting Enable and Enable Secret Passwords with Encryption	18
	Example: Setting a Telnet Password for a Terminal Line 18	
	Example: Setting the Privilege Level for a Command 18	
	Example: Configuring an Encrypted Preshared Key 19	
	Feature History for Controlling Switch Access with Passwords and Privileges	19
2	Configuring Login Block 21	
	Information About Login Enhancements-Login Block 21	
	Login Enhancements-Login Block Overview 21	
	Protecting Against Denial of Service and Dictionary Login Attacks 21	
	Delays Between Successive Login Attempts 22	
	Login Shutdown If DoS Attacks Are Suspected 22	
	How to Configure Login Enhancements-Login Block 22	
	Configuring Login Parameters 22	
	Verifying Login Parameters 24	
	Configuration Examples for Login Enhancements-Login Block 26	
	Example: Configuring Login Parameters 26	
	Feature History for Login Enhancements-Login Block 26	
3	Configuring Authentication 27	
	Prerequisites for Configuring Authentication 27	
	Restrictions for Configuring Authentication 27	
	Information About Authentication 27	
	Named Method Lists for Authentication 27	
	Method Lists and Server Groups 28	
	Login Authentication Using AAA 29	

18

Login Authentication Using Enable Password 29

Login Authentication Using Line Password 29 Login Authentication Using Local Password **30** Login Authentication Using Group RADIUS

Login Authentication Using Group TACACS 30

30

Login Authentication Using Kerberos 29

Login Authentication Using Group Name 30
PPP Authentication Using AAA 31
PPP Authentication Using Kerberos 31
PPP Authentication Using Local Password 31
PPP Authentication Using Group RADIUS 31
PPP Authentication Using Group TACACS 32
PPP Authentication Using Group Name 32
AAA Scalability for PPP Requests 33
ARAP Authentication Using AAA 33
ARAP Authentication Allowing Authorized Guest Logins 33
ARAP Authentication Allowing Guest Logins 33
ARAP Authentication Using Line Password 34
ARAP Authentication Using Local Password 34
ARAP Authentication Using Group RADIUS 34
ARAP Authentication Using Group TACACS 34
ARAP Authentication Using a Group Name 34
NASI Authentication Using AAA 35
NASI Authentication Using Enable Password 35
NASI Authentication Using Group RADIUS 35
NASI Authentication Using Group TACACS 35
NASI Authentication Using Line Password 36
NASI Authentication Using Local Password 36
NASI Authentication Using Group Name 36
Specifying the Amount of Time for Login Input 36
Password Protection at the Privileged Level 37
Changing the Text Displayed at the Password Prompt 37
Double Authentication of PPP Sessions 37
How Double Authentication Works 38
Accessing the User Profile After Double Authentication 38
CHAP or PAP Authentication 39
Enabling PPP Encapsulation 40
Enabling PAP or CHAP 40
Inbound and Outbound Authentication 41
Enabling Outbound PAP Authentication 41

Refusing PAP Authentication Requests 41 Creating a Common CHAP Password 41 Refusing CHAP Authentication Requests 42 Delaying CHAP Authentication Until Peer Authenticates 42 Using MS-CHAP 42 Domain Stripping 43 How to Configure Authentication 43 Configuring Login Authentication Using AAA 43 Configuring PPP Authentication Using AAA 45 Configuring ARAP Authentication Using AAA 47 Configuring NASI Authentication Using AAA 49 Preventing an Access Request with a Blank Username from Being Sent to the RADIUS Server 50 Configuring Message Banners for AAA Authentication 51 Configuring a Login Banner 51 Configuring a Failed-Login Banner 52 Configuring AAA Packet of Disconnect 53 Configuring Double Authentication 54 Enabling Automated Double Authentication 55 Configuring Domain Stripping at the Server Group Level 58 Configuring Non-AAA Authentication Methods 59 Configuring Line Password Protection 59 Establishing Username Authentication 60 Defining PPP Authentication Using MS-CHAP 62 Configuration Examples for Authentication 63 Example: Configuring Method Lists 63 Example: RADIUS Authentication 65 **Example: TACACS Authentication** 66 Example: Kerberos Authentication 67 Example: AAA Scalability 68 Example: Configuring Login and Failed-Login Banners for AAA Authentication 69 Example: AAA Packet of Disconnect Server Key **70** Example: Double Authentication 70 Example: Configuration of the Local Host for AAA with Double Authentication 70

	Example: Configuration of the AAA Server for First-Stage PPP Authentication and Authorization 71
	Example: Configuration of the AAA Server for Second-Stage Per-User Authentication and Authorization 71
	Example: Complete Configuration with TACACS 72
	Example: Automated Double Authentication 75
	Feature History for Configuring Authentication 76
CHAPTER 4	Configuring Authorization 79
	Prerequisites for Configuring Authorization 79
	Information About Configuring Authorization 80
	Named Method Lists for Authorization 80
	AAA Authorization Methods 80
	Authorization Methods 81
	Method Lists and Server Groups 82
	AAA Authorization Types 82
	Authorization Types 82
	Authorization Attribute-Value Pairs 83
	How to Configure Authorization 83
	Configuring AAA Authorization Using Named Method Lists 83
	Disabling Authorization for Global Configuration Commands 84
	Configuring Authorization for Reverse Telnet 85
	Configuration Examples for Authorization 86
	Example: TACACS Authorization 86
	Example: RADIUS Authorization 87
	Example: Reverse Telnet Authorization 87
	Feature History for Configuring Authorization 89
CHAPTER 5	Configuring Accounting 91
	Prerequisites for Configuring Accounting 91
	Restrictions for Configuring Accounting 91
	Information About Configuring Accounting 92
	Named Method Lists for Accounting 92
	Method Lists and Server Groups 93

AAA Accounting Methods 93 AAA Accounting Types 95 Network Accounting **95** EXEC Accounting 97 Command Accounting 99 Connection Accounting 99 System Accounting 101 Resource Accounting 102 AAA Accounting Enhancements 104 AAA Broadcast Accounting 104 AAA Session MIB 104 Accounting Attribute-Value Pairs 105 How to Configure AAA Accounting 105 Configuring AAA Accounting Using Named Method Lists 105 Suppressing Generation of Accounting Records for Null Username Sessions 106 Generating Interim Accounting Records 107 Configuring an Alternate Method to Enable Periodic Accounting Records 107 Generating Interim Service Accounting Records 108 Generating Accounting Records for a Failed Login or Session 109 Specifying Accounting NETWORK-Stop Records Before EXEC-Stop Records 109 Suppressing System Accounting Records over Switchover 110 Configuring AAA Resource Failure Stop Accounting 110 Configuring AAA Resource Accounting for Start-Stop Records 110 AAA Broadcast Accounting 111 Configuring Per-DNIS AAA Broadcast Accounting 111 Establishing a Session with a Device if the AAA Server Is Unreachable 111 Monitoring Accounting 111 Troubleshooting Accounting 112 Configuration Examples for AAA Accounting 112 Example: Configuring a Named Method List 112 Example: Configuring AAA Resource Accounting 114 Example: Configuring AAA Broadcast Accounting 115 Example: Configuring per-DNIS AAA Broadcast Accounting 115 Example: AAA Session MIB 116

	Additional References for Configuring Accounting 116
	Feature History for Configuring Accounting 116
CHAPTER 6	Configuring Local Authentication and Authorization 119
	How to Configure Local Authentication and Authorization 119
	Configuring the Switch for Local Authentication and Authorization 119
	Monitoring Local Authentication and Authorization 121
	Feature History for Local Authentication and Authorization 121
CHAPTER 7	Configuring AAA Authorization and Authentication Cache 123
	Prerequisites for Implementing Authorization and Authentication Profile Caching 123
	Information About Implementing Authorization and Authentication Profile Caching 123
	Network Performance Optimization Using Authorization and Authentication Profile Caching 124
	Authorization and Authentication Profile Caching as a Failover Mechanism 124
	Method Lists in Authorization and Authentication Profile Caching 125
	Authorization and Authentication Profile Caching Guidelines 125
	General Configuration Procedure for Implementing Authorization and Authentication Profile Caching 125
	How to Implement Authorization and Authentication Profile Caching 125
	Creating Cache Profile Groups and Defining Caching Rules 126
	Defining RADIUS and TACACS Server Groups that Use Cache Profile Group Information 129
	Updating Authorization and Authentication Method Lists to Specify How Cache Information is Used 130
	Configuration Examples for Implementing Authorization and Authentication Profile Caching 132
	Example: Implementing Authorization and Authentication Profile Caching for Network Optimization 132
	Example: Implementing Authorization and Authentication Profile Caching as a Failover Mechanism 132
	Feature History for Implementing Authorization and Authentication Profile Caching 133
CHAPTER 8	Configuring AAA Dead-Server Detection 135
	Prerequisites for AAA Dead-Server Detection 135
	Restrictions for AAA Dead-Server Detection 135
	Information About AAA Dead-Server Detection 135

Criteria for Marking a RADIUS Server As Dead 136 How to Configure AAA Dead-Server Detection 136 Configuring AAA Dead-Server Detection 136 Verifying AAA Dead-Server Detection 137 Configuration Examples for AAA Dead-Server Detection 138 Example: Configuring AAA Dead-Server Detection 138 Feature History for AAA Dead-Server Detection 139

CHAPTER 9 Configuring TACACS+ 141

Prerequisites for TACACS+ 141 Information About TACACS+ 142 TACACS+ and Switch Access 142 TACACS+ Overview 142 TACACS+ Operation 143 Method List 144 TACACS+ Configuration Options 144 TACACS+ Login Authentication 145 TACACS+ Authorization for Privileged EXEC Access and Network Services 145 TACACS+ Accounting 145 Default TACACS+ Configuration 145 How to Configure TACACS+ 145 Identifying the TACACS+ Server Host and Setting the Authentication Key 145 Configuring TACACS+ Login Authentication 147 Configuring TACACS+ Authorization for Privileged EXEC Access and Network Services 149 Starting TACACS+ Accounting 150 Establishing a Session with a Device if the AAA Server is Unreachable 151 Configuring TACACS Source-Interface Under a TACACS Server-Group 151 Monitoring TACACS+ 153 Additional References for TACACS+ 153 Feature History for TACACS+ 153

CHAPTER 10 Device Sensor 155

Restrictions for Device Sensor 155 Information About Device Sensor 155 Device Sensor 155 How to Configure Device Sensor 157 Enabling Accounting Augmentation 157 Creating a Protocol Filter 158 Applying a Protocol Filter to the Sensor Output 159 Tracking TLV Changes 160 Verifying the Device Sensor Configuration 161 Configuration Examples for Device Sensor 162 Examples: Configuring the Device Sensor 162 Feature History for Device Sensor 163

CHAPTER 11 Configuring RADIUS 165

Prerequisites for Configuring RADIUS 165 Restrictions for Configuring RADIUS 166 Information about RADIUS 166 RADIUS and Switch Access 166 RADIUS Overview 166 RADIUS Operation 167 RADIUS Change of Authorization 168 Change-of-Authorization Requests 169 CoA Request Response Code 171 CoA Request Commands 172 Default RADIUS Configuration 174 RADIUS Server Host 174 RADIUS Login Authentication 175 AAA Server Groups 175 AAA Authorization 175 RADIUS Accounting 176 Vendor-Specific RADIUS Attributes 176 Vendor-Proprietary RADIUS Server Communication 187 DSCP marking for RADIUS packets 187 How to Configure RADIUS 188 Identifying the RADIUS Server Host 188 Configuring RADIUS Login Authentication 189

CHAPTER 12

	Defining AAA Server Groups 191
	Configuring RADIUS Authorization for User Privileged Access and Network Services
	Starting RADIUS Accounting 194
	Configuring Settings for All RADIUS Servers 194
	Configuring the Device to Use Vendor-Specific RADIUS Attributes 195
	Configuring the Device for Vendor-Proprietary RADIUS Server Communication 196
	Configuring DSCP Marking on a RADIUS Server 197
	Configuring the Source Interface and DSCP Marking on RADIUS Server Group 198
	Configuring CoA on the Device 199
	Configuring RADIUS Source-Interface Under a RADIUS Server-Group 201
	Monitoring CoA Functionality 203
	Feature History for RADIUS 203
Conf	iguring RadSec 205
	Restrictions for Configuring RadSec 205
	Information About RadSec 206
	How to Configure RadSec 206
	Configuring RadSec over TLS 206
	Configuring Dynamic Authorization for TLS CoA 208
	Configuring RadSec over DTLS 209
	Configuring Dynamic Authorization for DTLS CoA 210
	Monitoring RadSec 211
	Monitoring RadSec 211 Configuration Examples for RadSec 211
	-
	Configuration Examples for RadSec 211
	Configuration Examples for RadSec 211 Example: Configuring RadSec over TLS 212
	Configuration Examples for RadSec 211 Example: Configuring RadSec over TLS 212 Example: Configuring Dynamic Authorization for TLS CoA 212

Prerequisites for RADIUS Server Load Balancing 215
Restrictions for RADIUS Server Load Balancing 215
Information About RADIUS Server Load Balancing 216
RADIUS Server Load Balancing Overview 216

CHAPTER 13

 RADIUS Server Status and Automated Testing 217 VRF-Aware RADIUS Automated Testing 217 How to Configure RADIUS Server Load Balancing 218 Enabling Load Balancing for a Named RADIUS Server Group 218 Troubleshooting RADIUS Server Load Balancing 219 Enabling VRF Aware RADIUS Automated Testing 220 Configuration Examples for RADIUS Server Load Balancing 221 Example: Enabling Load Balancing for a Named RADIUS Server Group 221 Example: Monitoring Idle Timer 224 Example: Configuring the Preferred Server with the Same Authentication and Authorization Server 224 Example: Configuring the Preferred Server with Different Authentication and Authorization Servers 225 Example: Configuring the Preferred Server with Overlapping Authentication and Authorization Servers 225
 How to Configure RADIUS Server Load Balancing 218 Enabling Load Balancing for a Named RADIUS Server Group 218 Troubleshooting RADIUS Server Load Balancing 219 Enabling VRF Aware RADIUS Automated Testing 220 Configuration Examples for RADIUS Server Load Balancing 221 Example: Enabling Load Balancing for a Named RADIUS Server Group 221 Example: Monitoring Idle Timer 224 Example: Configuring the Preferred Server with the Same Authentication and Authorization Server 224 Example: Configuring the Preferred Server with Different Authentication and Authorization Servers 225 Example: Configuring the Preferred Server with Overlapping Authentication and Authorization
 Enabling Load Balancing for a Named RADIUS Server Group 218 Troubleshooting RADIUS Server Load Balancing 219 Enabling VRF Aware RADIUS Automated Testing 220 Configuration Examples for RADIUS Server Load Balancing 221 Example: Enabling Load Balancing for a Named RADIUS Server Group 221 Example: Monitoring Idle Timer 224 Example: Configuring the Preferred Server with the Same Authentication and Authorization Server 224 Example: Configuring the Preferred Server with Different Authentication and Authorization Servers 225 Example: Configuring the Preferred Server with Overlapping Authentication and Authorization
Troubleshooting RADIUS Server Load Balancing 219 Enabling VRF Aware RADIUS Automated Testing 220 Configuration Examples for RADIUS Server Load Balancing 221 Example: Enabling Load Balancing for a Named RADIUS Server Group 221 Example: Monitoring Idle Timer 224 Example: Configuring the Preferred Server with the Same Authentication and Authorization Server 224 Example: Configuring the Preferred Server with Different Authentication and Authorization Servers 225 Example: Configuring the Preferred Server with Overlapping Authentication and Authorization
 Enabling VRF Aware RADIUS Automated Testing 220 Configuration Examples for RADIUS Server Load Balancing 221 Example: Enabling Load Balancing for a Named RADIUS Server Group 221 Example: Monitoring Idle Timer 224 Example: Configuring the Preferred Server with the Same Authentication and Authorization Server 224 Example: Configuring the Preferred Server with Different Authentication and Authorization Servers 225 Example: Configuring the Preferred Server with Overlapping Authentication and Authorization
 Configuration Examples for RADIUS Server Load Balancing 221 Example: Enabling Load Balancing for a Named RADIUS Server Group 221 Example: Monitoring Idle Timer 224 Example: Configuring the Preferred Server with the Same Authentication and Authorization Server 224 Example: Configuring the Preferred Server with Different Authentication and Authorization Servers 225 Example: Configuring the Preferred Server with Overlapping Authentication and Authorization
 Example: Enabling Load Balancing for a Named RADIUS Server Group 221 Example: Monitoring Idle Timer 224 Example: Configuring the Preferred Server with the Same Authentication and Authorization Server 224 Example: Configuring the Preferred Server with Different Authentication and Authorization Servers 225 Example: Configuring the Preferred Server with Overlapping Authentication and Authorization
 Example: Monitoring Idle Timer 224 Example: Configuring the Preferred Server with the Same Authentication and Authorization Server 224 Example: Configuring the Preferred Server with Different Authentication and Authorization Servers 225 Example: Configuring the Preferred Server with Overlapping Authentication and Authorization
 Example: Configuring the Preferred Server with the Same Authentication and Authorization Server 224 Example: Configuring the Preferred Server with Different Authentication and Authorization Servers 225 Example: Configuring the Preferred Server with Overlapping Authentication and Authorization
Server 224 Example: Configuring the Preferred Server with Different Authentication and Authorization Servers 225 Example: Configuring the Preferred Server with Overlapping Authentication and Authorization
Servers 225 Example: Configuring the Preferred Server with Overlapping Authentication and Authorization
Example: Configuring the Preferred Server with Authentication Servers As a Subset of Authorizatio Servers 226
Example: Configuring the Preferred Server with Authentication Servers As a Superset of Authorizatio Servers 226
Example: Enabling VRF Aware RADIUS Automated Testing 227
Additional References for RADIUS Server Load Balancing 227
Feature History for RADIUS Server Load Balancing 227

CHAPTER 14 Configuring Kerberos 229

Prerequisites for Kerberos 229

Information about Kerberos **229**

Kerberos and Switch Access 229

Kerberos Overview 230

Kerberos Operation 232

Authenticating to a Boundary Switch 232

Obtaining a TGT from a KDC 232

Authenticating to Network Services 233

How to Configure Kerberos 233

Monitoring the Kerberos Configuration 233

Feature History for Kerberos 233

CHAPTER 15

MACsec Encryption 235

Prerequisites for MACsec Encryption 235 Restrictions for MACsec Encryption 235 Information About MACsec Encryption 236 Recommendations for MACsec Encryption 236 MACsec Encryption Overview 237 Media Access Control Security and MACsec Key Agreement 237 MKA Policies 238 Definition of Policy-Map Actions 238 Virtual Ports 239 MKA Statistics 239 Key Lifetime and Hitless Key Rollover 239 Replay Protection Window Size 240 MACsec, MKA, and 802.1x Host Modes 240 Access Control Option for Smoother Migration 241 Certificate-Based MACsec Encryption 241 MACsec Connections Across Intermediate Switches 242 Limitations for MACsec Connections Across Intermediate Switches 242 Switch-to-switch MKA MACsec Must Secure Policy 242 MACsec Extended Packet Numbering (XPN) 243 MKA/MACsec for Port Channel 243 MACsec Cipher Announcement 243 How to Configure MACsec Encryption 244 Configuring MKA and MACsec 244 Configuring an MKA Policy 244 Configuring Switch-to-host MACsec Encryption 246 Configuring MKA MACsec using PSK 248 Configuring MACsec MKA using PSK 248 Configuring MACsec MKA on an Interface Using PSK 249 Configuring Certificate-Based MACsec Encryption 251 Generating Key Pairs 251 Configuring Enrollment using SCEP 252

Configuring Enrollment Manually 254
Configuring Switch-to-switch MACsec Encryption 256
Configuring MACsec XPN 258
Configuring an MKA Policy for XPN 258
Applying the XPN MKA Policy to an Interface 259
Configuring MKA/MACsec for Port Channel 259
Configuring MKA/MACsec for Port Channel using PSK 259
Configuring Port Channel Logical Interfaces for Layer 2 EtherChannels 261
Configuring Port Channel Logical Interfaces for Layer 3 EtherChannels 262
Configuring MACsec Cipher Announcement 263
Configuring an MKA Policy for Secure Announcement 263
Configuring Secure Announcement Globally 264
Configuring EAPOL Announcements on an Interface 265
Configuring Cisco TrustSec MACsec 266
Configuring Cisco TrustSec Switch-to-Switch Link Security in Manual Mode 266
Configuration Examples for MACsec Encryption 268
Example: Configuring MKA and MACsec 268
Example: Configuring MACsec MKA using PSK 268
Example: Configuring MACsec MKA Using Certificate-Based MACsec Encryption 270
Example: Configuring MACsec XPN 270
Example: Configuring MACsec MKA for Port Channel using PSK 272
Example: Configuring MACsec Cipher Announcement 279
Example: Displaying MKA Information 282
Additional References for MACsec Encryption 288
Feature History for MACsec Encryption 289

CHAPTER 16

Configuring Secure Shell 291

Configuring Secure Shell 291 Prerequisites for Configuring Secure Shell 291 Restrictions for Configuring Secure Shell 292 Information About Configuring Secure Shell 292 SSH Server 292 SSH Integrated Client 292 RSA Authentication Support 293 CHAPTER 17

SSH Configuration Guidelines 293 How to Configure Secure Shell 294 Setting Up the Device to Run SSH 294 Configuring an SSH Server 295 Invoking an SSH Client 296 Configuration Examples for Secure Shell 297 Example: Configuring an SSH Server 297 Example: Invoking an SSH Client 297 Example: Invoking an SSH Client 297 Additional References for Secure Shell 298 Feature History for Configuring Secure Shell 298 Prerequisites for Secure Shell 298 Restrictions for Secure Shell Version 2 Support 299 Restrictions for Secure Shell Version 2 Support 300 Information About Secure Shell Version 2 Support 300 Secure Shell Version 2 300 Secure Shell Version 2 Enhancements 301 Secure Shell Version 2 Enhancements 301 Secure Shell Version 302 RSH And Switch Access 302 SSH Keyboard Interactive Authentication 302 How to Configure Secure Shell Version 2 Support 303 Configuring a Device for SSH Version 2 Using a Hostname and Domain Name 303 Configuring the Cisco 3SH Server to Perform RSA-Based User Authentication 305 Configuring the Cisco 105 SSH Client to Perform RSA-Based Server Authentication 305 Karting an Encrypted Session with a Remote Device 308 Verifying the Status of the Secure Shell Version 2 311 Configuration Examples for Secure Shell Version 2 311 Configuration Examples for Secure Shell Version 2 311	SSH Servers, Integrated Clients, and Supported Versions 293
Setting Up the Device to Run SSH 294 Configuring an SSH Server 295 Invoking an SSH Client 296 Configuration Examples for Secure Shell 297 Example: Configuring an SSH Server 297 Example: Invoking an SSH Client 297 Example: Verifying SSH 297 Additional References for Secure Shell 298 Feature History for Configuring Secure Shell 298 Secure Shell Version 2 Support 299 Prerequisites for Secure Shell Version 2 Support 299 Restrictions for Secure Shell Version 2 Support 300 Information About Secure Shell Version 2 Support 300 Secure Shell Version 2 a00 Secure Shell Version 2 Enhancements 301 Secure Shell Version 2 Enhancements 301 Secure Shell Version 2 Enhancements 301 Secure Shell Version 2 Enhancements 302 SSH And Switch Access 302 SSH Keyboard Interactive Authentication 302 How to Configure Secure Shell Version 2 Support 303 Configuring a Device for SSH Version 2 Using a Hostname and Domain Name 303 Configuring a Device for SSH Version 2 Using RSA Key Pairs 304 Configuring the Cisco SSH Server to Perform RSA-Based User Authentication 305 Configuring the Cisco IOS SSH Client to Perform RSA-Based Server Authentication 305 Starting an Encrypted Session with a Remote Device 308 Verifying the Status of the Secure Shell Version 2 Satus 310 Monitoring and Maintaining Secure Shell Version 2 311	SSH Configuration Guidelines 293
Configuring an SSH Server 295 Invoking an SSH Client 296 Configuration Examples for Secure Shell 297 Example: Configuring an SSH Server 297 Example: Invoking an SSH Client 297 Example: Verifying SSH 297 Additional References for Secure Shell 298 Secure Shell Version 2 Support 299 Prerequisites for Secure Shell Version 2 Support 299 Restrictions for Secure Shell Version 2 Support 300 Information About Secure Shell Version 2 Support 300 Secure Shell Version 2 Enhancements 301 Secure Shell Version 2 Enhancements 301 Secure Shell Version 2 Enhancements for RSA Keys 301 SSH And Switch Access 302 SNMP Trap Generation 302 SSH Keyboard Interactive Authentication 302 How to Configure Secure Shell Version 2 Support 303 Configuring a Device for SSH Version 2 Using a Hostname and Domain Name 303 Configuring a Device for SSH Version 2 Using RSA Key Pairs 304 Configuring a Device for SSH Version 2 Using RSA Key Pairs 304 Configuring the Cisco IOS SSH Client to Perform RSA-Based User Authentication 305 Katring an Encrypted Session with a Remote Device 308 Verifying the Status of the Secure Shell Connection 309 Verifying the Status of the Secure Shell Version 2 311	How to Configure Secure Shell 294
Invoking an SSH Client 296 Configuration Examples for Secure Shell 297 Example: Configuring an SSH Server 297 Example: Invoking an SSH Client 297 Example: Verifying SSH 297 Additional References for Secure Shell 298 Feature History for Configuring Secure Shell 298 Secure Shell Version 2 Support 299 Prerequisites for Secure Shell Version 2 Support 299 Restrictions for Secure Shell Version 2 Support 300 Information About Secure Shell Version 2 Support 300 Secure Shell Version 2 300 Secure Shell Version 2 a00 Secure Shell Version 2 Enhancements 301 Secure Shell Version 2 Enhancements for RSA Keys 301 SSH And Switch Access 302 SNMP Trap Generation 302 SSH Keyboard Interactive Authentication 302 How to Configuring a Device for SSH Version 2 Using a Hostname and Domain Name 303 Configuring a Device for SSH Version 2 Using RSA Key Pairs 304 Configuring a Device for SSH Version 2 Using RSA Key Pairs 304 Configuring the Cisco IOS SSH Client to Perform RSA-Based Server Authentication 305 Starting an Encrypted Session with a Remote Device 308 Verifying the Status of the Secure Shell Connection 309 Verifying the Status of the Secure Shell Connection 309 Verifying the Status of the Secure Shell Version 2 311	Setting Up the Device to Run SSH 294
Configuration Examples for Secure Shell 297 Example: Configuring an SSH Server 297 Example: Verifying SSH 297 Additional References for Secure Shell 298 Feature History for Configuring Secure Shell 298 Secure Shell Version 2 Support 299 Restrictions for Secure Shell Version 2 Support 299 Restrictions for Secure Shell Version 2 Support 300 Information About Secure Shell Version 2 Support 300 Secure Shell Version 2 Enhancements 301 Secure Shell Version 2 Enhancements 301 Secure Shell Version 2 Enhancements 301 Secure Shell Version 2 Enhancements for RSA Keys 301 SSH And Switch Access 302 SNMP Trap Generation 302 SSH Keyboard Interactive Authentication 302 How to Configure Secure Shell Version 2 Support 303 Configuring a Device for SSH Version 2 Using a Hostname and Domain Name 303 Configuring a Device for SSH Version 2 Using RSA Key Pairs 304 Configuring the Cisco SSH Server to Perform RSA-Based Server Authentication 305 Starting an Encrypted Session with a Remote Device 308 Verifying the Status of the Secure Shell Connection 309 Verifying the Status of the Secure Shell Connection 309 Verifying the Secure Shell Version 2 Satus 310 Monitoring and Maintaining Secure Shell Version 2 311	Configuring an SSH Server 295
Example: Configuring an SSH Server 297 Example: Invoking an SSH Client 297 Example: Verifying SSH 297 Additional References for Secure Shell 298 Feature History for Configuring Secure Shell 298 Secure Shell Version 2 Support 299 Restrictions for Secure Shell Version 2 Support 299 Restrictions for Secure Shell Version 2 Support 300 Information About Secure Shell Version 2 Support 300 Secure Shell Version 2 300 Secure Shell Version 2 Support 301 Secure Shell Version 2 Enhancements 301 Secure Shell Version 2 Enhancements 301 Secure Shell Version 2 Enhancements for RSA Keys 301 SSH And Switch Access 302 SSH And Switch Access 302 SSH Keyboard Interactive Authentication 302 How to Configure Secure Shell Version 2 Support 303 Configuring a Device for SSH Version 2 Using a Hostname and Domain Name 303 Configuring a Device for SSH Version 2 Using RSA Key Pairs 304 Configuring the Cisco SSH Server to Perform RSA-Based User Authentication 305 Starting an Encrypted Session with a Remote Device 308 Verifying the Status of the Secure Shell Connection 309 Verifying the Status of the Secure Shell Connection 309 Verifying the Secure Shell Version 2 Satus 310 Monitoring and Maintaining Secure Shell Version 2 311	Invoking an SSH Client 296
Example: Invoking an SSH Client 297 Example: Verifying SSH 297 Additional References for Secure Shell 298 Feature History for Configuring Secure Shell 298 Secure Shell Version 2 Support 299 Restrictions for Secure Shell Version 2 Support 299 Restrictions for Secure Shell Version 2 Support 300 Information About Secure Shell Version 2 Support 300 Secure Shell Version 2 300 Secure Shell Version 2 Enhancements 301 Secure Shell Version 2 Enhancements 301 Secure Shell Version 2 Enhancements for RSA Keys 301 SSH And Switch Access 302 SSH Keyboard Interactive Authentication 302 How to Configure Secure Shell Version 2 Support 303 Configuring a Device for SSH Version 2 Using a Hostname and Domain Name 303 Configuring the Cisco ISSH Server to Perform RSA-Based User Authentication 305 Configuring the Cisco IOS SSH Client to Perform RSA-Based Server Authentication 306 Starting an Encrypted Session with a Remote Device 308 Verifying the Status of the Secure Shell Connection 309 Verifying the Status of the Secure Shell Version 2 511	Configuration Examples for Secure Shell 297
Example: Verifying SSH 297 Additional References for Secure Shell 298 Feature History for Configuring Secure Shell 298 Secure Shell Version 2 Support 299 Prerequisites for Secure Shell Version 2 Support 299 Restrictions for Secure Shell Version 2 Support 300 Information About Secure Shell Version 2 Support 300 Secure Shell Version 2 300 Secure Shell Version 2 Enhancements 301 Secure Shell Version 2 Enhancements for RSA Keys 301 SSH And Switch Access 302 SNMP Trap Generation 302 SSH Keyboard Interactive Authentication 302 How to Configure Secure Shell Version 2 Support 303 Configuring a Device for SSH Version 2 Using a Hostname and Domain Name 303 Configuring the Cisco SSH Server to Perform RSA-Based User Authentication 305 Configuring the Cisco IOS SSH Client to Perform RSA-Based Server Authentication 306 Starting an Encrypted Session with a Remote Device 308 Verifying the Status of the Secure Shell Connection 309 Verifying the Secure Shell Version 2 Status 310 Monitoring and Maintaining Secure Shell Version 2 311	Example: Configuring an SSH Server 297
Additional References for Secure Shell 298 Feature History for Configuring Secure Shell 298 Secure Shell Version 2 Support 299 Prerequisites for Secure Shell Version 2 Support 299 Restrictions for Secure Shell Version 2 Support 300 Information About Secure Shell Version 2 Support 300 Secure Shell Version 2 2 300 Secure Shell Version 2 Enhancements 301 Secure Shell Version 2 Enhancements for RSA Keys 301 SSH And Switch Access 302 SNMP Trap Generation 302 SSH Keyboard Interactive Authentication 302 How to Configure Secure Shell Version 2 Support 303 Configuring a Device for SSH Version 2 Using RSA Key Pairs 304 Configuring the Cisco SSH Server to Perform RSA-Based User Authentication 305 Gonfiguring the Cisco IOS SSH Client to Perform RSA-Based Server Authentication 306 Starting an Encrypted Session with a Remote Device 308 Verifying the Status of the Secure Shell Connection 309 Verifying the Secure Shell Version 2 Status 310 Monitoring and Maintaining Secure Shell Version 2 311	Example: Invoking an SSH Client 297
Feature History for Configuring Secure Shell 298Secure Shell Version 2 Support 299Prerequisites for Secure Shell Version 2 Support 299Restrictions for Secure Shell Version 2 Support 300Information About Secure Shell Version 2 Support 300Secure Shell Version 2 300Secure Shell Version 2 Enhancements 301Secure Shell Version 2 Enhancements for RSA Keys 301SSH And Switch Access 302SNMP Trap Generation 302SSH Keyboard Interactive Authentication 302How to Configure Secure Shell Version 2 Using a Hostname and Domain Name 303Configuring a Device for SSH Version 2 Using RSA Key Pairs 304Configuring the Cisco IOS SSH Client to Perform RSA-Based User Authentication 305Starting an Encrypted Session with a Remote Device 308Verifying the Status of the Secure Shell Connection 309Verifying the Secure Shell Version 2 Status 310Monitoring and Maintaining Secure Shell Version 2 311	Example: Verifying SSH 297

I

Example: Configuring Secure Shell Version 2 314

	Configuration Examples for SSH Support over IPv6 323
	Example: Enabling SSH on an IPv6 Device 323
	Additional References for SSH Support over IPv6 323
	Feature History for SSH Support over IPv6 323
CHAPTER 19	Configuring SSH File Transfer Protocol 325
	Prerequisites for SSH File Transfer Protocol 325
	Restrictions for SSH File Transfer Protocol 325
	Information About SSH Support over IPv6 326
	SSH File Transfer Protocol Overview 326
	How to Configure SSH File Transfer Protocol 326
	Configuring SFTP 326
	Performing an SFTP Copy Operation 327
	Configuration Examples for SSH Support over IPv6 327
	Example: Configuring SSH File Transfer Protocol 327

Example: Configuring Secure Shell Versions 1 and 2 314

Examples: SSH Keyboard Interactive Authentication 315

Example: Enabling Client-Side Debugs 315

Examples: SSH Debugging Enhancements 317

Feature History for Secure Shell Version 2 Support 319

Prerequisites for SSH Support over IPv6 321 Information About SSH Support over IPv6 321

SSH over an IPv6 Transport 321

How to Configure SSH Support over IPv6

Enabling SSH on an IPv6 Device 322

Additional References for Secure Shell Version 2 Support 318

Example: Setting an SNMP Trap 314

Example: SNMP Debugging 317

SSH Support Over IPv6 321

CHAPTER 18

Example: Starting an Encrypted Session with a Remote Device 314

Example: Enabling ChPass with a Blank Password Change 315

Example: Enabling ChPass and Changing the Password on First Login **316** Example: Enabling ChPass and Expiring the Password After Three Logins **316**

	Additional References for SSH File Transfer Protocol 328
	Feature History for SSH File Transfer Protocol 328
CHAPTER 20	
	X.509v3 Certificates for SSH Authentication 329
	Prerequisites for X.509v3 Certificates for SSH Authentication 329
	Restrictions for X.509v3 Certificates for SSH Authentication 329
	Information About X.509v3 Certificates for SSH Authentication 329
	Digital Certificates 330
	Server and User Authentication using X.509v3 330
	How to Configure X.509v3 Certificates for SSH Authentication 330
	Configuring the SSH Server to Use Digital Certificates for Server Authentication 330
	Configuring the SSH Server to Verify Digital Certificates for User Authentication 331
	Configuring Trustpoint Authentication and Creating Device Certificate 333
	Verifying Configuration for Server and User Authentication Using Digital Certificates 335
	Configuration Examples for X.509v3 Certificates for SSH Authentication 335
	Example: Configuring the SSH Server to Use Digital Certificates for Server Authentication 336
	Example: Configuring the SSH Server to Verify Digital Certificates for User Authentication 336
	Feature History for X.509v3 Certificates for SSH Authentication 336
CHAPTER 21	– SSH Algorithms for Common Criteria Certification 337
	Restriction for SSH Algorithms for Common Criteria Certification 337
	Information About SSH Algorithms for Common Criteria Certification 337
	SSH Algorithms for Common Criteria Certification 337
	Cisco IOS SSH Server Algorithms 337
	Cisco IOS SSH Client Algorithms 338
	How to Configure SSH Algorithms for Common Criteria Certification 339
	Configuring an Encryption Key Algorithm for a Cisco IOS SSH Server and Client 339
	Troubleshooting Tips 340
	Configuring a MAC Algorithm for a Cisco IOS SSH Server and Client 340
	Troubleshooting Tips 341
	Configuring a Host Key Algorithm for a Cisco IOS SSH Server 342
	Troubleshooting Tips 343
	Configuration Examples For SSH Algorithms for Common Criteria Certification 343

Example: Configuring Encryption Key Algorithms for a Cisco IOS SSH Server	343
Example: Configuring Encryption Key Algorithms for a Cisco IOS SSH Client	343
Example: Configuring MAC Algorithms for a Cisco IOS SSH Server 343	
Example: Configuring Host Key Algorithms for a Cisco IOS SSH Server 344	
Verifying SSH Algorithms for Common Criteria Certification 344	
Feature History for Secure Shell Algorithms for Common Criteria Certification 34	45

CHAPTER 22 Configuring Secure Socket Layer HTTP 347 Information About Secure Socket Layer HTTP 347

Secure HTTP Servers and Clients Overview	347
Certificate Authority Trustpoints 347	
CipherSuites 349	
Default SSL Configuration 350	
SSL Configuration Guidelines 350	
How to Configure Secure Socket Layer HTTP	350
Configuring a CA Trustpoint 350	
Configuring the Secure HTTP Server 352	
Configuring the Secure HTTP Client 355	
Monitoring Secure HTTP Server and Client Sta	itus 356
Additional References for Secure Socket Layer	HTTP 357
Feature History for Secure Socket Layer HTTP	357

CHAPTER 23 IPv4 ACLs 359

Restrictions for IPv4 Access Control Lists Information About IPv4 Access Control Lists ACL Overview Access Control Entries ACL Supported Types Supported ACLs ACL Precedence Port ACLs Router ACLs VLAN Maps ACEs and Fragmented and Unfragmented Traffic

Standard and Extended IPv4 ACLs 365 IPv4 ACL Switch Unsupported Features 365 Access List Numbers 365 Numbered Standard IPv4 ACLs 366 Numbered Extended IPv4 ACLs 367 Named IPv4 ACLs 367 ACL Logging 368 Hardware and Software Treatment of IP ACLs 368 VLAN Map Configuration Guidelines 369 VLAN Maps with Router ACLs 370 VLAN Maps and Router ACL Configuration Guidelines 370 Time Ranges for ACLs 371 IPv4 ACL Interface Considerations 371 How to Configure IPv4 Access Control Lists 372 Configuring IPv4 ACLs 372 Creating a Numbered Standard ACL 372 Creating a Numbered Extended ACL 373 Creating Named Standard ACLs 376 Creating Extended Named ACLs 377 Configuring Time Ranges for ACLs 378 Applying an IPv4 ACL to a Terminal Line **379** Applying an IPv4 ACL to an Interface **379** Creating Named MAC Extended ACLs 380 Applying a MAC ACL to a Layer 2 Interface 382 Configuring an IPv4 ACL in Template Mode 382 Configuring VLAN Maps 384 Applying a VLAN Map to a VLAN 386 Monitoring IPv4 ACLs 387 Configuration Examples for IPv4 Access Control Lists 387 ACLs in a Small Networked Office 387 Examples: ACLs in a Small Networked Office 388 Example: Numbered ACLs 389 Examples: Extended ACLs 389 Examples: Named ACLs 390

Examples: ACL Logging 391 Example: ACEs and Fragmented and Unfragmented Traffic 392 Examples: Using Time Ranges with ACLs 393 Examples: Time Range Applied to an IP ACL 394 Examples: Including Comments in ACLs 394 Example: Creating an ACL and a VLAN Map to Deny a Packet 395 Example: Creating an ACL and a VLAN Map to Permit a Packet **395** Example: Default Action of Dropping IP Packets and Forwarding MAC Packets 395 Example: Default Action of Dropping MAC Packets and Forwarding IP Packets 396 Example: Default Action of Dropping All Packets 396 Example: Using VLAN Maps in a Network 397 Example: Wiring Closet Configuration 397 Example: Restricting Access to a Server on Another VLAN 398 Example: Denying Access to a Server on Another VLAN 398 Additional References for IPv4 Access Control Lists 399 Feature History for IPv4 Access Control Lists 399

CHAPTER 24

IPv6 ACLs 401

Restrictions for IPv6 ACLs 401 Information About IPv6 ACLs 402 IPv6 ACL Overview 402 Supported ACLs 402 Types of ACL 403 Per-User IPv6 ACL 403 Filter ID IPv6 ACL 403 ACL Precedence 403 VLAN Maps 403 Interactions with Other Features and Switches 404 How to Configure an IPv6 ACL 404 Default Configuration for IPv6 ACLs 404 Configuring IPv6 ACLs 405 Attaching an IPv6 ACL to an Interface 407 Configuring an IPv6 ACL in Template Mode 408 Configuring a VLAN Map 410

Applying a VLAN Map to a VLAN Monitoring IPv6 ACLs Configuration Examples for IPv6 ACL Example: Creating an IPv6 ACL Example: Displaying IPv6 ACLs Example: Displaying VLAN Access Map Configuration Feature History for IPv6 ACLs

CHAPTER 25 Object Groups for ACLs 415

Object Groups for ACLs 415
Restrictions for Object Groups for ACLs 415
Information About Object Groups for ACLs 416
Object Groups 416
ACLs Based on Object Groups 417
How to Configure Object Groups for ACLs 417
Creating a Network Object Group 418
Creating a Service Object Group 419
Creating an Object-Group-Based ACL 421
Applying an Object Group-Based ACL to an Interface 423
Verifying Object Groups for ACLs 424
Configuration Examples for Object Groups for ACLs 425
Example: Creating a Network Object Group 425
Example: Creating a Service Object Group 425
Example: Creating an Object Group-Based ACL 425
Applying an Object Group-Based ACL to an Interface 426
Example: Verifying Object Groups for ACLs 426
Additional References for Object Groups for ACLs 427
Feature History for Object Groups for ACLs 427

CHAPTER 26 Configuring IP Source Guard 429

Information About IP Source Guard 429 IP Source Guard 429 IP Source Guard for Static Hosts 429 IP Source Guard Configuration Guidelines 430

	How to Configure IP Source Guard 431
	Enabling IP Source Guard 431
	Configuring IP Source Guard for Static Hosts on a Layer 2 Access Port 432
	Monitoring IP Source Guard 433
	Feature History for IP Source Guard 433
CHAPTER 27	Configuring Dynamic ARP Inspection 435
	Restrictions for Dynamic ARP Inspection 435
	Information About Dynamic ARP Inspection 436
	Understanding Dynamic ARP Inspection 436
	Interface Trust States and Network Security 438
	Rate Limiting of ARP Packets 439
	Relative Priority of ARP ACLs and DHCP Snooping Entries 439
	Logging of Dropped Packets 439
	Default Dynamic ARP Inspection Configuration 439
	Relative Priority of ARP ACLs and DHCP Snooping Entries 440
	How to Configure Dynamic ARP Inspection 440
	Configuring ARP ACLs for Non-DHCP Environments 440
	Configuring Dynamic ARP Inspection in DHCP Environments 443
	Limiting the Rate of Incoming ARP Packets 444
	Performing Dynamic ARP Inspection Validation Checks 446
	Monitoring DAI 447
	Verifying the DAI Configuration 448
	Feature History for Dynamic ARP Inspection 448
CHAPTER 28	Configuring IPv6 First Hop Security 451
	Prerequisites for IPv6 First Hop Security 451
	Restrictions for IPv6 First Hop Security 451
	Information About IPv6 First Hop Security 451
	How to Configure IPv6 First Hop Security 455
	Configuring an IPv6 Snooping Policy 455
	Attaching an IPv6 Snooping Policy to an Interface 457
	Attaching an IPv6 Snooping Policy to a Layer 2 EtherChannel Interface 459
	Attaching an IPv6 Snooping Policy to VLANs Globally 460

	Configuring the IPv6 Binding Table Content 460
	Configuring an IPv6 Neighbor Discovery Inspection Policy 461
	Attaching an IPv6 Neighbor Discovery Inspection Policy to an Interface 463
	Attaching an IPv6 Neighbor Discovery Inspection Policy to a Layer 2 EtherChannel Interface 464
	Attaching an IPv6 Neighbor Discovery Inspection Policy to VLANs Globally 465
	Configuring an IPv6 Router Advertisement Guard Policy 466
	Attaching an IPv6 Router Advertisement Guard Policy to an Interface 468
	Attaching an IPv6 Router Advertisement Guard Policy to a Layer 2 EtherChannel Interface 469
	Attaching an IPv6 Router Advertisement Guard Policy to VLANs Globally 470

CHAPTER

Controlling Switch Access with Passwords and Privilege Levels

- Restrictions for Controlling Switch Access with Passwords and Privileges, on page 1
- Information About Controlling Switch Access with Passwords and Privileges, on page 2
- How to Configure Switch Access with Passwords and Privileges, on page 6
- Monitoring Switch Access with Passwords and Privileges, on page 18
- Configuration Examples for Switch Access with Passwords and Privilege Levels, on page 18
- Feature History for Controlling Switch Access with Passwords and Privileges, on page 19

Restrictions for Controlling Switch Access with Passwords and Privileges

The following are the restrictions for controlling switch access with passwords and privileges:

• Disabling password recovery will not work if you have set the switch to boot up manually by using the **boot manual** global configuration command. This command produces the boot loader prompt (*switch:*) after the switch is power cycled.

Restrictions and Guidelines for Reversible Password Types

- Password type 0 and 7 are replaced with password type 6. So password type 0 and 7, which were used for administrator login to the console, Telnet, SSH, webUI, and NETCONF must be migrated to password type 6. No action is required if username and password are type 0 and 7 for local authentication such as CHAP, EAP, and so on.
- If the startup configuration has a type 6 password and you downgrade to a version in which type 6 password is not supported, you can/may be locked out of the device.

Restrictions and Guidelines for Irreversible Password Types

• Username secret password type 5 and enable secret password type 5 must be migrated to the stronger password type 8 or 9. For more information, see Protecting Enable and Enable Secret Passwords with Encryption, on page 7.

• If the startup configuration of the device has convoluted type 9 secret (password that starts with \$14\$), then a downgrade can only be performed to a release in which the convoluted type 9 secret is supported. Convoluted type 9 secret is supported in Cisco IOS XE Gibraltar 16.11.2 and later releases. If the startup configuration has a convoluted type 9 secret, and you downgrade to a release prior to Cisco IOS XE Gibraltar 16.11.2, you can/may be locked out of the device.

Before you downgrade to any release in which convoluted type 9 secret is not supported, ensure that the type 9 secret (password that starts with \$9\$) must be part of the startup configuration instead of convoluted type 9 secret (password that starts with \$14\$) or type 5 secret (password that starts with \$1\$).

If a device is upgraded from Cisco IOS XE Fuji 16.9.x, Cisco IOS XE Gibraltar 16.10.x, or Cisco IOS XE Gibraltar 16.11.x to Cisco IOS XE Gibraltar 16.12.x, the type 5 secret is auto-converted to convoluted type 9 secret (password that starts with \$14\$). For example: username user1 secret 5 \$1\$dNmW\$7jWhqdtZ2qBVz2R4CSZZC0 is auto-converted to username user1 secret 9 \$14\$dNmW\$QykGZEEGmiEGrE\$C9D/fD0czicOtgaZAa1CTa2sgygi0Leyw3/cLqPY426. After the device is upgraded, run the **write memory** command in privileged EXEC mode for the convoluted type 9 secret to be permanently written into the startup configuration.

• Plain text passwords are converted to nonreversible encrypted password type 9.

Note This is supported in Cisco IOS XE Gibraltar 16.10.1 and later releases.

• Secret password type 4 is not supported.

Information About Controlling Switch Access with Passwords and Privileges

This section provides information about controlling switch access with passwords and privileges.

Preventing Unauthorized Access

You can prevent unauthorized users from reconfiguring your switch and viewing configuration information. Typically, you want network administrators to have access to your switch while you restrict access to users who dial from outside the network through an asynchronous port, connect from outside the network through a serial port, or connect through a terminal or workstation from within the local network.

To prevent unauthorized access into your switch, you should configure one or more of these security features:

- At a minimum, you should configure passwords and privileges at each switch port. These passwords are locally stored on the switch. When users attempt to access the switch through a port or line, they must enter the password specified for the port or line before they can access the switch.
- For an additional layer of security, you can also configure username and password pairs, which are locally stored on the switch. These pairs are assigned to lines or ports and authenticate each user before that user can access the switch. If you have defined privilege levels, you can also assign a specific privilege level (with associated rights and privileges) to each username and password pair.

- If you want to use username and password pairs, but you want to store them centrally on a server instead of locally, you can store them in a database on a security server. Multiple networking devices can then use the same database to obtain user authentication (and, if necessary, authorization) information.
- You can also enable the login enhancements feature, which logs both failed and unsuccessful login attempts. Login enhancements can also be configured to block future login attempts after a set number of unsuccessful attempts are made.

Default Password and Privilege Level Configuration

A simple way of providing terminal access control in your network is to use passwords and assign privilege levels. Password protection restricts access to a network or network device. Privilege levels define what commands users can enter after they have logged into a network device.

This table shows the default password and privilege level configuration.

Feature	Default Setting
Enable password and privilege level	No password is defined. The default is level 15 (privileged EXEC level). The password is not encrypted in the configuration file.
Enable secret password and privilege level	No password is defined. The default is level 15 (privileged EXEC level). The password is encrypted before it is written to the configuration file.
Line password	No password is defined.

Table 1: Default Password and Privilege Levels

Additional Password Security

The following sections provide information about unmasked and masked secret password.

Unmasked Secret Password

To provide an additional layer of security, particularly for passwords that cross the network or that are stored on a Trivial File Transfer Protocol (TFTP) server, you can use either the **enable password** or **enable secret** global configuration commands. Both commands accomplish the same thing; that is, you can establish an encrypted password that users must enter to access privileged EXEC mode (the default) or any privilege level you specify.

We recommend that you use the **enable secret** command because it uses an improved encryption algorithm. If you configure the **enable secret** command, it takes precedence over the **enable password** command; the two commands cannot be in effect simultaneously.

For a device that loads with no start-up configuration, the Enable Secret Password task is a mandatory configuration whether you select **Yes** or **No** at the "Would you like to enter the initial configuration dialog?" prompt of the initial configuration wizard. The configured password must contain a minimum of 10 and a maximum of 32 characters. It must also include a minimum of one uppercase letter, one lowercase letter, and one numeral. Additionally, the term 'cisco' must not be part of the password.

Note

In some cases where the device is connected to the internet, Cisco Plug and Play (PnP) can terminate the initial configuration wizard. In such cases, the enable secret configuration will not be prompted.

If you enable password encryption, it applies to all passwords including username passwords, authentication key passwords, the privileged command password, and console and virtual terminal line passwords.

Masked Secret Password

With **enable secret** command, password is encrypted but is visible on the terminal when you type the password. To mask the password on the terminal, use the **masked-secret** global configuration command. The encryption type for this password is type 9, by default.

You can use this command to configure masked secret password for common criteria policy.

Password Recovery

By default, any end user with physical access to the switch can recover from a lost password by interrupting the boot process while the switch is powering on and then by entering a new password.

The password-recovery disable feature protects access to the switch password by disabling part of this functionality. When this feature is enabled, the end user can interrupt the boot process only by agreeing to set the system back to the default configuration. With password recovery disabled, you can still interrupt the boot process and change the password, but the configuration file (config.text) and the VLAN database file (vlan.dat) are deleted.

If you disable password recovery, we recommend that you keep a backup copy of the configuration file on a secure server in case the end user interrupts the boot process and sets the system back to default values. Do not keep a backup copy of the configuration file on the switch. If the switch is operating in VTP transparent mode, we recommend that you also keep a backup copy of the VLAN database file on a secure server. When the switch is returned to the default system configuration, you can download the saved files to the switch by using the Xmodem protocol.

To re-enable password recovery, use the **no system disable password recovery switch** *number* | *all* global configuration command.

Terminal Line Telnet Configuration

When you power-up your switch for the first time, an automatic setup program runs to assign IP information and to create a default configuration for continued use. The setup program also prompts you to configure your switch for Telnet access through a password. If you did not configure this password during the setup program, you can configure it when you set a Telnet password for a terminal line.

Username and Password Pairs

You can configure username and password pairs, which are locally stored on the switch. These pairs are assigned to lines or ports and authenticate each user before that user can access the switch. If you have defined privilege levels, you can also assign a specific privilege level (with associated rights and privileges) to each username and password pair.

Privilege Levels

Cisco devices use privilege levels to provide password security for different levels of switch operation. By default, the Cisco IOS XE software operates in two modes (privilege levels) of password security: user EXEC (Level 1) and privileged EXEC (Level 15). You can configure up to 16 hierarchical levels of commands for each mode. By configuring multiple passwords, you can allow different sets of users to have access to specified commands.

Privilege Levels on Lines

Users can override the privilege level you set using the **privilege level** line configuration command by logging in to the line and enabling a different privilege level. They can lower the privilege level by using the **disable** command. If users know the password to a higher privilege level, they can use that password to enable the higher privilege level. You might specify a high level or privilege level for your console line to restrict line usage.

For example, if you want many users to have access to the **clear line** command, you can assign it level 2 security and distribute the level 2 password fairly widely. But if you want more restricted access to the **configure** command, you can assign it level 3 security and distribute that password to a more restricted group of users.

Command Privilege Levels

When you set a command to a privilege level, all commands whose syntax is a subset of that command are also set to that level. For example, if you set the **show ip traffic** command to level 15, the **show** commands and **show ip** commands are automatically set to privilege level 15 unless you set them individually to different levels.

AES Password Encryption and Master Encryption Keys

You can enable strong, reversible 128-bit Advanced Encryption Standard (AES) password encryption, also known as type 6 encryption. To start using type 6 encryption, enable the AES Password Encryption feature and configure a master encryption key to encrypt and decrypt passwords.

After you enable AES password encryption and configure a master key, all the existing and newly created cleartext passwords for the supported applications are stored in type 6 encrypted format, unless you disable type 6 password encryption. You can also configure the device to convert all the existing weakly encrypted passwords to type 6 encrypted passwords.

Type 0 and 7 passwords can be autoconverted to type 6 if the AES Password Encryption feature and master encryption key are configured.

- Type 6 encrypted password for the username password is supported from Cisco IOS XE Gibraltar 16.10.1 and later releases. Autoconversion to password type 6 is supported from Cisco IOS XE Gibraltar 16.11.1 and later releases.
- Type 6 username and password are backward compatible to Cisco IOS XE Gibraltar 16.10.x. If you downgrade to any release earlier than Cisco IOS XE Gibraltar 16.10.1, the type 6 username and password are rejected. After autoconversion, to prevent an administrator password from getting rejected during a downgrade, migrate the passwords used for administrator logins (management access) to irreversible password types manually.

How to Configure Switch Access with Passwords and Privileges

Setting or Changing a Static Enable Password

The enable password controls access to the privileged EXEC mode. Follow these steps to set or change a static enable password:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	enable password password	Defines a new password or changes an existing
	Example:	password for access to privileged EXEC mode. By default, no password is defined.
	Device (config) # enable password secret321	For <i>password</i> , specify a string from 1 to 25 alphanumeric characters. The string cannot start with a number, is case sensitive, and allows spaces but ignores leading spaces. It can contain the question mark (?) character if you precede the question mark with the key combination Crtl-v when you create the password; for example, to create the password abc?123, do this:
		a. Enter abc.b. Enter Crtl-v.
		c. Enter ?123.
		When the system prompts you to enter the enable password, you need not precede the question mark with the Ctrl-v; you can simply enter abc?123 at the password prompt.
Step 4	end	Exits global configuration mode and returns to
	Example:	privileged EXEC mode.

Command or Action	Purpose
 Device(config)# end	

Protecting Enable and Enable Secret Passwords with Encryption

Follow these steps to establish an encrypted password that users must enter to access privileged EXEC mode (the default) or any privilege level you specify:

Procedure

_

	Command or Action	Purpose
Step 1	enable Example:	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	Device> enable configure terminal	Enters global configuration mode.
010 2	Example:	Eners groour configuration mode.
	Device# configure terminal	
Step 3	<pre>Use one of the following: enable password [level level] {unencrypted-password encryption-type encrypted-password} enable secret [level level] {unencrypted-password encryption-type encrypted-password} Example: Device (config) # enable password level 12 example123 Or Device (config) # enable secret 9 \$9\$sMLBsTFXLnnHTk\$0L82</pre>	 Defines a new password or changes an existing password for access to privileged EXEC mode. Defines a secret password, which is saved using a nonreversible encryption method. (Optional) For <i>level</i>, the range is from 0 to 15. Level 1 is normal user EXEC mode privileges. The default level is 15 (privileged EXEC mode privileges). For <i>unencrypted-password</i>, specify a string from 1 to 25 alphanumeric characters. The string cannot start with a number, is case sensitive, and allows spaces but ignores leading spaces. By default, no password is defined. For <i>encryption-type</i>, the available options for enable password are type 0 and 7, and type 0, 5, 8, and 9 for enable secret. If you specify an encrypted password—an encrypted password that you copy from another

Command or Action	Purpose
	switch configuration. Secret encryption type 9 is more secure, so we recommend that you select type 9 to avoid any issues while upgrading or downgrading.

I

 Command or Action	Purpose
	Note

_

Command or Action	n	Purpose	
			 If you do not specify an encryption type for the secret password, the password is auto converted to type 9. This is applicable in Cisco IOS XE Gibraltar 16.10.1 and later releases.
			• If you specify an encryption type and then enter a clear text password, it will result in an error.
			• You can also configure type 9 encryption for the secret password manually by using the algorithm-type scrypt command in global configuration mode. For example:
			Device(config)# username userl algorithm-type scrypt secret cisco
			Or
			Device(config)# enable algorithm-type scrypt secret cisco
			Run the write memory command in privileged EXEC mode for the type 9 secret to be permanently

	Command or Action	Purpose
		written into the startup configuration.
Step 4	service password-encryption Example:	(Optional) Encrypts the password when the password is defined or when the configuration is written.
	Device(config)# service password-encryption	Encryption prevents the password from being readable in the configuration file.
Step 5	end Example:	Exits global configuration mode and returns to privileged EXEC mode.
	Device(config)# end	

Disabling Password Recovery

Follow these steps to disable password recovery to protect the security of your switch:

Before you begin

If you disable password recovery, we recommend that you keep a backup copy of the configuration file on a secure server in case the end user interrupts the boot process and sets the system back to default values. Do not keep a backup copy of the configuration file on the switch. If the switch is operating in VTP transparent mode, we recommend that you also keep a backup copy of the VLAN database file on a secure server. When the switch is returned to the default system configuration, you can download the saved files to the switch by using the Xmodem protocol.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	<pre>system disable password recovery switch {all <1-9>}</pre>	Disables password recovery.

	Command or Action	Purpose
	Example:	• <i>all</i> : Sets the configuration on switches in stack.
	<pre>Device(config)# system disable password recovery switch all</pre>	• <1-9>: Sets the configuration on the switch number selected.
		This setting is saved in an area of the flash memory that is accessible by the boot loader and the Cisco IOS image, but is not a part of the file system and is not accessible by any user.
Step 4	end	Exits global configuration mode and returns to
	Example:	privileged EXEC mode.
	Device(config)# end	

What to do next

To remove **disable password recovery**, use the **no system disable password recovery switch all** global configuration command.

Setting a Telnet Password for a Terminal Line

Beginning in user EXEC mode, follow these steps to set a Telnet password for the connected terminal line:

Before you begin

- Attach a PC or workstation with emulation software to the switch console port, or attach a PC to the Ethernet management port.
- The default data characteristics of the console port are 9600, 8, 1, no parity. You might need to press the Return key several times to see the command-line prompt.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	line vty 0 98	Configures the number of Telnet sessions
	Example:	(lines), and enters line configuration mode.

	Command or Action	Purpose
	Device(config)# line vty 0 98	There are 99 possible sessions on a command-capable device. The 0 and 98 mean that you are configuring all 99 possible Telnet sessions.
Step 4	password password	Sets a Telnet password for the line or lines.
	<pre>Example: Device(config-line)# password abcxyz543</pre>	For <i>password</i> , specify a string from 1 to 25 alphanumeric characters. The string cannot start with a number, is case sensitive, and allows spaces but ignores leading spaces. By default, no password is defined.
Step 5	end	Returns to privileged EXEC mode.
	<pre>Example: Device(config-line)# end</pre>	

Configuring Username and Password Pairs

Follow these steps to configure username and password pairs:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	username <i>name</i> [privilege <i>level</i>] { password <i>encryption-type password</i> }	Sets the username, privilege level, and password for each user.
	Example: Device(config)# username adamsample privilege 1 password secret456 Device(config)# username 11111111111 mac attribute	 For <i>name</i>, specify the user ID as one word or the MAC address. Spaces and quotation marks are not allowed. You can configure a maximum of 12000 clients each, for both username and MAC filter. (Optional) For <i>level</i>, specify the privilege level the user has after gaining access. The range is 0 to 15. Level 15 gives privileged

	Command or Action	Purpose	
		EXEC mode access. Level 1 gives user EXEC mode access.	
		 For <i>encryption-type</i>, enter 0 to specify that an unencrypted password will follow. Enter 7 to specify that a hidden password will follow. Enter 6 to specify that an encrypted password will follow. 	
		• For <i>password</i> , specify the password the user must enter to gain access to the device. The password must be from 1 to 25 characters, can contain embedded spaces, and must be the last option specified in the username command.	
Step 4	Use one of the following:	Enters line configuration mode, and configures	
	 line console 0 line vty 0 98	the console port (line 0) or the VTY lines (line 0 to 98).	
	Example:		
	Device(config)# line console 0		
	or		
	Device(config)# line vty 0 98		
Step 5	end	Exits line configuration mode and returns to	
	Example:	privileged EXEC mode.	
	Device(config-line)# end		

Setting the Privilege Level for a Command

Follow these steps to set the privilege level for a command:

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	

	Command or Action	Purpose
Step 3	privilege mode level level command	Sets the privilege level for a command.
	<pre>Example: Device(config)# privilege exec level 14 configure</pre>	• For <i>mode</i> , enter configure for global configuration mode, exec for EXEC mode, interface for interface configuration mode, or line for line configuration mode.
		• For <i>level</i> , the range is from 0 to 15. Level 1 is for normal user EXEC mode privileges. Level 15 is the level of access permitted by the enable password.
		• For <i>command</i> , specify the command to which you want to restrict access.
Step 4	enable password level level password	Specifies the password to enable the privilege
	Example: Device(config)# enable password level 14 SecretPswd14	privileges.For <i>password</i>, specify a string from 1 to 25 alphanumeric characters. The string
		cannot start with a number, is case sensitive, and allows spaces but ignores leading spaces. By default, no password is defined.
Step 5	end	Exits global configuration mode and returns to
	Example:	privileged EXEC mode.
	Device(config)# end	

Changing the Default Privilege Level for Lines

Follow these steps to change the default privilege level for the specified line:

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	

	Command or Action	Purpose
	Device# configure terminal	
Step 3	line vty line Example:	Selects the virtual terminal line on which to restrict access.
	Device(config)# line vty 10	
Step 4	privilege exec level	Changes the default privilege level for the line.
	Example: Device(config-line)# privilege exec level 15	For <i>level</i> , the range is from 0 to 15. Level 1 is for normal user EXEC mode privileges. Level 15 is the level of access permitted by the enable password.
Step 5	end Example:	Exits line configuration mode and returns to privileged EXEC mode.
	Device(config-line)# end	

What to do next

Users can override the privilege level you set using the **privilege level** line configuration command by logging in to the line and enabling a different privilege level. They can lower the privilege level by using the **disable** command. If users know the password to a higher privilege level, they can use that password to enable the higher privilege level. You might specify a high level or privilege level for your console line to restrict line usage.

Logging in to and Exiting a Privilege Level

Beginning in user EXEC mode, follow these steps to log into a specified privilege level and exit a specified privilege level.

Ρ	ro	ce	d	u	r	e

	Command or Action	Purpose
Step 1	enable level	Logs in to a specified privilege level.
	Example:	InI the example, Level 15 is privileged EXEC mode.
	Device> enable 15	For <i>level</i> , the range is 0 to 15.
Step 2	disable level	Exits to a specified privilege level.
	Example:	In the example, Level 1 is user EXEC mode.
	Device# disable 1	For <i>level</i> , the range is 0 to 15.
-		

Configuring an Encrypted Preshared Key

To configure an encrypted preshared key, perform the following steps.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	key config-key password-encrypt [text] Example:	Stores a type 6 encryption key in private NVRAM.
	Device(config)# key config-key password-encrypt	• To key in interactively (using the Enter key) and an encrypted key already exists, you will be prompted for the following: Old key, New key, and Confirm key.
		• To key in interactively, but an encryption key is not present, you will be prompted for the following: New key and Confirm key.
		• When removing the password that is already encrypted, you will see the following prompt:
		WARNING: All type 6 encrypted keys will become unusable. Continue wit master key deletion? [yes/no]:"
Step 4	password encryption aes	Enables the encrypted preshared key.
	Example:	
	Device(config)# password encryption aes	
Step 5	end	Exits global configuration mode and returns to
	Example:	privileged EXEC mode.
	Device(config)# end	

Monitoring Switch Access with Passwords and Privileges

Table 2: Commands for Displaying Privilege-Level Information

Command	Information
show privilege	Displays the privilege level configuration.

Configuration Examples for Switch Access with Passwords and Privilege Levels

Example: Setting or Changing a Static Enable Password

The following example shows how to change the enable password to *l1u2c3k4y5*. The password is not encrypted and provides access to level 15 (traditional privileged EXEC mode access):

```
Device> enable
Device# configure terminal
Device(config)# enable password l1u2c3k4y5
Device(config)# end
```

Example: Protecting Enable and Enable Secret Passwords with Encryption

The following example shows how to configure the encrypted password \$9\$sMLBsTFXLnnHTk\$0L82 for privilege level 2:

```
Device> enable
Device# configure terminal
Device(config)# enable secret level 2 9 $9$sMLBsTFXLnnHTk$0L82
Device(config)# end
```

Example: Setting a Telnet Password for a Terminal Line

The following example shows how to set the Telnet password to let45me67in89:

```
Device> enable
Device# configure terminal
Device(config)# line vty 10
Device(config-line)# password let45me67in89
Device(config-line)# end
```

Example: Setting the Privilege Level for a Command

The following example shows how to set the **configure** command to privilege level 14 and define *SecretPswd14* as the password users must enter to use level 14 commands:

L

```
Device> enable
Device# configure terminal
Device(config)# privilege exec level 14 configure
Device(config)# enable password level 14 SecretPswd14
Device(config)# end
```

Example: Configuring an Encrypted Preshared Key

The following example shows a configuration for which a type 6 preshared key has been encrypted. It includes the prompts and messages that a user might see.

```
Device> enable
Device# configure terminal
Device(config)# password encryption aes
Device(config)# key config-key password-encrypt
New key:
Confirm key:
Device(config)#
01:46:40: TYPE6_PASS: New Master key configured, encrypting the keys with
the new master key
Device(config)# end
```

Feature History for Controlling Switch Access with Passwords and Privileges

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.11.1	Controlling Switch Access with Passwords and Privileges	Password protection restricts access to a network or network device. Privilege levels define what commands users can enter after they have logged into a network device.
Cisco IOS XE Gibraltar 16.11.1	Autoconversion of Type 0 and Type 7 Username and Password to Type 6	From this release, type 0 and 7 username and password can be autoconverted to type 6.
Cisco IOS XE Cupertino 17.7.1	Enforce to Change the Administrator Default Password Function at first access to Device and to the Service Shell	For a device that loads with no start-up configuration, the Enable Secret Password task is a mandatory configuration in the initial configuration wizard.
Cisco IOS XE Cupertino 17.7.1	Controlling Switch Access with Passwords and Privileges	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

Configuring Login Block

- Information About Login Enhancements-Login Block, on page 21
- How to Configure Login Enhancements-Login Block, on page 22
- Verifying Login Parameters, on page 24
- Configuration Examples for Login Enhancements-Login Block, on page 26
- Feature History for Login Enhancements-Login Block, on page 26

Information About Login Enhancements-Login Block

Login Enhancements-Login Block Overview

The Login Enhancements (Login Block) feature allows users to enhance the security of a device by configuring options to automatically block further login attempts when a possible denial-of-service (DoS) attack is detected.

The login block and login delay options introduced by this feature can be configured for Telnet or SSH virtual connections. By enabling this feature, you can slow down "dictionary attacks" by enforcing a "quiet period" if multiple failed connection attempts are detected, thereby protecting the routing device from a type of denial-of-service attack.

Protecting Against Denial of Service and Dictionary Login Attacks

Connecting to a device for the purposes of administering (managing) the device, at either the User or Executive level, is most frequently performed using Telnet or SSH (secure shell) from a remote console (such as a PC). SSH provides a more secure connection option because communication traffic between the user's device and the managed device are encrypted. The Login Block capability, when enabled, applies to both Telnet connections and SSH connections. Beginning in Release versions 12.3(33)SRB2, 12.2(33)SXH2, and 12.4(15)T1, the Login Block capability also applies to HTTP connections."

The automated activation and logging of the Login Block and Quiet Period capabilities introduced by this feature are designed to further enhance the security of your devices by specifically addressing two well known methods that individuals use to attempt to disrupt or compromise network devices.

If the connection address of a device is discovered and is reachable, a malicious user may attempt to interfere with the normal operations of the device by flooding it with connection requests. This type of attack is referred to as an attempted Denial-of-Service, because it is possible that the device may become too busy trying to process the repeated login connection attempts to properly handle normal routing services or are not able to provide the normal login service to legitimate system administrators.

The primary intention of a dictionary attack, unlike a typical DoS attack, is to actually gain administrative access to the device. A dictionary attack is an automated process to attempt to login by attempting thousands, or even millions, of username/password combinations. (This type of attack is called a "dictionary attack" because it typically uses, as a start, every word found in a typical dictionary as a possible password.) As scripts or programs are used to attempt this access, the profile for such attempts is typically the same as for DoS attempts; multiple login attempts in a short period of time.

By enabling a detection profile, the device can be configured to react to repeated failed login attempts by refusing further connection request (login blocking). This block can be configured for a period of time, called a "quiet period". Legitimate connection attempts can still be permitted during a quiet period by configuring an access-list (ACL) with the addresses that you know to be associated with system administrators.

Delays Between Successive Login Attempts

A device can accept virtual connections as fast as they can be processed. Introducing a delay between login attempts helps to protect the device against malicious login connections such as dictionary attacks and DoS attacks. Delays can be enabled in one of the following ways:

- Through the **auto secure** command. If you enable the AutoSecure feature, the default login delay time of one second is automatically enforced.
- Through the **login block-for** command. You must enter this command before issuing the **login delay** command. If you enter only the **login block-for** command, the default login delay time of one second is automatically enforced.
- Through the global configuration mode command, **login delay**, which allows you to specify login delay time to be enforced, in seconds.

Login Shutdown If DoS Attacks Are Suspected

If the configured number of connection attempts fail within a specified time period, the device does not accept any additional connections for a "quiet period." (Hosts that are permitted by a predefined access-control list [ACL] are excluded from the quiet period.)

The number of failed connection attempts that trigger the quiet period can be specified through the new global configuration mode command **login block-for**. The predefined ACL that is excluded from the quiet period can be specified through the new global configuration mode command **login quiet-mode access-class**.

This functionality is disabled by default, and it is not enabled if AutoSecure if enabled.

How to Configure Login Enhancements-Login Block

Configuring Login Parameters

Use this task to configure your device for login parameters that help detect suspected DoS attacks and slow down dictionary attacks.

All login parameters are disabled by default. You must issue the **login block-for** command, which enables default login functionality, before using any other login commands. After the **login block-for** command is enabled, the following defaults are enforced:

- A default login delay of one second
- All login attempts made through Telnet or SSH are denied during the quiet period; that is, no ACLs are exempt from the login period until the **login quiet-mode access-class** command is issued.

	Command or Action	Purpose	
Step 1	enable	Enables privileged EXEC mode.	
	Example:	• Enter your password if prompted.	
	Device> enable		
Step 2	configure terminal	Enters global configuration mode.	
	Example:		
	Device# configure terminal		
Step 3	login block-for seconds attempts tries within seconds	Configures your device for login parameters that help provide DoS detection.	
	Example:	Note This command must be issued before any other login command	
	Device(config)# login block-for 100 attempts 2 within 100	can be used.	
Step 4	login quiet-mode access-class {acl-name acl-number}	(Optional) Although this command is optional it is recommended that it be configured to specify an ACL that is to be applied to the device when the device switches to quiet mode	
	Example:		
	Device(config)# login quiet-mode access-class myacl	When the device is in quiet mode, all login requests are denied and the only available connection is through the console.	
		If this command is not configured, then the default ACL sl_def_acl is created on the device. This ACL is hidden in the running configuration. Use the show access-list sl_def_acl to view the parameters for the default ACL.	
		For example:	
		Device# show access-lists sl_def_acl	
		Extended IP access list sl_def_acl 10 deny tcp any any eq telnet 20 deny tcp any any eq www 30 deny tcp any any eq 22 40 permit ip any any	

	Command or Action	Purpose
Step 5	login delay seconds	(Optional) Configures a delay between
	Example:	successive login attempts.
	Device(config)# login delay 10	
Step 6	exit	Exits global configuration mode and returns to
	Example:	privileged EXEC mode.
	Device(config)# exit	
Step 7	show login failures	Displays login parameters.
	Example:	• failures Displays information related only to failed login attempts.
	Device# show login	

Verifying Login Parameters

Use this task to verify the applied login configuration and present login status on your device.

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	show login failures	Displays login parameters.
	Example:	• failures Displays information related only to failed login attempts.
	Device# show login	

Examples

The following sample output from the **show login** command verifies that no login parameters have been specified:

Device# **show login** No login delay has been applied. No Quiet-Mode access list has been configured. All successful login is logged and generate SNMP traps. All failed login is logged and generate SNMP traps Router NOT enabled to watch for login Attacks The following sample output from the **show login** command verifies that the **login block-for** command is issued. In this example, the command is configured to block login hosts for 100 seconds if 16 or more login requests fail within 100 seconds; five login requests have already failed.

Device# show login

```
A default login delay of 1 seconds is applied.
No Quiet-Mode access list has been configured.
All successful login is logged and generate SNMP traps.
All failed login is logged and generate SNMP traps.
Router enabled to watch for login Attacks.
If more than 15 login failures occur in 100 seconds or less, logins will be disabled for
100 seconds.
Router presently in Watch-Mode, will remain in Watch-Mode for 95 seconds.
Present login failure count 5.
```

The following sample output from the **show login** command verifies that the device is in quiet mode. In this example, the **login block-for** command was configured to block login hosts for 100 seconds if 3 or more login requests fail within 100 seconds.

Device# show login

A default login delay of 1 seconds is applied. No Quiet-Mode access list has been configured. All successful login is logged and generate SNMP traps. All failed login is logged and generate SNMP traps. Router enabled to watch for login Attacks. If more than 2 login failures occur in 100 seconds or less, logins will be disabled for 100 seconds. Router presently in Quiet-Mode, will remain in Quiet-Mode for 93 seconds. Denying logins from all sources.

The following sample output from **show login failures** command shows all failed login attempts on the device:

Device# show login failures

Information about login failure's with the device								
Username	Source IPAddr	lPort	Count	TimeStamp				
try1	10.1.1.1	23	1	21:52:49 UTC	: Sun	Feb	24	2019
try2	10.1.1.2	23	1	21:52:52 UTC	Sun	Feb	23	2019

The following sample output from **show login failures** command verifies that no information is presently logged:

Device# show login failures

*** No logged failed login attempts with the device.***

Configuration Examples for Login Enhancements-Login Block

Example: Configuring Login Parameters

The following example shows how to configure your device to enter a 100 second quiet period if 15 failed login attempts is exceeded within 100 seconds; all login requests are denied during the quiet period except hosts from the ACL "myacl."

```
Device> enable
Device# configure terminal
Device(config)# login block-for 100 attempts 15 within 100
Device(config)# login quiet-mode access-class myacl
Device(config)# end
```

Feature History for Login Enhancements-Login Block

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.11.1	Login Enhancements -Login Block	The Login Enhancements-Login Block feature allows users to enhance the security of a router by configuring options to automatically block further login attempts when a possible DoS attack is detected.
Cisco IOS XE Cupertino 17.7.1	Login Enhancements -Login Block	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

Configuring Authentication

Authentication provides a method to identify users, which includes the login and password dialog, challenge and response, messaging support, and encryption, depending on the selected security protocol. Authentication is the way a user is identified prior to being allowed access to the network and network services.

- Prerequisites for Configuring Authentication, on page 27
- Restrictions for Configuring Authentication, on page 27
- Information About Authentication, on page 27
- How to Configure Authentication, on page 43
- Configuration Examples for Authentication, on page 63
- Feature History for Configuring Authentication, on page 76

Prerequisites for Configuring Authentication

The implementation of authentication is divided into Authentication, Authorization, and Accounting (AAA) authentication and nonauthentication methods. Cisco recommends that, whenever possible, AAA security services be used to implement authentication.

Restrictions for Configuring Authentication

- The number of AAA method lists that can be configured is 250.
- If you configure the same RADIUS server IP address for a different UDP destination port for accounting requests by using the **acct-port** keyword and a UDP destination port for authentication requests by using the **auth-port** keyword with and without the nonstandard option, the RADIUS server does not accept the nonstandard option.

Information About Authentication

Named Method Lists for Authentication

A named list of authentication methods is first defined before AAA authentication can be configured, and the named list is then applied to various interfaces. The method list defines the types of authentication and the

sequence in which they are performed; it must be applied to a specific interface before any of the defined authentication methods are performed. The only exception is the default method list (which is named "default"). The default method list is automatically applied to all interfaces, except those that have a named method list explicitly defined. A defined method list overrides the default method list.

A method list is a sequential list describing the authentication methods to be queried to authenticate a user. Method lists enable you to designate one or more security protocols to be used for authentication, thus ensuring a backup system for authentication in case the initial method fails. Cisco software uses the first listed method to authenticate users. If that method fails to respond, the Cisco software selects the next authentication method listed in the method list. This process continues until there is successful communication with a listed authentication method, or all methods defined in the method list are exhausted.

Note that the software attempts authentication with the next listed authentication method only when there is no response from the previous method. If authentication fails at any point in this cycle, that is, the security server or local username database responds by denying the user access, then the authentication process stops and no other authentication methods are attempted.

Method Lists and Server Groups

A server group is a way to group existing RADIUS or TACACS+ server hosts for use in method lists. The figure below shows a typical AAA network configuration that includes four security servers: R1 and R2 are RADIUS servers and T1 and T2 are TACACS+ servers. R1 and R2 make up the group of RADIUS servers. T1 and T2 make up the group of TACACS+ servers.

Using server groups, you can specify a subset of the configured server hosts and use them for a particular service. For example, server groups allow you to define R1 and R2 as a server group, and define T1 and T2 as a separate server group. For example, you can specify R1 and T1 in the method list for authentication login, while specifying R2 and T2 in the method list for PPP authentication.

Server groups also can include multiple host entries for the same server, as long as each entry has a unique identifier. The combination of an IP address and a UDP port number creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. In other words, this unique identifier enables RADIUS requests to be sent to different UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service--for

example, authentication--the second host entry configured acts as failover backup to the first one. Using this example, if the first host entry fails to provide accounting services, the network access server will try the second host entry configured on the same device for accounting services. (The RADIUS host entries will be tried in the order in which they are configured.)

For more information about configuring server groups and about configuring server groups based on Dialed Number Identification Service (DNIS) numbers, see the "Configuring RADIUS" or "Configuring TACACS+" chapters.

Login Authentication Using AAA

Login Authentication Using Enable Password

Use the **aaa authentication login**command with the **enable** keyword to specify the enable password as the login authentication method. For example, to specify the enable password as the method of user authentication at login when no other method list has been defined, enter the following command:

Device(config) # aaa authentication login default enable

Before you can use the enable password as the login authentication method, you need to define the enable password. For more information about defining enable passwords, see chapter "Controlling Switch Access with Passwords and Privilege Levels."

Login Authentication Using Kerberos

Authentication via Kerberos is different from most other authentication methods: the user's password is never sent to the remote access server. Remote users logging in to the network are prompted for a username. If the key distribution center (KDC) has an entry for that user, it creates an encrypted ticket granting ticket (TGT) with the password for that user and sends it back to the device. The user is then prompted for a password, and the device attempts to decrypt the TGT with that password. If it succeeds, the user is authenticated and the TGT is stored in the user's credential cache on the device.

While krb5 does use the KINIT program, a user does not need to run the KINIT program to get a TGT to authenticate to the device. This is because KINIT has been integrated into the login procedure in the Cisco IOS XE implementation of Kerberos.

Use the **aaa authentication login**command with the **krb5** keyword to specify Kerberos as the login authentication method. For example, to specify Kerberos as the method of user authentication at login when no other method list has been defined, enter the following command:

Device(config) # aaa authentication login default krb5

Before you can use Kerberos as the login authentication method, you need to enable communication with the Kerberos security server. For more information about establishing communication with a Kerberos server, refer to the chapter "Configuring Kerberos."

Login Authentication Using Line Password

Use the **aaa authentication login default** command with the **line** keyword to specify the line password as the login authentication method. For example, to specify the line password as the method of user authentication at login when no other method list has been defined, enter the following command:

Device (config) # aaa authentication login default line

Before you can use a line password as the login authentication method, you need to define a line password.

Login Authentication Using Local Password

Use the **aaa authentication login default**command with the **local** keyword to specify that the Cisco device will use the local username database for authentication. For example, to specify the local username database as the method of user authentication at login when no other method list has been defined, enter the following command:

Device (config) # aaa authentication login default local

Login Authentication Using Group RADIUS

Use the **aaa authentication login default**command with the **group radius** to specify RADIUS as the login authentication method. For example, to specify RADIUS as the method of user authentication at login when no other method list has been defined, enter the following command:

Device (config) # aaa authentication login default group radius

Before you can use RADIUS as the login authentication method, you need to enable communication with the RADIUS security server. For more information about establishing communication with a RADIUS server, refer to the chapter "Configuring RADIUS."

RADIUS Attribute 8 in Access Requests

After you have used the **aaa authentication login** command to specify RADIUS and your login host has been configured to request its IP address from the NAS, you can send attribute 8 (Framed-IP-Address) in access-request packets by using the **radius-server attribute 8 include-in-access-req** command in global configuration mode. This command makes it possible for NAS to provide the RADIUS server a hint of the user IP address in advance for user authentication.

Login Authentication Using Group TACACS

Use the **aaa authentication login default** command with the **group tacacs**+ to specify TACACS+ as the login authentication method. For example, to specify TACACS+ as the method of user authentication at login when no other method list has been defined, enter the following command:

Device(config)# aaa authentication login default group tacacs+

Before you can use TACACS+ as the login authentication method, you need to enable communication with the TACACS+ security server. For more information about establishing communication with a TACACS+ server, refer to the chapter "Configuring TACACS+."

Login Authentication Using Group Name

Use the **aaa authentication login default** command with the **group** *group-name* method to specify a subset of RADIUS or TACACS+ servers to use as the login authentication method. To specify and define the group name and the members of the group, use the **aaa group server** command. For example, use the **aaa group server** command to first define the members of **group loginrad**:

```
Device> enable
Device# configure terminal
```

```
Device(config)# aaa group server radius loginrad
Device(config-sg-radius)# server 172.16.2.3
Device(config-sg-radius)# server 172.16.2 17
Device(config-sg-radius)# server 172.16.2.32
Device(config-sg-radius)# end
```

This command specifies RADIUS servers 172.16.2.3, 172.16.2.17, and 172.16.2.32 as members of the group *loginrad*.

To specify **group loginrad** as the method of user authentication at login when no other method list has been defined, enter the following command:

Device(config)# aaa authentication login default group loginrad

Before you can use a group name as the login authentication method, you need to enable communication with the RADIUS or TACACS+ security server. For more information about establishing communication with a RADIUS server, refer to the chapter "Configuring RADIUS." For more information about establishing communication with a TACACS+ server, refer to the chapter "Configuring TACACS+."

PPP Authentication Using AAA

PPP Authentication Using Kerberos

Use the **aaa authentication ppp default Device**command with the **krb5** keyword to specify Kerberos as the authentication method for use on interfaces running PPP. For example, to specify Kerberos as the method of user authentication when no other method list has been defined, enter the following command:

Device(config) # aaa authentication ppp default krb5

Before you can use Kerberos as the PPP authentication method, you need to enable communication with the Kerberos security server. For more information about establishing communication with a Kerberos server, refer to the chapter "Configuring Kerberos".

Kerberos login authentication works only with PPP PAP authentication.

PPP Authentication Using Local Password

Use the **aaa authentication ppp default** command with the **local** keyword to specify that the Cisco device will use the local username database for authentication. For example, to specify the local username database as the method of authentication for use on lines running PPP when no other method list has been defined, enter the following command:

Device(config) # aaa authentication ppp default local

PPP Authentication Using Group RADIUS

Use the **aaa authentication ppp default group radius** command to specify RADIUS as the login authentication method. For example, to specify RADIUS as the method of user authentication at login when no other method list has been defined, enter the following command:

Device(config) # aaa authentication ppp default group radius

Before you can use RADIUS as the PPP authentication method, you need to enable communication with the RADIUS security server. For more information about establishing communication with a RADIUS server, refer to the chapter "Configuring RADIUS."

RADIUS Attribute 44 in Access Requests

After you have used the **aaa authentication ppp default group radius** command to specify RADIUS as the login authentication method, you can configure your device to send attribute 44 (Acct-Session-ID) in access-request packets by using the **radius-server attribute 44 include-in-access-req** command in global configuration mode. This command allows the RADIUS daemon to track a call from the beginning to the end.

PPP Authentication Using Group TACACS

Use the **aaa authentication ppp default group tacacs**+ command to specify TACACS+ as the login authentication method. For example, to specify TACACS+ as the method of user authentication at login when no other method list has been defined, enter the following command:

Device(config) # aaa authentication ppp default group tacacs+

Before you can use TACACS+ as the PPP authentication method, you need to enable communication with the TACACS+ security server. For more information about establishing communication with a TACACS+ server, refer to the chapter "Configuring TACACS+."

PPP Authentication Using Group Name

Use the **aaa authentication ppp default** command with the **group** *group-name* method to specify a subset of RADIUS or TACACS+ servers to use as the login authentication method. To specify and define the group name and the members of the group, use the **aaa group server** command. For example, use the **aaa group server** command to first define the members of **group ppprad**:

```
Device> enable
Device# configure terminal
Device(config)# aaa group server radius ppprad
Device(config-sg-radius)# server 172.16.2.3
Device(config-sg-radius)# server 172.16.2.17
Device(config-sg-radius)# server 172.16.2.32
Device(config-sg-radius)# end
```

This command specifies RADIUS servers 172.16.2.3, 172.16.2.17, and 172.16.2.32 as members of the group *ppprad*.

To specify **group ppprad** as the method of user authentication at login when no other method list has been defined, enter the following command:

Device(config) # aaa authentication ppp default group ppprad

Before you can use a group name as the PPP authentication method, you need to enable communication with the RADIUS or TACACS+ security server. For more information about establishing communication with a RADIUS server, refer to the chapter "Configuring RADIUS". For more information about establishing communication with a TACACS+ server, refer to the chapter "Configuring TACACS+."

AAA Scalability for PPP Requests

You can configure and monitor the number of background processes allocated by the PPP manager in the network access server (NAS) to deal with AAA authentication and authorization requests. The AAA Scalability feature enables you to configure the number of processes used to handle AAA requests for PPP, thus increasing the number of users that can be simultaneously authenticated or authorized.

To allocate a specific number of background processes to handle AAA requests for PPP, use the following command in global configuration mode:

Device(config) # aaa processes 5000

The argument *number* defines the number of background processes earmarked to process AAA authentication and authorization requests for PPP and can be configured for any value from 1 to 2147483647. Because of the way the PPP manager handles requests for PPP, this argument also defines the number of new users that can be simultaneously authenticated. This argument can be increased or decreased at any time.

Allocating additional background processes can be expensive. You should configure the minimum number of background processes capable of handling the AAA requests for PPP.

ARAP Authentication Using AAA

ARAP Authentication Allowing Authorized Guest Logins

Use the **aaa authentication arap default** command with the **auth-guest** keyword to allow guest logins only if the user has already successfully logged in to the EXEC. This method must be the first listed in the ARAP authentication method list but it can be followed by other methods if it does not succeed. For example, to allow all authorized guest logins--meaning logins by users who have already successfully logged in to the EXEC-as the default method of authentication, using RADIUS only if that method fails, enter the following command:

Device (config) # aaa authentication arap default auth-guest group radius

Note By default, guest logins through ARAP are disabled when you initialize AAA. To allow guest logins, you must use the **aaa authentication arap** {*authentication-list* | **default** command with either the **guest** or the **auth-guest** keyword.

ARAP Authentication Allowing Guest Logins

Use the **aaa authentication arap** {**default** | *authentication-list*} command with the **guest** keyword to allow guest logins. This method must be the first listed in the ARAP authentication method list but it can be followed by other methods if it does not succeed. For example, to allow all guest logins as the default method of authentication, using RADIUS only if that method fails, enter the following command:

Device(config) # aaa authentication arap default guest group radius

ARAP Authentication Using Line Password

Use the **aaa authentication arap** {**default** | *authentication-list*} command with the **line** keyword to specify the line password as the authentication method. For example, to specify the line password as the method of ARAP user authentication when no other method list has been defined, enter the following command:

Device(config) # aaa authentication arap default line

Before you can use a line password as the ARAP authentication method, you need to define a line password.

ARAP Authentication Using Local Password

Use the **aaa authentication arap** {**default** | *authentication-list*} command with the **local** keyword to specify that the Cisco device will use the local username database for authentication. For example, to specify the local username database as the method of ARAP user authentication when no other method list has been defined, enter the following command:

Device (config) # aaa authentication arap default local

ARAP Authentication Using Group RADIUS

Use the **aaa authentication arap** {**default** | *authentication-list*} command with the **group radius** *method* to specify RADIUS as the ARAP authentication method. For example, to specify RADIUS as the method of user authentication at login when no other method list has been defined, enter the following command:

Device (config) # aaa authentication arap default group radius

Before you can use RADIUS as the ARAP authentication method, you need to enable communication with the RADIUS security server. For more information about establishing communication with a RADIUS server, refer to the chapter "Configuring RADIUS."

ARAP Authentication Using Group TACACS

Use the **aaa authentication arap** {**default** | *authentication-list*} command with the **group tacacs**+ *method* to specify TACACS+ as the ARAP authentication method. For example, to specify TACACS+ as the method of user authentication at login when no other method list has been defined, enter the following command:

Device (config) # aaa authentication arap default group tacacs+

Before you can use TACACS+ as the ARAP authentication method, you need to enable communication with the TACACS+ security server. For more information about establishing communication with a TACACS+ server, refer to the chapter "Configuring TACACS+."

ARAP Authentication Using a Group Name

Use the **aaa authentication arap** {**default** | *authentication-list*} command with the **group** *group-name* method to specify a subset of RADIUS or TACACS+ servers to use as the ARAP authentication method. To specify and define the group name and the members of the group, use the **aaa group server** command. For example, use the **aaa group server** command to first define the members of **group araprad**:

```
Device> enable
Device# configure terminal
Device(config)# aaa group server radius araprad
```

Device(config-sg-radius)# server 172.16.2.3
Device(config-sg-radius)# server 172.16.2 17
Device(config-sg-radius)# server 172.16.2.32
Device(config-sg-radius)# end

This command specifies RADIUS servers 172.16.2.3, 172.16.2.17, and 172.16.2.32 as members of the group *araprad*.

To specify **group araprad** as the method of user authentication at login when no other method list has been defined, enter the following command:

Device(config) # aaa authentication arap default group araprad

Before you can use a group name as the ARAP authentication method, you need to enable communication with the RADIUS or TACACS+ security server. For more information about establishing communication with a RADIUS server, refer to the chapter "Configuring RADIUS." For more information about establishing communication with a TACACS+ server, refer to the chapter "Configuring TACACS+."

NASI Authentication Using AAA

NASI Authentication Using Enable Password

Use the **aaa authentication nasi** command with the keyword **enable** to specify the enable password as the authentication method. For example, to specify the enable password as the method of NASI user authentication when no other method list has been defined, use the following command:

Devie(config) # aaa authentication nasi default enable

Before you can use the enable password as the authentication method, you need to define the enable password.

NASI Authentication Using Group RADIUS

Use the **aaa authentication nasi** command with the **group radius** method to specify RADIUS as the NASI authentication method. For example, to specify RADIUS as the method of NASI user authentication when no other method list has been defined, enter the following command:

Device (config) # aaa authentication nasi default group radius

Before you can use RADIUS as the NASI authentication method, you need to enable communication with the RADIUS security server.

NASI Authentication Using Group TACACS

Use the **aaa authentication nasi** command with the **group tacacs**+ keyword to specify TACACS+ as the NASI authentication method. For example, to specify TACACS+ as the method of NASI user authentication when no other method list has been defined, enter the following command:

Device(config)# aaa authentication nasi default group tacacs+

Before you can use TACACS+ as the authentication method, you need to enable communication with the TACACS+ security server.

NASI Authentication Using Line Password

Use the **aaa authentication nasi** command with the keyword **line** to specify the line password as the authentication method. For example, to specify the line password as the method of NASI user authentication when no other method list has been defined, enter the following command:

Device (config) # aaa authentication nasi default line

Before you can use a line password as the NASI authentication method, you need to define a line password.

NASI Authentication Using Local Password

Use the **aaa authentication nasi** command with the keyword **local** to specify that the Cisco rdevice will use the local username database for authentication information. For example, to specify the local username database as the method of NASI user authentication when no other method list has been defined, enter the following command:

Device(config) # aaa authentication nasi default local

NASI Authentication Using Group Name

Use the **aaa authentication nasi** command with the **group** *group-name* method to specify a subset of RADIUS or TACACS+ servers to use as the NASI authentication method. To specify and define the group name and the members of the group, use the **aaa group server** command. For example, use the **aaa group server** command to first define the members of **group nasirad**:

```
Device> enable
Device# configure terminal
Device(config)# aaa group server radius nasirad
Device(config-sg-radius)# server 172.16.2.3
Device(config-sg-radius)# server 172.16.2.17
Device(config-sg-radius)# server 172.16.2.32
Device(config-sg-radius)# end
```

This command specifies RADIUS servers 172.16.2.3, 172.16.2.17, and 172.16.2.32 as members of the group *nasirad*.

To specify **group nasirad** as the method of user authentication at login when no other method list has been defined, enter the following command:

Device(config) # aaa authentication nasi default group nasirad

Before you can use a group name as the NASI authentication method, you need to enable communication with the RADIUS or TACACS+ security server.

Specifying the Amount of Time for Login Input

The **timeout login response**command allows you to specify how long the system will wait for login input (such as username and password) before timing out. The default login value is 30 seconds; with the **timeout login response** command, you can specify a timeout value from 1 to 300 seconds. To change the login timeout value from the default of 30 seconds, use the following command in line configuration mode:

```
Device(config-line) # timeout login response 30
```

Password Protection at the Privileged Level

Use the **aaa authentication enable default** command to create a series of authentication methods that are used to determine whether a user can access the privileged EXEC command level. You can specify up to four authentication methods. The additional methods of authentication are used only if the previous method returns an error, not if it fails. To specify that the authentication should succeed even if all methods return an error, specify **none** as the final method in the command line.

Use the following command in global configuration mode:

Device(config)# authentication enable default radius

or

Device(config) # authentication enable default tacacs

Changing the Text Displayed at the Password Prompt

Use the **aaa authentication password-prompt** command to change the default text that the Cisco IOS XE software displays when prompting a user to enter a password. This command changes the password prompt for the enable password as well as for login passwords that are not supplied by remote security servers. The **no** form of this command returns the password prompt to the following default value:

Password:

The **aaa authentication password-prompt** command does not change any dialog that is supplied by a remote TACACS+ or RADIUS server.

The **aaa authentication password-prompt** command works when RADIUS is used as the login method. You will be able to see the password prompt defined in the command shown even when the RADIUS server is unreachable. The **aaa authentication password-prompt** command does not work with TACACS+. TACACS+ supplies the NAS with the password prompt to display to the users. If the TACACS+ server is reachable, the NAS gets the password prompt from the server and uses that prompt instead of the one defined in the **aaa authentication password-prompt** command. If the TACACS+ server is not reachable, the password prompt defined in the **aaa authentication password-prompt** command may be used.

Use the following command in global configuration mode:

Device(config)# aaa authentication password-prompt "Enter your password now:"

Double Authentication of PPP Sessions

PPP sessions can be authenticated only by using a single authentication method: either PAP or CHAP. Double authentication requires remote users to pass a second stage of authentication (after CHAP or PAP authentication) before gaining network access.

This second ("double") authentication requires a password that is known to the user but *not* stored on the user's remote host. Therefore, the second authentication is specific to a user, not to a host. This provides an additional level of security that will be effective even if information from the remote host is stolen. In addition, this also provides greater flexibility by allowing customized network privileges for each user.

The second stage authentication can use one-time passwords such as token card passwords, which are not supported by CHAP. If one-time passwords are used, a stolen user password is of no use to the perpetrator.

How Double Authentication Works

With double authentication, there are two authentication/authorization stages. These two stages occur after a remote user dials in and a PPP session is initiated.

In the first stage, the user logs in using the remote host name; CHAP (or PAP) authenticates the remote host, and then PPP negotiates with AAA to authorize the remote host. In this process, the network access privileges associated with the remote host are assigned to the user.

Note

We suggest that the network administrator restrict authorization at this first stage to allow only Telnet connections to the local host.

In the second stage, the remote user must Telnet to the network access server to be authenticated. When the remote user logs in, the user must be authenticated with AAA login authentication. The user then must enter the **access-profile** command to be reauthorized using AAA. When this authorization is complete, the user has been double authenticated, and can access the network according to per-user network privileges.

The system administrator determines what network privileges remote users will have after each stage of authentication by configuring appropriate parameters on a security server. To use double authentication, the user must activate it by issuing the **access-profile**command.

<u>/</u>!

Caution

Double authentication can cause certain undesirable events if multiple hosts share a PPP connection to a network access server, as shown in the figure below. First, if a user, Bob, initiates a PPP session and activates double authentication at the network access server (per the figure below), any other user will automatically have the same network privileges as Bob until Bob's PPP session expires. This happens because Bob's authorization profile is applied to the network access server's interface during the PPP session and any PPP traffic from other users will use the PPP session Bob established. Second, if Bob initiates a PPP session and activates double authentication, and then--before Bob's PPP session has expired--another user, Jane, executes the access-profile command (or, if Jane Telnets to the network access server and autocommand access-profile is profile. This can disrupt or halt Bob's PPP traffic, or grant Bob additional authorization privileges Bob should not have.

Figure 2: Possibly Risky Topology: Multiple Hosts Share a PPP Connection to a Network Access Server

Accessing the User Profile After Double Authentication

In double authentication, when a remote user establishes a PPP link to the local host using the local host name, the remote host is CHAP (or PAP) authenticated. After CHAP (or PAP) authentication, PPP negotiates with

AAA to assign network access privileges associated with the remote host to the user. (We suggest that privileges at this stage be restricted to allow the user to connect to the local host only by establishing a Telnet connection.)

When the user needs to initiate the second phase of double authentication, establishing a Telnet connection to the local host, the user enters a personal username and password (different from the CHAP or PAP username and password). This action causes AAA reauthentication to occur according to the personal username/password. The initial rights associated with the local host, though, are still in place. By using the **access-profile** command, the rights associated with the local host are replaced by or merged with those defined for the user in the user's profile.

To access the user profile after double authentication, use the following command in EXEC configuration mode:

Device> access-profile merge ignore-sanity-checks

If you configured the **access-profile** command to be executed as an autocommand, it will be executed automatically after the remote user logs in.

CHAP or PAP Authentication

One of the most common transport protocols used in ISPs dial solutions is the Point-to-Point Protocol (PPP). Traditionally, remote users dial in to an access server to initiate a PPP session. After PPP has been negotiated, remote users are connected to the ISP network and to the Internet.

Because ISPs want only customers to connect to their access servers, remote users are required to authenticate to the access server before they can start up a PPP session. Normally, a remote user authenticates by typing in a username and password when prompted by the access server. Although this is a workable solution, it is difficult to administer and awkward for the remote user.

A better solution is to use the authentication protocols built into PPP. In this case, the remote user dials in to the access server and starts up a minimal subset of PPP with the access server. This does not give the remote user access to the ISP's network--it merely allows the access server to talk to the remote device.

PPP currently supports two authentication protocols: Password Authentication Protocol (PAP) and Challenge Handshake Authentication Protocol (CHAP). Both are specified in RFC 1334 and are supported on synchronous and asynchronous interfaces. Authentication via PAP or CHAP is equivalent to typing in a username and password when prompted by the server. CHAP is considered to be more secure because the remote user's password is never sent across the connection.

PPP (with or without PAP or CHAP authentication) is also supported in dialout solutions. An access server utilizes a dialout feature when it initiates a call to a remote device and attempts to start up a transport protocol such as PPP.

Note To use CHAP or PAP, you must be running PPP encapsulation.

When CHAP is enabled on an interface and a remote device attempts to connect to it, the access server sends a CHAP packet to the remote device. The CHAP packet requests or "challenges" the remote device to respond. The challenge packet consists of an ID, a random number, and the host name of the local device.

When the remote device receives the challenge packet, it concatenates the ID, the remote device's password, and the random number, and then encrypts all of it using the remote device's password. The remote device sends the results back to the access server, along with the name associated with the password used in the encryption process.

When the access server receives the response, it uses the name it received to retrieve a password stored in its user database. The retrieved password should be the same password the remote device used in its encryption process. The access server then encrypts the concatenated information with the newly retrieved password--if the result matches the result sent in the response packet, authentication succeeds.

The benefit of using CHAP authentication is that the remote device's password is never transmitted in clear text. This prevents other devices from stealing it and gaining illegal access to the ISP's network.

CHAP transactions occur only at the time a link is established. The access server does not request a password during the rest of the call. (The local device can, however, respond to such requests from other devices during a call.)

When PAP is enabled, the remote device attempting to connect to the access server is required to send an authentication request. If the username and password specified in the authentication request are accepted, the Cisco IOS XE software sends an authentication acknowledgment.

After you have enabled CHAP or PAP, the access server will require authentication from remote devices dialing in to the access server. If the remote device does not support the enabled protocol, the call will be dropped.

To use CHAP or PAP, you must perform the following tasks:

- Enable PPP encapsulation.
- Enable CHAP or PAP on the interface.
- For CHAP, configure host name authentication and the secret or password for each remote system with which authentication is required.

Enabling PPP Encapsulation

To enable PPP encapsulation, use the following command in interface configuration mode:

Device(config-if) # encapsulation ppp

This command enables PPP on an interface.

Enabling PAP or CHAP

To enable CHAP or PAP authentication on an interface configured for PPP encapsulation, use the following command in interface configuration mode:

Device(config-if) # ppp authentication chap pap

Defines the authentication protocols supported and the order in which they are used. In this command, *protocol1*, *protocol2* represent the following protocols: CHAP, MS-CHAP, and PAP. PPP authentication is attempted first using the first authentication method, which is *protocol1*. If *protocol1* is unable to establish authentication, the next configured protocol is used to negotiate authentication.

If you configure **ppp authentication chap** on an interface, all incoming calls on that interface that initiate a PPP connection will have to be authenticated using CHAP; likewise, if you configure **ppp authentication pap**, all incoming calls that start a PPP connection will have to be authenticated via PAP. If you configure **ppp authentication chap pap**, the access server will attempt to authenticate all incoming calls that start a PPP session with CHAP. If the remote device does not support CHAP, the access server will try to authenticate the call using PAP. If the remote device does not support either CHAP or PAP, authentication will fail and the call will be dropped. If you configure **ppp authentication pap chap**, the access server will attempt to authenticate all incoming calls that start a PPP session with PAP. If the remote device does not support either CHAP or PAP, authentication will fail and the call will be dropped. If you configure **ppp authentication pap chap**, the access server will attempt to authenticate all incoming calls that start a PPP session with PAP. If the remote device does not support PAP, the access server will try to authenticate the call using CHAP. If the remote device does not support either

protocol, authentication will fail and the call will be dropped. If you configure the **ppp authentication** command with the **callin** keyword, the access server will only authenticate the remote device if the remote device initiated the call.

Authentication method lists and the **one-time** keyword are only available if you have enabled AAA; these will not be available if you are using TACACS or extended TACACS. If you specify the name of an authentication method list with the **ppp authentication** command, PPP will attempt to authenticate the connection using the methods defined in the specified method list. If AAA is enabled and no method list is defined by name, PPP will attempt to authenticate the connection using the methods defined to authenticate the connection using the methods defined as the default. The **ppp authentication** command with the **one-time** keyword enables support for one-time passwords during authentication.

The **if-needed** keyword is only available if you are using TACACS or extended TACACS. The **ppp authentication**command with the **if-needed** keyword means that PPP will only authenticate the remote device via PAP or CHAP if they have not yet authenticated during the life of the current call. If the remote device authenticated via a standard login procedure and initiated PPP from the EXEC prompt, PPP will not authenticate via CHAP if **ppp authentication chap if-needed** is configured on the interface.

```
Caution
```

n If you use a *list-name* that has not been configured with the **aaa authentication ppp**command, you disable PPP on the line.

Inbound and Outbound Authentication

PPP supports two-way authentication. Normally, when a remote device dials in to an access server, the access server requests that the remote device prove that it is allowed access. This is known as inbound authentication. At the same time, the remote device can also request that the access server prove that it is who it says it is. This is known as outbound authentication. An access server also does outbound authentication when it initiates a call to a remote device.

Enabling Outbound PAP Authentication

To enable outbound PAP authentication, use the following command in interface configuration mode:

Device(config-if) # ppp pap sent-username username1 password password1

The access server uses the username and password specified by the **ppp pap sent-username** command to authenticate itself whenever it initiates a call to a remote device or when it has to respond to a remote device's request for outbound authentication.

Refusing PAP Authentication Requests

To refuse PAP authentication from peers requesting it, meaning that PAP authentication is disabled for all calls, use the following command in interface configuration mode:

Device(config-if) # ppp pap refuse

If the **refuse** keyword is not used, the device will not refuse any PAP authentication challenges received from the peer.

Creating a Common CHAP Password

For remote CHAP authentication, you can configure your device to create a common CHAP secret password to use in response to challenges from an unknown peer. For example, if your device calls a rotary of devices

(either from another vendor, or running an older version of the Cisco IOS XE software) to which a new (that is, unknown) device has been added. The **ppp chap password** command allows you to replace several username and password configuration commands with a single copy of this command on any dialer interface or asynchronous group interface.

To enable a device calling a collection of devices to configure a common CHAP secret password, use the following command in interface configuration mode:

Device(config-if) # ppp chap password secret

Refusing CHAP Authentication Requests

To refuse CHAP authentication from peers requesting it, meaning that CHAP authentication is disabled for all calls, use the following command in interface configuration mode:

Device(config-if) # ppp chap refuse calling

If the **calling** keyword is used, the device will refuse to answer CHAP authentication challenges received from the peer, but will still require the peer to answer any CHAP challenges the device sends.

If outbound PAP has been enabled (using the **ppp pap sent-username** command), PAP is used as the authentication method in the refusal packet.

Delaying CHAP Authentication Until Peer Authenticates

To specify that the device will not authenticate to a peer requesting CHAP authentication until after the peer has authenticated itself to the device, use the following command in interface configuration mode:

Device(config-if) # ppp chap wait secret

This command (which is the default) specifies that the device will not authenticate to a peer requesting CHAP authentication until the peer has authenticated itself to the device. The **no ppp chap wait**commandspecifies that the device will respond immediately to an authentication challenge.

Using MS-CHAP

Microsoft Challenge Handshake Authentication Protocol (MS-CHAP) is the Microsoft version of CHAP and is an extension of RFC 1994. Like the standard version of CHAP, MS-CHAP is used for PPP authentication; in this case, authentication occurs between a PC using Microsoft Windows NT or Microsoft Windows 95 and a Cisco device or access server acting as a network access server.

MS-CHAP differs from the standard CHAP as follows:

- MS-CHAP is enabled by negotiating CHAP Algorithm 0x80 in LCP option 3, Authentication Protocol.
- The MS-CHAP Response packet is in a format designed to be compatible with Microsoft Windows NT 3.5 and 3.51, Microsoft Windows 95, and Microsoft LAN Manager 2.*x*. This format does not require the authenticator to store a clear or reversibly encrypted password.
- MS-CHAP provides an authenticator-controlled authentication retry mechanism.
- MS-CHAP provides an authenticator-controlled change password mechanism.
- MS-CHAP defines a set of "reason-for failure" codes returned in the Failure packet message field.

Depending on the security protocols you have implemented, PPP authentication using MS-CHAP can be used with or without AAA security services. If you have enabled AAA, PPP authentication using MS-CHAP can

be used in conjunction with both TACACS+ and RADIUS. The table below lists the vendor-specific RADIUS attributes (IETF Attribute 26) that enable RADIUS to support MS-CHAP.

Vendor-ID Number	Vendor-Type Number	Vendor-Proprietary Attribute	Description
311	11	MSCHAP-Challenge	Contains the challenge sent by a network access server to an MS-CHAP user. It can be used in both Access-Request and Access-Challenge packets.
211	11	MSCHAP-Response	Contains the response value provided by a PPP MS-CHAP user in response to the challenge. It is only used in Access-Request packets. This attribute is identical to the PPP CHAP Identifier.

Table 3: Vendor-Specific RADIUS Attributes for MS-CHAP

Domain Stripping

The AAA Broadcast Accounting feature allows accounting information to be sent to multiple AAA servers at the same time, that is, accounting information can be broadcast to one or more AAA servers simultaneously. This functionality allows you to send accounting information to private and public AAA servers. It also provides redundant billing information for voice applications.

The Domain Stripping feature allows domain stripping to be configured at the server group level.

Per-server group configuration overrides the global configuration. If domain stripping is not enabled globally, but it is enabled in a server group, then it is enabled only for that server group. Also, if virtual routing and forwarding (VRF)-specific domain stripping is configured globally and in a server group for a different VRF, domain stripping is enabled in both the VRFs. VRF configurations are taken from server-group configuration mode. If server-group configurations are disabled in global configuration mode but are available in server-group configurations in server-group configuration mode are applicable.

After the domain stripping and broadcast accounting are configured, you can create separate accounting records as per the configurations.

If both **domain-stripping** and **directed-request** commands are enabled, domain stripping takes precedence and directed request functionality will not work.

How to Configure Authentication

Configuring Login Authentication Using AAA

The AAA security services facilitate a variety of login authentication methods. Use the **aaa authentication login**command to enable AAA authentication no matter which of the supported login authentication methods you decide to use. With the **aaa authentication login**command, you create one or more lists of authentication methods that are tried at login. These lists are applied using the **login authentication** line configuration command.

I

To configure login authentication by using AAA, use the following commands beginning in global configuration mode:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	aaa new-model	Enables AAA.
	Example:	
	Device(config)# aaa new-model	
Step 4	aaa authentication login {default list-name} method1[method2]	Creates a local authentication list.
	Example:	
	Device(config)# aaa authentication login default local	
Step 5	line [aux console tty vty] line-number [ending-line-number]	Enters line configuration mode for the lines to which you want to apply the authentication list.
	Example:	
	Device(config)# line vty 1	
Step 6	login authentication {default <i>list-name</i> }	Applies the authentication list to a line or set of
	Example:	lines.
	Device(config-line)# login authentication default	
Step 7	end	Exits line configuration mode and returns to
	Example:	privileged EXEC mode.
	Device(config-line)# end	

What to do next

The *list-name* is a character string used to name the list you are creating. The method argument refers to the actual method the authentication algorithm tries. The additional methods of authentication are used only if the previous method returns an error, not if it fails. To specify that the authentication should succeed even if all methods return an error, specify **none** as the final method in the command line.

For example, to specify that authentication should succeed even if (in this example) the TACACS+ server returns an error, enter the following command:

Device(config) # aaa authentication login default group tacacs+ none

Note

Because the **none** keyword enables *any* user logging in to successfully authenticate, it should be used only as a backup method of authentication.

To create a default list that is used when a named list is *not* specified in the **login authentication** command, use the **default** keyword followed by the methods that are to be used in default situations. The default method list is automatically applied to all interfaces.

For example, to specify RADIUS as the default method for user authentication during login, enter the following command:

Device(config) # aaa authentication login default group radius

Configuring PPP Authentication Using AAA

The AAA security services facilitate a variety of authentication methods for use on serial interfaces running PPP. Use the **aaa authentication ppp**command to enable AAA authentication no matter which of the supported PPP authentication methods you decide to use.

To configure AAA authentication methods for serial lines using PPP, use the following commands in global configuration mode:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	aaa new-model	Enables AAA.
	Example:	

	Command or Action	Purpose
	Device(config)# aaa new-model	
Step 4	aaa authentication ppp{default list-name} method1[method2]	Creates a local authentication list.
	Example:	
	Device(config)# aaa authentication ppp-auth default local	
Step 5	interface interface-type interface-number	Enters interface configuration mode for the
	Example:	interface to which you want to apply the authentication list.
	<pre>Device(config)# interface gigabitethernet 0/1/0</pre>	
Step 6	<pre>ppp authentication {protocol1 [protocol2]} [if-needed] {default list-name} [callin] [one-time][optional]</pre>	Applies the authentication list to a line or set of lines. In this command, <i>protocol1</i> and <i>protocol2</i> represent the following protocols: CHAP,
	Example:	MS-CHAP, and PAP. PPP authentication is attempted first using the first authentication
	Device(config)# ppp authentication ms-chap ppp-auth	method, specified by <i>protocol1</i> . If <i>protocol1</i> is unable to establish authentication, the next configured protocol is used to negotiate authentication.
Step 7	end	Exits global configuration mode and returns to
	Example:	privileged EXEC mode.
	Device(config)# end	

What to do next

With the **aaa authentication ppp**command, you create one or more lists of authentication methods that are tried when a user tries to authenticate via PPP. These lists are applied using the **ppp authentication** line configuration command.

To create a default list that is used when a named list is *not* specified in the **ppp authentication** command, use the **default** keyword followed by the methods you want used in default situations.

For example, to specify the local username database as the default method for user authentication, enter the following command:

Device (config) # aaa authentication ppp default local

The *list-name* is any character string used to name the list you are creating. The method argument refers to the actual method the authentication algorithm tries. The additional methods of authentication are used only

if the previous method returns an error, not if it fails. To specify that the authentication should succeed even if all methods return an error, specify **none** as the final method in the command line.

For example, to specify that authentication should succeed even if (in this example) the TACACS+ server returns an error, enter the following command:

```
Device(config) # aaa authentication ppp default group tacacs+ none
```

Note Because **none** allows all users logging in to authenticate successfully, it should be used as a backup method of authentication.

Configuring ARAP Authentication Using AAA

Using the **aaa authentication arap** command, you can create one or more lists of authentication methods that are tried when AppleTalk Remote Access Protocol (ARAP) users attempt to log in to the device. These lists are used with the **arap authentication** line configuration command.

Use the following commands starting in global configuration mode:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	aaa new-model	Enables AAA.
	Example:	
	Device(config)# aaa new-model	
Step 4	aaa authentication arap	
	Example:	
	Device(config)# aaa authentication arap	
	Example:	
	Enables authentication for ARAP users.	

	Command or Action	Purpose	
Step 5	line number	(Optional) Changes to line configuration mode.	
	Example:		
	Device(config)# line 1		
Step 6	Device(config-line)# autoselect arap	(Optional) Enables autoselection of ARAP.	
	Example:		
	Device(config-line)# auto-select arap		
Step 7	autoselect during-login	(Optional) Starts the ARAP session	
	Example:	automatically at user login.	
	Device(config-line)# autoselect during-login		
Step 8	arap authentication list-name	(Optional—not needed if default is used in the	
	Example:	aaa authentication arap command) Enables TACACS+ authentication for ARAP on a line.	
	Device(config-line)# arap authentication arap-authen		
Step 9	end	Exits line configuration mode and returns to the	
	Example:	privileged EXEC mode.	
	Device(config-line)# end		

What to do next

The *list-name* is any character string used to name the list you are creating. The *method* argument refers to the actual list of methods the authentication algorithm tries, in the sequence entered.

To create a default list that is used when a named list is *not* specified in the **arap authentication** command, use the **default** keyword followed by the methods you want to use in default situations.

The additional methods of authentication are used only if the previous method returns an error, not if it fails. To specify that the authentication should succeed even if all methods return an error, specify **none** as the final method in the command line.

Note Because **none** allows all users logging in to be authenticated, it should be used as a backup method of authentication.

For example, to create a default AAA authentication method list used with ARAP, use the following command:

Device(config) # aaa authentication arap default if-needed none

To create the same authentication method list for ARAP and name the list *MIS-access*, use the following command:

Device(config) # aaa authentication arap MIS-access if-needed none

Configuring NASI Authentication Using AAA

Using the **aaa authentication nasi** command, you can create one or more lists of authentication methods that are tried when NetWare Asynchronous Services Interface (NASI) users attempt to log in to the device. These lists are used with the **nasi authentication line** configuration command.

To configure NASI authentication using AAA, use the following commands starting in global configuration mode:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	aaa new-model	Enables AAA globally.
	Example:	
	Device(config)# aaa new-model	
Step 4	aaa authentication nasi	Enables authentication for NASI users.
	Example:	
	Device(config)# aaa authentication nasi	
Step 5	line number	(Optionalnot needed if default is used in the
	Example:	aaa authentication nasi command.) Enters line configuration mode.
	Device(config)# line 4	

	Command or Action	Purpose
Step 6	nasi authentication list-name	(Optionalnot needed if default is used in the
	Example:	aaa authentication nasi command.) Enables authentication for NASI on a line.
	Device(config-line)# nasi authentication nasi-authen	
Step 7	end	Exits line configuration mode and returns to the
	Example:	privileged EXEC mode.
	Device(config-line)# end	

What to do next

The *list-name* is any character string used to name the list you are creating. The *method* argument refers to the actual list of methods that the authentication algorithm tries, in the sequence entered.

To create a default list that is used when a named list is *not* specified in the **aaa authentication nasi** command, use the **default** keyword followed by the methods you want to use in default situations.

The additional methods of authentication are used only if the previous method returns an error, not if it fails. To specify that the authentication should succeed even if all methods return an error, specify **none** as the final method in the command line.

Note Because **none** allows all users logging in to be authenticated, it should be used as a backup method of authentication.

Preventing an Access Request with a Blank Username from Being Sent to the RADIUS Server

The following configuration steps provide the ability to prevent an Access Request with a blank username from being sent to the RADIUS server. This functionality ensures that unnecessary RADIUS server interaction is avoided, and RADIUS logs are kept short.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	

	Command or Action	Purpose
	Device# configure terminal	
Step 3	aaa new-model	Enables AAA globally.
	Example:	
	Device(config)# configure terminal	
Step 4	aaa authentication suppress null-username Example:	Prevents an Access Request with a blank username from being sent to the RADIUS server.
	Device(config)# aaa authentication suppress null-username	
Step 5	end	Exits global configuration mode and returns to
	Example:	privileged EXEC mode.
	Device(config)# end	

Configuring Message Banners for AAA Authentication

AAA supports the use of configurable, personalized login and failed-login banners. You can configure message banners that will be displayed when a user logs in to the system to be authenticated using AAA and when, for whatever reason, authentication fails.

Configuring a Login Banner

To configure a banner that is displayed when a user logs in (replacing the default message for login), perform the following task:

Before you begin

To create a login banner, you must configure a delimiting character that notifies the system that the following text string must be displayed as the banner, and then the text string itself. The delimiting character is repeated at the end of the text string to signify the end of the banner. The delimiting character can be any single character in the extended ASCII character set, but once defined as the delimiter, that character cannot be used in the text string for the banner.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	

Command or Action	Purpose
configure terminal	Enters global configuration mode.
Example:	
Device# configure terminal	
aaa new-model	Enables AAA.
Example:	
Device(config)# aaa new-model	
aaa authentication banner delimiter string delimiter	Creates a personalized login banner.
Example:	
Device(config)# aaa authentication banner *Unauthorized use is prohibited.*	
end	Exits global configuration mode and returns to
Example:	privileged EXEC mode.
Device(config)# end	
	<pre>configure terminal Example: Device# configure terminal aaa new-model Example: Device(config)# aaa new-model aaa authentication banner delimiter string delimiter Example: Device(config)# aaa authentication banner *Unauthorized use is prohibited.* end Example:</pre>

Configuring a Failed-Login Banner

To configure a message that is displayed when a user login fails (replacing the default message for failed login), perform the following task:

Before you begin

To create a failed-login banner, you must configure a delimiting character, which notifies the system that the following text string must be displayed as the banner, and then configure the text string itself. The delimiting character is repeated at the end of the text string to signify the end of the failed-login banner. The delimiting character can be any single character in the extended ASCII character set, but once defined as the delimiter, that character cannot be used in the text string making up the banner.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	

Command or Action	Purpose
Device# configure terminal	
aaa new-model	Enables AAA.
Example:	
Device(config)# aaa new-model	
aaa authentication fail-message delimiter string delimiter	Creates a message to be displayed when a user login fails.
Example:	
Device(config)# aaa authentication fail-message *Failed login. Try again.*	
end	Exits global configuration mode and returns to
Example:	privileged EXEC mode.
Device(config)# end	
_	<pre>aaa new-model Example: Device(config)# aaa new-model aaa authentication fail-message delimiter string delimiter Example: Device(config)# aaa authentication fail-message *Failed login. Try again.* end Example:</pre>

Configuring AAA Packet of Disconnect

Packet of disconnect (POD) terminates connections on the network access server (NAS) when particular session attributes are identified. By using session information obtained from AAA, the POD client residing on a UNIX workstation sends disconnect packets to the POD server running on the network access server. The NAS terminates any inbound user session with one or more matching key attributes. It rejects requests when required fields are missing or when an exact match is not found.

To configure POD, perform the following tasks in global configuration mode:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	aaa accounting network default start-stop radius	Enables AAA accounting records.

	Command or Action	Purpose
	Example:	
	Device(config)# aaa accounting network default start-stop radius	
Step 4	aaa accounting delay-start Example:	(Optional) Delays generation of the start accounting record until the Framed-IP-Address is assigned, allowing its use in the POD packet.
	Device(config)# aaa accounting delay-start	
Step 5	aaa pod server server-key string	Enables POD reception.
	Example:	
	Device(config)# aaa pod server server-key xyz123	
Step 6	radius server name non-standard Example:	Configures a RADIUS server and enters RADIUS server configuration mode.
	Device(config)# radius server radser	
Step 7	address {ipv4 ipv6} hostname	Configures a RADIUS host.
	Example:	
	Device(config-radius-server)# address ipv4 radius-host	
Step 8	end	Exits RADIUS server configuration mode and
	Example:	returns to privileged EXEC mode.
	Device(config-radius-server)# end	

Configuring Double Authentication

To configure double authentication, perform the following steps:

- 1. Enable AAA by using the aaa-new model global configuration command.
- **2.** Use the **aaa authentication** command to configure your network access server to use login and PPP authentication method lists, then apply those method lists to the appropriate lines or interfaces.
- 3. Use the aaa authorization command to configure AAA network authorization at login.
- 4. Configure security protocol parameters (for example, RADIUS or TACACS+).

- 5. Use access control list AV pairs on the security server that the user can connect to the local host only by establishing a Telnet connection.
- 6. (Optional) Configure the access-profilecommand as an autocommand. If you configure the autocommand, remote users will not have to manually enter the access-profile command to access authorized rights associated with their personal user profile.

Note If the **access-profile** command is configured as an autocommand, users will still have to Telnet to the local host and log in to complete double authentication.

Follow these rules when creating the user-specific authorization statements (These rules relate to the default behavior of the **access-profile** command):

- Use valid AV pairs when configuring access control list AV pairs on the security server.
- For remote users to use the interface's existing authorization (that which existed prior to the second stage authentication/authorization), but you want them to have different access control lists (ACLs), you should specify *only* ACL AV pairs in the user-specific authorization definition. This might be desirable if you set up a default authorization profile to apply to the remote host, but want to apply specific ACLs to specific users.
- When these user-specific authorization statements are later applied to the interface, they can either be *added to* the existing interface configuration or they can *replace* the existing interface configuration--depending on which form of the **access-profile** command is used to authorize the user. You should understand how the **access-profile** command works before configuring the authorization statements.
- If you will be using ISDN or Multilink PPP, you must also configure virtual templates at the local host.

Enabling Automated Double Authentication

You can make the double authentication process easier for users by implementing automated double authentication. Automated double authentication provides all of the security benefits of double authentication, but offers a simpler, more user-friendly interface for remote users. With double authentication, a second level of user authentication is achieved when the user Telnets to the network access server or router and enters a username and password. With automated double authentication, the user does not have to Telnet to the network access server; instead the user responds to a dialog box that requests a username and password or personal identification number (PIN). To use the automated double authentication feature, the remote user hosts must be running a companion client application.

Note Automated double authentication, like the existing double authentication feature, is for Multilink PPP ISDN connections only. Automated double authentication cannot be used with other protocols such as X.25 or SLIP.

Automated double authentication is an enhancement to the existing double authentication feature. To configure automated double authentication, you must first configure double authentication by completing the following steps:

1. Enable AAA by using the **aaa-new model** global configuration command.

- 2. Use the **aaa authentication** command to configure your network access server to use login and PPP authentication method lists, then apply those method lists to the appropriate lines or interfaces.
- 3. Use the **aaa authorization** command to configure AAA network authorization at login.
- 4. Configure security protocol parameters (for example, RADIUS or TACACS+).
- 5. Use access control list AV pairs on the security server that the user can connect to the local host only by establishing a Telnet connection.
- 6. Configure the access-profilecommand as an autocommand. If you configure the autocommand, remote users will not have to manually enter the access-profile command to access authorized rights associated with their personal user profile.

Note If the **access-profile** command is configured as an autocommand, users will still have to Telnet to the local host and log in to complete double authentication.

Follow these rules when creating the user-specific authorization statements (These rules relate to the default behavior of the **access-profile** command):

- Use valid AV pairs when configuring access control list AV pairs on the security server.
- If you want remote users to use the interface's existing authorization (that which existed prior to the second stage authentication/authorization), but you want them to have different access control lists (ACLs), you should specify *only* ACL AV pairs in the user-specific authorization definition. This might be desirable if you set up a default authorization profile to apply to the remote host, but want to apply specific ACLs to specific users.
- When these user-specific authorization statements are later applied to the interface, they can either be *added to* the existing interface configuration, or *replace* the existing interface configuration-depending on which form of the **access-profile** command is used to authorize the user. You should understand how the **access-profile** command works before configuring the authorization statements.
- If you will be using ISDN or Multilink PPP, you must also configure virtual templates at the local host.

Configuring Automated Double Authentication

To configure automated double authentication, perform the following task:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	

	Command or Action	Purpose
Step 3	ip trigger-authentication [timeout seconds] [port number]	Enables automation of double authentication.
	Example:	
	Device(config)# ip trigger-authentication timeout 120	
Step 4	interface type number	Configures an interface and enter the interface
	Example:	configuration mode.
	Device(config)# interface gigabitethernet 1/0/17	
Step 5	ip trigger-authentication	Applies automated double authentication to the
	Example:	interface.
	Device(config-if)# ip rigger-authentication	
Step 6	end	Exits interface configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-if)# end	

Troubleshooting Automated Double Authentication

To troubleshoot automated double authentication, use the following commands in privileged EXEC mode:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	show ip trigger-authentication	Displays the list of remote hosts for which
-	Example:	automated double authentication has been attempted (successfully or unsuccessfully)
	Device# show ip trigger-authentication	
Step 3	clear ip trigger-authentication	Clears the list of remote hosts for which
	Example:	automated double authentication has been

	Command or Action	Purpose
	Device# clear ip trigger-authentication	attempted. (This clears the table displayed by the show ip trigger-authentication command.)
Step 4	debug ip trigger-authentication Example:	Displays debug output related to automated double authentication.
	Device# debug ip trigger-authentication	

Configuring Domain Stripping at the Server Group Level

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	aaa group server radius server-name	Adds the RADIUS server and enters server
	Example:	group RADIUS configuration mode.
	Device(config)# aaa group server radius radl	• The <i>server-name</i> argument specifies the RADIUS server group name.
Step 4	domain-stripping [strip-suffix word] [right-to-left] [prefix-delimiter word] [delimiter word]	Configures domain stripping at the server group level.
	Example:	
	Device(config-sg-radius)# domain-stripping delimiter username@example.com	
Step 5	end	Exits server group RADIUS configuration mode
	Example:	and returns to the privileged EXEC mode.
	Device(config-sg-radius)# end	

Configuring Non-AAA Authentication Methods

Configuring Line Password Protection

This task is used to provide access control on a terminal line by entering the password and establishing password checking.

Note If you configure line password protection and then configure TACACS or extended TACACS, the TACACS username and password take precedence over line passwords. If you have not yet implemented a security policy, we recommend that you use AAA.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	line [aux console tty vty] line-number [ending-line-number]	Enters line configuration mode.
	Example:	
	Device(config)# line console 0	
Step 4	password password	Assigns a password to a terminal or other device
	Example:	on a line. The password checker is case sensitive and can include spaces; for example, the
	Device(config-line)# secret word	password "Secret" is different from the password "secret," and "two words" is an acceptable password.
Step 5	login	Enables password checking at login.
	Example:	You can disable line password verification by disabling password checking by using the no
	Device(config-line)# login	version of this command.

	Command or Action	Purpose
		NoteThe login command only changes username and privilege level but it does not execute a shell; therefore autocommands will not be executed. To execute autocommands under this circumstance, you need to establish a Telnet session back into the device (loop-back). Make sure that the device has been configured for secure Telnet sessions if you choose to implement autocommands this way.
Step 6	end Example:	Exits line configuration mode and returns to privileged EXEC mode.
	Device(config-line)# end	

Establishing Username Authentication

You can create a username-based authentication system, which is useful in the following situations:

- To provide a TACACS-like username and encrypted password-authentication system for networks that cannot support TACACS
- To provide special-case logins: for example, access list verification, no password verification, autocommand execution at login, and "no escape" situations

To establish username authentication, perform the following task:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	

	Command or Action	Purpose
Step 3	<pre>Do one of the following: • username name [nopassword password password encryption-type encrypted password] • username name [access-class number] Example: Device(config)# username superuser password superpassword password 7 encrypted-password Device(config)# username user1</pre>	Establishes username authentication with encrypted passwords. or (Optional) Establishes username authentication by access list.
Step 4	access-class access-user username name [privilege level] Example: Device(config) # username user1 privilege 5	(Optional) Sets the privilege level for the user
Step 5	username name [autocommand command] Example: Device(config) # username user1 autocommand show users	(Optional) Specifies a command to be executed automatically.
Step 6	username name [noescape] [nohangup] Example: Device (config) # username user1 noescapee	(Optional) Sets a "no escape" login environment.
Step 7	end Example: Device(config)# end	Exits global configuration mode and returns to privileged EXEC mode.

What to do next

The keyword **noescape** prevents users from using escape characters on the hosts to which they are connected. The **nohangup** feature does not disconnect after using the autocommand.

Caution

Passwords will be displayed in clear text in your configuration unless you enable the **service password-encryption** command.

Defining PPP Authentication Using MS-CHAP

To define PPP authentication using MS-CHAP, use the following commands in interface configuration mode:

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	encapsulation ppp	Enables PPP encapsulation.
	Example:	
	Device(config)# encapsulation ppp	
Step 4	interface type number	Configures an interface and enters interface
	Example:	configuration mode.
	Device(config)# interface gigabitethernet 1/0/2	
Step 5	ppp authentication ms-chap [if-needed] [<i>list-name</i> default] [callin] [one-time]	Defines PPP authentication using MS-CHAP.
	Example:	
	Device(config-if)# ppp authentication ms-chap default callin	
Step 6	end	Exits interface configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-if)# end	

What to do next

If you configure **ppp authentication ms-chap** on an interface, all incoming calls on that interface that initiate a PPP connection will have to be authenticated using MS-CHAP. If you configure the **ppp authentication** command with the **callin** keyword, the access server will only authenticate the remote device if the remote device initiated the call.

Authentication method lists and the **one-time** keyword are only available if you have enabled AAA--they will not be available if you are using TACACS or extended TACACS. If you specify the name of an

authentication method list with the **ppp authentication** command, PPP will attempt to authenticate the connection using the methods defined in the specified method list. If AAA is enabled and no method list is defined by name, PPP will attempt to authenticate the connection using the methods defined as the default. The **ppp authentication** command with the **one-time** keyword enables support for one-time passwords during authentication.

The **if-needed** keyword is only available if you are using TACACS or extended TACACS. The **ppp authentication**command with the **if-needed** keyword means that PPP will only authenticate the remote device via MS-CHAP if that device has not yet authenticated during the life of the current call. If the remote device authenticated through a standard login procedure and initiated PPP from the EXEC prompt, PPP will not authenticate through MS-CHAP if **ppp authentication chap if-needed** is configured.

Note

 If PPP authentication using MS-CHAP is used with username authentication, you must include the MS-CHAP secret in the local username/password database.

Configuration Examples for Authentication

Example: Configuring Method Lists

Suppose the system administrator has decided on a security solution where all interfaces will use the same authentication methods to authenticate PPP connections. In the RADIUS group, R1 is contacted first for authentication information, then if there is no response, R2 is contacted. If R2 does not respond, T1 in the TACACS+ group is contacted; if T1 does not respond, T2 is contacted. If all designated servers fail to respond, authentication falls to the local username database on the access server itself. To implement this solution, the system administrator would create a default method list by entering the following command:

Device> enable Device# configure terminal Device(config)# aaa authentication ppp default group radius group tacacs+ local Device(config)# exit

In this example, "default" is the name of the method list. The protocols included in this method list are listed after the name, in the order they are to be queried. The default list is automatically applied to all interfaces.

When a remote user attempts to dial in to the network, the network access server first queries R1 for authentication information. If R1 authenticates the user, it issues a PASS response to the network access server and the user is allowed to access the network. If R1 returns a FAIL response, the user is denied access and the session is terminated. If R1 does not respond, then the network access server processes that as an ERROR and queries R2 for authentication information. This pattern would continue through the remaining designated methods until the user is either authenticated or rejected, or until the session is terminated.

It is important to remember that a FAIL response is significantly different from an ERROR. A FAIL means that the user has not met the criteria contained in the applicable authentication database to be successfully authenticated. Authentication ends with a FAIL response. An ERROR means that the security server has not responded to an authentication query. Because of this, no authentication has been attempted. Only when an ERROR is detected will AAA select the next authentication method defined in the authentication method list.

Suppose the system administrator wants to apply a method list only to a particular interface or set of interfaces. In this case, the system administrator creates a named method list and then applies this named list to the applicable interfaces. The following example shows how the system administrator can implement an authentication method that will be applied only to interface 3:

```
Device> enable
Device# configure terminal
Device(config)# Device(config)#
Device(config)# aaa authentication ppp server-group1 group radius group tacacs+ local none
Device(config)# interface gigabitethernet 1/0/3
Device(config-if)# ppp authentication chap server-group1
Device(config-if)# end
```

In this example, "apple" is the name of the method list, and the protocols included in this method list are listed after the name in the order in which they are to be performed. After the method list has been created, it is applied to the appropriate interface. Note that the method list name (apple) in both the AAA and PPP authentication commands must match.

In the following example, the system administrator uses server groups to specify that only R2 and T2 are valid servers for PPP authentication. To do this, the administrator must define specific server groups whose members are R2 (172.16.2.7) and T2 (172.16.2.77), respectively. In this example, the RADIUS server group "rad2only" is defined as follows using the **aaa group server** command:

```
Device> enable
Device# configure terminal
Device(config)# aaa group server radius rad2only
Device(config-sg-radius)# server 172.16.2.7
Device(config-sg-radius)# end
```

The TACACS+ server group "tac2only" is defined as follows using the **aaa group server** command:

```
Device> enable
Device# configure terminal
Device(config)# aaa group server tacacs+ tac2only
Device(config-sg-tacacs)# server 172.16.2.77
Device(config-sg-tacacs)# end
```

The administrator then applies PPP authentication using the server groups. In this example, the default methods list for PPP authentication follows this order: group rad2only, group tac2only, and local:

```
Device> enable
Device# configure terminal
Device(config)# aaa authentication ppp default group rad2only group tac2only local
Device(config)# exit
```

If a method list is configured under VTY lines, the corresponding method list must be added to AAA. The following example shows how to configure a method list under a VTY line:

```
Device> enable
Device# configure terminal
Device(config)# line vty 0 4
Device(config-line)# authorization commands 15 auth1
Device(config-line)# exit
```

The following example shows how to configure a method list in AAA:

```
Device> enable
Device# configure terminal
Device(config)# aaa new-model
Device(config)# aaa authorization commands 15 auth1 group tacacs+
Device(config)# exit
```

If no method list is configured under VTY lines, the default method list must be added to AAA. The following example shows a VTY configuration without a method list:

```
Device> enable
Device# configure terminal
Device(config)# line vty 0 4
Device(config-line)# end
```

The following example shows how to configure the default method list:

```
Device> enable
Device# configure terminal
Device(config)# aaa new-model
Device(config)# aaa authorization commands 15 default group tacacs+
Device(config)# exit
```

Example: RADIUS Authentication

This section provides two sample configurations using RADIUS.

The following example shows how to configure the router to authenticate and authorize using RADIUS:

```
Device> enable
Device# configure terminal
Device(config)# aaa authentication login radius-login group radius local
Device(config)# aaa authentication ppp radius-ppp if-needed group radius
Device(config)# aaa authorization exec default group radius if-authenticated
Device(config)# aaa authorization network default group radius
Device(config)# line 3
Device(config-line)# login authentication radius-login
Device(config-line)# exit
Device(config)# interface gigabitethernet 1/0/1
Device(config-if)# ppp authentication radius-ppp
Device(config-if)# end
```

The lines in this sample RADIUS authentication and authorization configuration are defined as follows:

- The aaa authentication login radius-login group radius local command configures the router to use RADIUS for authentication at the login prompt. If RADIUS returns an error, the user is authenticated using the local database.
- The aaa authentication ppp radius-ppp if-needed group radius command configures the Cisco IOS XE software to use PPP authentication using CHAP or PAP if the user has not already logged in. If the EXEC facility has authenticated the user, PPP authentication is not performed.
- The aaa authorization exec default group radius if-authenticated command queries the RADIUS database for information that is used during EXEC authorization, such as autocommands and privilege levels, but only provides authorization if the user has successfully authenticated.
- The aaa authorization network default group radius command queries RADIUS for network authorization, address assignment, and other access lists.
- The login authentication radius-login command enables the radius-login method list for line 3.
- The ppp authentication radius-ppp command enables the radius-ppp method list for serial interface 0.

The following example shows how to configure the router to prompt for and verify a username and password, authorize the user's EXEC level, and specify it as the method of authorization for privilege level 2. In this example, if a local username is entered at the username prompt, that username is used for authentication.

If the user is authenticated using the local database, EXEC authorization using RADIUS will fail because no data is saved from the RADIUS authentication. The method list also uses the local database to find an autocommand. If there is no autocommand, the user becomes the EXEC user. If the user then attempts to issue commands that are set at privilege level 2, TACACS+ is used to attempt to authorize the command.

```
Device> enable
Device# configure terminal
Device(config)# aaa authentication login default group radius local
Device(config)# aaa authorization exec default group radius local
Device(config)# aaa authorization command 2 default group tacacs+ if-authenticated
Device(config)# radius server radserver
Device(config-sg-radius)# address ipv4 10.2.3.1
Device(config)# radius-server attribute 44 include-in-access-req
Device(config)# radius-server attribute 8 include-in-access-req
Device(config)# end
```

The lines in this sample RADIUS authentication and authorization configuration are defined as follows:

- The aaa authentication login default group radius local command specifies that the username and password are verified by RADIUS or, if RADIUS is not responding, by the router's local user database.
- The aaa authorization exec default group radius local command specifies that RADIUS authentication information be used to set the user's EXEC level if the user authenticates with RADIUS. If no RADIUS information is used, this command specifies that the local user database be used for EXEC authorization.
- The aaa authorization command 2 default group tacacs+ if-authenticated command specifies TACACS+ authorization for commands set at privilege level 2, if the user has already successfully authenticated.
- The radius-server attribute 44 include-in-access-req command sends RADIUS attribute 44 (Acct-Session-ID) in access-request packets.
- The radius-server attribute 8 include-in-access-req command sends RADIUS attribute 8 (Framed-IP-Address) in access-request packets.

Example: TACACS Authentication

The following example shows how to configure TACACS+ as the security protocol to be used for PPP authentication:

```
Device> enable
Device# configure terminal
Device(config)# aaa new-model
Device(config)# aaa authentication ppp test group tacacs+ local
Device(config)# interface gigabitethernet 1/1/2
Device(config-if)# ppp authentication chap pap test
Device(config-if)# exit
Device(config)# tacacs server server1
Device(config-server-tacacs)# address ipv4 192.0.2.3
Device(config-server-tacacs)# key key1
Device(config-server-tacacs)# end
```

The lines in this sample TACACS+ authentication configuration are defined as follows:

• The aaa new-model command enables the AAA security services.

- The **aaa authentication** command defines a method list, "test," to be used on serial interfaces running PPP. The keywords **group tacacs**+ means that authentication will be done through TACACS+. If TACACS+ returns an ERROR of some sort during authentication, the keyword **local** indicates that authentication will be attempted using the local database on the network access server.
- The interface command selects the line.
- The **ppp authentication** command applies the test method list to this line.
- The address ipv4 command identifies the TACACS+ daemon as having an IP address of 192.0.2.3.
- The key command defines the shared encryption key to be "key1."

The following example shows how to configure AAA authentication for PPP:

Device(config)# aaa authentication ppp default if-needed group tacacs+ local

In this example, the keyword **default** means that PPP authentication is applied by default to all interfaces. The **if-needed** keyword means that if the user has already authenticated by going through the ASCII login procedure, then PPP is not necessary and can be skipped. If authentication is needed, the keywords **group tacacs**+ means that authentication will be done through TACACS+. If TACACS+ returns an ERROR of some sort during authentication, the keyword **local** indicates that authentication will be attempted using the local database on the network access server.

The following example shows how to create the same authentication algorithm for PAP, but it calls the method list "MIS-access" instead of "default":

```
Device> enable
Device# configure terminal
Device(config)# aaa authentication ppp MIS-access if-needed group tacacs+ local
Device(config)# interface gigabitethernet 1/1/2
Device(config)# ppp authentication pap MIS-access
Device(config)# end
```

In this example, because the list does not apply to any interfaces (unlike the default list, which applies automatically to all interfaces), the administrator must select interfaces to which this authentication scheme should apply by using the **interface** command. The administrator must then apply this method list to those interfaces by using the **ppp authentication** command.

Example: Kerberos Authentication

To specify Kerberos as the login authentication method, use the following command:

```
Device> enable
Device# configure terminal
Device(config)# aaa authentication login default krb5
Device(config)# end
```

To specify Kerberos authentication for PPP, use the following command:

```
Device> enable
Device# configure terminal
Device(config)# aaa authentication ppp default krb5
Device(config)# end
```

Example: AAA Scalability

The following example shows a general security configuration using AAA with RADIUS as the security protocol. In this example, the network access server is configured to allocate 16 background processes to handle AAA requests for PPP.

```
Device> enable
Device# configure terminal
Device (config) # aaa new-model
Device (config) # radius server radserver
Device (config-sg-radius) # address ipv4 radius-host
Device(config-sg-radius) # key myRaDiUSpassWoRd
Device (config-sg-radius) # exit
Device(config)# radius-server configure-nas
Device (config) # username root password ALongPassword
Device (config) # aaa authentication ppp dialins group radius local
Device(config)# aaa authentication login admins local
Device (config) # aaa authorization network default group radius local
Device (config) # aaa accounting network default start-stop group radius
Device(config) # aaa processes 16
Device(config) # line 1 16
Device (config-line) # autoselect ppp
Device (config-line) # autoselect during-login
Device (config-line) # login authentication admins
Device(config-line) # modem dialin
Device (config-line) # exit
Device (config) # interface gigabitethernet 1/2/0
Device (config-if) # group-range 1 16
Device(config-if) # encapsulation ppp
Device(config-if) # ppp authentication pap dialins
Device (config-if) # end
```

The lines in this sample RADIUS AAA configuration are defined as follows:

- The aaa new-model command enables AAA network security services.
- The **address ipv4** {*host-address*} command defines the name of the RADIUS server host.
- The key command defines the shared secret text string between the network access server and the RADIUS server host.
- The **radius-server configure-nas** command defines that the Cisco router or access server will query the RADIUS server for static routes and IP pool definitions when the device first starts up.
- The **username** command defines the username and password to be used for the PPP Password Authentication Protocol (PAP) caller identification.
- The **aaa authentication ppp dialins group radius local** command defines the authentication method list "dialins," which specifies that RADIUS authentication, then (if the RADIUS server does not respond) local authentication will be used on serial lines using PPP.
- The **aaa authentication login admins local** command defines another method list, "admins," for login authentication.
- The **aaa authorization network default group radius local** command is used to assign an address and other network parameters to the RADIUS user.
- The aaa accounting network default start-stop group radius command tracks PPP usage.
- The aaa processes command allocates 16 background processes to handle AAA requests for PPP.

- The line command switches the configuration mode from global configuration to line configuration and identifies the specific lines being configured.
- The **autoselect ppp** command allows a PPP session to start up automatically on these selected lines.
- The **autoselect during-login** command is used to display the username and password prompt without pressing the Return key. After the user logs in, the autoselect function (in this case, PPP) begins.
- The login authentication admins command applies the "admins" method list for login authentication.
- The **modem dialin** command configures modems attached to the selected lines to only accept incoming calls.
- The interface group-async command selects and defines an asynchronous interface group.
- The group-range command defines the member asynchronous interfaces in the interface group.
- The encapsulation ppp command sets PPP as the encapsulation method used on the specified interfaces.
- The **ppp authentication pap dialins**command applies the "dialins" method list to the specified interfaces.

Example: Configuring Login and Failed-Login Banners for AAA Authentication

The following example shows how to configure a login banner that is displayed when a user logs in to the system, (in this case, the phrase "Unauthorized Access Prohibited"). The asterisk (*) is used as the delimiting character. RADIUS is specified as the default login authentication method.

```
Device> enable
Device# configure terminal
Device(config)# aaa new-model
Device(config)# aaa authentication banner *Unauthorized Access Prohibited*
Device(config)# aaa authentication login default group radius
Device(config)# end
```

This configuration displays the following login banner:

Unauthorized Access Prohibited Username:

The following example shows how to configure a failed-login banner that is displayed when a user tries to log in to the system and fails, (in this case, the phrase "Failed login. Try again"). The asterisk (*) is used as the delimiting character. RADIUS is specified as the default login authentication method.

```
Device> enable
Device# configure terminal
Device(config)# aaa new-model
Device(config)# aaa authentication banner *Unauthorized Access Prohibited*
Device(config)# aaa authentication fail-message *Failed login. Try again.*
Device(config)# aaa authentication login default group radius
Device(config)# end
```

This configuration displays the following login and failed-login banner:

```
Unauthorized Access Prohibited
Username:
Password:
Failed login. Try again.
```

Example: AAA Packet of Disconnect Server Key

The following example shows how to configure POD (packet of disconnect), which terminates connections on the network access server (NAS) when particular session attributes are identified.

```
Device> enable
Device# configure terminal
Device(config)# aaa new-model
Device(config)# aaa authentication ppp default radius
Device(config)# aaa accounting network default start-stop radius
Device(config)# aaa accounting delay-start
Device(config)# aaa pod server server-key xyz123
Device(config)# radius server non-standard
Device(config-sg-radius)# address ipv4 10.2.1.1
Device(config-sg-radius)# key rad123
Device(config-sg-radius)# end
```

Example: Double Authentication

The examples in this section illustrate possible configurations to be used with double authentication. Your configurations could differ significantly, depending on your network and security requirements.

These configuration examples include specific IP addresses and other specific information. This information is for illustration purposes only: your configuration will use different IP addresses, different usernames and passwords, and different authorization statements.

Example: Configuration of the Local Host for AAA with Double Authentication

These two examples show how to configure a local host to use AAA for PPP and login authentication, and for network and EXEC authorization. An example each is shown for RADIUS and for TACACS+.

In both the examples, the first three lines configure AAA with a specific server as the AAA server. The next two lines configure AAA for PPP and login authentication, and the last two lines configure network and EXEC authorization. The last line is necessary only if the **access-profile** command will be executed as an autocommand.

The following example shows device configuration with a RADIUS AAA server:

```
Device> enable
Device# configure terminal
Device(config)# aaa new-model
Device(config)# radius server radserver
Device(config-sg-radisu)# address ipv4 secureserver
Device(config-sg-radius)# key myradiuskey
Device(config)# aaa authentication ppp default group radius
Device(config)# aaa authentication login default group radius
Device(config)# aaa authorization network default group radius
Device(config)# aaa authorization exec default group radius
Device(config)# end
```

The following example shows device configuration with a TACACS+ server:

Device> enable Device# configure terminal

```
Device(config)# aaa new-model
Device(config)# tacacs server server1
Device(config-server-tacacs)# address ipv4 192.0.2.3
Device(config-server-tacacs)# key mytacacskey
Device(config-server-tacacs)# exit
Device(config)# aaa authentication ppp default group tacacs+
Device(config)# aaa authentication login default group tacacs+
Device(config)# aaa authorization network default group tacacs+
Device(config)# aaa authorization exec default group tacacs+
Device(config)# end
```

Example: Configuration of the AAA Server for First-Stage PPP Authentication and Authorization

This example shows a configuration on the AAA server. A partial sample AAA configuration is shown for RADIUS.

TACACS+ servers can be configured similarly. (See the Complete Configuration with TACACS Example.)

This example defines authentication/authorization for a remote host named "hostx" that will be authenticated by CHAP in the first stage of double authentication. Note that the ACL AV pair limits the remote host to Telnet connections to the local host. The local host has the IP address 10.0.0.2.

The following example shows a partial AAA server configuration for RADIUS:

```
hostx Password = "welcome"
User-Service-Type = Framed-User,
Framed-Protocol = PPP,
cisco-avpair = "lcp:interface-config=ip unnumbered fastethernet 0",
cisco-avpair = "ip:inacl#3=permit tcp any 172.21.114.0 0.0.0.255 eq telnet",
cisco-avpair = "ip:inacl#4=deny icmp any any",
cisco-avpair = "ip:route#5=10.0.0.0 255.0.0.0",
cisco-avpair = "ip:route#6=10.10.0.0 255.0.0.0",
cisco-avpair = "ip:x:inacl#3=deny any"
```

Example: Configuration of the AAA Server for Second-Stage Per-User Authentication and Authorization

This section contains partial sample AAA configurations on a RADIUS server. These configurations define authentication and authorization for a user with the username "user1," who will be user-authenticated in the second stage of double authentication.

TACACS+ servers can be configured similarly.

Three examples show sample RADIUS AAA configurations that could be used with each of the three forms of the **access-profile** command.

The first example shows a partial sample AAA configuration that works with the default form (no keywords) of the **access-profile** command. Note that only ACL AV pairs are defined. This example also sets up the **access-profile** command as an autocommand.

```
user1 Password = "welcome"
User-Service-Type = Shell-User,
cisco-avpair = "shell:autocmd=access-profile"
User-Service-Type = Framed-User,
Framed-Protocol = PPP,
cisco-avpair = "ip:inacl#3=permit tcp any host 10.0.0.2 eq telnet",
cisco-avpair = "ip:inacl#4=deny icmp any any"
```

The second example shows a partial sample AAA configuration that works with the **access-profile merge** form of the **access-profile** command. This example also sets up the **access-profile merge** command as an autocommand.

```
user1 Password = "welcome"
User-Service-Type = Shell-User,
cisco-avpair = "shell:autocmd=access-profile merge"
User-Service-Type = Framed-User,
Framed-Protocol = PPP,
cisco-avpair = "ip:inacl#3=permit tcp any any"
cisco-avpair = "ip:route=10.0.0.0 255.255.0.0",
cisco-avpair = "ip:route=10.1.0.0 255.255.0.0",
cisco-avpair = "ip:route=10.2.0.0 255.255.0.0"
```

The third example shows a partial sample AAA configuration that works with the **access-profile replace** form of the **access-profile** command. This example also sets up the **access-profile replace** command as an autocommand.

```
user1 Password = "welcome"
User-Service-Type = Shell-User,
cisco-avpair = "shell:autocmd=access-profile replace"
User-Service-Type = Framed-User,
Framed-Protocol = PPP,
cisco-avpair = "ip:inacl#3=permit tcp any any",
cisco-avpair = "ip:inacl#4=permit icmp any any",
cisco-avpair = "ip:route=10.10.0.0 255.255.0.0",
cisco-avpair = "ip:route=10.11.0.0 255.255.0.0",
cisco-avpair = "ip:route=10.12.0.0 255.255.0.0"
```

Example: Complete Configuration with TACACS

This example shows TACACS+ authorization profile configurations both for the remote host (used in the first stage of double authentication) and for specific users (used in the second stage of double authentication).

This sample configuration shows authentication/authorization profiles on the TACACS+ server for the remote host "hostx" and for three users, with the usernames "user_default," "user_merge," and "user_replace." The configurations for these three usernames illustrate different configurations that correspond to the three different forms of the **access-profile** command. The three user configurations also illustrate setting up the autocommand for each form of the **access-profile** command.

The figure below shows the topology. The example that follows the figure shows a TACACS+ configuration file.

Figure 3: Example Topology for Double Authentication

This sample configuration shows authentication/authorization profiles on the TACACS+ server for the remote host "hostx" and for three users, with the usernames "user_default," "user_merge," and "user_replace."

```
key = "mytacacskey"
default authorization = permit
#-----Remote Host (BRI)------
# This allows the remote host to be authenticated by the local host
# during fist-stage authentication, and provides the remote host
# authorization profile.
#_____
user = hostx
{
   login = cleartext "welcome"
   chap = cleartext "welcome"
   service = ppp protocol = lcp {
               interface-config="ip unnumbered fastethernet 0"
   }
   service = ppp protocol = ip {
           # It is important to have the hash sign and some string after
           # it. This indicates to the NAS that you have a per-user
           # config.
           inacl#3="permit tcp any 172.21.114.0 0.0.0.255 eq telnet"
           inacl#4="deny icmp any any"
           route#5="10.0.0.0 255.0.0.0"
           route#6="10.10.0.0 255.0.0.0"
   }
   service = ppp protocol = ipx {
           # see previous comment about the hash sign and string, in protocol = ip
           inacl#3="deny any"
   }
#----- "access-profile" default user "only acls" ------
# Without arguments, access-profile removes any access-lists it can find
# in the old configuration (both per-user and per-interface), and makes sure
# that the new profile contains ONLY access-list definitions.
# -
user = user default
{
       login = cleartext "welcome"
       chap = cleartext "welcome"
       service = exec
       {
               # This is the autocommand that executes when user default logs in.
               autocmd = "access-profile"
       }
       service = ppp protocol = ip {
               # Put whatever access-lists, static routes, whatever
               # here.
               # If you leave this blank, the user will have NO IP
               # access-lists (not even the ones installed prior to
               # this)!
               inacl#3="permit tcp any host 10.0.0.2 eq telnet"
               inacl#4="deny icmp any any"
       service = ppp protocol = ipx {
               # Put whatever access-lists, static routes, whatever
               # here.
               # If you leave this blank, the user will have NO IPX
               # access-lists (not even the ones installed prior to
               # this)!
       }
}
```

```
#----- "access-profile merge" user ------
# With the 'merge' option, first all old access-lists are removed (as before),
# but then (almost) all AV pairs are uploaded and installed. This will allow
# for uploading any custom static routes, sap-filters, and so on, that the user
# may need in his or her profile. This needs to be used with care, as it leaves
# open the possibility of conflicting configurations.
# - - -
user = user_merge
{
       login = cleartext "welcome"
       chap = cleartext "welcome"
       service = exec
               # This is the autocommand that executes when user merge logs in.
               autocmd = "access-profile merge"
       1
       service = ppp protocol = ip
        {
               # Put whatever access-lists, static routes, whatever
               # here.
               # If you leave this blank, the user will have NO IP
               # access-lists (not even the ones installed prior to
               # this)!
               inacl#3="permit tcp any any"
               route#2="10.0.0.0 255.255.0.0"
               route#3="10.1.0.0 255.255.0.0"
               route#4="10.2.0.0 255.255.0.0"
       }

Feature History for Configuring Authentication

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.11.1	AAA Authentication	Authentication provides a method to identify users, which includes the login and password dialog, challenge and response, messaging support, and encryption, depending on the selected security protocol. Authentication is the way a user is identified prior to being allowed access to the network and network services.
Cisco IOS XE Cupertino 17.7.1	AAA Authentication	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

Configuring Authorization

AAA authorization enables you to limit the services available to a user. When AAA authorization is enabled, the network access server uses information retrieved from the user's profile, which is located either in the local user database or on the security server, to configure the user's session. Once this is done, the user will be granted access to a requested service only if the information in the user profile allows it.

- Prerequisites for Configuring Authorization, on page 79
- Information About Configuring Authorization, on page 80
- How to Configure Authorization, on page 83
- Configuration Examples for Authorization, on page 86
- Feature History for Configuring Authorization, on page 89

Prerequisites for Configuring Authorization

Before configuring authorization using named method lists, you must first perform the following tasks:

- Enable authentication, authorization, and accounting (AAA) on your network access server.
- Configure AAA authentication. Authorization generally takes place after authentication and relies on authentication to work properly. For more information about AAA authentication, refer to the "Configuring Authentication" module.
- Define the characteristics of your RADIUS or TACACS+ security server if you are issuing RADIUS or TACACS+ authorization. For more information about configuring your Cisco network access server to communicate with your RADIUS security server, refer to the chapter "Configuring RADIUS". For more information about configuring your Cisco network access server to communicate with your TACACS+ security server, refer to the "Configuring TACACS+" module.
- Define the rights associated with specific users by using the **username** command if you are issuing local authorization.

Information About Configuring Authorization

Named Method Lists for Authorization

Method lists for authorization define the ways that authorization will be performed and the sequence in which these methods will be performed. A method list is simply a named list describing the authorization methods to be queried (such as RADIUS or TACACS+), in sequence. Method lists enable you to designate one or more security protocols to be used for authorization, thus ensuring a backup system in case the initial method fails. Cisco IOS XE software uses the first method listed to authorize users for specific network services; if that method fails to respond, the Cisco IOS XE software selects the next method listed in the list. This process continues until there is successful communication with a listed authorization method, or all methods defined are exhausted.

Note The Cisco IOS XE software attempts authorization with the next listed method only when there is no response from the previous method. If authorization fails at any point in this cycle--meaning that the security server or local username database responds by denying the user services--the authorization process stops and no other authorization methods are attempted.

Method lists are specific to the authorization type requested:

- Commands: Applies to the EXEC mode commands a user issues. Command authorization attempts authorization for all EXEC mode commands, including global configuration commands, associated with a specific privilege level.
- EXEC: Applies to the attributes associated with a user EXEC terminal session.
- Network: Applies to network connections. This can include a PPP, SLIP, or ARAP connection.
- · Reverse Access: Applies to reverse Telnet sessions.

When you create a named method list, you are defining a particular list of authorization methods for the indicated authorization type.

Once defined, method lists must be applied to specific lines or interfaces before any of the defined methods will be performed. The only exception is the default method list (which is named "default"). If the **aaa authorization** command for a particular authorization type is issued without a named method list specified, the default method list is automatically applied to all interfaces or lines except those that have a named method list explicitly defined. (A defined method list overrides the default method list.) If no default method list is defined, local authorization takes place by default.

AAA Authorization Methods

AAA supports five different methods of authorization:

• TACACS+: The network access server exchanges authorization information with the TACACS+ security daemon. TACACS+ authorization defines specific rights for users by associating attribute-value pairs, which are stored in a database on the TACACS+ security server, with the appropriate user.

- If-Authenticated: The user is allowed to access the requested function provided the user has been authenticated successfully.
- None: The network access server does not request authorization information; authorization is not performed over this line/interface.
- Local: The router or access server consults its local database, as defined by the **username** command, for example, to authorize specific rights for users. Only a limited set of functions can be controlled via the local database.
- RADIUS: The network access server requests authorization information from the RADIUS security server. RADIUS authorization defines specific rights for users by associating attributes, which are stored in a database on the RADIUS server, with the appropriate user.

Note With CSCuc32663, passwords and authorization logs are masked before being sent to the TACACS+, LDAP, or RADIUS security servers. Use the **aaa authorization commands visible-keys** command to send unmasked information to the TACACS+, LDAP, or RADIUS security servers.

Authorization Methods

To have the network access server request authorization information via a TACACS+ security server, use the **aaa authorization** command with the **group tacacs**+ *method* keyword. For more specific information about configuring authorization using a TACACS+ security server, refer to the chapter "Configuring TACACS+." For an example of how to enable a TACACS+ server to authorize the use of network services, including PPP and ARA, see the TACACS Authorization Examples.

To allow users to have access to the functions they request as long as they have been authenticated, use the **aaa authorization** command with the **if-authenticated** *method* keyword. If you select this method, all requested functions are automatically granted to authenticated users.

There may be times when you do not want to run authorization from a particular interface or line. To stop authorization activities on designated lines or interfaces, use the **none** *method* keyword. If you select this method, authorization is disabled for all actions.

To select local authorization, which means that the router or access server consults its local user database to determine the functions a user is permitted to use, use the **aaa authorization** command with the **local** *method* keyword. The functions associated with local authorization are defined by using the **username** global configuration command. For a list of permitted functions, refer to the chapter "Configuring Authentication."

To have the network access server request authorization via a RADIUS security server, use the **radius** *method* keyword. For more specific information about configuring authorization using a RADIUS security server, refer to the Configuring RADIUS chapter.

To have the network access server request authorization via a RADIUS security server, use the **aaa authorization** command with the **group radius** *method* keyword. For more specific information about configuring authorization using a RADIUS security server, refer to the chapter Configuring RADIUS. For an example of how to enable a RADIUS server to authorize services, see the RADIUS Authorization Example.

Note

Authorization method lists for SLIP follow whatever is configured for PPP on the relevant interface. If no lists are defined and applied to a particular interface (or no PPP settings are configured), the default setting for authorization applies.

Method Lists and Server Groups

A server group is a way to group existing RADIUS or TACACS+ server hosts for use in method lists. The figure below shows a typical AAA network configuration that includes four security servers: R1 and R2 are RADIUS servers, and T1 and T2 are TACACS+ servers. R1 and R2 make up the group of RADIUS servers. T1 and T2 make up the group of TACACS+ servers.

Using server groups, you can specify a subset of the configured server hosts and use them for a particular service. For example, server groups allow you to define R1 and R2 as separate server groups, and T1 and T2 as separate server groups. This means you can specify either R1 and T1 in the method list or R2 and T2 in the method list, which provides more flexibility in the way that you assign RADIUS and TACACS+ resources.

Server groups also can include multiple host entries for the same server, as long as each entry has a unique identifier. The combination of an IP address and a UDP port number creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. In other words, this unique identifier enables RADIUS requests to be sent to different UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service--for example, authorization--the second host entry configured acts as fail-over backup to the first one. Using this example, if the first host entry fails to provide accounting services, the network access server will try the second host entry configured on the same device for accounting services. (The RADIUS host entries will be tried in the order they are configured.)

For more information about configuring server groups and about configuring server groups based on DNIS numbers, refer to the chapter Configuring RADIUS or the chapter Configuring TACACS+.

AAA Authorization Types

Cisco IOS XE software supports five different types of authorization:

- Commands: Applies to the EXEC mode commands a user issues. Command authorization attempts authorization for all EXEC mode commands, including global configuration commands, associated with a specific privilege level.
- EXEC: Applies to the attributes associated with a user EXEC terminal session.
- Network: Applies to network connections. This can include a PPP, SLIP, or ARAP connection.
- Reverse Access: Applies to reverse Telnet sessions.
- Configuration: Applies to downloading configurations from the AAA server.
- IP Mobile: Applies to authorization for IP mobile services.

Authorization Types

Named authorization method lists are specific to the indicated type of authorization.

To create a method list to enable authorization that applies specific security policies on a per-user basis, use the auth-proxy keyword. For detailed information on the authentication proxy feature, refer to the chapter "Configuring Authentication Proxy" in the "Traffic Filtering and Firewalls" part of this book.

To create a method list to enable authorization for all network-related service requests (including SLIP, PPP, PPP NCPs, and ARAP), use the **network** keyword.

To create a method list to enable authorization to determine if a user is allowed to run an EXEC shell, use the **exec** keyword.

To create a method list to enable authorization for specific, individual EXEC commands associated with a specific privilege level, use the **commands**keyword. (This allows you to authorize all commands associated with a specified command level from 0 to 15.)

To create a method list to enable authorization for reverse Telnet functions, use the reverse-access keyword.

For information about the types of authorization supported by the Cisco IOS XE software, refer to the AAA Authorization Types.

Authorization Attribute-Value Pairs

RADIUS and TACACS+ authorization both define specific rights for users by processing attributes, which are stored in a database on the security server. For both RADIUS and TACACS+, attributes are defined on the security server, associated with the user, and sent to the network access server where they are applied to the user's connection.

For a list of supported RADIUS attributes, refer to the "RADIUS Attributes Overview and RADIUS IETF Attributes" chapter. For a list of supported TACACS+ AV pairs, refer to the "Configuring TACACS+" chapter.

How to Configure Authorization

Configuring AAA Authorization Using Named Method Lists

To configure AAA authorization using named method lists, use the following commands beginning in global configuration mode:

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	

	Command or Action	Purpose
Step 3	aaa authorization {auth-proxy network exec commands level reverse-access configuration ipmobile} { default list-name } [method1 [method2]]	Creates an authorization method list for a particular authorization type and enable authorization.
	Example:	
	Device(config)# aaa authorization auth-proxy default	
Step 4	Do one of the following:	Enters the line configuration mode for the lines
	• line [aux console tty vty] line-number [ending-line-number]	to which you want to apply the authorization method list.
	• interface interface-type interface-number	Alternately, enters the interface configuration
	Example:	mode for the interfaces to which you want to apply the authorization method list.
	Device(config)# line 1	
	Device(config)# interface gigabitethernet 0/1/1	
Step 5	Do one of the following:	Applies the authorization list to a line or set of
	 authorization {arap commands level exec reverse-access} {default list-name} 	lines. Alternately, applies the authorization list to an interface or set of interfaces.
	• ppp authorization {default <i>list-name</i> }	
	Example:	
	Device(config-line)# authorization commands default	
	Device(config-if) # ppp authorization default	
Step 6	end	Exits line configuration mode and returns to
	Example:	privileged EXEC mode.
	Device(config-line)# end	Exits interface configuration mode and returns to privileged EXEC mode.
	Device(config-if)# end	

Disabling Authorization for Global Configuration Commands

The **aaa authorization** command with the keyword **commands** attempts authorization for all EXEC mode commands, including global configuration commands, associated with a specific privilege level. Because there are configuration commands that are identical to some EXEC-level commands, there can be some confusion in the authorization process. Using **no aaa authorization config-commands** stops the network access server from attempting configuration command authorization.

To disable AAA authorization for all global configuration commands, use the following command in global configuration mode:

Command	Purpose
Device(config)# no aaa authorization	Disables authorization for all global configuration commands.
config-commands	

To disable AAA authorization on the console, use the following command in global configuration mode:

Note

AAA authorization is disabled on the console by default. If AAA authorization is enabled on the console, disable it by configuring the **no aaa authorization console** command during the AAA configuration stage. AAA should be disabled on the console for user authentication.

Command	Purpose
Device(config)# no aaa authorization console	Disables authorization on the console.

Configuring Authorization for Reverse Telnet

Telnet is a standard terminal emulation protocol used for remote terminal connection. Normally, you log in to a network access server (typically through a dialup connection) and then use Telnet to access other network devices from that network access server. There are times, however, when it is necessary to establish a reverse Telnet session. In reverse Telnet sessions, the Telnet connection is established in the opposite direction--from inside a network to a network access server on the network periphery to gain access to modems or other devices connected to that network access server. Reverse Telnet is used to provide users with dialout capability by allowing them to Telnet to modem ports attached to a network access server.

It is important to control access to ports accessible through reverse Telnet. Failure to do so could, for example, allow unauthorized users free access to modems where they can trap and divert incoming calls or make outgoing calls to unauthorized destinations.

Authentication during reverse Telnet is performed through the standard AAA login procedure for Telnet. Typically the user has to provide a username and password to establish either a Telnet or reverse Telnet session. Reverse Telnet authorization provides an additional (optional) level of security by requiring authorization in addition to authentication. When enabled, reverse Telnet authorization can use RADIUS or TACACS+ to authorize whether or not this user is allowed reverse Telnet access to specific asynchronous ports, after the user successfully authenticates through the standard Telnet login procedure.

Reverse Telnet authorization offers the following benefits:

- An additional level of protection by ensuring that users engaged in reverse Telnet activities are indeed authorized to access a specific asynchronous port using reverse Telnet.
- An alternative method (other than access lists) to manage reverse Telnet authorization.

To configure a network access server to request authorization information from a TACACS+ or RADIUS server before allowing a user to establish a reverse Telnet session, use the following command in global configuration mode:

Command	Purpose
Device(config)# aaa authorization	Configures the network access server to request authorization information before allowing a user to establish a reverse Telnet session.
reverse-access	
method1 [method2	
]	

This feature enables the network access server to request reverse Telnet authorization information from the security server, whether RADIUS or TACACS+. You must configure the specific reverse Telnet privileges for the user on the security server itself.

Configuration Examples for Authorization

Example: TACACS Authorization

The following examples show how to use a TACACS+ server to authorize the use of network services, including PPP and ARA. If the TACACS+ server is not available or an error occurs during the authorization process, the fallback method (none) is to grant all authorization requests:

Device (config) # aaa authorization network default group tacacs+ none

The following example shows how to allow network authorization using TACACS+:

Device (config) # aaa authorization network default group tacacs+

The following example shows how to provide the same authorization, but it also creates address pools called *"mci"* and *"att"*:

```
Device> enable
Device# configure terminal
Device(config)# aaa authorization network default group tacacs+
Device(config)# interface gigabitethernet 01/1/
Device(config-if)# ip address-pool local
Device(config)# ip local-pool mci 172.16.0.1 172.16.0.255
Device(config)# ip local-pool att 172.17.0.1 172.17.0.255
Device(config-if)# end
```

These address pools can then be selected by the TACACS daemon. A sample configuration of the daemon follows:

```
user = mci_customer1 {
    login = cleartext "some password"
    service = ppp protocol = ip {
        addr-pool=mci
    }
}
user = att_customer1 {
    login = cleartext "some other password"
    service = ppp protocol = ip {
        addr-pool=att
    }
```

Example: RADIUS Authorization

The following example shows how to configure the router to authorize using RADIUS:

```
Device> enable
Device# configure terminal
Device(config)# aaa new-model
Device(config)# aaa authorization exec default group radius if-authenticated
Device(config)# aaa authorization network default group radius
Device(config)# radius server ip
Device(config-radius-server)# key sharedkey
Device(config-radius-server)# end
```

The lines in this sample RADIUS authorization configuration are defined as follows:

The aaa authorization exec default group radius if-authenticated command configures the network
access server to contact the RADIUS server to determine if users are permitted to start an EXEC shell
when they log in. If an error occurs when the network access server contacts the RADIUS server, the
fallback method is to permit the CLI to start, provided the user has been properly authenticated.

The RADIUS information returned may be used to specify an autocommand or a connection access list be applied to this connection.

 The aaa authorization network default group radius command configures network authorization via RADIUS. This can be used to govern address assignment, the application of access lists, and various other per-user quantities.

Note Because no fallback method is specified in this example, authorization will fail if, for any reason, there is no response from the RADIUS server.

Example: Reverse Telnet Authorization

The following examples show how to cause the network access server to request authorization information from a TACACS+ security server before allowing a user to establish a reverse Telnet session:

```
Device> enable
Device# configure terminal
Device(config)# aaa new-model
Device(config)# aaa authentication login default group tacacs+
Device(config)# aaa authorization reverse-access default group tacacs+
Device(config)# tacacs server server1
Device(config-server-tacacs)# address ipv4 172.31.255.0
Device(config-server-tacacs)# timeout 90
Device(config-server-tacacs)# key sharedkey
Device(config-server-tacacs)# end
```

The lines in this sample TACACS+ reverse Telnet authorization configuration are defined as follows:

- The aaa new-model command enables AAA.
- The **aaa authentication login default group tacacs**+ command specifies TACACS+ as the default method for user authentication during login.

- The **aaa authorization reverse-access default group tacacs**+ command specifies TACACS+ as the method for user authorization when trying to establish a reverse Telnet session.
- The tacacs server command identifies the TACACS+ server.
- The **timeout** command sets the interval of time that the network access server waits for the TACACS+ server to reply.
- The key command defines the encryption key used for all TACACS+ communications between the network access server and the TACACS+ daemon.

The following example shows how to configure a generic TACACS+ server to grant a user, pat, reverse Telnet access to port tty2 on the network access server named "maple" and to port tty5 on the network access server named "oak":

```
user = pat
login = cleartext lab
service = raccess {
   port#1 = maple/tty2
   port#2 = oak/tty5
```

Note

In this example, "maple" and "oak" are the configured host names of network access servers, not DNS names or alias.

The following example shows how to configure the TACACS+ server (CiscoSecure) to grant a user named pat reverse Telnet access:

```
user = pat
profile_id = 90
profile_cycle = 1
member = Tacacs_Users
service=shell {
  default cmd=permit
  }
service=raccess {
  allow "c251le0" "tty1" ".*"
refuse ".*" ".*" ".*"
password = clear "goaway"
```

Note CiscoSecure only supports reverse Telnet using the command line interface in versions 2.1(x) through version 2.2(1).

An empty "service=raccess {}" clause permits a user to have unconditional access to network access server ports for reverse Telnet. If no "service=raccess" clause exists, the user is denied access to any port for reverse Telnet.

For more information about configuring TACACS+, refer to the "Configuring TACACS" chapter. For more information about configuring CiscoSecure, refer to the *CiscoSecure Access Control Server User Guide*, version 2.1(2) or greater.

The following example shows how to cause the network access server to request authorization from a RADIUS security server before allowing a user to establish a reverse Telnet session:

```
Device> enable
Device# configure terminal
```

```
Device(config)# aaa new-model
Device(config)# aaa authentication login default group radius
Device(config)# aaa authorization reverse-access default group radius
Device(config)# radius server ip
Device(config-radius-server)# key sharedkey
Device(config-radius-server)# address ipv4 172.31.255.0 auth-port 1645 acct-port 1646
Device(config-radius-server)# end
```

The lines in this sample RADIUS reverse Telnet authorization configuration are defined as follows:

- The aaa new-model command enables AAA.
- The **aaa authentication login default group radius** command specifies RADIUS as the default method for user authentication during login.
- The **aaa authorization reverse-access default group radius** command specifies RADIUS as the method for user authorization when trying to establish a reverse Telnet session.
- The radius command identifies the RADIUS server.
- The **key** command defines the encryption key used for all RADIUS communications between the network access server and the RADIUS daemon.

The following example shows how to send a request to the RADIUS server to grant a user named "pat" reverse Telnet access at port tty2 on the network access server named "maple":

```
Username = "pat"
Password = "goaway"
User-Service-Type = Shell-User
cisco-avpair = "raccess:port#1=maple/tty2"
```

The syntax "raccess:port=any/any" permits a user to have unconditional access to network access server ports for reverse Telnet. If no "raccess:port={*nasname* }/{*tty number* }" clause exists in the user profile, the user is denied access to reverse Telnet on all ports.

For more information about configuring RADIUS, refer to the chapter "Configuring RADIUS."

Feature History for Configuring Authorization

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.11.1	AAA Authorization	AAA authorization enables you to limit the services available to a user. When AAA authorization is enabled, the network access server uses information retrieved from the user's profile, which is located either in the local user database or on the security server, to configure the user's session. Once this is done, the user will be granted access to a requested service only if the information in the user profile allows it.
Cisco IOS XE Cupertino 17.7.1	AAA Authorization	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

Configuring Accounting

The AAA accounting feature allows the services that users are accessing and the amount of network resources that users are consuming to be tracked. When AAA accounting is enabled, the network access server reports user activity to the TACACS+ or RADIUS security server (depending on which security method is implemented) in the form of accounting records. Each accounting record contains accounting attribute-value (AV) pairs and is stored on the security server. This data can then be analyzed for network management, client billing, and auditing.

- Prerequisites for Configuring Accounting, on page 91
- Restrictions for Configuring Accounting, on page 91
- Information About Configuring Accounting, on page 92
- How to Configure AAA Accounting, on page 105
- Configuration Examples for AAA Accounting, on page 112
- Additional References for Configuring Accounting, on page 116
- Feature History for Configuring Accounting, on page 116

Prerequisites for Configuring Accounting

The following tasks must be performed before configuring accounting using named method lists:

- Enable AAA on the network access server by using the **aaa new-model**command in global configuration mode.
- Define the characteristics of the RADIUS or TACACS+ security server if RADIUS or TACACS+ authorization is issued. For more information about configuring the Cisco network access server to communicate with the RADIUS security server, see the Configuring RADIUS module. For more information about configuring the Cisco network access server to communicate with the TACACS+ security server, see the Configuring TACACS+ module.

Restrictions for Configuring Accounting

• Accounting information can be sent simultaneously to a maximum of only four AAA servers.

Information About Configuring Accounting

Named Method Lists for Accounting

Similar to authentication and authorization method lists, method lists for accounting define the way accounting is performed and the sequence in which these methods are performed.

Named accounting method lists allow particular security protocol to be designated and used on specific lines or interfaces for accounting services. The only exception is the default method list (which is named default). The default method list is automatically applied to all interfaces except those that have a named method list explicitly defined. A defined method list overrides the default method list.

A method list is simply a named list describing the accounting methods to be queried (such as RADIUS or TACACS+), in sequence. Method lists allow one or more security protocols to be designated and used for accounting, thus ensuring a backup system for accounting in case the initial method fails. Cisco IOS software uses the first method listed to support accounting; if that method fails to respond, the Cisco IOS software selects the next accounting method listed in the method list. This process continues until there is successful communication with a listed accounting method, or all methods defined are exhausted.

Note The Cisco IOS software attempts accounting with the next listed accounting method only when there is no response from the previous method. If accounting fails at any point in this cycle--meaning that the security server responds by denying the user access--the accounting process stops and no other accounting methods are attempted.

Accounting method lists are specific to the type of accounting being requested. AAA supports seven different types of accounting:

- Network : Provides information for all PPP, SLIP, or ARAP sessions, including packet and byte counts.
- EXEC : Provides information about user EXEC terminal sessions of the network access server.
- **Commands** : Provides information about the EXEC mode commands that a user issues. Command accounting generates accounting records for all EXEC mode commands, including global configuration commands, associated with a specific privilege level.
- **Connection** : Provides information about all outbound connections made from the network access server, such as Telnet, local-area transport (LAT), TN3270, packet assembler/disassembler (PAD), and rlogin.
- System : Provides information about system-level events.
- **Resource** : Provides "start" and "stop" records for calls that have passed user authentication, and provides "stop" records for calls that fail to authenticate.
- VRRS : Provides information about Virtual Router Redundancy Service (VRRS).

Note System accounting does not use named accounting lists; only the default list for system accounting can be defined.

When a named method list is created, a particular list of accounting methods for the indicated accounting type are defined.

Accounting method lists must be applied to specific lines or interfaces before any of the defined methods are performed. The only exception is the default method list (which is named "default"). If the **aaa accounting** command for a particular accounting type is issued without specifying a named method list, the default method list is automatically applied to all interfaces or lines except those that have a named method list explicitly defined (A defined method list overrides the default method list). If no default method list is defined, then no accounting takes place.

This section includes the following subsections:

Method Lists and Server Groups

A server group is a way to group existing RADIUS or TACACS+ server hosts for use in method lists. The figure below shows a typical AAA network configuration that includes four security servers: R1 and R2 are RADIUS servers, and T1 and T2 are TACACS+ servers. R1 and R2 comprise the group of RADIUS servers. T1 and T2 comprise the group of TACACS+ servers.

In Cisco IOS software, RADIUS and TACACS+ server configurations are global. A subset of the configured server hosts can be specified using server groups. These server groups can be used for a particular service. For example, server groups allow R1 and R2 to be defined as separate server groups (SG1 and SG2), and T1 and T2 as separate server groups (SG3 and SG4). This means either R1 and T1 (SG1 and SG3) or R2 and T2 (SG2 and SG4) can be specified in the method list, which provides more flexibility in the way that RADIUS and TACACS+ resources are assigned.

Server groups also can include multiple host entries for the same server, as long as each entry has a unique identifier. The combination of an IP address and a UDP port number creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. In other words, this unique identifier enables RADIUS requests to be sent to different UDP ports on a server from the same IP address. If two different host entries on the same RADIUS server are configured for the same service: for example, accounting; the second host entry configured acts as failover backup to the first one. Using this example, if the first host entry fails to provide accounting services, the network access server tries the second host entry configured on the same device for accounting services (The RADIUS host entries are tried in the order in which they are configured).

For more information about configuring server groups and about configuring server groups based on Dialed Number Identification Service (DNIS) numbers, see the "Configuring RADIUS" or "Configuring TACACS+" modules.

AAA Accounting Methods

The following two methods of accounting are supported:

- TACACS+: The network access server reports user activity to the TACACS+ security server in the form of accounting records. Each accounting record contains accounting AV pairs and is stored on the security server.
- RADIUS: The network access server reports user activity to the RADIUS security server in the form of accounting records. Each accounting record contains accounting AV pairs and is stored on the security server.

Note

Passwords and accounting logs are masked before being sent to the TACACS+ or RADIUS security servers. Use the **aaa accounting commands visible-keys** command to send unmasked information to the TACACS+ or RADIUS security servers.

Accounting Record Types

For minimal accounting, use the **stop-only** keyword, which instructs the specified method (**RADIUS** or **TACACS+**) to send a stop record accounting notice at the end of the requested user process. For more accounting information, use the **start-stop** keyword to send a start accounting notice at the beginning of the requested event and a stop accounting notice at the end of the event. To stop all accounting activities on this line or interface, use the **none** keyword.

Accounting Methods

The table below lists the supported accounting methods.

Table 4: AAA Accounting Methods

Keyword	Description
group radius	Uses the list of all RADIUS servers for accounting.
group tacacs+	Uses the list of all TACACS+ servers for accounting.
group group-name	Uses a subset of RADIUS or TACACS+ servers for accounting as defined by the server group <i>group-name</i> .

The method argument refers to the actual method the authentication algorithm tries. Additional methods of authentication are used only if the previous method returns an error, not if it fails. To specify that the authentication should succeed even if all other methods return an error, specify additional methods in the command. For example, to create a method list named acct_tac1 that specifies RADIUS as the backup method of authentication in the event that TACACS+ authentication returns an error, enter the following command:

aaa accounting network acct tac1 stop-only group tacacs+ group radius

To create a default list that is used when a named list is not specified in the **aaa accounting**command, use the **default** keyword followed by the methods that are wanted to be used in default situations. The default method list is automatically applied to all interfaces.

For example, to specify RADIUS as the default method for user authentication during login, enter the following command:

aaa accounting network default stop-only group radius

AAA Accounting supports the following methods:

- group tacacs : To have the network access server send accounting information to a TACACS+ security server, use the group tacacs+ *method* keyword.
- group radius : To have the network access server send accounting information to a RADIUS security server, use the group radius *method* keyword.

Note

method, use the **aaa accounting**command with the **group** *group-name* method. To specify and define the group name and the members of the group, use the **aaa group server** command. For example, use the **aaa group server** command to first define the members of **group loginrad**:

```
aaa group server radius loginrad
server 172.16.2.3
server 172.16.2 17
server 172.16.2.32
```

This command specifies RADIUS servers 172.16.2.3, 172.16.2.17, and 172.16.2.32 as members of the **group** loginrad.

To specify **group loginrad** as the method of network accounting when no other method list has been defined, enter the following command:

aaa accounting network default start-stop group loginrad

Before a group name can be used as the accounting method, communication with the RADIUS or TACACS+ security server must be enabled.

AAA Accounting Types

Network Accounting

Network accounting provides information for all PPP, SLIP, or ARAP sessions, including packet and byte counts.

The following example shows the information contained in a RADIUS network accounting record for a PPP user who comes in through an EXEC session:

```
Wed Jun 27 04:44:45 2001
       NAS-IP-Address = "172.16.25.15"
       NAS-Port = 5
       User-Name = "username1"
       Client-Port-DNIS = "4327528"
       Caller-ID = "562"
       Acct-Status-Type = Start
       Acct-Authentic = RADIUS
        Service-Type = Exec-User
        Acct-Session-Id = "0000000D"
        Acct-Delay-Time = 0
        User-Id = "username1"
       NAS-Identifier = "172.16.25.15"
Wed Jun 27 04:45:00 2001
       NAS-IP-Address = "172.16.25.15"
       NAS-Port = 5
       User-Name = "username1"
```

Client-Port-DNIS = "4327528" Caller-ID = 562''Acct-Status-Type = Start Acct-Authentic = RADIUS Service-Type = Framed Acct-Session-Id = "0000000E" Framed-IP-Address = "10.1.1.2" Framed-Protocol = PPP Acct-Delay-Time = 0User-Id = "username1" NAS-Identifier = "172.16.25.15" Wed Jun 27 04:47:46 2001 NAS-IP-Address = "172.16.25.15" NAS-Port = 5User-Name = "username1" Client-Port-DNIS = "4327528" Caller-ID = "562" Acct-Status-Type = Stop Acct-Authentic = RADIUS Service-Type = Framed Acct-Session-Id = "0000000E" Framed-IP-Address = "10.1.1.2" Framed-Protocol = PPPAcct-Input-Octets = 3075 Acct-Output-Octets = 167 Acct-Input-Packets = 39 Acct-Output-Packets = 9 Acct-Session-Time = 171 Acct-Delay-Time = 0User-Id = "username1" NAS-Identifier = "172.16.25.15" Wed Jun 27 04:48:45 2001 NAS-IP-Address = "172.16.25.15" NAS-Port = 5User-Name = "username1" Client-Port-DNIS = "4327528" Caller-ID = "408" Acct-Status-Type = Stop Acct-Authentic = RADIUS Service-Type = Exec-User Acct-Session-Id = "0000000D" Acct-Delay-Time = 0User-Id = "username1" NAS-Identifier = "172.16.25.15"

The following example shows the information contained in a TACACS+ network accounting record for a PPP user who first started an EXEC session:

Wed Jun 27 04:00:35 2001 172.16.25.15	username1	tty4	562/4327528	starttask_id=28
service=shell				
Wed Jun 27 04:00:46 2001 172.16.25.15	username1	tty4	562/4327528	starttask id=30
addr=10.1.1.1 service=ppp				_
Wed Jun 27 04:00:49 2001 172.16.25.15	username1	tty4	408/4327528	updattask id=30
addr=10.1.1.1 service=ppp	protocol=ip	addr	=10.1.1.1	
Wed Jun 27 04:01:31 2001 172.16.25.15	username1	tty4	562/4327528	stoptask id=30
addr=10.1.1.1 service=ppp	protocol=ip	add	r=10.1.1.1	_
	bytes in=2	844	bytes out=1	.682 paks in=36
paks out=24 elapsed time=51	_		_	_

service=shell elapsed_time=5	7			

Note

te The precise format of accounting packets records may vary depending on the security server daemon.

The following example shows the information contained in a RADIUS network accounting record for a PPP user who comes in through autoselect:

```
Wed Jun 27 04:30:52 2001
        NAS-IP-Address = "172.16.25.15"
        NAS-Port = 3
       User-Name = "username1"
        Client-Port-DNIS = "4327528"
        Caller-ID = "562"
        Acct-Status-Type = Start
        Acct-Authentic = RADIUS
        Service-Type = Framed
        Acct-Session-Id = "0000000B"
        Framed-Protocol = PPP
        Acct-Delay-Time = 0
        User-Id = "username1"
        NAS-Identifier = "172.16.25.15"
Wed Jun 27 04:36:49 2001
        NAS-IP-Address = "172.16.25.15"
        NAS-Port = 3
        User-Name = "username1"
        Client-Port-DNIS = "4327528"
        Caller-ID = 562''
        Acct-Status-Type = Stop
        Acct-Authentic = RADIUS
        Service-Type = Framed
        Acct-Session-Id = "0000000B"
        Framed-Protocol = PPP
        Framed-IP-Address = "10.1.1.1"
        Acct-Input-Octets = 8630
        Acct-Output-Octets = 5722
        Acct-Input-Packets = 94
        Acct-Output-Packets = 64
        Acct-Session-Time = 357
        Acct-Delay-Time = 0
        User-Id = "username1"
        NAS-Identifier = "172.16.25.15"
```

The following example shows the information contained in a TACACS+ network accounting record for a PPP user who comes in through autoselect:

Wed Jun 27 04:02:19	2001 172.16.25.15	username1	Async5	562/4327528	starttask_id=35

		bytes in=3	3366 b	ytes out=2149	paks in=42
paks out=28	elapsed time=164				

EXEC Accounting

EXEC accounting provides information about user EXEC terminal sessions (user shells) on the network access server, including username, date, start and stop times, the access server IP address, and (for dial-in users) the telephone number the call originated from.

The following example shows the information contained in a RADIUS EXEC accounting record for a dial-in user:

```
Wed Jun 27 04:26:23 2001
        NAS-IP-Address = "172.16.25.15"
        NAS-Port = 1
        User-Name = "username1"
        Client-Port-DNIS = "4327528"
        Caller-ID = "5622329483"
        Acct-Status-Type = Start
        Acct-Authentic = RADIUS
        Service-Type = Exec-User
        Acct-Session-Id = "00000006"
        Acct-Delay-Time = 0
        User-Id = "username1"
       NAS-Identifier = "172.16.25.15"
Wed Jun 27 04:27:25 2001
       NAS-IP-Address = "172.16.25.15"
        NAS-Port = 1
        User-Name = "username1"
        Client-Port-DNIS = "4327528"
        Caller-ID = "5622329483"
        Acct-Status-Type = Stop
        Acct-Authentic = RADIUS
        Service-Type = Exec-User
        Acct-Session-Id = "00000006"
        Acct-Session-Time = 62
        Acct-Delay-Time = 0
        User-Id = "username1"
        NAS-Identifier = "172.16.25.15"
```

The following example shows the information contained in a TACACS+ EXEC accounting record for a dial-in user:

```
Wed Jun 27 03:46:21 2001 172.16.25.15 username1 tty3 5622329430/4327528
start
task_id=2 service=shell
Wed Jun 27 04:08:55 2001 172.16.25.15 username1 tty3 5622329430/4327528
stop
task_id=2 service=shell elapsed_time=1354
```

The following example shows the information contained in a RADIUS EXEC accounting record for a Telnet user:

```
Wed Jun 27 04:48:32 2001
       NAS-IP-Address = "172.16.25.15"
       NAS-Port = 26
        User-Name = "username1"
        Caller-ID = "10.68.202.158"
       Acct-Status-Type = Start
        Acct-Authentic = RADIUS
        Service-Type = Exec-User
        Acct-Session-Id = "00000010"
        Acct-Delay-Time = 0
        User-Id = "username1"
        NAS-Identifier = "172.16.25.15"
Wed Jun 27 04:48:46 2001
        NAS-IP-Address = "172.16.25.15"
        NAS-Port = 26
        User-Name = "username1"
        Caller-ID = "10.68.202.158"
```

```
Acct-Status-Type = Stop
Acct-Authentic = RADIUS
Service-Type = Exec-User
Acct-Session-Id = "00000010"
Acct-Session-Time = 14
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"
```

The following example shows the information contained in a TACACS+ EXEC accounting record for a Telnet user:

```
      Wed Jun 27 04:06:53 2001
      172.16.25.15
      username1
      tty26
      10.68.202.158

      starttask_id=41
      service=shell

      Wed Jun 27 04:07:02 2001
      172.16.25.15
      username1
      tty26
      10.68.202.158

      stoptask id=41
      service=shell
      elapsed time=9
```

Command Accounting

Command accounting provides information about the EXEC shell commands for a specified privilege level that are being executed on a network access server. Each command accounting record includes a list of the commands executed for that privilege level, as well as the date and time each command was executed, and the user who executed it.

The following example shows the information contained in a TACACS+ command accounting record for privilege level 1:

 Wed Jun 27 03:46:47 2001
 172.16.25.15
 username1

stop task_id=6 service=shell priv-lvl=15 cmd=configure terminal <cr>
Wed Jun 27 03:47:21 2001 172.16.25.15 username1 tty3 5622329430/4327528
stop task_id=7 service=shell priv-lvl=15 cmd=interface Serial 0 <cr>
Wed Jun 27 03:47:29 2001 172.16.25.15 username1 tty3 5622329430/4327528
stop task_id=8 service=shell priv-lvl=15 cmd=ip address 10.1.1.1 255.255.255.0
<cr>
```

Note

The Cisco implementation of RADIUS does not support command accounting.

Connection Accounting

Connection accounting provides information about all outbound connections made from the network access server such as Telnet, LAT, TN3270, PAD, and rlogin.

The following example shows the information contained in a RADIUS connection accounting record for an outbound Telnet connection:

Wed Jun 27 04:28:00 2001 NAS-IP-Address = "172.16.25.15" NAS-Port = 2User-Name = "username1" Client-Port-DNIS = "4327528" Caller-ID = "5622329477" Acct-Status-Type = Start Acct-Authentic = RADIUS Service-Type = Login Acct-Session-Id = "00000008" Login-Service = Telnet Login-IP-Host = "10.68.202.158" Acct-Delay-Time = 0User-Id = "username1" NAS-Identifier = "172.16.25.15" Wed Jun 27 04:28:39 2001 NAS-IP-Address = "172.16.25.15" NAS-Port = 2User-Name = "username1" Client-Port-DNIS = "4327528" Caller-ID = "5622329477" Acct-Status-Type = Stop Acct-Authentic = RADIUS Service-Type = Login Acct-Session-Id = "00000008" Login-Service = Telnet Login-IP-Host = "10.68.202.158" Acct-Input-Octets = 10774 Acct-Output-Octets = 112Acct-Input-Packets = 91 Acct-Output-Packets = 99 Acct-Session-Time = 39 Acct-Delay-Time = 0User-Id = "username1"

NAS-Identifier = "172.16.25.15"

The following example shows the information contained in a TACACS+ connection accounting record for an outbound Telnet connection:

Wed Jun 27 03:47:43 2001 172.16.25.15 username1 tty3 5622329430/4327528
start task_id=10 service=connection username1-sun
Wed Jun 27 03:48:38 2001 172.16.25.15 username1 tty3 5622329430/4327528
stop task_id=10 service=connection protocol=telnet addr=10.68.202.158 cmd=telnet
username1-sun bytes in=4467 bytes out=96 paks in=61 paks out=72 elapsed time=55

The following example shows the information contained in a RADIUS connection accounting record for an outbound rlogin connection:

```
Wed Jun 27 04:29:48 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 2
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "5622329477"
Acct-Status-Type = Start
Acct-Authentic = RADIUS
Service-Type = Login
Acct-Session-Id = "0000000A"
Login-Service = Rlogin
```

```
Login-IP-Host = "10.68.202.158"
       Acct-Delay-Time = 0
        User-Id = "username1"
       NAS-Identifier = "172.16.25.15"
Wed Jun 27 04:30:09 2001
       NAS-IP-Address = "172.16.25.15"
       NAS-Port = 2
       User-Name = "username1"
       Client-Port-DNIS = "4327528"
       Caller-ID = "5622329477"
       Acct-Status-Type = Stop
       Acct-Authentic = RADIUS
       Service-Type = Login
       Acct-Session-Id = "0000000A"
       Login-Service = Rlogin
        Login-IP-Host = "10.68.202.158"
        Acct-Input-Octets = 18686
       Acct-Output-Octets = 86
        Acct-Input-Packets = 90
       Acct-Output-Packets = 68
       Acct-Session-Time = 22
        Acct-Delay-Time = 0
        User-Id = "username1"
        NAS-Identifier = "172.16.25.15"
```

The following example shows the information contained in a TACACS+ connection accounting record for an outbound rlogin connection:

```
Wed Jun 27 03:48:46 2001 172.16.25.15 username1 tty3 5622329430/4327528
start task_id=12 service=connection protocol=rlogin addr=10.68.202.158 cmd=rlogin
username1-sun /user username1
Wed Jun 27 03:51:37 2001 172.16.25.15 username1 tty3 5622329430/4327528
stop task_id=12 service=connection protocol=rlogin addr=10.68.202.158 cmd=rlogin
username1-sun /user username1 bytes_in=659926 bytes_out=138 paks_in=2378 paks_
out=1251 elapsed time=171
```

The following example shows the information contained in a TACACS+ connection accounting record for an outbound LAT connection:

Wed Jun 27 03:53:06 2001172.16.25.15username1tty35622329430/4327528starttask_id=18service=connectionprotocol=lataddr=VAXcmd=latVAXWed Jun 27 03:54:15 2001172.16.25.15username1tty35622329430/4327528stoptask_id=18service=connectionprotocol=lataddr=VAXcmd=latVAXbytes in=0bytes out=0paks in=0paks out=0elapsed time=6

System Accounting

System accounting provides information about all system-level events (for example, when the system reboots or when accounting is turned on or off).

The following accounting record shows a typical TACACS+ system accounting record server indicating that AAA Accounting has been turned off:

```
Wed Jun 27 03:55:32 2001 172.16.25.15 unknown unknown unknown start task_id=25
service=system
event=sys acct reason=reconfigure
```

Note

The precise format of accounting packets records may vary depending on the TACACS+ daemon.

The following accounting record shows a TACACS+ system accounting record indicating that AAA Accounting has been turned on:

```
Wed Jun 27 03:55:22 2001 172.16.25.15 unknown unknown unknown stop task_id=23
   service=system
event=sys_acct reason=reconfigure
```

Resource Accounting

The Cisco implementation of AAA accounting provides "start" and "stop" record support for calls that have passed user authentication. The additional feature of generating "stop" records for calls that fail to authenticate as part of user authentication is also supported. Such records are necessary for users employing accounting records to manage and monitor their networks.

This section includes the following subsections:

AAA Resource Failure Stop Accounting

Before AAA resource failure stop accounting, there was no method of providing accounting records for calls that failed to reach the user authentication stage of a call setup sequence. Such records are necessary for users employing accounting records to manage and monitor their networks and their wholesale customers.

This functionality generates a "stop" accounting record for any calls that do not reach user authentication; "stop" records are generated from the moment of call setup. All calls that pass user authentication behave as they did before; that is, no additional accounting records are seen.

The figure below illustrates a call setup sequence with normal call flow (no disconnect) and without AAA resource failure stop accounting enabled.

Figure 4: Modem Dial-In Call Setup Sequence With Normal Flow and Without Resource Failure Stop Accounting Enabled

The figure below illustrates a call setup sequence with normal call flow (no disconnect) and with AAA resource failure stop accounting enabled.

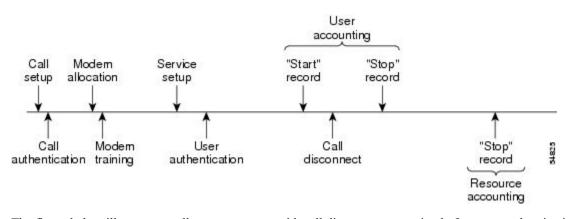

Figure 5: Modem Dial-In Call Setup Sequence With Normal Flow and WIth Resource Failure Stop Accounting Enabled

The figure below illustrates a call setup sequence with call disconnect occurring before user authentication and with AAA resource failure stop accounting enabled.

Figure 6: Modem Dial-In Call Setup Sequence With Call Disconnect Occurring Before User Authentication and With Resource Failure Stop Accounting Enabled

The figure below illustrates a call setup sequence with call disconnect occurring before user authentication and without AAA resource failure stop accounting enabled.

AAA Resource Accounting for Start-Stop Records

AAA resource accounting for start-stop records supports the ability to send a "start" record at each call setup, followed by a corresponding "stop" record at the call disconnect. This functionality can be used to manage and monitor wholesale customers from one source of data reporting, such as accounting records.

With this feature, a call setup and call disconnect "start-stop" accounting record tracks the progress of the resource connection to the device. A separate user authentication "start-stop" accounting record tracks the user management progress. These two sets of accounting records are interlinked by using a unique session ID for the call.

The figure below illustrates a call setup sequence with AAA resource start-stop accounting enabled.

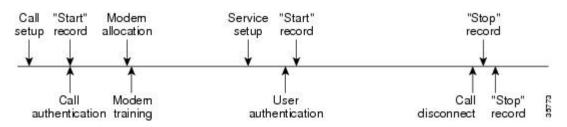

Figure 8: Modem Dial-In Call Setup Sequence With Resource Start-Stop Accounting Enabled

AAA Accounting Enhancements

AAA Broadcast Accounting

AAA broadcast accounting allows accounting information to be sent to multiple AAA servers at the same time; that is, accounting information can be broadcast to one or more AAA servers simultaneously. This functionality allows service providers to send accounting information to their own private AAA servers and to the AAA servers of their end customers. It also provides redundant billing information for voice applications.

Broadcasting is allowed among groups of RADIUS or TACACS+ servers, and each server group can define its backup servers for failover independently of other groups.

Thus, service providers and their end customers can use different protocols (RADIUS or TACACS+) for the accounting server. Service providers and their end customers can also specify their backup servers independently. As for voice applications, redundant accounting information can be managed independently through a separate group with its own failover sequence.

AAA Session MIB

The AAA session MIB feature allows customers to monitor and terminate their authenticated client connections using Simple Network Management Protocol (SNMP). The data of the client is presented so that it correlates directly to the AAA Accounting information reported by either the RADIUS or the TACACS+ server. AAA session MIB provides the following information:

- Statistics for each AAA function (when used in conjunction with the show radius statistics command)
- Status of servers providing AAA functions
- Identities of external AAA servers
- Real-time information (such as idle times), providing additional criteria for use by SNMP networks for assessing whether or not to terminate an active call

The table below shows the SNMP user-end data objects that can be used to monitor and terminate authenticated client connections with the AAA session MIB feature.

Table 5: SNMP End-User Data Objects

SessionId	The session identification used by the AAA Accounting protocol (same value as reported by RADIUS attribute 44 (Acct-Session-ID)).
UserId	The user login ID or zero-length string if a login is unavailable.
IpAddr	The IP address of the session or 0.0.0.0 if an IP address is not applicable or unavailable.

L

IdleTime	The elapsed time in seconds that the session has been idle.
Disconnect	The session termination object used to disconnect the given client.
CallId	The entry index corresponding to this accounting session that the Call Tracker record stored.

The table below describes the AAA summary information provided by the AAA session MIB feature using SNMP on a per-system basis.

Table 6: SNMP AAA Session Summary

ActiveTableEntries	Number of sessions currently active.
ActiveTableHighWaterMark	Maximum number of sessions present at once since last system reinstallation.
TotalSessions	Total number of sessions since last system reinstallation.
DisconnectedSessions	Total number of sessions that have been disconnected using since last system reinstallation.

Accounting Attribute-Value Pairs

The network access server monitors the accounting functions defined in either TACACS+ AV pairs or RADIUS attributes, depending on which security method is implemented.

How to Configure AAA Accounting

Configuring AAA Accounting Using Named Method Lists

To configure AAA Accounting using named method lists, perform the following steps:

Note System accounting does not use named method lists. For system accounting, define only the default method list.

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	

	Command or Action	Purpose	
	Device# configure terminal		
Step 3	aaa accounting {system network exec connection commands level} {default list-name} {start-stop stop-only none} [method1 [method2]]	Creates an accounting method list and enables accounting. The argument <i>list-name</i> is a character string used to name the created list.	
	Example:		
	Device(config)# aaa accounting system default start-stop		
Step 4	Do one of the following:	Enters the line configuration mode for the lines	
	• line [aux console tty vty] line-number [ending-line-number]	to which the accounting method list is applied or	
	• interface interface-type interface-number Example:	Enters the interface configuration mode for the interfaces to which the accounting method list is applied.	
	Device(config)# line aux line1		
Step 5	Do one of the following: accounting {arap commands level connection exec} {default list-name} 	Applies the accounting method list to a line or set of lines. or	
	• ppp accounting{default <i>list-name</i> } Example:	Applies the accounting method list to an interface or set of interfaces.	
	Device(config-line)# accounting arap default		
Step 6	end	(Optional) Exits line configuration mode and	
	Example:	returns to privileged EXEC mode.	
	Device(config-line)# end		

Suppressing Generation of Accounting Records for Null Username Sessions

When AAA Accounting is activated, the Cisco IOS software issues accounting records for all users on the system, including users whose username string, because of protocol translation, is NULL. An example of this is users who come in on lines where the **aaa authentication login** *method-list* **none** command is applied. To prevent accounting records from being generated for sessions that do not have usernames associated with them, use the following command in global configuration mode:

Pupose
Prevent
acorig
record
from
being
generate
for
users
whos
usemen
string
is
NUL

Generating Interim Accounting Records

To enable periodic interim accounting records to be sent to the accounting server, use the following command in global configuration mode:

Command	Purpose
Device(config)# aaa accounting update	Enables periodic interim accounting records to be sent to the accounting server.
[newinfo] [periodic] number	

When the **aaa accounting update**commandis activated, the Cisco IOS software issues interim accounting records for all users on the system. If the keyword **newinfo** is used, interim accounting records are sent to the accounting server every time there is new accounting information to report. An example of this would be when IPCP completes IP address negotiation with the remote peer. The interim accounting record includes the negotiated IP address used by the remote peer.

When used with the keyword **periodic**, interim accounting records are sent periodically as defined by the *number* argument. The interim accounting record contains all of the accounting information recorded for that user up to the time the interim accounting record is sent.

∕!∖

Caution Using the **aaa accounting update periodic** command can cause heavy congestion when many users are logged in to the network.

Configuring an Alternate Method to Enable Periodic Accounting Records

You can use the following alternative method to enable periodic interim accounting records to be sent to the accounting server.

Procedure

	Command or Action	Purpose	
Step 1	enable	Enables privileged EXEC mode.	
	Example:	• Enter your password if prompted.	
	Device> enable		
Step 2	configure terminal	Enters global configuration mode.	
	Example:		
	Device# configure terminal		
Step 3	aaa accounting network default	Configures the default accounting for all	
	Example:	network-related service requests and enters accounting method list configuration mode.	
	Device(config)# aaa accounting network default		
Step 4	action-type {none start-stop [periodic {disable interval minutes}] stop-only}	Specifies the type of action to be performed on accounting records.	
	Example:	• (Optional) The periodic keyword specifies periodic accounting action.	
	<pre>Device(cfg-acct-mlist)# action-type start-stop</pre>	• The interval keyword specifies the periodic accounting interval.	
	Example:		
	periodic interval 5	• The <i>value</i> argument specifies the intervals for accounting update records (in minutes).	
		• The disable keyword disables periodic accounting.	
Step 5	end	Exits accounting method list configuration	
	Example:	mode and returns to privileged EXEC mode	
	Device(cfg-acct-mlist)# end		

Generating Interim Service Accounting Records

Perform this task to enable the generation of interim service accounting records at periodic intervals for subscribers.

Before you begin

RADIUS Attribute 85 in the user service profile always takes precedence over the configured interim-interval value. RADIUS Attribute 85 must be in the user service profile. See the RADIUS Attributes Overview and RADIUS IETF Attributes feature document for more information.

Note If RADIUS Attribute 85 is not in the user service profile, then the interim-interval value configured in Generating Interim Accounting Records is used for service interim accounting records.

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	subscriber service accounting interim-interval minutes	Enables the generation of interim service
	interim-interval minutes	accounting records at periodic intervals for subscribers. The <i>minutes</i> argument indicates
	Example:	the number of periodic intervals to send
	Device(config)# subscriber service accounting interim-interval 10	accounting update records from 1 to 71582 minutes.
Step 4	end	Exits global configuration mode and returns to
	Example:	privileged EXEC mode.
	Device(config)# end	

Generating Accounting Records for a Failed Login or Session

When AAA accounting is activated, the Cisco IOS XE software does not generate accounting records for system users who fail login authentication, or who succeed in login authentication but fail PPP negotiation for some reason.

To specify that accounting stop records be generated for users who fail to authenticate at login or during session negotiation, use the following command in global configuration mode:

Command or Action	Purpose
aaa accounting send stop-record	Generates "stop" records for users who fail to authenticate
authentication failure	at login or during session negotiation using PPP.

Specifying Accounting NETWORK-Stop Records Before EXEC-Stop Records

For PPP users who start EXEC terminal sessions, it can be specified that NETWORK records be generated before EXEC-stop records. In some cases, such as billing customers for specific services, is can be desirable

to keep network start and stop records together, essentially "nesting" them within the framework of the EXEC start and stop messages. For example, a user dialing in using PPP can create the following records: EXEC-start, NETWORK-start, EXEC-stop, NETWORK-stop. By nesting the network accounting records, NETWORK-stop records follow NETWORK-start messages: EXEC-start, NETWORK-start, NETWORK-stop, EXEC-stop.

To nest accounting records for user sessions, use the following command in global configuration mode:

Command or Action	Purpose
aaa accounting nested	Nests network accounting records.

Suppressing System Accounting Records over Switchover

To suppress the system accounting-on and accounting-off messages during switchover, use the following command in global configuration mode:

Command or Action	Purpose
aaa accounting redundancy suppress system-records	Suppresses the system accounting messages during switchover.

Configuring AAA Resource Failure Stop Accounting

To enable resource failure stop accounting, use the following command in global configuration mode:

Command	Purpose	
Device(config)# aaa accounting resource method-list stop-failure group server-group	authenticat	a "stop" record for any calls that do not reach user ion. Before configuring this feature, the tasks described in the Prerequisites for Configuring Accounting, on page 91 section must be performed, and SNMP must be enabled on the network access server.

Configuring AAA Resource Accounting for Start-Stop Records

To enable full resource accounting for start-stop records, use the following command in global configuration mode:

Command	Purpose
Device(config)# aaa accounting resource method-list start-stop group server-group	Supports the ability to send a "start" record at each call setup. followed with a corresponding "stop" record at the call disconnect.NoteBefore configuring this feature, the tasks described in the Prerequisites for Configuring Accounting, on page 91 section must be performed, and SNMP must be enabled on the network access server.

AAA Broadcast Accounting

AAA broadcast accounting allows accounting information to be sent to multiple AAA servers at the same time; that is, accounting information can be broadcast to one or more AAA servers simultaneously. This functionality allows service providers to send accounting information to their own private AAA servers and to the AAA servers of their end customers. It also provides redundant billing information for voice applications.

Broadcasting is allowed among groups of RADIUS or TACACS+ servers, and each server group can define its backup servers for failover independently of other groups.

Thus, service providers and their end customers can use different protocols (RADIUS or TACACS+) for the accounting server. Service providers and their end customers can also specify their backup servers independently. As for voice applications, redundant accounting information can be managed independently through a separate group with its own failover sequence.

Configuring Per-DNIS AAA Broadcast Accounting

To configure AAA broadcast accounting per DNIS, use the **aaa dnis map accounting network**command in global configuration mode:

Command	Purpose	
Device(config)# aaa	Allows per-DNIS accounting configuration. This command has precedence over the global aaa accounting command.	
dnis map dnis-number accounting network [start-stop	Enables sending accounting records to multiple AAA servers. Simultaneously sends accounting records to the first server in each group. If the first server is unavailable, failover occurs using the backup servers defined within that	
<pre>stop-only none] [broadcast] method1 [method2]</pre>	group.	

Establishing a Session with a Device if the AAA Server Is Unreachable

To establish a console session with a device if the AAA server is unreachable, use the following command in global configuration mode:

Command or Action	Purpose	
no aaa accounting system guarantee-first	The aaa accounting system guarantee-first command guarantees system accounting as the first record, which is the default condition.	
	In some situations, users may be prevented from starting a session on the console or terminal connection until after the system reloads, which can take more than three minutes. To resolve this problem, use the no aaa accounting system guarantee-first command.	

Monitoring Accounting

No specific **show** command exists for either RADIUS or TACACS+ accounting. To obtain accounting records displaying information about users logged in, use the following command in privileged EXEC mode:

Command or Action	Purpose	
show accounting	Allows display of the active accountable events on the network and helps collect information in the event of a data loss on the accounting server.	

Troubleshooting Accounting

To troubleshoot accounting information, use the following command in privileged EXEC mode:

Command or Action	Purpose	
debug aaa accounting	Displays information on accountable events as they occur.	

Configuration Examples for AAA Accounting

Example: Configuring a Named Method List

The following example shows how to configure a Cisco device (enabled for AAA and communication with a RADIUS security server) in order for AAA services to be provided by the RADIUS server. If the RADIUS server fails to respond, then the local database is queried for authentication and authorization information, and accounting services are handled by a TACACS+ server.

```
Device# configure terminal
Device (config) # aaa new-model
Device (config) # aaa authentication login admins local
Device (config) # aaa authentication ppp dialins group radius local
Device (config) # aaa authorization network network1 group radius local
Device (config) # aaa accounting network network2 start-stop group radius group tacacs+
Device (config) # username root password ALongPassword
Device (config) # tacacs server server1
Device(config-server-tacacs) # address ipv4 172.31.255.0
Device (config-server-tacacs) # key goaway
Device (config-server-tacacs) # exit
Device (config) # radius server isp
Device (config-sg-radius) # key myRaDiUSpassWoRd
Device(config-sg-radius)# exit
Device (config) # interface group-async 1
Device(config-if) # group-range 1 16
Device (config-if) # encapsulation ppp
Device (config-if) # ppp authentication chap dialins
Device(config-if) # ppp authorization network1
Device(config-if) # ppp accounting network2
Device(config-if) # exit
Device(config) # line 1 16
Device (config-line) # autoselect ppp
Device(config-line)# autoselect during-login
Device (config-line) # login authentication admins
Device(config-line) # modem dialin
Device (config-line) # end
```

The lines in this sample RADIUS AAA configuration are defined as follows:

• The aaa new-model command enables AAA network security services.

- The **aaa authentication login admins local** command defines a method list, "admins", for login authentication.
- The **aaa authentication ppp dialins group radius local** command defines the authentication method list "dialins", which specifies that first RADIUS authentication and then (if the RADIUS server does not respond) local authentication is used on serial lines using PPP.
- The **aaa authorization network network1 group radius local** command defines the network authorization method list named "network1", which specifies that RADIUS authorization is used on serial lines using PPP. If the RADIUS server fails to respond, then local network authorization is performed.
- The aaa accounting network network2 start-stop group radius group tacacs+ command defines the network accounting method list named "network2", which specifies that RADIUS accounting services (in this case, start and stop records for specific events) are used on serial lines using PPP. If the RADIUS server fails to respond, accounting services are handled by a TACACS+ server.
- The **username** command defines the username and password to be used for the PPP Password Authentication Protocol (PAP) caller identification.
- The tacacs server command defines the name of the TACACS+ server host.
- The **key** command defines the shared secret text string between the network access server and the TACACS+ server host.
- The radius server command defines the name of the RADIUS server host.
- The key command defines the shared secret text string between the network access server and the RADIUS server host.
- The interface group-async command selects and defines an asynchronous interface group.
- The group-range command defines the member asynchronous interfaces in the interface group.
- The encapsulation ppp command sets PPP as the encapsulation method used on the specified interfaces.
- The**ppp authentication chap dialins** command selects Challenge Handshake Authentication Protocol (CHAP) as the method of PPP authentication and applies the "dialins" method list to the specified interfaces.
- Theppp authorization network1 command applies the blue1 network authorization method list to the specified interfaces.
- The**ppp accounting network2** command applies the red1 network accounting method list to the specified interfaces.
- The **line** command switches the configuration mode from global configuration to line configuration and identifies the specific lines being configured.
- The **autoselect ppp** command configures the Cisco IOS XE software to allow a PPP session to start up automatically on these selected lines.
- The **autoselect during-login** command is used to display the username and password prompt without pressing the Return key. After the user logs in, the autoselect function (in this case, PPP) begins.
- The login authentication admins command applies the admins method list for login authentication.

• The **modem dialin** command configures modems attached to the selected lines to accept only incoming calls.

The **show accounting** command yields the following output for the preceding configuration:

```
Active Accounted actions on tty1, User username2 Priv 1
Task ID 5, Network Accounting record, 00:00:52 Elapsed
task id=5 service=ppp protocol=ip address=10.0.0.98
```

The table below describes the fields contained in the preceding output.

Table 7: show accounting Field Descriptions

Field	Description	
Active Accounted actions on	Terminal line or interface name user with which the user logged in.	
User	User's ID.	
Priv	User's privilege level.	
Task ID	Unique identifier for each accounting session.	
Accounting Record	Type of accounting session.	
Elapsed	Length of time (hh:mm:ss) for this session type.	
attribute=value	AV pairs associated with this accounting session.	

Example: Configuring AAA Resource Accounting

The following example shows how to configure the resource failure stop accounting and resource accounting for start-stop records functions:

```
!Enable AAA on your network access server.
Device(config) # aaa new-model
!Enable authentication at login and list the AOL string name to use for login authentication.
Device (config) # aaa authentication login AOL group radius local
!Enable authentication for ppp and list the default method to use for PPP authentication.
Device (config) # aaa authentication ppp default group radius local
!Enable authorization for all exec sessions and list the AOL string name to use for
authorization.
Device (config) # aaa authorization exec AOL group radius if-authenticated
!Enable authorization for all network-related service requests and list the default method
to use for all network-related authorizations.
Device (config) # aaa authorization network default group radius if-authenticated
!Enable accounting for all exec sessions and list the default method to use for all start-stop
 accounting services.
Device (config) # aaa accounting exec default start-stop group radius
!Enable accounting for all network-related service requests and list the default method to
use
for all start-stop accounting services.
Device (config) # aaa accounting network default start-stop group radius
!Enable failure stop accounting.
```

Device (config) # aaa accounting resource default stop-failure group radius

```
!Enable resource accounting for start-stop records.
Device(config)# aaa accounting resource default start-stop group radius
```

Example: Configuring AAA Broadcast Accounting

The following example shows how to turn on broadcast accounting using the global **aaa accounting** command:

```
Device> enable
Device# configure terminal
Device(config)# aaa group server radius isp
Device(config-sg-radius)# server 10.0.0.1
Device(config-sg-radius)# server 10.0.0.2
Device(config)# aaa group server tacacs+ isp_customer
Device(config)# aaa group server tacacs+ isp_customer
Device config-sg-tacacs+)# server 172.0.0.1
Device config-sg-tacacs+)# exit
Device(config)# aaa accounting network default start-stop broadcast group isp group
isp_customer
Device(config)# tacacs server server1
Device(config-server-tacacs)# address ipv4 172.0.0.1
Device(config-server-tacacs)# key key2
Device(config-server-tacacs)# end
```

The **broadcast** keyword causes "start" and "stop" accounting records for network connections to be sent simultaneously to server 10.0.0.1 in the group isp and to server 172.0.0.1 in the group isp_customer. If server 10.0.0.1 is unavailable, failover to server 10.0.0.2 occurs. If server 172.0.0.1 is unavailable, no failover occurs because backup servers are not configured for the group isp_customer.

Example: Configuring per-DNIS AAA Broadcast Accounting

The following example shows how to turn on per-DNIS broadcast accounting using the global **aaa dnis map accounting network** command:

```
Device> enable
Device# configure terminal
Device(config) # aaa group server radius isp
Device(config-sg-radius)# server 10.0.0.1
Device(config-sq-radius)# server 10.0.0.2
Device(config-sg-radius)# exit
Device(config)# aaa group server tacacs+ isp_customer
Device config-sg-tacacs+) # server 172.0.0.1
Device config-sg-tacacs+) # exit
Device (config) # aaa dnis map enable
Device (config) # aaa dnis map 7777 accounting network start-stop broadcast group isp group
isp_customer
Device(config) # tacacs server server1
Device (config-server-tacacs) # address ipv4 172.0.0.1
Device(config-server-tacacs) # key key 2
Device (config-server-tacacs) # end
```

The **broadcast** keyword causes "start" and "stop" accounting records for network connection calls having DNIS number 7777 to be sent simultaneously to server 10.0.0.1 in the group isp and to server 172.0.0.1 in the group isp_customer. If server 10.0.0.1 is unavailable, failover to server 10.0.0.2 occurs. If server 172.0.0.1 is unavailable, no failover occurs because backup servers are not configured for the group isp_customer.

Example: AAA Session MIB

The following example shows how to set up the AAA session MIB feature to disconnect authenticated client connections for PPP users:

```
Device> enable

Device# configure terminal

Device(config)# aaa new-model

Device(config)# aaa authentication ppp default group radius

Device(config)# aaa authorization network default group radius

Device(config)# aaa accounting network default start-stop group radius

Device(config)# aaa session-mib disconnect

Device(config)# end
```

Feature History for Configuring Accounting

This table provides release and related information for the features explained in this module.

I

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.11.1	AAA Broadcast Accounting	AAA broadcast accounting allows accounting information to be sent to multiple AAA servers at the same time; that is, accounting information can be broadcast to one or more AAA servers simultaneously.
Cisco IOS XE Gibraltar 16.11.1	AAA Session MIB	The AAA session MIB feature allows customers to monitor and terminate their authenticated client connections using SNMP.
Cisco IOS XE Gibraltar 16.11.1	Connection Accounting	Connection accounting provides information about all outbound connections made from the network access server, such as Telnet, local-area transport, TN3270, packet assembler/disassembler (PAD), and rlogin.
Cisco IOS XE Gibraltar 16.11.1	AAA Interim Accounting	AAA interim accounting allows accounting records to be sent to the accounting server every time there is new accounting information to report, or on a periodic basis.
Cisco IOS XE Cupertino 17.7.1	AAA Broadcast Accounting	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

Configuring Local Authentication and Authorization

- How to Configure Local Authentication and Authorization, on page 119
- Monitoring Local Authentication and Authorization, on page 121
- Feature History for Local Authentication and Authorization, on page 121

How to Configure Local Authentication and Authorization

Configuring the Switch for Local Authentication and Authorization

You can configure AAA to operate without a server by setting the switch to implement AAA in local mode. The switch then handles authentication and authorization. No accounting is available in this configuration.

Note To secure the switch for HTTP access by using AAA methods, you must configure the switch with the ip http authentication aaa global configuration command. Configuring AAA authentication does not secure the switch for HTTP access by using AAA methods.

Follow these steps to configure AAA to operate without a server by setting the switch to implement AAA in local mode:

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	

	Command or Action	Purpose
	Device# configure terminal	
Step 3	aaa new-model	Enables AAA.
	Example:	
	Device(config)# aaa new-model	
Step 4	aaa authentication login default local Example: Device(config)# aaa authentication login default local	Sets the login authentication to use the local username database. The default keyword applies the local user database authentication to all ports.
Step 5	aaa authorization exec default local	Configures user AAA authorization, check the
	Example:	local database, and allow the user to run an EXEC shell.
	Device(config)# aaa authorization exec default local	
Step 6	aaa authorization network default local	Configures user AAA authorization for all
	Example:	network-related service requests.
	Device(config)# aaa authorization network default local	
Step 7	username <i>name</i> [privilege <i>level</i>] { password <i>encryption-type password</i> }	Enters the local database, and establishes a username-based authentication system.
	Example:	Repeat this command for each user.
	Device(config)# username your_user_name privilege 1 password 7 secret567	• For <i>name</i> , specify the user ID as one word. Spaces and quotation marks are not allowed.
		• (Optional) For <i>level</i> , specify the privilege level the user has after gaining access. The range is 0 to 15. Level 15 gives privileged EXEC mode access. Level 0 gives user EXEC mode access.
		• For <i>encryption-type</i> , enter 0 to specify that an unencrypted password follows. Enter 7 to specify that a hidden password follows.
		• For <i>password</i> , specify the password the user must enter to gain access to the switch. The password must be from 1 to

L

	Command or Action	Purpose
		25 characters, can contain embedded spaces, and must be the last option specified in the username command.
Step 8	end	Exits global configuration mode and returns to
	Example:	privileged EXEC mode.
	Device(config)# end	

Monitoring Local Authentication and Authorization

To display Local Authentication and Authorization configuration, use the **show running-config** command in privileged EXEC mode.

Feature History for Local Authentication and Authorization

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.11.1	Local Authentication and Authorization	This feature helps AAA to operate without a server by setting the device to implement AAA in local mode.
Cisco IOS XE Cupertino 17.7.1	Local Authentication and Authorization	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

CHAPTER

Configuring AAA Authorization and Authentication Cache

The AAA Authorization and Authentication Cache feature allows you to cache authorization and authentication responses for a configured set of users or service profiles, providing performance improvements and an additional level of network reliability. Users and service profiles that are returned from authorization and authentication responses can be queried from multiple sources and need not depend solely on an offload server. This feature also provides a failover mechanism so that if a network RADIUS or TACACS+ server is unable to provide authorization and authentication responses network users and administrators can still access the network.

- Prerequisites for Implementing Authorization and Authentication Profile Caching, on page 123
- Information About Implementing Authorization and Authentication Profile Caching, on page 123
- How to Implement Authorization and Authentication Profile Caching, on page 125
- Configuration Examples for Implementing Authorization and Authentication Profile Caching, on page 132
- Feature History for Implementing Authorization and Authentication Profile Caching, on page 133

Prerequisites for Implementing Authorization and Authentication Profile Caching

The following prerequisites apply to implementing authorization and authentication profile caching:

- Understand how you want to implement profile caching, that is, are profiles being cached to improve network performance or as a failover mechanism if your network authentication and authorization servers (RADIUS and TACACS+) become unavailable.
- RADIUS and TACACS+ server groups must already be configured.

Information About Implementing Authorization and Authentication Profile Caching

The following sections provide information about implementing authorization and authentication profile caching.

Network Performance Optimization Using Authorization and Authentication Profile Caching

RADIUS and TACACS+ clients run on Cisco devices and send authentication requests to a central RADIUS or TACACS+ server that contains all user authentication and network service access information. The device is required to communicate with an offload RADIUS or TACACS+ server to authenticate a given call and then apply a policy or service to that call. Unlike authentication, authorization, and accounting (AAA) accounting, AAA authentication and authorization is a blocking procedure, which means the call setup may not proceed while the call is being authenticated and authorized. Thus, the time required to process the call setup is directly impacted by the time required to process such an authentication or authorization request from the device to the offload RADIUS or TACACS+ server, and back again. Any communication problems in the transmission, offload server utilization, and numerous other factors cause significant degradation in a device's call setup performance because of the AAA authentication and authorization server needed for a single call or session.

A solution to this problem is to minimize the impact of such authentication requests by caching the authentication and authorization responses for specific users on the device, thereby removing the need to send the requests to an offload server again and again. This profile caching adds significant performance improvements to the call setup times. Profile caching also provides an additional level of network reliability because user and service profiles that are returned from authentication and authorization responses can be queried from multiple sources and need not depend solely on an offload server.

To take advantage of this performance optimization, you need to configure the authentication method list so that the AAA cache profile is queried first when a user attempts to authenticate to the device. See Method Lists in Authorization and Authentication Profile Caching section for more information.

Authorization and Authentication Profile Caching as a Failover Mechanism

If, for whatever reason, RADIUS or TACACS+ servers are unable to provide authentication and authorization responses, network users and administrators can be locked out of the network. The profile caching feature allows usernames to be authorized without having to complete the authentication phase. For example, a user by the name *user100@example.com* with the password *secretpassword1* can be stored in a profile cache using the regular expression .*@example.com. Another user by the name *user101@example.com* with the password *secretpassword2* can also be stored using the same regular expression, and so on. Because the number of users in the .*@example.com profile could run into thousands, it is not feasible to authenticate each user with their personal password. Therefore, authentication is disabled, and each user simply accesses authorization profiles from a common Access Response stored in the cache.

The same reasoning applies in cases where higher-end security mechanisms such as Challenge Handshake Authentication Protocol (CHAP), Microsoft Challenge Handshake Authentication Protocol (MS-CHAP), or Extensible Authentication Protocol (EAP), which use an encrypted password between a client and AAA offload server. To allow these unique secure username and password profiles to retrieve their authorization profiles, authentication is bypassed.

To take advantage of this failover capability, you need to configure the authentication and authorization method list so that the cache server group is queried last when a user attempts to authenticate to the device. See Method Lists in Authorization and Authentication Profile Caching section for more information.

Method Lists in Authorization and Authentication Profile Caching

A method list is a sequential list describing the authentication methods to be queried in order to authenticate a user. Cisco support methods such as local (use the local Cisco IOS XE database), none (do nothing), RADIUS server group, or TACACS+ server group. Typically, more than one method can be configured into a method list. Cisco IOS XE software uses the first listed method to authenticate users. If that method fails to respond, the Cisco IOS XE software selects the next authentication method listed in the method list. This process continues until there is successful communication with a listed authentication method, or until all the methods defined in the method list are exhausted.

To optimize network performance or provide failover capability using the profile caching feature, change the order of the authentication and authorization methods in the method list. To optimize network performance, make sure the cache server group appears first in the method list. For failover capability, the cache server group should appear last in the method list.

Authorization and Authentication Profile Caching Guidelines

Because the number of usernames and profiles that can request to be authenticated or authorized at a given device on a given point of presence (POP) can be quite extensive, it is not feasible to cache all of them. Therefore, only usernames and profiles that are commonly used or that share a common authentication and authorization response should be configured to use caching. Commonly used usernames such as aolip and aolnet, which are used for America Online (AOL) calls, or preauthentication dialed number identification service (DNIS) numbers used to connect Public Switched Telephone Network (PSTN) calls to a network-attached storage device, along with domain-based service profiles, are all examples of usernames and profiles that can benefit from authentication and authorization caching.

General Configuration Procedure for Implementing Authorization and Authentication Profile Caching

To implement authorization and authentication profile caching, complete the following procedure:

1. Create cache profile groups and define the rules for what information is cached in each group.

Entries that match based on exact username and regular expressions, or specify all authentication and authorization requests, can be cached.

- 2. Update existing server groups to reference newly defined cache groups.
- **3.** Update authentication or authorization method lists to use the cached information to optimize network performance or provide a failover mechanism.

How to Implement Authorization and Authentication Profile Caching

The following sections provide information about the various tasks that comprise authorization and authentication profile-caching configuration.

Creating Cache Profile Groups and Defining Caching Rules

Perform this task to create a cache profile group, define the rules for what information is cached in that group, and verify and manage cache profile entries.

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	aaa new-model	Enables the AAA access control model.
	Example:	
	Device(config)# aaa new-model	
Step 4	aaa cache profile group-name	Defines an authentication and authorization
	Example:	cache profile server group and enters profile map configuration mode.
	Device(config)# aaa cache profile networkusers@companyname	
Step 5	profile name [no-auth]	Creates an individual authentication and
	Example:	authorization cache profile based on a username match.
	Device(config-profile-map)# profile networkuser1 no-auth	• The <i>name</i> argument must be an exact match to a username being queried by an authentication or authorization service request.
		• Use the no-auth keyword to bypass authentication for this user.

I

	Command or Action	Purpose
		Note• For EAP-PEAP with MSCHAPv2 and EAP-PEAP with GTG methods, AAA authentication cachin for 802.1x is supporte with or without bypas authentication. However, for EAP methods such as EAP-TLS and EAP-MD5, AAA authentication cachin for 802.1x is only supported with bypas authentication.
		 For EAP-MSCHAPV use cases that do not use no-auth (bypass authentication), the administrator must configure the Cisco AV-pairs AS-username and AS-passwordHash or the Cisco Identity Services Engine (ISE) such that Cisco ISE sends these RADIUS attributes through the RADIUS ACCESS-Accept message to the network access serve (NAS) device. Also, AS-passwordHash must be configured with nt-hash of the user password.
		Repeat this step for each username that you want to add to the profile group in Step 4.
Step 6	<pre>regexp matchexpression {any only} [no-auth]</pre>	(Optional) Creates an entry in a cache profi group that matches a regular expression.
	Example:	• If you use the any keyword, all the unique usernames matching the regular expression are saved.

	Command or Action	Purpose
	Device(config-profile-map)# regexp .*@example.com any no-auth	• If you use the only keyword, only one profile entry is cached for all the usernames matching the regular expression.
		• Use the no-auth keyword to bypass authentication for a user or set of users.
		• Because the number of entries in a regular expression cache profile group could run into thousands, and validating each request against a regular expression can be time consuming, we recommend that you do not use regular expression entries in cache profile groups.
		Repeat this step for each regular expression that you want to add to the cache profile group defined in Step 4.
Step 7	all [no-auth]	(Optional) Specifies that all authentication and authorization requests are cached.
	<pre>Example: Device(config-profile-map)# all no-aut)</pre>	• Use the all keyword for specific service
Step 8	end	Exits profile map configuration mode and
	Example:	returns to privileged EXEC mode.
	Device(config-profile-map)# end	
Step 9	<pre>show aaa cache group name {profile name all}</pre>	(Optional) Displays an individual server group profile details or all the server group profile
	Example:	details.
	Device# show aaa cache group networkusers@companyname all	
Step 10	clear aaa cache group name {profile name all}	(Optional) Clears an individual entry or all the entries in the cache.
	Example:	
	Device# clear aaa cache group networkusers@companyname profile networkuser1	
Step 11	debug aaa cache group	(Optional) Displays debug information about
	Example:	cached entries.

Command or Action	Purpose
Device# debug aaa cache group	

Defining RADIUS and TACACS Server Groups that Use Cache Profile Group Information

Perform this task to define how RADIUS and TACACS+ server groups use the information stored in each cache profile group.

Before you begin

RADIUS and TACACS+ server groups must be created.

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	aaa new-model	Enables the AAA access control model.
	Example:	
	Device(config)# aaa new-model	
Step 4	aaa group server radius group-name or aaa group server tacacs+ group-name	Enters RADIUS server group configuration mode.
	Example:	To enter TACACS+ server group configuration mode, use the aaa group server tacacs +
	Device(config)# aaa group server radius networkusers@companyname	
Step 5	cache authorization profile name	Activates the authorization caching rules in the
	Example:	networkusers profile for this RADIUS or TACACS+ server group.
	Device(config-sg-radius)# cache authorization profile networkusers@companyname	The <i>name</i> argument is a AAA cache profile group name.

	Command or Action	Purpose
Step 6	cache authentication profile <i>name</i> Example:	Activates the authentication-caching rules in the networkusers profile for this RADIUS or TACACS+ server group.
	Device(config-sg-radius)# cache authentication profile networkusers@companyname	
Example:	cache expiry hours {enforce failover}	(Optional) Sets the amount of time before a cache profile entry expires (becomes stale).
	Device(config-sg-radius)# cache expiry	Use the enforce keyword to specify that after a cache profile entry expires, it is not used again.
		Use the failover keyword to specify that an expired cache profile entry can be used if all other methods to authenticate and authorize the user fails.
Step 8	end	Returns to privileged EXEC mode.
	Example:	
	Device(config-sg-radius)# end	

Updating Authorization and Authentication Method Lists to Specify How Cache Information is Used

Perform this task to update authorization and authentication method lists to use the authorization and authentication cache information.

Before you begin

Method lists must already be defined.

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	

I

	Command or Action	Purpose
Step 3	aaa new-model	Enables the AAA access control model.
	Example:	
	Device(config)# aaa new-model	
Step 4	aaa authorization {network exec commands level reverse-access configuration} {default list-name} [method1 [method2]]	Enables AAA authorization and creates method lists, which define the authorization methods used when a user accesses a specified function
	Example:	
	Device(config)# aaa authorization network default cache networkusers@companyname group networkusers@companyname	
Step 5	aaa authentication ppp {default list-name} method1 [method2]	Specifies one or more authentication methods for use on serial interfaces that are running PPP
	Example:	
	Device(config)# aaa authentication ppp default cache networkusers@companyname group networkusers@companyname	
Step 6	aaa authentication login {default list-name} method1 [method2]	Sets the authentication at login.
	Example:	
	Device(config)# aaa authentication login default cache adminusers group adminusers	
Step 7	aaa authentication dot1x {default list-name} method1 [method2]	Sets the authentication for use on interfaces running IEEE 802.1x.
	Example:	
	Device(config)# aaa authentication dot1x default cache RADGRP group RADGRP	
Step 8	end	Returns to privileged EXEC mode.
	Example:	
	Device(config)# end	

Configuration Examples for Implementing Authorization and Authentication Profile Caching

This following sections display configuration examples for implementing authorization and authentication profile caching.

Example: Implementing Authorization and Authentication Profile Caching for Network Optimization

The following configuration example shows how to:

- Define a cache profile group admin_users that contains the names of all the administrators on the network and sets this list as the default list that is used for all login and privileged exec sessions.
- Activate the new caching rules for a RADIUS server group.
- Add the new cache profile group in the authentication and authorization method list and change the method order so that the cache profile group is queried first.

```
configure terminal
aaa new-model
 ! Define aaa cache profile groups and the rules for what information is saved to cache.
aaa cache profile admin users
profile adminuser1
profile adminuser2
profile adminuser3
profile adminuser4
profile adminuser5
exit
 ! Define server groups that use the cache information in each profile group.
aaa group server radius admins@companyname.com
cache authorization profile admin users
 cache authentication profile admin users
 ! Update authentication and authorization method lists to specify how profile groups and
server groups are used.
aaa authentication login default cache admins@companyname.com group admins@companyname.com
 aaa authorization exec default cache admins@companyname.com group admins@companyname.com
 end
```

Example: Implementing Authorization and Authentication Profile Caching as a Failover Mechanism

The following configuration example shows how to:

• Create a cache profile group admin_users that contains all the administrators on the network so that if the RADIUS or TACACS+ server should become unavailable the administrators can still access the network.

- Create a cache profile group abc_users that contains all the *ABC* company users on the network so that if the RADIUS or TACACS+ server should become unavailable, these users will be authorized to use the network.
- Activate the new caching rules for each profile group on a RADIUS server.
- Add the new cache profile group in the authentication and authorization method list and change the method order so that the cache profile group is queried last.

```
configure terminal
aaa new-model
 ! Define aaa cache profile groups and the rules for what information is saved to cache.
 aaa cache profile admin users
profile admin1
profile admin2
profile admin3
exit
aaa cache profile abcusers
profile .*@example.com only no-auth
exit
 ! Define server groups that use the cache information in each cache profile group.
aaa group server tacacs+ admins@companyname.com
server 10.1.1.1
server 10.20.1.1
cache authentication profile admin_users
cache authorization profile admin users
exit
aaa group server radius abcusers@example.com
server 172.16.1.1
 server 172.20.1.1
cache authentication profile abcusers
cache authorization profile abcusers
exit
 ! Update authentication and authorization method lists to specify how cache is used.
aaa authentication login default cache admins@companyname.com group admins@companyname.com
aaa authorization exec default cache admins@companyname.com group admins@companyname.com
 aaa authentication ppp default group abcusers@example.com cache abcusers@example.com
```

```
aaa authorization network default group abcusers@example.com cache abcusers@example.com end
```

Feature History for Implementing Authorization and Authentication Profile Caching

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.11.1	AAA Authorization and Authentication Cache	This feature optimizes network performance and provides a failover mechanism in the event a network RADIUS or TACACS+ server becomes unavailable for any reason.

Release	Feature	Feature Information
Cisco IOS XE Cupertino 17.7.1	AAA Cache for 802.1x	AAA authentication caching support for 802.1x has been introduced.
Cisco IOS XE Cupertino 17.7.1	AAA Authorization and Authentication Cache	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

Configuring AAA Dead-Server Detection

The AAA Dead-Server Detection feature allows you to configure the criteria to be used to mark a RADIUS server as dead. If no criteria are explicitly configured, the criteria are computed dynamically on the basis of the number of outstanding transactions. Using this feature will result in less deadtime and quicker packet processing.

- Prerequisites for AAA Dead-Server Detection, on page 135
- Restrictions for AAA Dead-Server Detection, on page 135
- Information About AAA Dead-Server Detection, on page 135
- How to Configure AAA Dead-Server Detection, on page 136
- Configuration Examples for AAA Dead-Server Detection, on page 138
- Feature History for AAA Dead-Server Detection, on page 139

Prerequisites for AAA Dead-Server Detection

- You must have access to a RADIUS server.
- You should be familiar with configuring a RADIUS server.
- You should be familiar with configuring authentication, authorization, and accounting (AAA).
- Before a server can be marked as dead, you must first configure the **radius-server deadtime** command. If this command is not configured, even if the criteria are met for the server to be marked as dead, the server state will be in the up state.

Restrictions for AAA Dead-Server Detection

• Original transmissions are not counted in the number of consecutive timeouts that must occur on the device before the server is marked as dead; only the number of retransmissions are counted.

Information About AAA Dead-Server Detection

This section provides information about the AAA Dead-Server Detection feature.

Criteria for Marking a RADIUS Server As Dead

The AAA Dead-Server Detection feature allows you to determine the criteria that are used to mark a RADIUS server as dead. That is, you can configure the minimum amount of time, in seconds, that must elapse from the time that the device last received a valid packet from the RADIUS server to the time the server is marked as dead. If a packet has not been received since the device booted, and there is a timeout, the time criterion will be treated as though it has been met.

In addition, you can configure the number of consecutive timeouts that must occur on the device before the RADIUS server is marked as dead. If the server performs both authentication and accounting, both types of packets are included in the number. Improperly constructed packets are counted as though they are timeouts. Only retransmissions are counted, not the initial transmission. (Each timeout causes one retransmission to be sent.)

Note Both the time criterion and the tries criterion must be met for the server to be marked as dead.

The RADIUS dead-server detection configuration will result in the prompt detection of RADIUS servers that have stopped responding. This configuration will also result in the avoidance of servers being improperly marked as dead when they are swamped (responding slowly) and the avoidance of the state of servers being rapidly changed from dead to live to dead again. This prompt detection of nonresponding RADIUS servers and the avoidance of swamped and dead-to-live-to-dead-again servers will result in less deadtime and quicker packet processing.

Each AAA RADIUS global and server groups can have its own deadtime configured. The deadtime configured on the server group takes precedence over the global deadtime configuration. When a deadtime is configured on any AAA RADIUS server group, it clears the existing dead timer on all global server groups that are marked as dead, and not just the specified server group.

How to Configure AAA Dead-Server Detection

This section describes how to configure AAA dead-server detection.

Configuring AAA Dead-Server Detection

To configure AAA Dead-Server Detection, perform the following steps.

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	

	Command or Action	Purpose	
	Device# configure terminal		
Step 3	aaa new-model	Enables the AAA access control model.	
	Example:		
	Device(config)# aaa new-model		
Step 4	radius-server deadtime minutes	Improves RADIUS response times when some	
	Example:	servers might be unavailable and causes the unavailable servers to be skipped immediately.	
	Device(config)# radius-server deadtime 5		
Step 5	radius-server dead-criteria [time seconds] [tries number-of-tries]	Forces one or both of the criteria, used to mar a RADIUS server as dead, to be the indicated	
	Example:	constant.	
	Device(config)# radius-server dead-criteria time 5 tries 4		
Step 6	end	Returns to privileged EXEC mode.	
	Example:		
	Device(config)# end		
Step 7	show running-config	Verifies your configuration.	
	Example:	After you have configured AAA Dead-Server	
	Device# show running-config	Detection, you should verify your configuration using this command. This verification is especially important if you have used the no form of the radius-server dead-criteria command. The output of this command must show the same values in the Dead Criteria Details field that you configured using the radius-server dead-criteria command.	

Verifying AAA Dead-Server Detection

To verify your AAA Dead-Server Detection configuration, perform the following steps. The **show** and **debug** commands may be used in any order.

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password if prompted.

	Command or Action	Purpose
	Device> enable	
Step 2	debug aaa dead-criteria transactions	Displays AAA dead-criteria transaction values.
	Example:	
	Device# debug aaa dead-criteria transactions	
Step 3	show aaa dead-criteria	Displays dead-criteria information for a AAA server.
	Example:	
	Device# show aaa dead-criteria	
Step 4	show aaa servers [private public]	 Displays the status and number of packets that are sent to and received from all public and private authentication, authorization, and accounting (AAA) RADIUS servers. The private keyword optionally displays the AAA servers only.
	Example:	
	Device# show aaa server private	
		• The public keyword optionally displays the AAA servers only.

Configuration Examples for AAA Dead-Server Detection

The following sections show configuration examples of AAA dead-server detection:

Example: Configuring AAA Dead-Server Detection

The following example shows that the device will be considered dead after 5 seconds and four tries:

```
Device> enable
Device# configure terminal
Device(config)# aaa new-model
Device(config)# radius-server deadtime 5
Device(config)# radius-server dead-criteria time 5 tries 4
```

The following output example shows dead-criteria transaction information for a particular server group:

Device> enable Device# debug aaa dead-criteria transactions

AAA Transaction debugs debugging is on *Nov 14 23:44:17.403: AAA/SG/TRANSAC: Computed Retransmit Tries: 22, Current Max Tries: 22 *Nov 14 23:44:17.403: AAA/SG/TRANSAC: Computed Dead Detect Interval: 25s, Current Max Interval: 25s *Nov 14 23:44:17.403: AAA/SG/TRANSAC: Estimated Outstanding Transactions: 6, Current Max Transactions: 6 The following output example shows that dead-server-detection information has been requested for a RADIUS server at the IP address 172.19.192.80:

```
Device> enable
Device# show aaa dead-criteria radius 172.19.192.80 radius
RADIUS Server Dead Criteria:
 _____
Server Details:
   Address : 172.19.192.80
   Auth Port : 1645
   Acct Port : 1646
Server Group : radius
Dead Criteria Details:
   Configured Retransmits : 62
   Configured Timeout : 27
   Estimated Outstanding Transactions: 5
   Dead Detect Time : 25s
   Computed Retransmit Tries: 22
   Statistics Gathered Since Last Successful Transaction
Max Computed Outstanding Transactions: 5
Max Computed Dead Detect Time: 25s
Max Computed Retransmits : 22
```

Feature History for AAA Dead-Server Detection

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.11.1	AAA Dead-Server Detection	This feature allows you to configure the criteria to be used to mark a RADIUS server as dead.
Cisco IOS XE Cupertino 17.7.1	AAA Dead-Server Detection	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

Configuring TACACS+

- Prerequisites for TACACS+, on page 141
- Information About TACACS+, on page 142
- How to Configure TACACS+, on page 145
- Monitoring TACACS+, on page 153
- Additional References for TACACS+, on page 153
- Feature History for TACACS+, on page 153

Prerequisites for TACACS+

The following are the prerequisites for set up and configuration of switch access with TACACS+ (must be performed in the order presented):

- 1. Configure the switches with the TACACS+ server addresses.
- 2. Set an authentication key.
- 3. Configure the key from Step 2 on the TACACS+ servers.
- 4. Enable authentication, authorization, and accounting (AAA).
- 5. Create a login authentication method list.
- 6. Apply the list to the terminal lines.
- 7. Create an authorization and accounting method list.

The following are the prerequisites for controlling switch access with TACACS+:

- You must have access to a configured TACACS+ server to configure TACACS+ features on your switch. Also, you must have access to TACACS+ services maintained in a database on a TACACS+ daemon typically running on a LINUX or Windows workstation.
- You need a system running the TACACS+ daemon software to use TACACS+ on your switch.
- To use TACACS+, it must be enabled.
- Authorization must be enabled on the switch to be used.
- Users must first successfully complete TACACS+ authentication before proceeding to TACACS+ authorization.

- To use any of the AAA commands listed in this section or elsewhere, you must first enable AAA with the **aaa new-model** command.
- At a minimum, you must identify the host or hosts maintaining the TACACS+ daemon and define the method lists for TACACS+ authentication. You can optionally define method lists for TACACS+ authorization and accounting.
- The method list defines the types of authentication to be performed and the sequence in which they are performed; it must be applied to a specific port before any of the defined authentication methods are performed. The only exception is the default method list (which, by coincidence, is named *default*). The default method list is automatically applied to all ports except those that have a named method list explicitly defined. A defined method list overrides the default method list.
- Use TACACS+ for privileged EXEC access authorization if authentication was performed by using TACACS+.
- Use the local database if authentication was not performed by using TACACS+.

Information About TACACS+

TACACS+ and Switch Access

This section describes TACACS+. TACACS+ provides detailed accounting information and flexible administrative control over the authentication and authorization processes. It is facilitated through authentication, authorization, accounting (AAA) and can be enabled only through AAA commands.

TACACS+ Overview

TACACS+ is a security application that provides centralized validation of users attempting to gain access to your switch.

TACACS+ provides for separate and modular authentication, authorization, and accounting facilities. TACACS+ allows for a single access control server (the TACACS+ daemon) to provide each service—authentication, authorization, and accounting—independently. Each service can be tied into its own database to take advantage of other services available on that server or on the network, depending on the capabilities of the daemon.

The goal of TACACS+ is to provide a method for managing multiple network access points from a single management service. Your switch can be a network access server along with other Cisco routers and access servers.

Figure 9: Typical TACACS+ Network Configuration

TACACS+, administered through the AAA security services, can provide these services:

 Authentication—Provides complete control of authentication through login and password dialog, challenge and response, and messaging support.

The authentication facility can conduct a dialog with the user (for example, after a username and password are provided, to challenge a user with several questions, such as home address, mother's maiden name, service type, and social security number). The TACACS+ authentication service can also send messages to user screens. For example, a message could notify users that their passwords must be changed because of the company's password aging policy.

- Authorization—Provides fine-grained control over user capabilities for the duration of the user's session, including but not limited to setting autocommands, access control, session duration, or protocol support. You can also enforce restrictions on what commands a user can execute with the TACACS+ authorization feature.
- Accounting—Collects and sends information used for billing, auditing, and reporting to the TACACS+ daemon. Network managers can use the accounting facility to track user activity for a security audit or to provide information for user billing. Accounting records include user identities, start and stop times, executed commands (such as PPP), number of packets, and number of bytes.

The TACACS+ protocol provides authentication between the switch and the TACACS+ daemon, and it ensures confidentiality because all protocol exchanges between the switch and the TACACS+ daemon are encrypted.

TACACS+ Operation

When a user attempts a simple ASCII login by authenticating to a switch using TACACS+, this process occurs:

1. When the connection is established, the switch contacts the TACACS+ daemon to obtain a username prompt to show to the user. The user enters a username, and the switch then contacts the TACACS+

daemon to obtain a password prompt. The switch displays the password prompt to the user, the user enters a password, and the password is then sent to the TACACS+ daemon.

TACACS+ allows a dialog between the daemon and the user until the daemon receives enough information to authenticate the user. The daemon prompts for a username and password combination, but can include other items, such as the user's mother's maiden name.

- 2. The switch eventually receives one of these responses from the TACACS+ daemon:
 - ACCEPT—The user is authenticated and service can begin. If the switch is configured to require authorization, authorization begins at this time.
 - REJECT—The user is not authenticated. The user can be denied access or is prompted to retry the login sequence, depending on the TACACS+ daemon.
 - ERROR—An error occurred at some time during authentication with the daemon or in the network connection between the daemon and the switch. If an ERROR response is received, the switch typically tries to use an alternative method for authenticating the user.
 - CONTINUE—The user is prompted for additional authentication information.

After authentication, the user undergoes an additional authorization phase if authorization has been enabled on the switch. Users must first successfully complete TACACS+ authentication before proceeding to TACACS+ authorization.

- **3.** If TACACS+ authorization is required, the TACACS+ daemon is again contacted, and it returns an ACCEPT or REJECT authorization response. If an ACCEPT response is returned, the response contains data in the form of attributes that direct the EXEC or NETWORK session for that user and the services that the user can access:
 - Telnet, Secure Shell (SSH), rlogin, or privileged EXEC services
 - · Connection parameters, including the host or client IP address, access list, and user timeouts

Method List

A method list defines the sequence and methods to be used to authenticate, to authorize, or to keep accounts on a user. You can use method lists to designate one or more security protocols to be used, thus ensuring a backup system if the initial method fails. The software uses the first method listed to authenticate, to authorize, or to keep accounts on users; if that method does not respond, the software selects the next method in the list. This process continues until there is successful communication with a listed method or the method list is exhausted.

TACACS+ Configuration Options

You can configure the switch to use a single server or AAA server groups to group existing server hosts for authentication. You can group servers to select a subset of the configured server hosts and use them for a particular service. The server group is used with a global server-host list and contains the list of IP addresses of the selected server hosts.

TACACS+ Login Authentication

A method list describes the sequence and authentication methods to be queried to authenticate a user. You can designate one or more security protocols to be used for authentication, thus ensuring a backup system for authentication in case the initial method fails. The software uses the first method listed to authenticate users; if that method fails to respond, the software selects the next authentication method in the method list. This process continues until there is successful communication with a listed authentication method or until all defined methods are exhausted. If authentication fails at any point in this cycle—meaning that the security server or local username database responds by denying the user access—the authentication process stops, and no other authentication methods are attempted.

TACACS+ Authorization for Privileged EXEC Access and Network Services

AAA authorization limits the services available to a user. When AAA authorization is enabled, the switch uses information retrieved from the user's profile, which is located either in the local user database or on the security server, to configure the user's session. The user is granted access to a requested service only if the information in the user profile allows it.

TACACS+ Accounting

The AAA accounting feature tracks the services that users are accessing and the amount of network resources that they are consuming. When AAA accounting is enabled, the switch reports user activity to the TACACS+ security server in the form of accounting records. Each accounting record contains accounting attribute-value (AV) pairs and is stored on the security server. This data can then be analyzed for network management, client billing, or auditing.

Default TACACS+ Configuration

TACACS+ and AAA are disabled by default.

To prevent a lapse in security, you cannot configure TACACS+ through a network management application. When enabled, TACACS+ can authenticate users accessing the switch through the CLI.

Although TACACS+ configuration is performed through the CLI, the TACACS+ server authenticates HTTP connections that have been configured with a privilege level of 15.

How to Configure TACACS+

This section describes how to configure your switch to support TACACS+.

Identifying the TACACS+ Server Host and Setting the Authentication Key

Follow these steps to identify the TACACS+ server host and set the authentication key:

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	tacacs server server-name	Identifies the IP host or hosts maintaining a
	Example:	TACACS+ server. Enter this command
	Device(config)# tacacs server yourserver	multiple times to create a list of preferred hosts. The software searches for hosts in the
		order in which you specify them.
		For server-name, specify the server name.
Step 4	address {ipv4 ipv6} ip address	Configures the IP address for the TACACS
	Example:	server.
	Device(config-server-tacacs)# address ipv4 10.0.1.12	
Step 5	key [encryption-type] [key-string]	Sets the authentication encryption key used for
	Example:	all TACACS+ communications between the access server and the TACACS+ daemon. This
	<pre>Device(config-server-tacacs) # key 0 auth-key</pre>	encryption key must match the key used on the TACACS+ daemon.
		<i>encryption-type</i> is optional, and if nothing is specified it is considered as clear text. Enter 0 to specify that an unencrypted key will follow Enter 6 to specify that an encrypted key will follow. Enter 7 to specify that a hidden key will follow.
Step 6	exit	Exits the TACACS server mode and enters the
	Example:	global configuration mode.
	Device(config-server-tacacs)# exit	
Step 7	aaa new-model	Enables AAA.
	Example:	
	Device(config)# aaa new-model	
Step 8	aaa group server tacacs+ group-name	(Optional) Defines the AAA server-group with
	Example:	a group name, and enters server group
	Device(config)# aaa group server tacacs+ your_server_group	configuration mode.

L

	Command or Action	Purpose	
Step 9	<pre>server name server-name Example: Device(config-sg-tacacs)# server name yourserver</pre>	(Optional) Associates a particular TACACS+ server with the defined server group. Repeat this step for each TACACS+ server in the AAA server group. Each server in the group must be previously defined in Step 3.	
Step 10	<pre>end Example: Device(config-sg-tacacs)# end</pre>	Exits server group configuration mode and returns to privileged EXEC mode.	

Configuring TACACS+ Login Authentication

Follow these steps to configure TACACS+ login authentication:

Before you begin

To configure AAA authentication, you define a named list of authentication methods and then apply that list to various ports.

Note To secure the device for HTTP access by using AAA methods, you must configure the device with the **ip http authentication aaa** global configuration command. Configuring AAA authentication does not secure the device for HTTP access by using AAA methods.

	Command or Action	Purpose	
Step 1	enable	Enables privileged EXEC mode.	
	Example:	• Enter your password if prompted.	
	Device> enable		
Step 2 configure terminal		Enters global configuration mode.	
	Example:		
	Device# configure terminal		
Step 3	aaa new-model	Enables AAA.	
	Example:		
	Device(config)# aaa new-model		

	Command or Action	Purpose
Step 4	Command or Action aaa authentication login {default list-name} method1 [method2] Example: Device (config) # aaa authentication login default tacacs+ local	 Creates a login authentication method list. To create a default list that is used when a named list is <i>not</i> specified in the login authentication command, use the default
		 authentication method, you must define an enable password by using the enable <i>password</i> global configuration command. <i>group tacacs+</i>—Uses TACACS+ authentication. Before you can use this authentication method, you must configure the TACACS+ server. <i>line</i>—Use the line password for authentication. Before you can use this authentication method, you must define a
		 line password. Use the password password line configuration command. local—Use the local username database for authentication. You must enter username information in the database. Use the username password global configuration command. local-case—Use a case-sensitive local username database for authentication. You must enter username information in the database by using the username name password global configuration command.
		 <i>none</i>—Do not use any authentication for login.

L

	Command or Action	Purpose	
Step 5	<pre>line [console tty vty] line-number [ending-line-number] Example: Device(config)# line 2 4</pre>	Enters line configuration mode, and configures the lines to which you want to apply the authentication list.	
Step 6	<pre>login authentication {default list-name} Example: Device(config-line)# login authentication default</pre>	 Applies the authentication list to a line or set of lines. If you specify default, use the default list created with the aaa authentication login command. For <i>list-name</i>, specify the list created with the aaa authentication login command. 	
Step 7	<pre>end Example: Device(config-line)# end</pre>	Exits line configuration mode and returns to privileged EXEC mode.	

Configuring TACACS+ Authorization for Privileged EXEC Access and Network Services

You can use the **aaa authorization** global configuration command with the **tacacs**+ keyword to set parameters that restrict a user's network access to privileged EXEC mode.

Note Authorization is bypassed for authenticated users who log in through the CLI even if authorization has been configured.

Follow these steps to specify TACACS+ authorization for privileged EXEC access and network services:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	

I

	Command or Action	Purpose	
	Device# configure terminal		
Step 3	aaa authorization networkauthorization-list tacacs+	Configures the switch for user TACACS+ authorization for all network-related service	
	Example:	requests.	
	Device(config)# aaa authorization network list1 tacacs+	c	
Step 4	aaa authorization exec <i>default</i> tacacs+ Example:	Configures the switch for user TACACS+ authorization if the user has privileged EXEC access.	
	Device(config)# aaa authorization exec default tacacs+	The exec keyword might return user profile information (such as autocommand information).	
Step 5	end Example:	Exits global configuration mode and returns to privileged EXEC mode.	
	Device(config)# end		

Starting TACACS+ Accounting

Follow these steps to start TACACS+ Accounting:

Command or Action	Purpose	
enable	Enables privileged EXEC mode.	
Example:	• Enter your password if prompted.	
Device> enable		
configure terminal	Enters global configuration mode.	
Example:		
Device# configure terminal		
aaa accounting network authorization-list start-stop tacacs+	Enables TACACS+ accounting for all network-related service requests.	
Example:		
Device(config)# aaa accounting network list1 start-stop tacacs+		
	<pre>enable enable Example: Device> enable configure terminal Example: Device# configure terminal aaa accounting network authorization-list start-stop tacacs+ Example: Device(config)# aaa accounting network</pre>	

	Command or Action	Purpose
Step 4	aaa accounting exec default start-stop tacacs+ Example: Device(config)# aaa accounting exec default start-stop tacacs+	Enables TACACS+ accounting to send a start-record accounting notice at the beginning of a privileged EXEC process and a stop-record at the end.
Step 5	end Example: Device(config)# end	Exits global configuration mode and returns to privileged EXEC mode.

What to do next

To establish a session with a device if the AAA server is unreachable, use the **aaa accounting system guarantee-first** command. It guarantees system accounting as the first record, which is the default condition. In some situations, users might be prevented from starting a session on the console or terminal connection until after the system reloads, which can take more than 3 minutes.

To establish a console or Telnet session with the router if the AAA server is unreachable when the router reloads, use the **no aaa accounting system guarantee-first** command.

Establishing a Session with a Device if the AAA Server is Unreachable

To establishing a session with a device if the AAA server is unreachable, use the **aaa accounting system guarantee-first** command. It guarantees system accounting as the first record, which is the default condition. In some situations, users might be prevented from starting a session on the console or terminal connection until after the system reloads, which can take more than 3 minutes.

To establish a console or Telnet session with the device if the AAA server is unreachable when the device reloads, use the **no aaa accounting system guarantee-first** command.

Configuring TACACS Source-Interface Under a TACACS Server-Group

The TACACS source-interface can be configured under a TACACS server-group in either of the following methods:

- Configure a TACACS source-interface under the TACACS server-group using the **ip tacacs source-interface** *interface-name* command.
- Configure a VRF using the **vrf** *vrf*-*name* command under the TACACS server-group, and then associate the configured VRF globally to a source-interface using the **ip tacacs source interface** *interface-name* **vrf** *vrf*-*name* command.

Priority will be given to the source-interface under the server-group configuration in case both methods are configured.

To configure TACACS source-interface under a TACACS server-group, perform the following:

Before you begin

You must configure a VRF routing table and associate VRF to an interface

	Command or Action	Purpose	
Step 1	enable	Enables privileged EXEC mode.	
	Example:	Enter your password if prompted.	
	Device> enable		
Step 2	configure terminal	Enters global configuration mode.	
	Example:		
	Device# configure terminal		
Step 3	{ ip ipv6 }tacacs source-interface	Forces TACACS to use the IP address of a	
	interface-number vrf vrf-name	specified interface for all outgoing TACACS	
	Example:	packets, and enables the specification on a per-VRF basis.	
	Device(config)# ip tacacs source-interface GigabitEthernet1/0/23 vrf vrf17	• <i>interface-name</i> : Specifies the name of the interface that TACACS+ uses for all of its outgoing packets.	
		• vrf <i>vrf-name</i> : Specifies the per-VRF configuration.	
Step 4	aaa group server tacacs group_name	Groups different TACACS server hosts into	
	Example:	distinct lists and distinct methods and enters	
	Device(config-sg-tacacs+)# aa group server tacacs rad-grp	server-group configuration mode.	
Step 5	ip vrf forwarding vrf-name	(Optional) Configures a VRF for the interface.	
	Example:		
	<pre>Device(config-sg-tacacs+)# ip vrf forwarding vrf17</pre>		
Step 6	{ ip ipv6 } tacacs source-interface <i>interface-number</i>	(Optional) Forces TACACS+ to use the IP address of a specified interface for all outgoing	
	Example:	TACACS packets from the TACACS+ group server.	
	<pre>Device(config-sg-tacacs+)# ip tacacs source-interface loopback0</pre>	<i>interface-name</i> : Specifies the name of the interface that TACACS uses for all of its outgoing packets.	
Step 7	end	Returns to privileged EXEC mode.	
	Example:		
	Device(config-sg-tacacs+)# end		

Monitoring TACACS+

Table 8: Commands for Displaying TACACS+ Information

Command	Purpose
show tacacs	Displays TACACS+ server statistics.

Feature History for TACACS+

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.11.1	TACACS+	TACACS+ provides detailed accounting information and flexible administrative control over authentication and authorization processes. TACACS+ is facilitated through AAA and can be enabled only through AAA commands.

Release	Feature	Feature Information
Cisco IOS XE Cupertino 17.7.1	TACACS+	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

Device Sensor

The Device Sensor feature is used to gather raw endpoint data from network devices using protocols such as Cisco Discovery Protocol (CDP), Link Layer Discovery Protocol (LLDP), Dynamic Host Configuration Protocol (DHCP), DHCP version 6, and multicast DNS (mDNS). The endpoint data that is gathered is made available to registered clients in the context of an access session.

- Restrictions for Device Sensor, on page 155
- Information About Device Sensor, on page 155
- How to Configure Device Sensor, on page 157
- Configuration Examples for Device Sensor, on page 162
- Feature History for Device Sensor, on page 163

Restrictions for Device Sensor

- Only Cisco Discovery Protocol (CDP), Link Layer Discovery Protocol (LLDP), Dynamic Host Configuration Protocol (DHCP), Dynamic Host Configuration Protocol ersion 6 (DHCPv6), and multicast DNS (mDNS) protocols are supported.
- The session limit for profiling ports is 32.
- The length of one Type-Length-Value (TLV) must not be more than 1024 and the total length of TLVs (combined length of TLVs) of all protocols must not be more than 4096.
- The sensor profiles devices that are only one hop away.
- The Device Sensor feature is enabled by default, but cannot be disabled. Disabling device classifier using **no device classifier** command in global configuration mode does not disable device sensor. This is because device sensor is independent of IP device tracking and device classifier.

Information About Device Sensor

Device Sensor

The device sensor is used to gather raw endpoint data from network devices. The endpoint information that is gathered helps in completing the profiling capability of devices. Profiling is the determination of the endpoint

type based on information gleaned from various protocol packets from an endpoint during its connection to a network.

The profiling capability consists of two parts:

- · Collector-Gathers endpoint data from network devices.
- Analyzer—Processes the data and determines the type of device.

The device sensor represents the embedded collector functionality. The illustration below shows the Cisco sensor in the context of the profiling system and also features other possible clients of the sensor.

A device with sensor capability gathers endpoint information from network devices using protocols such as Cisco Discovery Protocol, LLDP, DHCPv6, mDNS and DHCP, subject to statically configured filters, and makes this information available to its registered clients in the context of an access session. An access session represents an endpoint's connection to the network device.

The device sensor has internal and external clients. The internal clients include components such as the embedded Device Classifier (local analyzer), ATM switch processor (ASP), MSI-Proxy, and EnergyWise (EW). The external client, that is the Identity Services Engine (ISE) analyzer, will use RADIUS accounting to receive additional endpoint data.

Client notifications and accounting messages containing profiling data along with the session events and other session-related data, such as the MAC address and the ingress port, are generated and sent to the internal and external clients (ISE). By default, for each supported peer protocol, client notifications and accounting events are only generated where an incoming packet includes a TLV that has not previously been received in the context of a given session. You can enable client notifications and accounting events for all TLV changes,

where either a new TLV has been received or a previously received TLV has been received with a different value using CLI commands.

The device sensor's port security protects the switch from consuming memory and crashing during deliberate or unintentional denial-of-service (DoS) type attacks. The sensor limits the maximum device monitoring sessions to 32 per port (access ports and trunk ports). In case of lack of activity from hosts, the idle session time is 12 hours.

How to Configure Device Sensor

The device sensor is enabled by default.

The following tasks are applicable only if you want to configure the sensor based on your specific requirements.

Note If you do not perform these configuration tasks, then the following TLVs are included by default:

- Cisco Discovery Protocol filter—secondport-status-type and powernet-event-type (type 28 and 29).
- LLDP filter-organizationally-specific (type 127).
- DHCP filter—message-type (type 53).

Enabling Accounting Augmentation

Perform this task to add device sensor protocol data to accounting records.

Before you begin

For the sensor protocol data to be added to the accounting messages, you must enable session accounting by using the standard authentication, authorization, and accounting (AAA), and RADIUS configuration commands.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	device-sensor accounting	Enables the addition of sensor protocol data to
	Example:	accounting records and also enables the generation of additional accounting events when new sensor data is detected.

I

	Command or Action	Purpose
	Device(config)# device-sensor accounting	
Step 4	end	Exits global configuration mode and returns to
	Example:	privileged EXEC mode.
	Device(config)# end	

Creating a Protocol Filter

Perform this task to create a CDP, LLDP, DHCP, mDNS, or DHCPv6 filter containing TLVs that can be included or excluded in the device sensor output.

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	<pre>device-sensor {filter-listcdp dhcp dhcpv6 mdns lldp} {listtlv-list-name} Example: Device(config) # device-sensor filter-list cdp list cdp-list</pre>	 Applies a sensor protocol filter list and enters configuration mode, where you can configure individual TLVs. cdp - Applies a Cisco Discovery Protocol TLV filter list. lldp - Applies an Link Layer Discovery protocol TLV filter list. dhcp - Applies a Dynamic Host Configuration Protocol TLV filter list. dhcpv6 - Applies a Dynamic Host Configuration Protocol version 6 TLV filter list. mdns - Applies a Multicast DNS Protocol TLV filter list. listlist-name - Specifies the protocol TLV filter list name.

	Command or Action	Purpose
Step 4	option { name <i>option-name</i> number <i>option-number</i> }	This step applies only to DHCP protocol. Adds individual DHCP options to the option list.
	<pre>Example: Device(config-sensor-cdplist)# tlv number 10</pre>	You can delete the option list without individually removing options from the list by using the no device-sensor filter-list dhcp list <i>option-list-name</i> command.
		• You can delete the TLV list without individually removing TLVs from the list by using the no device-sensor filter-list cdp list <i>tlv-list-name</i> command.
Step 5	<pre>tlv {name tlv-name number tlv-number} Example: Device(config-sensor-cdplist)# tlv number 10</pre>	 Adds individual Cisco Discovery Protocol TLVs to the TLV list. You can delete the TLV list without individually removing TLVs from the list by using the no device-sensor filter-list cdp list <i>tlv-list-name</i> command.
Step 6	end	Returns to privileged EXEC mode.
	Example:	
	Device(config-sensor-cdplist)# end	

Applying a Protocol Filter to the Sensor Output

Perform this task to apply a Cisco Discovery Protocol, LLDP, or DHCP filter to the sensor output. Session notifications are sent to internal sensor clients and accounting requests.

	Command or Action	Purpose	
Step 1	enable	Enables privileged EXEC mode. Enter your password, if prompted.	
	Example:		
	Device> enable		
Step 2	configure terminal	Enters global configuration mode.	
	Example:		
	Device# configure terminal		
Step 3	device-sensor filter-spec {cdp dhcp lldp} {exclude {all list list-name} include list list-name}	Applies a specific protocol filter containing a list of TLV fields to the device sensor output.	

	Command or Action	Purpose
	Example: Device(config)# device-sensor filter-spectod cdp include list list1	 cdp—Applies a Cisco Discovery Protocol TLV filter list to the device sensor output. lldp—Applies an LLDP TLV filter list to the device sensor output. dhcp—Applies a DHCP TLV filter list to the device sensor output. dhcpv6—Applies a DHCPv6 TLV filter list to the device sensor output. mdns—Applies an mDNS TLV filter list to the device sensor output. exclude—Specifies the TLVs that must be excluded from the device sensor output. include—Specifies the TLVs that must be included from the device sensor output. all—Disables all notifications for the associated protocol. list <i>list-name</i>—Specifies the protocol TLV filter list name.
Step 4	<pre>end Example: Device(config)# end</pre>	Exits global configuration mode and returns to privileged EXEC mode.

Tracking TLV Changes

Perform this task to enable client notifications and accounting events for all TLV changes. By default, for each supported peer protocol, client notifications and accounting events will only be generated where an incoming packet includes a TLV that has not previously been received in the context of a given session.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	

	Command or Action	Purpose	
Step 3	<pre>device-sensor notify all-changes Example: Device(config)# device-sensor notify all-changes</pre>	Enables client notifications and accounting events for all TLV changes, that is, where either a new TLV is received or a previously received TLV is received with a new value in the context of a given session.	
		Note Use the default device-sensor notify or the device-sensor notify new-tlvs command to return to the default TLV.	
Step 4	end Example: Device(config)# end	Exits global configuration mode and returns to privileged EXEC mode.	

Verifying the Device Sensor Configuration

Perform this task to verify the sensor cache entries for all devices.

Step 1	enable
	Enables privileged EXEC mode.
	Example:
	Device> enable
Step 2	show device-sensor details
	Displays protocol configuration details for all devices.
	Example:
	Device# show device-sensor details
Step 3	show device-sensor cache mac mac-address
	Displays sensor cache entries (the list of protocol TLVs or options received from a device) for a specific device.
	Example:
	Device# show device-sensor cache mac 0024.14dc.df4d
Step 4	show device-sensor cache all
	Displays sensor cache entries for all devices.
	Example:

```
Device# show device-sensor cache all
Device: 001c.0f74.8480 on port GigabitEthernet2/1
```

Configuration Examples for Device Sensor

Examples: Configuring the Device Sensor

The following example shows how to create a Cisco Discovery Protocol filter containing a list of TLVs:

```
Device> enable
Device# configure terminal
Device(config)# device-sensor filter-list cdp list cdp-list
Device(config-sensor-cdplist)# tlv name address-type
Device(config-sensor-cdplist)# tlv name device-name
Device(config-sensor-cdplist)# tlv number 34
Device(config-sensor-cdplist)# end
```

The following example shows how to create an LLDP filter containing a list of TLVs:

```
Device> enable
Device# configure terminal
Device(config)# device-sensor filter-list lldp list lldp-list
Device(config-sensor-lldplist)# tlv name chassis-id
Device(config-sensor-lldplist)# tlv name management-address
Device(config-sensor-lldplist)# tlv number 28
Device(config-sensor-lldplist)# end
```

The following example shows how to create a DHCP filter containing a list of options:

```
Device> enable
Device# configure terminal
Device(config)# device-sensor filter-list dhcp list dhcp-list
Device(config-sensor-lldplist)# option name address-type
Device(config-sensor-lldplist)# option name device-name
Device(config-sensor-lldplist)# option number 34
Device(config-sensor-lldplist)# end
```

The following example shows how to apply a Cisco Discovery Protocol TLV filter list to the device sensor output:

```
Device> enable
Device# configure terminal
Device(config)# device-sensor filter-spec cdp include cdp-list1
Device(config
Device(config
Device(config-sensor-lldplist)# end)# end
```

The following example shows how to enable client notifications and accounting events for all TLV changes:

Device> enable Device# configure terminal

Device(config)# device-sensor notify all-changes
Device(config)# end

Feature History for Device Sensor

This table provides release and related information for features explained in this module.

These features are available on all releases subsequent to the one they were introduced in, unless noted otherwise.

Table 9: Feature	e Information for	Device Sensor
------------------	-------------------	---------------

Release	Feature	Feature Information
Cisco IOS XE Fuji 16.8.1a Cisco IOS XE Gibraltar 16.11.1	Device Sensor	The Device Sensor feature is used to gather raw endpoint data from network devices using protocols such as Cisco Discovery Protocol, Link Layer Discovery Protocol (LLDP), and DHCP. The endpoint data that is gathered is made available to registered clients in the context of an access session.
Cisco IOS XE Cupertino 17.7.1	Device Sensor	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module.

Use Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

Configuring RADIUS

- Prerequisites for Configuring RADIUS, on page 165
- Restrictions for Configuring RADIUS, on page 166
- Information about RADIUS, on page 166
- How to Configure RADIUS, on page 188
- Monitoring CoA Functionality, on page 203
- Feature History for RADIUS, on page 203

Prerequisites for Configuring RADIUS

This section lists the prerequisites for controlling device access with RADIUS.

General:

- RADIUS and Authentication, Authorization, and Accounting (AAA) must be enabled to use any of the configuration commands in this chapter.
- RADIUS is facilitated through AAA and can be enabled only through AAA commands.
- Use the aaa new-model global configuration command to enable AAA.
- Use the **aaa authentication** global configuration command to define method lists for RADIUS authentication.
- Use line and interface commands to enable the defined method lists to be used.
- At a minimum, you must identify the host or hosts that run the RADIUS server software and define the method lists for RADIUS authentication. You can optionally define method lists for RADIUS authorization and accounting.
- You should have access to and should configure a RADIUS server before configuring RADIUS features on your device.
- The RADIUS host is normally a multiuser system running RADIUS server software from Cisco (Cisco Secure Access Control Server Version 3.0), Livingston, Merit, Microsoft, or another software provider. For more information, see the RADIUS server documentation.
- To use the Change-of-Authorization (CoA) interface, a session must already exist on the switch. CoA can be used to identify a session and enforce a disconnect request. The update affects only the specified session.

RADIUS operation:

- Users must first successfully complete RADIUS authentication before proceeding to RADIUS authorization, if it is enabled.
- For RADIUS over IPv6 configurations, users must enable IPv6 unicast routing by enabling the ipv6 unicast-routing command.

Restrictions for Configuring RADIUS

General:

• To prevent a lapse in security, you cannot configure RADIUS through a network management application.

RADIUS is not suitable in the following network security situations:

- Multiprotocol access environments. RADIUS does not support AppleTalk Remote Access (ARA), NetBIOS Frame Control Protocol (NBFCP), NetWare Asynchronous Services Interface (NASI), or X.25 PAD connections.
- Switch-to-switch or router-to-router situations. RADIUS does not provide two-way authentication. RADIUS can be used to authenticate from one device to a non-Cisco device if the non-Cisco device requires authentication.
- Networks using a variety of services. RADIUS generally binds a user to one service model.

DSCP marking support for RADIUS packets:

- DSCP marking for authentication and accounting is not supported for private servers, fully qualified domain name (FQDN) servers and radsec servers.
- In the case of wired IEEE 802.1x authentication, when source port extension is not enabled, the default ports are in use. The DSCP marking is set to the default ports and all the requests will be marked with the same DSCP value.
- DSCP marking is not supported in the case of wireless IEEE 802.1x authentication, where the source
 port extension is enabled by default.

Information about RADIUS

RADIUS and Switch Access

This section describes how to enable and configure RADIUS. RADIUS provides detailed accounting information and flexible administrative control over the authentication and authorization processes.

RADIUS Overview

RADIUS is a distributed client/server system that secures networks against unauthorized access. RADIUS clients run on supported Cisco devices. Clients send authentication requests to a central RADIUS server, which contains all user authentication and network service access information.

Use RADIUS in these network environments that require access security:

- Networks with multiple-vendor access servers, each supporting RADIUS. For example, access servers
 from several vendors use a single RADIUS server-based security database. In an IP-based network with
 multiple vendors' access servers, dial-in users are authenticated through a RADIUS server that has been
 customized to work with the Kerberos security system.
- Turnkey network security environments in which applications support the RADIUS protocol, such as in an access environment that uses a *smart card* access control system.
- Networks already using RADIUS. You can add a Cisco device containing a RADIUS client to the network. This might be the first step when you make a transition to a TACACS+ server. See the illustration: Transitioning from RADIUS to TACACS+ Services below.

Figure 10: Transitioning from RADIUS to TACACS+ Services

- Network in which the user must only access a single service. Using RADIUS, you can control user access to a single host, to a single utility such as Telnet, or to the network through a protocol such as IEEE 802.1x. For more information about this protocol, see the chapter *Configuring IEEE 802.1x Port-Based Authentication*.
- Networks that require resource accounting. You can use RADIUS accounting independently of RADIUS authentication or authorization. The RADIUS accounting functions allow data to be sent at the start and end of services, showing the amount of resources (such as time, packets, bytes, and so forth) used during the session. An Internet service provider might use a freeware-based version of RADIUS access control and accounting software to meet special security and billing needs.

RADIUS Operation

When a user attempts to log in and authenticate to a device that is access controlled by a RADIUS server, these events occur:

- 1. The user is prompted to enter a username and password.
- **2.** The username and encrypted password are sent over the network to the RADIUS server.
- 3. The user receives one of the following responses from the RADIUS server:
 - ACCEPT—The user is authenticated.

- REJECT—The user is either not authenticated and is prompted to re-enter the username and password, or access is denied.
- CHALLENGE—A challenge requires additional data from the user.
- CHALLENGE PASSWORD—A response requests the user to select a new password.

The ACCEPT or REJECT response is bundled with additional data that is used for privileged EXEC or network authorization. The additional data included with the ACCEPT or REJECT packets includes these items:

- Telnet, SSH, rlogin, or privileged EXEC services
- Connection parameters, including the host or client IP address, access list, and user timeouts

RADIUS Change of Authorization

The RADIUS Change of Authorization (CoA) provides a mechanism to change the attributes of an authentication, authorization, and accounting (AAA) session after it is authenticated. When a policy changes for a user or user group in AAA, administrators can send RADIUS CoA packets from the AAA server such as a Cisco Secure Access Control Server (ACS) to reinitialize authentication and apply the new policy. This section provides an overview of the RADIUS interface including available primitives and how they are used during a CoA.

- Change-of-Authorization Requests
- CoA Request Response Code
- CoA Request Commands
- Session Reauthentication
- Stacking Guidelines for Session Termination

A standard RADIUS interface is typically used in a pulled model where the request originates from a network attached device and the response come from the queried servers. Cisco devices support the RADIUS CoA extensions defined in RFC 5176 that are typically used in a pushed model and allow for the dynamic reconfiguring of sessions from external AAA or policy servers.

Cisco devices supports these per-session CoA requests:

- Session reauthentication
- Session termination
- Session termination with port shutdown
- Session termination with port bounce

This feature is integrated with Cisco Secure Access Control Server (ACS) 5.1.

The RADIUS interface is enabled by default on Cisco devices. However, some basic configuration is required for the following attributes:

• Security and Password—refer to the "Preventing Unauthorized Access to Your Switch" section in this guide.

• Accounting—refer to the "Starting RADIUS Accounting" section in the Configuring Switch-Based Authentication chapter in this guide.

Cisco IOS XE software supports the RADIUS CoA extensions defined in RFC 5176 that are typically used in a push model to allow the dynamic reconfiguring of sessions from external AAA or policy servers. Per-session CoA requests are supported for session identification, session termination, host reauthentication, port shutdown, and port bounce. This model comprises one request (CoA-Request) and two possible response codes:

- CoA acknowledgement (ACK) [CoA-ACK]
- CoA nonacknowledgement (NAK) [CoA-NAK]

The request is initiated from a CoA client (typically a AAA or policy server) and directed to the device that acts as a listener.

The table below shows the RADIUS CoA commands and vendor-specific attributes (VSAs) supported by Identity-Based Networking Services. All CoA commands must include the session identifier between the device and the CoA client.

CoA Command	Cisco VSA		
Activate service	Cisco:Avpair="subscriber:command=activate-service"		
	Cisco:Avpair="subscriber:service-name= <service-name>"</service-name>		
	Cisco:Avpair="subscriber:precedence= <precedence-number>"</precedence-number>		
	Cisco:Avpair="subscriber:activation-mode=replace-all"		
Deactivate service	Cisco:Avpair="subscriber:command=deactivate-service"		
	Cisco:Avpair="subscriber:service-name= <service-name>"</service-name>		
Bounce host port	Cisco:Avpair="subscriber:command=bounce-host-port"		
Disable host port	Cisco:Avpair="subscriber:command=disable-host-port"		
Session query	Cisco:Avpair="subscriber:command=session-query"		
Session reauthenticate	Cisco:Avpair="subscriber:command=reauthenticate"		
	Cisco:Avpair="subscriber:reauthenticate-type=last" or		
	Cisco:Avpair="subscriber:reauthenticate-type=rerun"		
Session terminate	This is a standard disconnect request and does not require a VSA.		
Interface template	Cisco:AVpair="interface-template-name= <interfacetemplate>"</interfacetemplate>		

Table 10: RADIUS CoA Commands Supported by Identity-Based Networking Services

Change-of-Authorization Requests

Change of Authorization (CoA) requests, as described in RFC 5176, are used in a push model to allow for session identification, host reauthentication, and session termination. The model is comprised of one request (CoA-Request) and two possible response codes:

• CoA acknowledgment (ACK) [CoA-ACK]

• CoA non-acknowledgment (NAK) [CoA-NAK]

The request is initiated from a CoA client (typically a RADIUS or policy server) and directed to the switch that acts as a listener.

RFC 5176 Compliance

The Disconnect Request message, which is also referred to as Packet of Disconnect (POD), is supported by the switch for session termination.

This table shows the IETF attributes are supported for this feature.

Attribute Number	Attribute Name	
24	State	
31	Calling-Station-ID	
44	Acct-Session-ID	
80	Message-Authenticator	
101	Error-Cause	

Table 11: Supported IETF Attributes

This table shows the possible values for the Error-Cause attribute.

Table 12: Error-Cause Values

Value	Explanation
201	Residual Session Context Removed
202	Invalid EAP Packet (Ignored)
401	Unsupported Attribute
402	Missing Attribute
403	NAS Identification Mismatch
404	Invalid Request
405	Unsupported Service
406	Unsupported Extension
407	Invalid Attribute Value
501	Administratively Prohibited
502	Request Not Routable (Proxy)
503	Session Context Not Found

Value	Explanation
504	Session Context Not Removable
505	Other Proxy Processing Error
506	Resources Unavailable
507	Request Initiated
508	Multiple Session Selection Unsupported

CoA Request Response Code

The CoA Request response code can be used to convey a command to the switch.

The packet format for a CoA Request Response code as defined in RFC 5176 consists of the following fields: Code, Identifier, Length, Authenticator, and Attributes in the Type:Length:Value (TLV) format. The Attributes field is used to carry Cisco vendor-specific attributes (VSAs).

Session Identification

For disconnect and CoA requests targeted at a particular session, the switch locates the session based on one or more of the following attributes:

- Acct-Session-Id (IETF attribute #44)
- Audit-Session-Id (Cisco VSA)
- Calling-Station-Id (IETF attribute #31 which contains the host MAC address)
- IPv6 Attributes, which can be one of the following:
 - Framed-IPv6-Prefix (IETF attribute #97) and Framed-Interface-Id (IETF attribute #96), which together create a full IPv6 address per RFC 3162
 - Framed-IPv6-Address
- Plain IP Address (IETF attribute #8)

Unless all session identification attributes included in the CoA message match the session, the switch returns a Disconnect-NAK or CoA-NAK with the "Invalid Attribute Value" error-code attribute.

If more than one session identification attribute is included in the message, all the attributes must match the session or the switch returns a Disconnect- negative acknowledgment (NAK) or CoA-NAK with the error code "Invalid Attribute Value."

The packet format for a CoA Request code as defined in RFC 5176 consists of the fields: Code, Identifier, Length, Authenticator, and Attributes in Type:Length:Value (TLV) format.

The attributes field is used to carry Cisco vendor-specific attributes (VSAs).

For CoA requests targeted at a particular enforcement policy, the device returns a CoA-NAK with the error code "Invalid Attribute Value" if any of the above session identification attributes are included in the message.

CoA ACK Response Code

If the authorization state is changed successfully, a positive acknowledgment (ACK) is sent. The attributes returned within CoA ACK will vary based on the CoA Request and are discussed in individual CoA Commands.

CoA NAK Response Code

A negative acknowledgment (NAK) indicates a failure to change the authorization state and can include attributes that indicate the reason for the failure. Use **show** commands to verify a successful CoA.

CoA Request Commands

Command 1	Cisco VSA
Reauthenticate host	Cisco:Avpair="subscriber:command=reauthenticate"
Terminate session	This is a standard disconnect request that does not require a VSA.
Bounce host port	Cisco:Avpair="subscriber:command=bounce-host-port"
Disable host port	Cisco:Avpair="subscriber:command=disable-host-port"

Table 13: Supported CoA Commands

¹ All CoA commands must include the session identifier between the device and the CoA client.

Session Reauthentication

The AAA server typically generates a session reauthentication request when a host with an unknown identity or posture joins the network and is associated with a restricted access authorization profile (such as a guest VLAN). A reauthentication request allows the host to be placed in the appropriate authorization group when its credentials are known.

To initiate session authentication, the AAA server sends a standard CoA-Request message which contains a Cisco VSA in this form: *Cisco:Avpair="subscriber:command=reauthenticate"* and one or more session identification attributes.

The current session state determines the switch response to the message. If the session is currently authenticated by IEEE 802.1x, the switch responds by sending an EAPoL (Extensible Authentication Protocol over Lan) -RequestId message to the server.

If the session is currently authenticated by MAC authentication bypass (MAB), the switch sends an access-request to the server, passing the same identity attributes used for the initial successful authentication.

If session authentication is in progress when the switch receives the command, the switch terminates the process, and restarts the authentication sequence, starting with the method configured to be attempted first.

If the session is not yet authorized, or is authorized via guest VLAN, or critical VLAN, or similar policies, the reauthentication message restarts the access control methods, beginning with the method configured to be attempted first. The current authorization of the session is maintained until the reauthentication leads to a different authorization result.

Session Termination

There are three types of CoA requests that can trigger session termination. A CoA Disconnect-Request terminates the session, without disabling the host port. This command causes re-initialization of the authenticator state machine for the specified host, but does not restrict that host access to the network.

To restrict a host's access to the network, use a CoA Request with the Cisco:Avpair="subscriber:command=disable-host-port" VSA. This command is useful when a host is known to be causing problems on the network, and you need to immediately block network access for the host. When

you want to restore network access on the port, re-enable it using a non-RADIUS mechanism.

When a device with no supplicant, such as a printer, needs to acquire a new IP address (for example, after a VLAN change), terminate the session on the host port with port-bounce (temporarily disable and then re-enable the port).

CoA Disconnect-Request

This command is a standard Disconnect-Request. If the session cannot be located, the device returns a Disconnect-NAK message with the "Session Context Not Found" error-code attribute. If the session is located, the device terminates the session. After the session has been completely removed, the device returns a Disconnect-ACK.

If the device fails-over to a standby device before returning a Disconnect-ACK to the client, the process is repeated on the new active device when the request is re-sent from the client. If the session is not found following re-sending, a Disconnect-ACK is sent with the "Session Context Not Found" error-code attribute.

CoA Request: Disable Host Port

The RADIUS server CoA disable port command administratively shuts down the authentication port that is hosting a session, resulting in session termination. This command is useful when a host is known to cause problems on the network and network access needs to be immediately blocked for the host. To restore network access on the port, reenable it using a non-RADIUS mechanism. This command is carried in a standard CoA-Request message that has this new vendor-specific attribute (VSA):

Cisco:Avpair="subscriber:command=disable-host-port"

Because this command is session-oriented, it must be accompanied by one or more of the session identification attributes described in the "Session Identification" section. If the session cannot be located, the device returns a CoA-NAK message with the "Session Context Not Found" error-code attribute. If the session is located, the device disables the hosting port and returns a CoA-ACK message.

If the device fails before returning a CoA-ACK to the client, the process is repeated on the new active device when the request is re-sent from the client. If the device fails after returning a CoA-ACK message to the client but before the operation has completed, the operation is restarted on the new active device.

Note

A Disconnect-Request failure following command re-sending could be the result of either a successful session termination before change-over (if the Disconnect-ACK was not sent) or a session termination by other means (for example, a link failure) that occurred after the original command was issued and before the standby device became active.

CoA Request: Bounce-Port

A RADIUS server CoA bounce port sent from a RADIUS server can cause a link flap on an authentication port, which triggers DHCP renegotiation from one or more hosts connected to this port. This incident can occur when there is a VLAN change and the endpoint is a device (such as a printer) that does not have a mechanism to detect a change on this authentication port. The CoA bounce port is carried in a standard CoA-Request message that contains the following VSA:

Cisco:Avpair="subscriber:command=bounce-host-port"

Because this command is session-oriented, it must be accompanied by one or more of the session identification attributes. If the session cannot be located, the device returns a CoA-NAK message with the "Session Context Not Found" error-code attribute. If the session is located, the device disables the hosting port for a period of 10 seconds, re-enables it (port-bounce), and returns a CoA-ACK.

If the device fails before returning a CoA-ACK to the client, the process is repeated on the new active device when the request is re-sent from the client. If the device fails after returning a CoA-ACK message to the client but before the operation has completed, the operation is re-started on the new active device.

Default RADIUS Configuration

RADIUS and AAA are disabled by default.

To prevent a lapse in security, you cannot configure RADIUS through a network management application. When enabled, RADIUS can authenticate users accessing the device through the CLI.

RADIUS Server Host

Device-to-RADIUS-server communication involves several components:

- · Hostname or IP address
- Authentication destination port
- Accounting destination port
- Key string
- Timeout period
- Retransmission value

You identify RADIUS security servers by their hostname or IP address, hostname and specific UDP port numbers, or their IP address and specific UDP port numbers. The combination of the IP address and the UDP port number creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. This unique identifier enables RADIUS requests to be sent to multiple UDP ports on a server at the same IP address.

If two different host entries on the same RADIUS server are configured for the same service—for example, accounting—the second host entry configured acts as a fail-over backup to the first one. Using this example, if the first host entry fails to provide accounting services, the %RADIUS-4-RADIUS_DEAD message appears, and then the device tries the second host entry configured on the same device for accounting services. (The RADIUS host entries are tried in the order that they are configured.)

A RADIUS server and the device use a shared secret text string to encrypt passwords and exchange responses. To configure RADIUS to use the AAA security commands, you must specify the host running the RADIUS server daemon and a secret text (key) string that it shares with the device.

The timeout, retransmission, and encryption key values can be configured globally for all RADIUS servers, on a per-server basis, or in some combination of global and per-server settings.

RADIUS Login Authentication

To configure AAA authentication, you define a named list of authentication methods and then apply that list to various ports. The method list defines the types of authentication to be performed and the sequence in which they are performed; it must be applied to a specific port before any of the defined authentication methods are performed. The only exception is the default method list. The default method list is automatically applied to all ports except those that have a named method list explicitly defined.

A method list describes the sequence and authentication methods to be queried to authenticate a user. You can designate one or more security protocols to be used for authentication, thus ensuring a backup system for authentication in case the initial method fails. The software uses the first method listed to authenticate users; if that method fails to respond, the software selects the next authentication method in the method list. This process continues until there is successful communication with a listed authentication method or until all defined methods are exhausted. If authentication fails at any point in this cycle—meaning that the security server or local username database responds by denying the user access—the authentication process stops, and no other authentication methods are attempted.

AAA Server Groups

You can configure the device to use AAA server groups to group existing server hosts for authentication. You select a subset of the configured server hosts and use them for a particular service. The server group is used with a global server-host list, which lists the IP addresses of the selected server hosts.

Server groups also can include multiple host entries for the same server if each entry has a unique identifier (the combination of the IP address and UDP port number), allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. This unique identifier enables RADIUS requests to be sent to different UDP ports on a server at the same IP address. If you configure two different host entries on the same RADIUS server for the same service, (for example, accounting), the second configured host entry acts as a fail-over backup to the first one. If the first host entry fails to provide accounting services, the network access server tries the second host entry configured on the same device for accounting services. (The RADIUS host entries are tried in the order in which they are configured.)

AAA Authorization

AAA authorization limits the services available to a user. When AAA authorization is enabled, the device uses information retrieved from the user's profile, which is in the local user database or on the security server, to configure the user's session. The user is granted access to a requested service only if the information in the user profile allows it.

RADIUS Accounting

The AAA accounting feature tracks the services that users are using and the amount of network resources that they are consuming. When you enable AAA accounting, the device reports user activity to the RADIUS security server in the form of accounting records. Each accounting record contains accounting attribute-value (AV) pairs and is stored on the security server. You can then analyze the data for network management, client billing, or auditing.

Vendor-Specific RADIUS Attributes

The Internet Engineering Task Force (IETF) draft standard specifies a method for communicating vendor-specific information between the device and the RADIUS server by using the vendor-specific attribute (attribute 26). Vendor-specific attributes (VSAs) allow vendors to support their own extended attributes not suitable for general use. The Cisco RADIUS implementation supports one vendor-specific option by using the format recommended in the specification. Cisco's vendor-ID is 9, and the supported option has vendor-type 1, which is named *cisco-avpair*. The value is a string with this format:

protocol : attribute sep value *

Protocol is a value of the Cisco protocol attribute for a particular type of authorization. *Attribute* and *value* are an appropriate attributevalue (AV) pair defined in the Cisco TACACS+ specification, and *sep* is = for mandatory attributes and is * for optional attributes. The full set of features available for TACACS+ authorization can then be used for RADIUS.

For example, the following AV pair causes Cisco's "multiple named IP address pools" feature to be activated during IP authorization (during PPP's Internet Protocol Control Protocol (IPCP) address assignment):

cisco-avpair= "ip:addr-pool=first"

If you insert an "*", the AV pair "ip:addr-pool=first" becomes optional. Note that any AV pair can be made optional:

```
cisco-avpair= "ip:addr-pool*first"
```

The following example shows how to cause a user logging in from a network access server to have immediate access to EXEC commands:

```
cisco-avpair= "shell:priv-lvl=15"
```

Other vendors have their own unique vendor-IDs, options, and associated VSAs. For more information about vendor-IDs and VSAs, see RFC 2138, "Remote Authentication Dial-In User Service (RADIUS)."

Attribute 26 contains the following three elements:

- Type
- Length
- String (also known as data)
 - Vendor-ID
 - Vendor-Type
 - · Vendor-Length
 - Vendor-Data

The figure below shows the packet format for a VSA encapsulated "behind" attribute 26.

Figure 11: VSA Encapsulated Behind Attribute 26

Note It is up to the vendor to specify the format of their VSA. The Attribute-Specific field (also known as Vendor-Data) is dependent on the vendor's definition of that attribute.

51325

The table below describes significant fields listed in the Vendor-Specific RADIUS IETF Attributes table (second table below), which lists supported vendor-specific RADIUS attributes (IETF attribute 26).

Table 14: Vendor-Specific Attributes Table Field Descriptions

Field	Description
Number	All attributes listed in the following table are extensions of IETF attribute 26.
Vendor-Specific Command Codes	A defined code used to identify a particular vendor. Code 9 defines Cisco VSAs, 311 defines Microsoft VSAs, and 529 defines Ascend VSAs.
Sub-Type Number	The attribute ID number. This number is much like the ID numbers of IETF attributes, except it is a "second layer" ID number encapsulated behind attribute 26.
Attribute	The ASCII string name of the attribute.
Description	Description of the attribute.

Table 15: Vendor-Specific RADIUS IETF Attributes

Number	Vendor-Specific Company Code	Sub-Type Number	Attribute	Description
MS-CHAP Attr	ibutes	•		
26	311	1	MSCHAP-Response	Contains the response value provided by a PPP MS-CHAP user in response to the challenge. It is only used in Access-Request packets. This attribute is identical to the PPP CHAP Identifier. (RFC 2548

I

Number	Vendor-Specific Company Code	Sub-Type Number	Attribute	Description
26	311	11	MSCHAP-Challenge	Contains the challenge sent by a network access server to an MS-CHAP user. It can be used in both Access-Request and Access-Challenge packets. (RFC 2548)
VPDN Attribute	es			
26	9	1	12tp-cm-local-window-size	Specifies the maximum receive window size for L2TP control messages. This value is advertised to the peer during tunnel establishment.
26	9	1	12tp-drop-out-of-order	Respects sequence numbers on data packets by dropping those that are received out of order. This does not ensure that sequence numbers will be sent on data packets, just how to handle them if they are received.
26	9	1	l2tp-hello-interval	Specifies the number of seconds for the hello keepalive interval. Hello packets are sent when no data has been sent on a tunnel for the number of seconds configured here.
26	9	1	12tp-hidden-avp	When enabled, sensitive AVPs in L2TP control messages are scrambled or hidden.
26	9	1	12tp-nosession-timeout	Specifies the number of seconds that a tunnel will stay active with no sessions before timing out and shutting down.

Number	Vendor-Specific Company Code	Sub-Type Number	Attribute	Description
26	9	1	tunnel-tos-reflect	Copies the IP ToS field from the IP header of each payload packet to the IP header of the tunnel packet for packets entering the tunnel at the LNS.
26	9	1	l2tp-tunnel-authen	If this attribute is set, it performs L2TP tunnel authentication.
26	9	1	l2tp-tunnel-password	Shared secret used for L2TP tunnel authentication and AVP hiding.
26	9	1	l2tp-udp-checksum	This is an authorization attribute and defines whether L2TP should perform UDP checksums for data packets. Valid values are "yes" and "no." The default is no.
Store and Forwa	rd Fax Attributes			
26	9	3	Fax-Account-Id-Origin	Indicates the account ID origin as defined by system administrator for the mmoip aaa receive-id or the mmoip aaa send-id commands.
26	9	4	Fax-Msg-Id=	Indicates a unique fax message identification number assigned by Store and Forward Fax.
26	9	5	Fax-Pages	Indicates the number of pages transmitted or received during this fax session. This page count includes cover pages.

I

Number	Vendor-Specific Company Code	Sub-Type Number	Attribute	Description
26	9	6	Fax-Coverpage-Flag	Indicates whether or not a cover page was generated by the off-ramp gateway for this fax session. True indicates that a cover page was generated; false means that a cover page was not generated.
26	9	7	Fax-Modem-Time	Indicates the amount of time in seconds the modem sent fax data (x) and the amount of time in seconds of the total fax session (y), which includes both fax-mail and PSTN time, in the form x/y. For example, 10/15 means that the transfer time took 10 seconds, and the total fax session took 15 seconds.
26	9	8	Fax-Connect-Speed	Indicates the modem speed at which this fax-mail was initially transmitted or received. Possible values are 1200, 4800, 9600, and 14400.
26	9	9	Fax-Recipient-Count	Indicates the number of recipients for this fax transmission. Until e-mail servers support Session mode, the number should be 1.
26	9	10	Fax-Process-Abort-Flag	Indicates that the fax session was terminated or successful. True means that the session was terminated; false means that the session was successful.
26	9	11	Fax-Dsn-Address	Indicates the address to which DSNs will be sent.

Number	Vendor-Specific Company Code	Sub-Type Number	Attribute	Description
26	9	12	Fax-Dsn-Flag	Indicates whether or not DSN has been enabled. True indicates that DSN has been enabled; false means that DSN has not been enabled.
26	9	13	Fax-Mdn-Address	Indicates the address to which MDNs will be sent.
26	9	14	Fax-Mdn-Flag	Indicates whether or not message delivery notification (MDN) has been enabled. True indicates that MDN had been enabled; false means that MDN had not been enabled.
26	9	15	Fax-Auth-Status	Indicates whether or not authentication for this fax session was successful. Possible values for this field are success, failed, bypassed, or unknown.
26	9	16	Email-Server-Address	Indicates the IP address of the e-mail server handling the on-ramp fax-mail message.
26	9	17	Email-Server-Ack-Flag	Indicates that the on-ramp gateway has received a positive acknowledgment from the e-mail server accepting the fax-mail message.
26	9	18	Gateway-Id	Indicates the name of the gateway that processed the fax session. The name appears in the following format: hostname.domain-name.
26	9	19	Call-Type	Describes the type of fax activity: fax receive or fax send.

Number	Vendor-Specific Company Code	Sub-Type Number	Attribute	Description
26	9	20	Port-Used	Indicates the slot/port number of the Cisco AS5300 used to either transmit or receive this fax-mail.
26	9	21	Abort-Cause	If the fax session terminates, indicates the system component that signaled the termination. Examples of system components that could trigger an termination are FAP (Fax Application Process), TIFF (the TIFF reader or the TIFF writer), fax-mail client, fax-mail server, ESMTP client, or ESMTP server.
H323 Attribute	S			
26	9	23	Remote-Gateway-ID (h323-remote-address)	Indicates the IP address of the remote gateway.
26	9	24	Connection-ID (h323-conf-id)	Identifies the conference ID.
26	9	25	Setup-Time (h323-setup-time)	Indicates the setup time for this connection in Coordinated Universal Time (UTC) formerly known as Greenwich Mean Time (GMT) and Zulu time.
26	9	26	Call-Origin (h323-call-origin)	Indicates the origin of the call relative to the gateway. Possible values are originating and terminating (answer).
26	9	27	Call-Type (h323-call-type)	Indicates call leg type. Possible values are telephony and VoIP.
26	9	28	Connect-Time (h323-connect-time)	Indicates the connection time for this call leg in UTC.

Number	Vendor-Specific Company Code	Sub-Type Number	Attribute	Description
26	9	29	Disconnect-Time (h323-disconnect-time)	Indicates the time this call leg was disconnected in UTC.
26	9	30	Disconnect-Cause (h323-disconnect-cause)	Specifies the reason a connection was taken offline per Q.931 specification.
26	9	31	Voice-Quality (h323-voice-quality)	Specifies the impairment factor (ICPIF) affecting voice quality for a call.
26	9	33	Gateway-ID (h323-gw-id)	Indicates the name of the underlying gateway.
Large Scale	Dialout Attributes	·		
26	9	1	callback-dialstring	Defines a dialing string to be used for callback.
26	9	1	data-service	No description available.
26	9	1	dial-number	Defines the number to dial.
26	9	1	force-56	Determines whether the network access server uses only the 56 K portion of a channel, even when all 64 K appear to be available.
26	9	1	map-class	Allows the user profile to reference information configured in a map class of the same name on the network access server that dials out.
26	9	1	send-auth	Defines the protocol to use (PAP or CHAP) for username-password authentication following CLID authentication.

Number	Vendor-Specific Company Code	Sub-Type Number	Attribute	Descriptio	n
26	9	1	send-name	To apply for configure to sent-name command of For PAP, "preauth:se be used as username as password for authenticat "preauth:se be used no outbound as but also for authenticat CHAP inb NAS will to defined in "preauth:se	and PAP for outbound tion. For CHAP, end-name" will t only for authentication, r inbound tion. For a ound case, the use the name end-name" in the backet to the
				Note	The send-name attribute has changed over time: Initially, it performed the functions now provided by both the send-name attributes. Because the remote-name attribute has been added, the send-name attribute is restricted to its current behavior.

Number	Vendor-Specific Company Code	Sub-Type Number	Attribute	Description
26	9	1	send-secret	PPP password authentication. The vendor-specific attributes (VSAs) "preauth:send-name" and "preauth:send-secret" will be used as the PAP username and PAP password for outbound authentication. For a CHAP outbound case, both "preauth:send-name" and "preauth:send-secret" will be used in the response packet.
26	9	1	remote-name	Provides the name of the remote host for use in large-scale dial-out. Dialer checks that the large-scale dial-out remote name matches the authenticated name, to protect against accidental user RADIUS misconfiguration. (For example, dialing a valid phone number but connecting to the wrong device.)
Miscellaneous A	Attributes			

Number	Vendor-Specific Company Code	Sub-Type Number	Attribute	Description
26	9	2	Cisco-NAS-Port	Specifies additional vendor specific attribute (VSA) information for NAS-Port accounting. To specify
26	9	1	min-links	Sets the minimum number of links for MLP.
26	9	1	proxyacl# <n></n>	Allows users to configure the downloadable user profiles (dynamic ACLs) by using the authentication proxy feature so that users can have the configured authorization to permit traffic going through the configured interfaces.

Number	Vendor-Specific Company Code	Sub-Type Number	Attribute	Description
26	9	1	spi	Carries the authentication information needed by the home agent to authenticate a mobile node during registration. The information is in the same syntax as the ip mobile secure host <addr></addr> configuration command. Basically it contains the rest of the configuration command that follows that string, verbatim. It provides the Security Parameter Index (SPI), key, authentication algorithm, authentication mode, and replay protection timestamp range.

Vendor-Proprietary RADIUS Server Communication

Although an IETF draft standard for RADIUS specifies a method for communicating vendor-proprietary information between the device and the RADIUS server, some vendors have extended the RADIUS attribute set in a unique way. Cisco IOS XE software supports a subset of vendor-proprietary RADIUS attributes.

As mentioned earlier, to configure RADIUS (whether vendor-proprietary or IETF draft-compliant), you must specify the host running the RADIUS server daemon and the secret text string it shares with the device. You specify the RADIUS host and secret text string by using the **radius server** global configuration commands.

DSCP marking for RADIUS packets

Differentiated Services (DiffServ) is a model in which traffic is treated by intermediate systems with relative priorities based on the type of services (ToS) field. The six most significant bits of the DiffServ field is called as the Differentiated Services Code Point (DSCP). Cisco IOS XE software supports DSCP marking for RADIUS packets. DSCP marking enables faster authentication and accounting of RADIUS packets.

You can configure DSCP marking on the RADIUS server, server group and in global configuration mode. When DSCP marking configuration is applied on RADIUS server, server group and global configuration mode, the DSCP marking values entered on the RADIUS server is taken.

- If there is no DSCP marking configuration on the RADIUS server, the DSCP marking values configured on the server group is applied to the RADIUS packets.
- If there is no DSCP marking configuration on the RADIUS server, RADIUS server group, the DSCP marking values configured at the global configuration mode is applied to the RADIUS packets.

How to Configure RADIUS

Identifying the RADIUS Server Host

To apply these settings globally to all RADIUS servers communicating with the device, use the three unique global configuration commands: **radius-server timeout**, **radius-server retransmit**, and **key** *string*.

You can configure the device to use AAA server groups to group existing server hosts for authentication.

You also need to configure some settings on the RADIUS server. These settings include the IP address of the device and the key string to be shared by both the server and the device.

Follow these steps to configure per-server RADIUS server communication.

Before you begin

If you configure both global and per-server functions (timeout, retransmission, and key commands) on the device, the per-server timer, retransmission, and key value commands override global timer, retransmission, and key value commands.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	radius server server name	Specifies the name for the RADIUS server
	Example:	configuration for Protected Access Credential
	Device(config)# radius server rsim	(PAC) provisioning, and enters RADIUS server configuration mode.
	Device(config)# factus server isim	
Step 4	address {ipv4 ipv6} <i>ip address</i> { auth-port	(Optional) Specifies the RADIUS server
	<pre>port number acct-port port number}</pre>	parameters.
	Example:	For auth-port port-number, specify the UDP
	Device(config-radius-server)# address	destination port for authentication requests. The default is 1645. The range is 0 to 65536.
	ipv4 124.2.2.12 auth-port 1612	For acct-port <i>port-number</i> , specify the UDP
		destination port for authentication requests. The
		default is 1646.

	Command or Action	Purpose
Step 5	key string Example:	(Optional) For key <i>string</i> , specify the authentication and encryption key used between the device and the RADIUS daemon running on the RADIUS server.
	Device(config-radius-server)# key rad123	Note The key is a text string that must match the encryption key used on the RADIUS server. Always configure the key as the last item in the radius server command. Leading spaces are ignored, but spaces within and at the end of the key are used. If you use spaces in your key, do not enclose the key in quotation marks unless the quotation marks are part of the key.
Step 6	<pre>retransmit value Example: Device(config-radius-server)# retransmit 10</pre>	(Optional) Specifies the number of times a RADIUS request is resent when the server is not responding or responding slowly. The range is 1 to 100. This setting overrides the radius-server retransmit global configuration command setting.
Step 7	<pre>timeout seconds Example: Device(config-radius-server)# timeout 60</pre>	(Optional) Specifies the time interval that the device waits for the RADIUS server to reply before sending a request again. The range is 1 to 1000. This setting overrides the radius-server timeout global configuration command setting.
Step 8	<pre>end Example: Device(config-radius-server)# end</pre>	Exits RADIUS server configuration mode and enters privileged EXEC mode.

Configuring RADIUS Login Authentication

Follow these steps to configure RADIUS login authentication:

Before you begin

To secure the device for HTTP access by using AAA methods, you must configur the **ip http authentication aaa** global configuration command. Configuring AAA authentication does not secure the device for HTTP access by using AAA methods.

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	aaa new-model	Enables AAA.
	Example:	
	Device(config)# aaa new-model	
Step 4	aaa authentication login {default <i>list-name</i> }	Creates a login authentication method list.
	method1 [method2]	• To create a default list that is used when
	Example:	named list is <i>not</i> specified in the login
	Device(config) # aaa authentication login	authentication command, use the defau keyword followed by the methods that an
	default local	to be used in default situations. The defau
		method list is automatically applied to a ports.
		• For <i>list-name</i> , specify a character string t name the list you are creating.
		• For <i>method1</i> , specify the actual metho
		the authentication algorithm tries. The
		additional methods of authentication are
		used only if the previous method returns an error, not if it fails.
		Select one of these methods:
		• <i>enable</i> —Use the enable password for
		authentication. Before you can use
		this authentication method, you mu
		define an enable password by using the enable password global
		configuration command.
		• group radius—Use RADIUS
		authentication. Before you can use
		this authentication method, you must configure the RADIUS server.
		• <i>line</i> —Use the line password for authentication. Before you can use
		this authentication method, you mus

	-
	define a line password. Use the password <i>password</i> line configuration command.
	• <i>local</i> —Use the local username database for authentication. You must enter username information in the database. Use the username <i>name</i> password global configuration command.
	 <i>local-case</i>—Use a case-sensitive local username database for authentication. You must enter username information in the database by using the username <i>password</i> global configuration command. <i>none</i>—Do not use any authentication for login.
<pre>line [console tty vty] line-number [ending-line-number] Example: Device(config)# line 1 4</pre>	Enters line configuration mode, and configure the lines to which you want to apply the authentication list.
login authentication {default <i>list-name</i> } Example:	Applies the authentication list to a line or set of lines.
Device(config-line)# login authentication default	• If you specify default , use the default list created with the aaa authentication login command.
	• For <i>list-name</i> , specify the list created with the aaa authentication login command.
end Example: Device(config-line)# end	Exits line configuration mode and enters privileged EXEC mode.
	<pre>[ending-line-number] Example: Device (config) # line 1 4 login authentication {default list-name} Example: Device (config-line) # login authentication default end Example:</pre>

Defining AAA Server Groups

You use the **server** group server configuration command to associate a particular server with a defined group server. You can either identify the server by its IP address or identify multiple host instances or entries by using the optional **auth-port** and **acct-port** keywords.

Follow these steps to define AAA server groups:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	radius server name	Specifies the name of the RADIUS server
	Example:	configuration for Protected Access Credential (PAC) provisioning and enters RADIUS server
	Device(config)# radius server ISE	configuration mode.
		The device also supports RADIUS for IPv6.
Step 4	address {ipv4 ipv6} {ip-address hostname}	Configures the IPv4 address for the RADIUS
	auth-port port-number acct-port port-number	server accounting and authentication
	Example:	parameters.
	<pre>Device(config-radius-server)# address ipv4 10.1.1.1 auth-port 1645 acct-port 1646</pre>	
Step 5	key string	Specifies the authentication and encryption key
	Example:	for all RADIUS communications between the device and the RADIUS server.
	Device(config-radius-server)# key cisco123	device and the RADIUS server.
Step 6	exit	Exits RADIUS server configuration mode and
	Example:	enters global configuration mode.
	Device(config-radius-server)# exit	
Step 7	aaa group server radius group_name	Defines the RADIUS server group configuration
	Example:	and enters RADIUS server group configuration mode.
	Device(config)# aaa group server radius abc	
Step 8	server name server	Associates the RADIUS server to the server
	Example:	group.
	Device(config-sg-radius)# server name ISE	
Step 9	end	Exits RADIUS server group configuration mode
	Example:	and returns to privileged EXEC mode.

Procedure

Device(config-sg-radius)# end

L

Configuring RADIUS Authorization for User Privileged Access and Network Services

Ø

Note Authorization is bypassed for authenticated users who log in through the CLI even if authorization has been configured.

Follow these steps to configure RADIUS authorization for user priviledged access and network services:

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	aaa authorization network <i>authorization-list</i> radius	Configures the device for user RADIUS authorization for all network-related service
	Example:	requests.
	Device(config)# aaa authorization network list1 radius	
Step 4	aaa authorization exec authorization-list radius	Configures the device for user RADIUS authorization if the user has privileged EXEC
	Example:	access.
	Device(config)# aaa authorization exec list1 radius	The exec keyword might return user profile information (such as autocommand information).
Step 5	end	Exits global configuration mode and returns to
	Example:	privileged EXEC mode.
	• Device(config)# end	

What to do next

You can use the **aaa authorization** global configuration command with the **radius** keyword to set parameters that restrict a user's network access to privileged EXEC mode.

The aaa authorization exec radius local command sets these authorization parameters:

- Use RADIUS for privileged EXEC access authorization if authentication was performed by using RADIUS.
- Use the local database if authentication was not performed by using RADIUS.

Starting RADIUS Accounting

Follow these steps to start RADIUS accounting:

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	aaa accounting network	Enables RADIUS accounting for all
	accounting-liststart-stop radius	network-related service requests.
	Example:	
	Device(config)# aaa accounting network start-stop radius	
Step 4	aaa accounting exec accounting-liststart-stop radius	start-record accounting notice at the beginning
	Example:	of a privileged EXEC process and a stop-record at the end
	Device(config)# aaa accounting exec acc-list start-stop radius	at the end.
Step 5	end	Exits global configuration mode and returns to
	Example:	privileged EXEC mode.
	Device(config)# end	

Configuring Settings for All RADIUS Servers

Beginning in privileged EXEC mode, follow these steps to configure settings for all RADIUS servers:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.

	Command or Action	Purpose	
	Example:	Enter your password, if prompted.	
	Device> enable		
Step 2	configure terminal	Enters global configuration mode.	
	Example:		
	Device# configure terminal		
Step 3	radius server server name	Specifies the name for the RADIUS server	
	Example:	configuration for Protected Access Credential (PAC) provisioning, and enters RADIUS serve	
	Device(config)# radius server rsim	configuration mode.	
Step 4	key string	Specifies the shared secret text string used	
	Example:	between the switch and all RADIUS servers.	
	Device(config-radius-server)# key your_server_key	Note The key is a text string that must match the encryption key used on the RADIUS server. Leading spaces are ignored, but spaces within and at the end of the key are used. If you use spaces in your key, do not enclose the key in quotation marks unless the quotation marks are part of the key.	
Step 5	retransmit retries	Specifies the number of times the switch sends	
	Example:	each RADIUS request to the server before giving up. The default is 3; the range 1 to 1000.	
	Device(config-radius-server)# retransmit 5		
Step 6	timeout seconds	Specifies the number of seconds a switch waits	
	Example:	for a reply to a RADIUS request before resending the request. The default is 5 seconds;	
	Device(config-radius-server)# timeout 3	the range is 1 to 1000.	
Step 7	end	Exits RADIUS server configuration mode and	
	Example:	enters privileged EXEC mode.	
	Device(config-radius-server)# end		

Configuring the Device to Use Vendor-Specific RADIUS Attributes

Follow these steps to configure vendor-specific RADIUS attributes:

Command or Action	Purpose
enable	Enables privileged EXEC mode.
Example:	Enter your password, if prompted.
Device> enable	
configure terminal	Enters global configuration mode.
Example:	
Device# configure terminal	
radius-server vsa send [accounting authentication]	Enables the device to recognize and use VSAs as defined by RADIUS IETF attribute 26.
<pre>Example: Device(config)# radius-server vsa send accounting</pre>	• (Optional) Use the accounting keyword to limit the set of recognized vendor-specific attributes to only accounting attributes.
	• (Optional) Use the authentication keyword to limit the set of recognized vendor-specific attributes to only authentication attributes.
	If you enter this command without keywords, both accounting and authentication vendor-specific attributes are used.
end	Exits global configuration mode and enters
Example:	privileged EXEC mode.
Device(config)# end	
	<pre>enable enable Example: Device> enable configure terminal Example: Device# configure terminal radius-server vsa send [accounting authentication] Example: Device (config)# radius-server vsa send accounting end Example:</pre>

Procedure

Configuring the Device for Vendor-Proprietary RADIUS Server Communication

Follow these steps to configure vendor-proprietary RADIUS server communication:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	

	Command or Action	Purpose
Step 3	<pre>radius server server name Example: Device(config)# radius server rsim</pre>	Specifies the name for the RADIUS server configuration for Protected Access Credential (PAC) provisioning, and enters RADIUS server configuration mode.
Step 4	<pre>address { ipv4 ipv6 } ip address Example: Device(config-radius-server)# address ipv4 172.24.25.10</pre>	(Optional) Specifies the IP address of the RADIUS server.
Step 5	<pre>non-standard Example: Device(config-radius-server)# non-standard</pre>	Identifies that the RADIUS server using a vendor-proprietary implementation of RADIUS.
Step 6	<pre>key string Example: Device(config-radius-server)# key rad123</pre>	Specifies the shared secret text string used between the device and the vendor-proprietary RADIUS server. The device and the RADIUS server use this text string to encrypt passwords and exchange responses.
Step 7	<pre>end Example: Device(config-radius-server)# end</pre>	Exits RADIUS server mode and enters privileged EXEC mode.

Configuring DSCP Marking on a RADIUS Server

Follow these steps to configure DSCP marking for authentication and accounting on a radius server:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example: Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	

	Command or Action	Purpose
Step 3	<pre>radius server server_name Example: Device(config)# radius server rsim</pre>	Specifies the name for the RADIUS server configuration for Protected Access Credential (PAC) provisioning, and enters RADIUS server configuration mode.
Step 4	<pre>address { ipv4 ipv6 } ip address [auth-port auth_port_number acct-port acct_port_number] Example: Device (config-radius-server) # address ipv4 10.1.1.1 auth-port 1645 acct-port 1646</pre>	 (Optional) Specifies the IP address of the RADIUS server. auth-port configures the port value for radius authentication server. The default value is 1812. acct-port configures the port value for radius accounting server. The default value is 1813.
Step 5	<pre>dscp {acct dscp_acct_value auth dscp_auth_value } Example: Device (config-radius-server) # dscp auth 10 acct 20</pre>	 Configures DSCP marking for authentication and accounting on the radius server. acct configures radius DSCP marking value for accounting. The valid range is from 1 to 63. The default value is 0. auth configures radius DSCP marking value for authentication. The valid range is from 1 to 63. The default value is 0.
Step 6	<pre>key string Example: Device(config-radius-server)# key rad123</pre>	Specifies the shared secret text string used between the device and the vendor-proprietary RADIUS server. The device and the RADIUS server use this text string to encrypt passwords and exchange responses.
Step 7	<pre>end Example: Device(config-radius-server)# end</pre>	Exits RADIUS server mode and enters privileged EXEC mode.

Configuring the Source Interface and DSCP Marking on RADIUS Server Group

Follow these steps to configure the source interface and DSCP marking for authentication and accounting on radius server groups:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	
	Device> enable	

	Command or Action	Purpose
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	aaa group server radius group_name	Defines the RADIUS server group configuration
	Example:	and enters RADIUS server group configuratio mode.
	<pre>Device(config)# aaa group server radius abc</pre>	node.
Step 4	server name name	Associates the RADIUS server to the server
	Example:	group.
	Device(config-sg-radius)# server name serv1	
Step 5	{ ip ipv6 } radius source-interface <i>type number</i>	Specifies an interface to use for the source address in RADIUS server.
	Example:	
	Device(config-sg-radius)# ipv6 radius source-interface ethernet 0/0	
Step 6	<pre>dscp {acct dscp_acct_value auth dscp_auth_value }</pre>	Configures DSCP marking for authentication and accounting on the radius server group.
	Example:	• acct configures radius DSCP marking
	Device (config-sg-radius) # dscp auth 10 acct 20	value for accounting. The valid range from 1 to 63. The default value is 0.
		• auth configures radius DSCP marking value for authentication. The valid range is from 1 to 63. The default value is 0.
Step 7	end	Exits RADIUS server mode and enters
	Example:	privileged EXEC mode.
	Device(config-radius-server)# end	

Configuring CoA on the Device

Follow these steps to configure CoA on a device. This procedure is required.

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	

	Command or Action	Purpose	
Step 2	configure terminal	Enters global configuration mode.	
	Example:		
	Device# configure terminal		
Step 3	aaa new-model	Enables AAA.	
	Example:		
	Device(config)# aaa new-model		
Step 4	aaa server radius dynamic-author	Configures the device as an authentication,	
•	Example:	authorization, and accounting (AAA) server to facilitate interaction with an external policy	
	Device(config)# aaa server radius dynamic-author	server, and enters dynamic authorization local server configuration mode.	
Step 5	client { <i>ip-address</i> <i>name</i> } [vrf <i>vrfname</i>] [server-key <i>string</i>]	Specifies a RADIUS client from which a device will accept CoA and disconnect	
	Example:	requests.	
	<pre>Device(config-locsvr-da-radius) # client client1 vrf vrf1</pre>		
Step 6	server-key [0 7] string	Configures the RADIUS key to be shared between a device and RADIUS clients.	
	Example:	between a device and KADIOS clients.	
	Device(config-locsvr-da-radius)# server-key your_server_key		
Step 7	port port-number	Specifies the port on which a device listens for	
	Example:	RADIUS requests from configured RADIUS clients.	
	Device(config-locsvr-da-radius)# port 25		
Step 8	auth-type {any all session-key}	Specifies the type of authorization the device uses for RADIUS clients.	
	Example:		
	Device(config-locsvr-da-radius)# auth-type any	The client must match all the configured attributes for authorization.	
Step 9	ignore server-key	(Optional) Configures the device to ignore the	
•	Example:	server-key.	

	Command or Action	Purpose
	<pre>Device(config-locsvr-da-radius)# ignore server-key</pre>	
Step 10	exit Example:	Exits dynamic authorization local server configuration mode and returns to global configuration mode.
	Device(config-locsvr-da-radius)# exit	
Step 11	authentication command bounce-port ignore Example:	(Optional) Configures the device to ignore a CoA request to temporarily disable the port hosting a session. The purpose of temporarily
	Device(config)# authentication command bounce-port ignore	disabling the port is to trigger a DHCP renegotiation from the host when a VLAN change occurs and there is no supplicant on the endpoint to detect the change.
Step 12	authentication command disable-port ignore Example: Device(config)# authentication command disable-port ignore	(Optional) Configures the device to ignore a nonstandard command requesting that the por hosting a session be administratively shut down. Shutting down the port results in termination of the session.
	disable port ignore	Use standard CLI or SNMP commands to re-enable the port.
Step 13	end Example:	Exits global configuration mode an returns to privileged EXEC mode.
	Device(config)# end	

Configuring RADIUS Source-Interface Under a RADIUS Server-Group

The RADIUS source-interface can be configured under a RADIUS server-group in either of the following methods:

- Configure a RADIUS source-interface under the RADIUS server-group using the **ip radius source-interface** *interface-name* command.
- Configure a VRF using the **vrf** *vrf*-name command under the RADIUS server-group, and then associate the configured VRF globally to a source-interface using the **ip radius source interface** *interface*-name **vrf** *vrf*-name command.

Priority will be given to the source-interface under the server-group configuration in case both methods are configured.

To configure RADIUS source-interface under a RADIUS server-group, perform the following:

Before you begin

You must configure a VRF routing table and associate VRF to an interface

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	{ ip ipv6 } radius source-interface <i>interface-number</i> vrf <i>vrf-name</i>	Forces RADIUS to use the IP address of a specified interface for all outgoing RADIUS packets, and enables the specification on a
	Example:	per-VRF basis.
	<pre>Device(config)# ip radius source-interface GigabitEthernet1/0/23 vrf vrf17</pre>	• <i>interface-name</i> : Specifies the name of the interface that RADIUS uses for all of its outgoing packets.
		• vrf <i>vrf-name</i> : Specifies the per-VRF configuration.
Step 4	aaa group server radius group_name	Groups different RADIUS server hosts into
	Example:	distinct lists and distinct methods and enters
	Device(config-sg-radius)# aa group server radius rad-grp	server-group configuration mode.
Step 5	ip vrf forwarding vrf-name	(Optional) Configures a VRF for the interface.
	Example:	
	<pre>Device(config-sg-radius)# ip vrf forwarding vrf17</pre>	
Step 6	{ ip ipv6 } radius source-interface <i>interface-number</i>	(Optional) Forces RADIUS to use the IP address of a specified interface for all outgoing
	Example:	RADIUS packets from the RADIUS group server.
	<pre>Device(config-sg-radius)# ip radius source-interface loopback0</pre>	<i>interface-name</i> : Specifies the name of the interface that RADIUS uses for all of its outgoing packets.
Step 7	end	Returns to privileged EXEC mode.
	Example:	
	Device(config-sg-radius)# end	

Monitoring CoA Functionality

Table 16: Privileged EXEC show Commands

Command	Purpose
show aaa attributes protocol radius	Displays AAA attributes of RADIUS commands.

Table 17: Global Troubleshooting Commands

Command	Purpose
debug radius	Displays information for troubleshooting RADIUS.
debug aaa coa	Displays information for troubleshooting CoA processing.
debug aaa pod	Displays information for troubleshooting POD packets.
debug aaa subsys	Displays information for troubleshooting POD packets.
debug cmdhd [detail error events]	Displays information for troubleshooting command headers.

Feature History for RADIUS

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.11.1	RADIUS	RADIUS is a distributed client/server system that secures networks against unauthorized access. RADIUS clients run on supported Cisco devices. Clients send authentication requests to a central RADIUS server, which contains all user authentication and network service access information.
Cisco IOS XE Bengaluru 17.5.1	DSCP marking on Radius servers	This feature allows you to configure Differentiated Services Code Point (DSCP) marking on RADIUS servers and RADIUS server groups using dscp command. The radius-server dscp command is used to configure DSCP marking for authentication and accounting on RADIUS servers in global configuration mode.
Cisco IOS XE Cupertino 17.7.1	RADIUS	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

Configuring RadSec

This chapter describes how to configure RadSec over Transport Layer Security (TLS) and Datagram Transport Layer Security (DTLS) servers.

- Restrictions for Configuring RadSec, on page 205
- Information About RadSec, on page 206
- How to Configure RadSec, on page 206
- Monitoring RadSec, on page 211
- Configuration Examples for RadSec, on page 211
- Feature History for Configuring RadSec, on page 213

Restrictions for Configuring RadSec

The following restrictions apply to the RadSec feature:

- A RADIUS client uses an ephemeral port as the source port. This source port should not be used for UDP, Datagram Transport Layer Security (DTLS), and Transport Layer Security (TLS) at the same time.
- Although there is no configuration restriction, we recommend that you use the same type—either only TLS or only DTLS—for a server under an AAA server group.
- RadSec is not supported on the DTLS port range 1 to 1024.

Note DTLS ports must be configured to work with the RADIUS server.

- RadSec is not supported with high availability.
- RADIUS Change of Authorization (CoA) reception of request and transmission of response over the same authentication channel is supported with RadSec over TLS only. It is not supported over DTLS or plain RADIUS.
- The tls watchdoginterval command is not applicable for Packet of Disconnect (PoD) use cases.
- FQDN configuration for CoA is not supported.

Information About RadSec

RadSec provides encryption services over the RADIUS server transported over a secure tunnel. RadSec over TLS and DTLS is implemented in both client and device servers. While the client side controls RADIUS AAA, the device side controls CoA.

You can configure the following parameters:

- Individual client-specific idle timeout, client trustpoint, and server trustpoint.
- Global CoA-specific TLS or DTLS listening port and the corresponding list of source interfaces.

Note You can disable TLS or DTLS for a specific server by using the **no tls** or **no dtls** command in radius server configuration mode.

RadSec CoA request reception and CoA response transmission over the same authentication channel can be enabled by configuring the **tls watchdoginterval** command. The TLS watchdog timer must be lesser than the TLS idle timer so that the established tunnel remains active if RADIUS test authentication packets are seen before the idle timer expires. If the tunnel is torn down and **tls watchdoginterval** command is enabled, the tunnel gets re-established immediately. If **tls watchdoginterval** command is disabled, CoA requests on the same authentication channel are discarded.

How to Configure RadSec

The following sections provide information about the various tasks that comprise RadSec configuration.

Configuring RadSec over TLS

Pro	ced	ure
-----	-----	-----

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example: Device# configure terminal	
Step 3	<pre>radius server radius-server-name Example: Device(config)# radius server R1</pre>	Specifies the name for the RADIUS server configuration for Protected Access Credential (PAC) provisioning, and enters RADIUS server configuration mode.

	Command or Action	Purpose
Step 4	Command or Actiontls [connectiontimeout connection-timeout-value] [idletimeout idle-timeout-value] [[ip ipv6] {radius source-interface interface-name vrf forwarding forwarding-table-name }][match-server-identity {email-address email-address hostname host-name ip-address ip-address] [port port-number][retries number-of-connection-retries][trustpoint {client trustpoint name server trustpoint name}] [watchdoginterval interval]Example: Device (config-radius-server) # tls idletimeout 10 Device (config-radius-server) # tls retries 15 Device (config-radius-server) # tls ip radius source-interface GigabitEthernet 1/0/1 Device (config-radius-server) # tls ip radius source-interface GigabitEthernet 1/0/1 Device (config-radius-server) # tls ipv6 vrf forwarding table-1 Device (config-radius-server) # tls trustpoint client TP-self-signed-721943660 Device (config-radius-server) # tls trustpoint server isetp Device (config-radius-server) # tls trustpoint server isetp Device (config-radius-server) # tls trustpoint server isetp	 Configures the TLS parameters. You can configure the following parameters: connection timeout: Configures TLS connection timeout value. The default is seconds. idletimeout: Configures the TLS idle timeout value. The default is 60 seconds ip: Configures IP source parameters. ipv6: Configures IPv6 source parameters match-server-identity: Configures RadSec certification validation parameters Note This is a mandatory configuration. port: Configures the TLS port number. The default is 2083. retries: Configures the number of TLS connection retries. The default is 5. trustpoint: Configures the TLS trustpoint for the client and server are th same, the trustpoint name should also be the same for both. watchdog interval: Configures the same
	<pre>Device(config-radius-server)# tls ipv6 vrf forwarding table-1 Device(config-radius-server)# tls match-server-identity ip-address 10.1.1.10 Device(config-radius-server)# tls port 10 Device(config-radius-server)# tls trustpoint client TP-self-signed-721943660 Device(config-radius-server)# tls trustpoint server isetp Device(config-radius-server)# tls</pre>	 connection retries. The default is 5. trustpoint: Configures the TLS trustpoin for a client and a server. If the TLS trustpoint for the client and server are th same, the trustpoint name should also be the same for both. watchdoginterval: Configures the watchdog interval. This enables CoA
		re-establishes the tunnel if it is torn down Note watchdoginterval value must be lesser than idletimeout, for the established tunnel to remain up.
Step 5	end Example: Device(config-radius-server)# end	Exits RADIUS server configuration mode an returns to privileged EXEC mode.

Configuring Dynamic Authorization for TLS CoA

Note

When the **tls watchdoginterval** command is enabled, the client IP configuration under **aaa server radius dynamic-author** command is not used. Instead, the key configured under **radius server** command is used for CoA transactions.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	aaa server radius dynamic-author	Enters dynamic authorization local server
	Example:	configuration mode and specifies the RADIUS client from which a device accepts CoA and
	Device(config)# aaa server radius	disconnect requests. Configures the device as
	dynamic-author	an AAA server to facilitate interaction with an
		external policy server.
Step 4	client {ip-addr hostname} [tls [client-tp	Configures the IP address or hostname of the
	client-tp-name] [idletimeout idletimeout-interval] [server-key server-key]	AAA server client. You can configure the following optional parameters:
	[server-tp server-tp-name]]	
	Example:	• tls: Enables TLS for the client.
	Device (config-locsvr-da-radius) # client	 client-tp: Configures the client trustpoint.
	10.104.49.14 tls idletimeout 100	-
	<pre>client-tp tls_ise server-tp tls_client server-key key1</pre>	• idletimeout: Configures the TLS idle timeout value.
		 server-key: Configures a RADIUS client server key.
		• server-tp: Configures the server trustpoint.
Step 5	end	Exits dynamic authorization local server
	Example:	configuration mode and returns to privileged EXEC mode.
	Device(config-locsvr-da-radius)# end	LALC mode.

Configuring RadSec over DTLS

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	J F
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	radius server radius-server-name	Specifies the name for the RADIUS server
	Example:	configuration for Protected Access Credential (PAC) provisioning, and enters RADIUS server
	Device(config)# radius server R1	configuration mode.
Step 4	dtls [connectiontimeout	Configures DTLS parameters. You can
	connection-timeout-value] [idletimeout	configure the following parameters:
	<i>idle-timeout-value</i>] [[ip ipv6] { radius source-interface <i>interface-name</i> vrf	• connectiontimeout: Configures the DTLS
	forwarding forwarding-table-name }]	connection timeout value. The default is 5
	[match-server-identity {email-address	seconds.
	email-address hostname host-name	• idletimeout: Configures the DTLS idle
	ip-address <i>ip-address</i>] [port <i>port-number</i>]	timeout value. The default is 60 seconds.
	[retries number-of-connection-retries]	
	[trustpoint {client trustpoint name server	Note When the idle timeout
	trustpoint name}]	expires, and there are no transactions after the last idle
	Example:	timeout, the DTLS session is
	Device(config-radius-server)# dtls	closed. When the session is
	connectiontimeout 10	re-established, restart the idle
	Device(config-radius-server)# dtls idletimeout 75	timer for the session to work.
	Device(config-radius-server)# dtls	If the configured idle timeout
	retries 15	is 30 seconds, when the
	Device(config-radius-server)# dtls ip radius source-interface GigabitEthernet	timeout expires, the number
	1/0/1	of RADIUS DTLS
	Device (config-radius-server) # dtls ipv6	
	<pre>vrf forwarding table-1 Device(config-radius-server)# tls</pre>	the RADIUS DTLS packets
	match-server-identity ip-address	are more than 0, the transaction counter is reset
	10.1.1.10	and the timer is started again
	Device(config-radius-server)# dtls port 10	und the time his started uguin.
	Device(config-radius-server)# dtls	• ip: Configures IP source parameters.
	trustpoint client	
	TP-self-signed-721943660 Device(config-radius-server)# dtls	• ipv6: Configures IPv6 source parameters
	trustpoint server isetp	• match-server-identity: Configures
	• • • • • •	RadSec certification validation parameters

	Command or Action	Purpose
		Note This is a mandatory configuration.
		• port : Configures the DTLS port number. The default is 2083.
		• retries : Configures the number of DTLS connection retries. The default is 5.
		• trustpoint : Configures the DTLS trustpoint for the client and the server. If the DTLS trustpoint for the client and server are the same, the trustpoint name should also be the same for both.
Step 5	end Example:	Exits RADIUS server configuration mode and returns to privileged EXEC mode.
	Device(config-radius-server)# end	

Configuring Dynamic Authorization for DTLS CoA

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	aaa server radius dynamic-author Example: Device(config)# aaa server radius dynamic-author	Enters dynamic authorization local server configuration mode and specifies a RADIUS client from which the device accepts CoA and disconnect requests. Configures the device as an AAA server to facilitate interaction with an external policy server.
Step 4	client {ip-addr hostname} [dtls [client-tp client-tp-name] [idletimeout idletimeout-interval] [server-key server-key] [server-tp server-tp-name]]	Configures the IP address or hostname of the AAA server client. You can configure the following optional parameters: • tls: Enables TLS for the client.
	Example: Device(config-locsvr-da-radius)# client 10.104.49.14 dtls idletimeout 100	 client-tp: Configures the client trustpoint.

	Command or Action	Purpose
	client-tp tls_ise server-tp tls_client server-key key1	 idletimeout: Configures the TLS idle timeout value. server-key: Configures a RADIUS client server key. server-tp: Configures the server trustpoint.
Step 5	<pre>dtls {{ip ipv6} radius source-interface interface-name port radius-dtls-server-port-number} Example: Device (config-locsvr-da-radius) # dtls ip radius source-interface GigabitEthernet 1/0/24 Device (config-locsvr-da-radius) # dtls port 100</pre>	
Step 6	end Example: Device(config-locsvr-da-radius)# end	Exits dynamic authorization local server configuration mode and returns to privileged EXEC mode.

Monitoring RadSec

Use the following commands to monitor TLS and DTLS server statistics.

Table 18: Monitoring TLS and DTLS Server Statistics

Command	Purpose
show aaa servers	Displays information related to TLS and DTLS servers.
clear aaa counters servers radius {server id all}	Clears the RADIUS TLS-specific or DTLS-specific statistics.
debug radius radsec	Enables RADIUS RadSec debugs.

Configuration Examples for RadSec

The following examples help you understand the RadSec configuration better.

Example: Configuring RadSec over TLS

The following example shows how to configure RadSec over TLS:

```
Device> enable
Device# configure terminal
Device(config)# radius server R1
Device(config-radius-server)# tls connectiontimeout 10
Device(config-radius-server)# tls idletimeout 75
Device(config-radius-server)# tls ip radius source-interface GigabitEthernet 1/0/1
Device(config-radius-server)# tls ip vrf forwarding table-1
Device(config-radius-server)# tls port 10
Device(config-radius-server)# tls trustpoint client TP-self-signed-721943660
Device(config-radius-server)# tls watchdoginterval 10
Device(config-radius-server)# tls watchdoginterval 10
```

Example: Configuring Dynamic Authorization for TLS CoA

The following example shows how to configure dynamic authorization for TLS CoA:

```
Device> enable
Device# configure terminal
Device(config)# aaa server radius dynamic-author
Device(config-locsvr-da-radius)# client 10.104.49.14 tls idletimeout 100
client-tp tls_ise server-tp tls_client
Device(config-locsvr-da-radius)# end
```

Example: Configuring RadSec over DTLS

The following example shows how to configure RadSec over DTLS:

```
Device> enable
Device# configure terminal
Device(config)# radius server R1
Device(config-radius-server)# dtls connectiontimeout 10
Device(config-radius-server)# dtls idletimeout 75
Device(config-radius-server)# dtls retries 15
Device(config-radius-server)# dtls ip radius source-interface GigabitEthernet 1/0/1
Device(config-radius-server)# dtls ip vrf forwarding table-1
Device(config-radius-server)# dtls port 10
Device(config-radius-server)# dtls trustpoint client TP-self-signed-721943660
Device(config-radius-server)# dtls trustpoint server isetp
Device(config-radius-server)# end
```

Example: Configuring Dynamic Authorization for DTLS CoA

The following example shows how to configure dynamic authorization for DTLS CoA:

```
Device> enable
Device# configure terminal
Device(config)# aaa server radius dynamic-author
Device(config-locsvr-da-radius)# client 10.104.49.14 dtls idletimeout 100
client-tp dtls_ise server-tp dtls_client
Device(config-locsvr-da-radius)# dtls ip radius source-interface GigabitEthernet 1/0/24
```

Device(config-locsvr-da-radius)# dtls port 100
Device(config-locsvr-da-radius)# end

Feature History for Configuring RadSec

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Bengaluru 17.4.1	Configuring RadSec	RadSec provides encryption services over the RADIUS server, which is transported over a secure tunnel.
Cisco IOS XE Bengaluru 17.6.1	Radsec CoA over Same Tunnel	RadSec CoA request reception and CoA response transmission can be done over the same authentication channel.
Cisco IOS XE Cupertino 17.7.1	Configuring RadSec	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

RADIUS Server Load Balancing

The RADIUS Server Load Balancing feature distributes authentication, authorization, and accounting (AAA) authentication and accounting transactions across RADIUS servers in a server group. These servers can share the AAA transaction load and thereby respond faster to incoming requests.

This module describes the RADIUS Server Load Balancing feature.

- Prerequisites for RADIUS Server Load Balancing, on page 215
- Restrictions for RADIUS Server Load Balancing, on page 215
- Information About RADIUS Server Load Balancing, on page 216
- How to Configure RADIUS Server Load Balancing, on page 218
- Configuration Examples for RADIUS Server Load Balancing, on page 221
- Additional References for RADIUS Server Load Balancing, on page 227
- Feature History for RADIUS Server Load Balancing, on page 227

Prerequisites for RADIUS Server Load Balancing

- Authentication, authorization, and accounting (AAA) must be configured on the RADIUS server.
- AAA RADIUS server groups must be configured.
- RADIUS must be configured for functions such as authentication, accounting, or static route download.

Restrictions for RADIUS Server Load Balancing

- Incoming RADIUS requests, such as Packet of Disconnect (POD) requests, are not supported.
- Load balancing is not supported on proxy RADIUS servers and for private server groups.

Information About RADIUS Server Load Balancing

RADIUS Server Load Balancing Overview

Load balancing distributes batches of transactions to RADIUS servers within a server group. Load balancing assigns each batch of transactions to the server with the lowest number of outstanding transactions in its queue. The process of assigning a batch of transactions is as follows:

- 1. The first transaction is received for a new batch.
- 2. All server transaction queues are checked.
- 3. The server with the lowest number of outstanding transactions is identified.
- **4.** The identified server is assigned the next batch of transactions.

The batch size is a user-configured parameter. Changes in the batch size may impact CPU load and network throughput. As batch size increases, CPU load decreases and network throughput increases. However, if a large batch size is used, all available server resources may not be fully utilized. As batch size decreases, CPU load increases and network throughput decreases.

Note There is no set number for large or small batch sizes. A batch with more than 50 transactions is considered large and a batch with fewer than 25 transactions is considered small.

Note

If a server group contains ten or more servers, we recommend that you set a high batch size to reduce CPU load.

Transaction Load Balancing Across RADIUS Server Groups

You can configure load balancing either per-named RADIUS server group or for the global RADIUS server group. The load balancing server group must be referred to as "radius" in the authentication, authorization, and accounting (AAA) method lists. All public servers that are part of the RADIUS server group are then load balanced.

You can configure authentication and accounting to use the same RADIUS server or different servers. In some cases, the same server can be used for preauthentication, authentication, or accounting transactions for a session. The preferred server, which is an internal setting and is set as the default, informs AAA to use the same server for the start and stop record for a session regardless of the server cost. When using the preferred server setting, ensure that the server that is used for the initial transaction (for example, authentication), the preferred server, is part of any other server group that is used for a subsequent transaction (for example, accounting).

The preferred server is not used if one of the following criteria is true:

- The load-balance method least-outstanding ignore-preferred-server command is used.
- The preferred server is dead.

- The preferred server is in quarantine.
- The want server flag has been set, overriding the preferred server setting.

The want server flag, an internal setting, is used when the same server must be used for all stages of a multistage transaction regardless of the server cost. If the want server is not available, the transaction fails.

You can use the **load-balance method least-outstanding ignore-preferred-server** command if you have either of the following configurations:

- Dedicated authentication server and a separate dedicated accounting server
- Network where you can track all call record statistics and call record details, including start and stop records and records that are stored on separate servers

If you have a configuration where authentication servers are a superset of accounting servers, the preferred server is not used.

RADIUS Server Status and Automated Testing

The RADIUS Server Load Balancing feature considers the server status when assigning batches. Transaction batches are sent only to live servers. We recommend that you test the status of all RADIUS load-balanced servers, including low usage servers (for example, backup servers).

Transactions are not sent to a server that is marked dead. A server is marked dead until its timer expires, at which time it moves to quarantine state. A server is in quarantine until it is verified alive by the RADIUS automated tester functionality.

To determine if a server is alive and available to process transactions, the RADIUS automated tester sends a request periodically to the server for a test user ID. If the server returns an Access-Reject message, the server is alive; otherwise the server is either dead or quarantined.

A transaction sent to an unresponsive server is failed over to the next available server before the unresponsive server is marked dead. We recommend that you use the retry reorder mode for failed transactions.

When using the RADIUS automated tester, verify that the authentication, authorization, and accounting (AAA) servers are responding to the test packets that are sent by the network access server (NAS). If the servers are not configured correctly, packets may be dropped and the server erroneously marked dead.

Caution

We recommend that you use a test user that is not defined on the RADIUS server for the RADIUS server automated testing to protect against security issues that may arise if the test user is not correctly configured.

Note

Use the **test aaa group** command to check load-balancing transactions.

VRF-Aware RADIUS Automated Testing

The RADIUS automated tester function works at a server-level configuration. There is no group associated with the function. A VRF is a group level configuration. All the information related to the VRF and the source-interface configurations is maintained in a group structure. If information regarding the VRF and the

source-interface configurations is available in the global source-interface, automated tester can access it. If the information is not available at the global source-interface or the default VRF, automated tester marks the server as a dead server.

Starting with Cisco IOS XE Bengaluru 17.4.1, you can configure automated tester to be VRF aware. You can use the **vrf** keyword with the **automate-tester** command to enable automate-tester for a non-default VRF.

Note For VRF aware automate-tester to work, you have to configure **global config ipv4/ipv6 source interface** *interface-name* **vrf** *vrf-name* command.

How to Configure RADIUS Server Load Balancing

Enabling Load Balancing for a Named RADIUS Server Group

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	aaa group server radius group-name	Enters server group configuration mode.
	Example:	
	Device(config)# aaa group server radius rad-sg	
Step 4	server ip-address [auth-port port-number]	Configures the IP address of the RADIUS
	[acct-port port-number]	server for the group server.
	Example:	
	Device (config-sg-radius) # server 192.0.2.238 auth-port 2095 acct-port 2096	
Step 5	load-balancemethodleast-outstanding[batch-sizenumber][ignore-preferred-server]	Enables the least-outstanding load balancing for a named server group.
	Example:	
	Device(config-sg-radius)# load-balance method least-outstanding batch-size 30	

	Command or Action	Purpose
Step 6	end	Exits server group configuration mode and
	Example:	returns to privileged EXEC mode.
	<pre>Device(config-sg-radius)# end</pre>	

Troubleshooting RADIUS Server Load Balancing

After configuring the RADIUS Server Load Balancing feature, you can monitor the idle timer, dead timer, and load balancing server selection or verify the server status by using a manual test command.

Procedure

Step 1 Use the **debug aaa test** command to determine when an idle timer or dead timer has expired, when test packets are sent, the status of the server, or to verify the server state.

The idle timer is used to check the server status and is updated with or without any incoming requests. Monitoring the idle timer helps to determine if there are nonresponsive servers and to keep the RADIUS server status updated to efficiently utilize available resources. For instance, an updated idle timer would help ensure that incoming requests are sent to servers that are alive.

The dead timer is used either to determine that a server is dead or to update a dead server's status appropriately.

Monitoring server selection helps to determine how often the server selection changes. Server selection is effective in analyzing if there are any bottlenecks, a large number of queued requests, or if only specific servers are processing incoming requests.

The following sample output from the **debug aaa test** command shows when the idle timer expired:

Example:

Device# debug aaa test

```
Jul 16 00:07:01: AAA/SG/TEST: Server (192.0.2.245:1700,1701) quarantined.
Jul 16 00:07:01: AAA/SG/TEST: Sending test request(s) to server (192.0.2.245:1700,1701)
Jul 16 00:07:01: AAA/SG/TEST: Sending 1 Access-Requests, 1 Accounting-Requests in current
batch.
Jul 16 00:07:01: AAA/SG/TEST(Req#: 1): Sending test AAA Access-Request.
Jul 16 00:07:01: AAA/SG/TEST(Req#: 1): Sending test AAA Accounting-Request.
Jul 16 00:07:01: AAA/SG/TEST: Obtained Test response from server (192.0.2.245:1700,1701)
Jul 16 00:07:01: AAA/SG/TEST: Obtained Test response from server (192.0.2.245:1700,1701)
Jul 16 00:07:01: AAA/SG/TEST: Necessary responses received from server (192.0.2.245:1700,1701)
Jul 16 00:07:01: AAA/SG/TEST: Server (192.0.2.245:1700,1701) marked ALIVE. Idle timer set
for 60 sec(s).
Jul 16 00:07:01: AAA/SG/TEST: Server (192.0.2.245:1700,1701) removed from quarantine.
```

Step 2 Use the **debug aaa sg-server selection** command to determine the server that is selected for load balancing.

The following sample output from the **debug aaa sg-server selection** command shows five access requests being sent to a server group with a batch size of three:

Example:

Device# debug aaa sg-server selection

Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Obtaining least loaded server. Jul 16 03:15:05: AAA/SG/SERVER SELECT: [3] transactions remaining in batch. Reusing server. Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Obtaining least loaded server. Jul 16 03:15:05: AAA/SG/SERVER_SELECT: [2] transactions remaining in batch. Reusing server. Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Obtaining least loaded server. Jul 16 03:15:05: AAA/SG/SERVER_SELECT: [1] transactions remaining in batch. Reusing server. Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Obtaining least loaded server. Jul 16 03:15:05: AAA/SG/SERVER_SELECT: No more transactions in batch. Obtaining a new server. Jul 16 03:15:05: AAA/SG/SERVER_SELECT: No more transactions in batch. Obtaining a new server. Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Obtaining a new least loaded server. Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Server[0] load: 3 Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Server[1] load: 0 Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Server[2] load: 0 Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Selected Server[1] with load 0 Jul 16 03:15:05: AAA/SG/SERVER_SELECT: [3] transactions remaining in batch. Jul 16 03:15:05: AAA/SG/SERVER_SELECT: [3] transactions remaining in batch. Jul 16 03:15:05: AAA/SG/SERVER_SELECT: [2] transactions remaining in batch. Reusing server.

Step 3 Use the **test aaa group** command to manually verify the RADIUS load-balanced server status.

The following sample output shows the response from a load-balanced RADIUS server that is alive when the username "test" does not match a user profile. The server is verified alive when it issues an Access-Reject response to an authentication, authorization, and accounting (AAA) packet generated using the **test aaa group** command.

Example:

Device# test aaa group SG1 test lab new-code

```
00:06:07: RADIUS/ENCODE(0000000):Orig. component type = INVALID
00:06:07: RADIUS/ENCODE(0000000): dropping service type, "radius-server attribute 6

Enabling VRF Aware RADIUS Automated Testing

To enable RADIUS automated testing for a non-default VRF, perform the following procedure:

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode. Enter your
	Example:	password, if prompted.
	Device> enable	

L

	Command or Action	Purpose	
Step 2	configure terminal	Enters global configuration mode.	
	Example:		
	Device# configure terminal		
Step 3	radius server name	Specifies the name of the RADIUS server	
	Example:	configuration and enters RADIUS server configuration mode.	
	Device(config)# radius server myserver	configuration mode.	
Step 4	address {ipv4 ipv6} {ip-address host-name}auth-port port-numer acct-port port-number	Configures the IPv4 address for the RADIUS server accounting and authentication parameters.	
	Example:		
	Device(config-radius-server)# address ipv4 192.0.2.1 auth-port 1812 acct-port 1813		
Step 5	automate-tester username user [ignore-auth-port] [ignore-acct-port] [idle-time minutes] vrf vrf-name or automate-tester username user probe-on vrf vrf-name	Enables RADIUS automated testing for a non-default VRF.	
	Example:		
	Device(config-radius-server)# automate-tester username user1 idle-time 2 vrf VRF1		
	or		
	Device(config-radius-server)# automate-tester username user1 probe-on vrf VRF1		
Step 6	end	Exits RADIUS server configuration mode and	
Step 6	end Example:	Exits RADIUS server configuration mode and returns to privileged EXEC mode.	

Configuration Examples for RADIUS Server Load Balancing

Example: Enabling Load Balancing for a Named RADIUS Server Group

The following examples show load balancing enabled for a named RADIUS server group. These examples are shown in three parts: the current configuration of the RADIUS command output, debug output, and authentication, authorization, and accounting (AAA) server status information.

The following sample output shows the relevant RADIUS configuration:

The lines in the current configuration of the preceding RADIUS command output are defined as follows:

- The **aaa group server radius** command shows the configuration of a server group with two member servers.
- The load-balance command enables load balancing for global RADIUS server groups with the batch size specified.
- The **aaa authentication ppp** command authenticates all PPP users using RADIUS.
- The **aaa accounting** command enables sending of all accounting requests to the AAA server when the client is authenticated and then disconnected using the **start-stop** keyword.

The show debug sample output below shows the selection of the preferred server and the processing of requests for the preceding configuration:

```
Device# show debug
```

```
*Feb 28 13:51:16.019:AAA/SG/SERVER SELECT(0000002C):No preferred server available.
*Feb 28 13:51:16.019:AAA/SG/SERVER SELECT:Obtaining least loaded server.
*Feb 28 13:51:16.019:AAA/SG/SERVER SELECT:No more transactions in batch. Obtaining a new
server.
*Feb 28 13:51:16.019:AAA/SG/SERVER SELECT:Obtaining a new least loaded server.
*Feb 28 13:51:16.019:AAA/SG/SERVER SELECT:Server[0] load:0
*Feb 28 13:51:16.019:AAA/SG/SERVER SELECT:Server[1] load:0
*Feb 28 13:51:16.019:AAA/SG/SERVER SELECT:Selected Server[0] with load 0
*Feb 28 13:51:16.019:AAA/SG/SERVER SELECT: [5] transactions remaining in batch.
*Feb 28 13:51:16.019:AAA/SG/SERVER SELECT(0000002C):Server (192.0.2.238:2095,2096) now being
used as preferred server
*Feb 28 13:51:16.019:AAA/SG/SERVER SELECT(0000002D):No preferred server available.
*Feb 28 13:51:16.019:AAA/SG/SERVER SELECT:Obtaining least loaded server.
*Feb 28 13:51:16.019:AAA/SG/SERVER SELECT:[4] transactions remaining in batch. Reusing
server.
*Feb 28 13:51:16.019:AAA/SG/SERVER SELECT(0000002D):Server (192.0.2.238:2095,2096) now being
used as preferred server
*Feb 28 13:51:16.019:AAA/SG/SERVER SELECT(0000002E):No preferred server available.
*Feb 28 13:51:16.019:AAA/SG/SERVER SELECT:Obtaining least loaded server.
*Feb 28 13:51:16.019:AAA/SG/SERVER SELECT:[3] transactions remaining in batch. Reusing
server.
*Feb 28 13:51:16.019:AAA/SG/SERVER SELECT(0000002E):Server (192.0.2.238:2095,2096) now being
used as preferred server
*Feb 28 13:51:16.019:AAA/SG/SERVER SELECT(0000002F):No preferred server available.
*Feb 28 13:51:16.019:AAA/SG/SERVER SELECT:Obtaining least loaded server.
*Feb 28 13:51:16.019:AAA/SG/SERVER SELECT:[2] transactions remaining in batch. Reusing
server.
*Feb 28 13:51:16.019:AAA/SG/SERVER SELECT(0000002F):Server (192.0.2.238:2095,2096) now being
used as preferred server
```

*Feb 28 13:51:16.019:AAA/SG/SERVER SELECT(00000030):No preferred server available. *Feb 28 13:51:16.019:AAA/SG/SERVER SELECT:Obtaining least loaded server. *Feb 28 13:51:16.019:AAA/SG/SERVER SELECT: [1] transactions remaining in batch. Reusing server. *Feb 28 13:51:16.019:AAA/SG/SERVER SELECT(00000030):Server (192.0.2.238:2095,2096) now being used as preferred server *Feb 28 13:51:16.023:AAA/SG/SERVER SELECT(00000031):No preferred server available. *Feb 28 13:51:16.023:AAA/SG/SERVER SELECT:Obtaining least loaded server. *Feb 28 13:51:16.023:AAA/SG/SERVER SELECT:No more transactions in batch. Obtaining a new server. *Feb 28 13:51:16.023:AAA/SG/SERVER SELECT:Obtaining a new least loaded server. *Feb 28 13:51:16.023:AAA/SG/SERVER SELECT:Server[1] load:0 *Feb 28 13:51:16.023:AAA/SG/SERVER SELECT:Server[0] load:5 *Feb 28 13:51:16.023:AAA/SG/SERVER SELECT:Selected Server[1] with load 0 *Feb 28 13:51:16.023:AAA/SG/SERVER SELECT:[5] transactions remaining in batch. *Feb 28 13:51:16.023:AAA/SG/SERVER SELECT(00000031):Server (192.0.2.238:2015,2016) now being used as preferred server *Feb 28 13:51:16.023:AAA/SG/SERVER SELECT(00000032):No preferred server available. *Feb 28 13:51:16.023:AAA/SG/SERVER SELECT:Obtaining least loaded server. *Feb 28 13:51:16.023:AAA/SG/SERVER SELECT: [4] transactions remaining in batch. Reusing server.

The following sample output from the **show aaa servers** command shows the AAA server status for the named RADIUS server group configuration:

The sample output shows the status of two RADIUS servers. Both servers are alive, and no requests have been processed since the counters were cleared 0 minutes ago.

Device# show aaa servers RADIUS: id 3, priority 1, host 9:76:239::219, auth-port 1812, acct-port 1813, hostname r6 State: current UP, duration 223000s, previous duration 301s Dead: total time 682s, count 2 Platform State from SMD: current UP, duration 222972s, previous duration 258s SMD Platform Dead: total time 702s, count 3 Platform State from WNCD (1) : current UP Platform State from WNCD (2) : current UP Platform State from WNCD (3) : current UP Platform State from WNCD (4) : current UP Platform State from WNCD (5) : current UP Platform State from WNCD (6) : current UP Platform State from WNCD (7) : current UP Platform State from WNCD (8) : current UP, duration 2451264s, previous duration 258s Platform Dead: total time 703s, count 3 Ouarantined: No Authen: request 68, timeouts 68, failover 0, retransmission 53

Platform State from WNCD (8) : current UP. ===> This is wireless BINOS i.e WNCD instance 8
```

Example: Monitoring Idle Timer

The following example shows idle timer and related server state for load balancing enabled for a named RADIUS server group. The current configuration of the RADIUS command output and debug command output are also displayed.

The following sample output shows the relevant RADIUS configuration:

Device(config) # do show run aaa

```
aaa group server radius server-group1
radius server server1
address ipv4 192.0.2.1 auth-port 1812 acct-port 1813
automate-tester username user1 idle-time 2 vrf VRF1
radius-server load-balance method least-outstanding batch-size 5
```

The lines in the current configuration of the preceding RADIUS command output are defined as follows:

- The aaa group server radius command shows the configuration of a server group.
- The **radius server** and **address** command defines the RADIUS server name and IP address of the RADIUS server with authorization and accounting ports specified.
- The radius-server load-balance command enables load balancing for the RADIUS server with the batch size specified.

The **show debug** sample output below shows test requests being sent to servers. The response to the test request sent to the server is received, the server is removed from quarantine as appropriate, the server is marked alive, and then the idle timer is reset.

```
Device# show debug
```

```
*Feb 28 13:52:20.835:AAA/SG/TEST:Server (192.0.2.238:2015,2016) quarantined.
*Feb 28 13:52:20.835:AAA/SG/TEST:Sending test request(s) to server (192.0.2.238:2015,2016)
*Feb 28 13:52:20.835:AAA/SG/TEST:Sending 1 Access-Requests, 1 Accounting-Requests in current
batch.
*Feb 28 13:52:20.835:AAA/SG/TEST(Req#:1):Sending test AAA Access-Request.
*Feb 28 13:52:20.835:AAA/SG/TEST(Req#:1):Sending test AAA Accounting-Request.
*Feb 28 13:52:20.835:AAA/SG/TEST(Req#:1):Sending test AAA Accounting-Request.
*Feb 28 13:52:21.087:AAA/SG/TEST:Obtained Test response from server (192.0.2.238:2015,2016)
*Feb 28 13:52:22.651:AAA/SG/TEST:Obtained Test response from server (192.0.2.238:2015,2016)
*Feb 28 13:52:22.651:AAA/SG/TEST:Necessary responses received from server
(192.0.2.238:2015,2016)
*Feb 28 13:52:22.651:AAA/SG/TEST:Server (192.0.2.238:2015,2016) marked ALIVE. Idle timer
set for 60 secs(s).
*Feb 28 13:52:22.651:AAA/SG/TEST:Server (192.0.2.238:2015,2016) removed from quarantine.
.
```

Example: Configuring the Preferred Server with the Same Authentication and Authorization Server

The following example shows an authentication server group and an authorization server group that use the same servers 209.165.200.225 and 209.165.200.226. Both server groups have the preferred server flag enabled.

```
Device> enable
Device# configure terminal
Device(config)# aaa group server radius authentication-group
Device(config-sg-radius)# server 209.165.200.225 key radkey1
```

```
Device(config-sg-radius)# server 209.165.200.226 key radkey2
Device(config-sg-radius)# exit
Device(config)# aaa group server radius accounting-group
Device(config-sg-radius)# server 209.165.200.225 key radkey1
Device(config-sg-radius)# server 209.165.200.226 key radkey2
Device(config-sg-radius)# end
```

When a preferred server is selected for a session, all transactions for that session will continue to use the original preferred server. The servers 209.165.200.225 and 209.165.200.226 are load balanced based on sessions rather than transactions.

Example: Configuring the Preferred Server with Different Authentication and Authorization Servers

The following example shows an authentication server group that uses servers 209.165.200.225 and 209.165.200.226 and an authorization server group that uses servers 209.165.201.1 and 209.165.201.2. Both server groups have the preferred server flag enabled.

```
Device> enable
Device# configure terminal
Device(config)# aaa group server radius authentication-group
Device(config-sg-radius)# server 209.165.200.225 key radkey1
Device(config-sg-radius)# server 209.165.200.226 key radkey2
Device(config-sg-radius)# exit
Device(config)# aaa group server radius accounting-group
Device(config-sg-radius)# server 209.165.201.1 key radkey3
Device(config-sg-radius)# server 209.165.201.2 key radkey4
Device(config-sg-radius)# end
```

The authentication server group and the accounting server group do not share any common servers. A preferred server is never found for accounting transactions; therefore, authentication and accounting servers are load-balanced based on transactions. Start and stop records are sent to the same server for a session.

Example: Configuring the Preferred Server with Overlapping Authentication and Authorization Servers

The following example shows an authentication server group that uses servers 209.165.200.225, 209.165.200.226, and 209.165.201.1 and an accounting server group that uses servers 209.165.201.1 and 209.165.201.2. Both server groups have the preferred server flag enabled.

```
Device> enable
Device# configure terminal
Device(config)# aaa group server radius authentication-group
Device(config-sg-radius)# server 209.165.200.225 key radkey1
Device(config-sg-radius)# server 209.165.200.226 key radkey2
Device(config-sg-radius)# server 209.165.201.1 key radkey3
Device(config-sg-radius)# exit
Device(config)# aaa group server radius accounting-group
Device(config-sg-radius)# server 209.165.201.1 key radkey3
Device(config-sg-radius)# server 209.165.201.1 key radkey4
Device(config-sg-radius)# server 209.165.201.2 key radkey4
```

If all servers have equal transaction processing capability, one-third of all authentication transactions are directed toward the server 209.165.201.1. Therefore, one-third of all accounting transactions are also directed toward the server 209.165.201.1. The remaining two-third of accounting transactions are load balanced equally

between servers 209.165.201.1 and 209.165.201.2. The server 209.165.201.1 receives fewer authentication transactions because the server 209.165.201.1 has outstanding accounting transactions.

Example: Configuring the Preferred Server with Authentication Servers As a Subset of Authorization Servers

The following example shows an authentication server group that uses servers 209.165.200.225 and 209.165.200.226 and an authorization server group that uses servers 209.165.200.225, 209.165.200.226, and 209.165.201.1. Both server groups have the preferred server flag enabled.

```
Device> enable
Device# configure terminal
Device(config)# aaa group server radius authentication-group
Device(config-sg-radius)# server 209.165.200.225 key radkey1
Device(config-sg-radius)# server 209.165.200.226 key radkey2
Device(config-sg-radius)# exit
Device(config)# aaa group server radius accounting-group
Device(config-sg-radius)# server 209.165.200.225 key radkey1
Device(config-sg-radius)# server 209.165.200.226 key radkey2
Device(config-sg-radius)# server 209.165.200.226 key radkey3
Device(config-sg-radius)# server 209.165.201.1 key radkey3
Device(config-sg-radius)# end
```

One-half of all authentication transactions are sent to the server 209.165.200.225 and the other half to the server 209.165.200.226. Servers 209.165.200.225 and 209.165.200.226 are preferred servers for authentication and accounting transaction. Therefore, there is an equal distribution of authentication and accounting transactions across servers 209.165.200.225 and 209.165.200.226. The server 209.165.201.1 is relatively unused.

Example: Configuring the Preferred Server with Authentication Servers As a Superset of Authorization Servers

The following example shows an authentication server group that uses servers 209.165.200.225, 209.165.200.226, and 209.165.201.1 and an authorization server group that uses servers 209.165.200.225 and 209.165.200.226. Both server groups have the preferred server flag enabled.

```
Device> enable
Device# configure terminal
Device(config)# aaa group server radius authentication-groupp
Device(config-sg-radius)# server 209.165.200.225 key radkey1
Device(config-sg-radius)# server 209.165.201.1 key radkey3
Device(config-sg-radius)# exit
Device(config)# aaa group server radius accounting-group
Device(config-sg-radius)# server 209.165.200.225 key radkey1
Device(config-sg-radius)# server 209.165.200.226 key radkey2
Device(config-sg-radius)# server 209.165.200.226 key radkey2
Device(config-sg-radius)# server 209.165.200.226 key radkey2
```

Initially, one-third of authentication transactions are assigned to each server in the authorization server group. As accounting transactions are generated for more sessions, accounting transactions are sent to servers 209.165.200.225 and 209.165.200.226 because the preferred server flag is on. As servers 209.165.200.226 begin to process more transactions, authentication transactions will start to be sent to server 209.165.201.1. Transaction requests authenticated by server 209.165.201.1 do not have any preferred server setting and are split between servers 209.165.200.225 and 209.165.200.226, which negates the use of the preferred server flag. This configuration should be used cautiously.

Example: Enabling VRF Aware RADIUS Automated Testing

The following examples show how to enable automated testing for a non-default VRF on the RADIUS server:

```
Device(config)# radius server myserver
Device(config-radius-server)# address ipv4 192.0.2.1 auth-port 1812 acct-port 1813
Device(config-radius-server)# automate-tester username user1 idle-time 2 vrf VRF1
Device(config-radius-server)# end
Device(config-radius-server)# address ipv4 192.0.2.1 auth-port 1812 acct-port 1813
Device(config-radius-server)# automate-tester username user1 probe-on vrf VRF1
Device(config-radius-server)# automate-tester username user1 probe-on vrf VRF1
Device(config-radius-server)# end
```

Feature History for RADIUS Server Load Balancing

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Everest 16.11.1	RADIUS Server Load Balancing	The RADIUS Server Load Balancing feature distributes authentication, authorization, and accounting (AAA) authentication and accounting transactions across servers in a server group. These servers can share the AAA transaction load and thereby respond faster to incoming requests.
Cisco IOS XE Bengaluru 17.4.1	VRF Aware RADIUS Automated Testing	You can configure RADIUS automated testing for a non-default VRF.
Cisco IOS XE Cupertino 17.7.1	RADIUS Server Load Balancing	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

Configuring Kerberos

- Prerequisites for Kerberos, on page 229
- Information about Kerberos, on page 229
- How to Configure Kerberos, on page 233
- Monitoring the Kerberos Configuration, on page 233
- Feature History for Kerberos, on page 233

Prerequisites for Kerberos

The following are the prerequisites for controlling switch access with Kerberos.

- So that remote users can authenticate to network services, you must configure the hosts and the KDC in the Kerberos realm to communicate and mutually authenticate users and network services. To do this, you must identify them to each other. You add entries for the hosts to the Kerberos database on the KDC and add KEYTAB files generated by the KDC to all hosts in the Kerberos realm. You also create entries for the users in the KDC database.
- A Kerberos server can be a switch that is configured as a network security server and that can authenticate users by using the Kerberos protocol.

When you add or create entries for the hosts and users, follow these guidelines:

- The Kerberos principal name *must* be in all lowercase characters.
- The Kerberos instance name *must* be in all lowercase characters.
- The Kerberos realm name *must* be in all uppercase characters.

Information about Kerberos

This section provides the following Kerberos information.

Kerberos and Switch Access

This section describes how to enable and configure the Kerberos security system, which authenticates requests for network resources by using a trusted third party.

In the Kerberos configuration examples, the trusted third party can be any switch that supports Kerberos, that is configured as a network security server, and that can authenticate users by using the Kerberos protocol.

Kerberos Overview

Kerberos is a secret-key network authentication protocol, which was developed at the Massachusetts Institute of Technology (MIT). It uses the Data Encryption Standard (DES) cryptographic algorithm for encryption and authentication and authenticates requests for network resources. Kerberos uses the concept of a trusted third party to perform secure verification of users and services. This trusted third party is called the *key distribution center* (KDC).

Kerberos verifies that users are who they claim to be and the network services that they use are what the services claim to be. To do this, a KDC or trusted Kerberos server issues tickets to users. These tickets, which have a limited life span, are stored in user credential caches. The Kerberos server uses the tickets instead of user names and passwords to authenticate users and network services.

Note

A Kerberos server can be any switch that is configured as a network security server and that can authenticate users by using the Kerberos protocol.

The Kerberos credential scheme uses a process called *single logon*. This process authenticates a user once and then allows secure authentication (without encrypting another password) wherever that user credential is accepted.

This software release supports Kerberos 5, which allows organizations that are already using Kerberos 5 to use the same Kerberos authentication database on the KDC that they are already using on their other network hosts (such as UNIX servers and PCs).

Kerberos supports these network services:

- Telnet
- rlogin
- rsh

This table lists the common Kerberos-related terms and definitions.

Table 19: Kerberos Terms

Term	Definition	
Authentication	A process by which a user or service identifies itself to another service. For example, a client can authenticate to a switch or a switch can authenticate to another switch.	
Authorization	A means by which the switch identifies what privileges the user has in a network or on the switch and what actions the user can perform.	

Term	Definition A general term that refers to authentication tickets, such as TGTs ² and service credentials. Kerberos credentials verify the identity of a user or service. If a network service decides to trust the Kerberos server that issued a ticket, it can be used in place of re-entering a username and password. Credentials have a default life span of eight hours.		
Credential			
Instance	An authorization level label for Kerberos principals. Most Kerberos principals are of the form <i>user@REALM</i> (for example, smith@EXAMPLE.COM). A Kerberos principal with a Kerberos instance has the form <i>user/instance@REALM</i> (for example, smith/admin@EXAMPLE.COM). The Kerberos instance can be used to specify the authorization level for the user if authentication is successful. The server of each network service might implement and enforce the authorization mappings of Kerberos instances but is not required to do so.		
	Note The Kerberos principal and instance names <i>must</i> be in all lowercase characters.		
	Note The Kerberos realm name <i>must</i> be in all uppercase characters.		
KDC ³	Key distribution center that consists of a Kerberos server and database program that is running on a network host.		
Kerberized	A term that describes applications and services that have been modified to support the Kerberos credential infrastructure.		
Kerberos realm	A domain consisting of users, hosts, and network services that are registered to a Kerberos server. The Kerberos server is trusted to verify the identity of a user or network service to another user or network service.		
	Note The Kerberos realm name <i>must</i> be in all uppercase characters.		
Kerberos server	A daemon that is running on a network host. Users and network services register their identity with the Kerberos server. Network services query the Kerberos server to authenticate to other network services.		
KEYTAB ⁴	A password that a network service shares with the KDC. In Kerberos 5 and later Kerberov versions, the network service authenticates an encrypted service credential by using the KEYTAB to decrypt it. In Kerberos versions earlier than Kerberos 5, KEYTAB is referred to as SRVTAB ⁵ .		
Principal	Also known as a Kerberos identity, this is who you are or what a service is according to the Kerberos server.		
	Note The Kerberos principal name <i>must</i> be in all lowercase characters.		
Service credential	A credential for a network service. When issued from the KDC, this credential is encrypted with the password shared by the network service and the KDC. The password is also shared with the user TGT.		
SRVTAB	A password that a network service shares with the KDC. In Kerberos 5 or later Kerberos, SRVTAB is referred to as KEYTAB.		

Term	Definition
	Ticket granting ticket that is a credential that the KDC issues to authenticated users. When users receive a TGT, they can authenticate to network services within the Kerberos realm represented by the KDC.

² ticket granting ticket

Kerberos Operation

A Kerberos server can be a device that is configured as a network security server and that can authenticate remote users by using the Kerberos protocol. Although you can customize Kerberos in a number of ways, remote users attempting to access network services must pass through three layers of security before they can access network services.

To authenticate to network services by using a device as a Kerberos server, remote users must follow these steps:

Authenticating to a Boundary Switch

This section describes the first layer of security through which a remote user must pass. The user must first authenticate to the boundary switch. This process then occurs:

- 1. The user opens an un-Kerberized Telnet connection to the boundary switch.
- 2. The switch prompts the user for a username and password.
- 3. The switch requests a TGT from the KDC for this user.
- 4. The KDC sends an encrypted TGT that includes the user identity to the switch.
- 5. The switch attempts to decrypt the TGT by using the password that the user entered.
 - If the decryption is successful, the user is authenticated to the switch.
 - If the decryption is not successful, the user repeats Step 2 either by re-entering the username and password (noting if Caps Lock or Num Lock is on or off) or by entering a different username and password.

A remote user who initiates a un-Kerberized Telnet session and authenticates to a boundary switch is inside the firewall, but the user must still authenticate directly to the KDC before getting access to the network services. The user must authenticate to the KDC because the TGT that the KDC issues is stored on the switch and cannot be used for additional authentication until the user logs on to the switch.

Obtaining a TGT from a KDC

This section describes the second layer of security through which a remote user must pass. The user must now authenticate to a KDC and obtain a TGT from the KDC to access network services.

Authenticating to Network Services

This section describes the third layer of security through which a remote user must pass. The user with a TGT must now authenticate to the network services in a Kerberos realm.

How to Configure Kerberos

To set up a Kerberos-authenticated server-client system, follow these steps:

- Configure the KDC by using Kerberos commands.
- Configure the switch to use the Kerberos protocol.

Monitoring the Kerberos Configuration

To display the Kerberos configuration, use the following commands:

- show running-config
- show kerberos creds: Lists the credentials in a current user's credentials cache.
- **clear kerberos creds**: Destroys all credentials in a current user's credentials cache, including those forwarded.

Feature History for Kerberos

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.11.1	Kerberos	Kerberos is a secret-key network authentication protocol, which was developed at the Massachusetts Institute of Technology (MIT). It uses the Data Encryption Standard (DES) cryptographic algorithm for encryption and authentication and authenticates requests for network resources. Kerberos uses the concept of a trusted third party to perform secure verification of users and services.
Cisco IOS XE Cupertino 17.7.1	Kerberos	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

MACsec Encryption

- Prerequisites for MACsec Encryption, on page 235
- Restrictions for MACsec Encryption, on page 235
- Information About MACsec Encryption, on page 236
- How to Configure MACsec Encryption, on page 244
- Configuration Examples for MACsec Encryption, on page 268
- Additional References for MACsec Encryption, on page 288
- Feature History for MACsec Encryption, on page 289

Prerequisites for MACsec Encryption

Prerequisites for MACsec Encryption

- Enable the **ssci-based-on-sci** command while configuring MACsec encryption on the device to allow interoperability with non-Cisco and non-IOS XE devices.
- Ensure that 802.1x authentication and AAA are configured on your device.

Prerequisites for Certificate-Based MACsec

- Ensure that you have a Certificate Authority (CA) server configured for your network.
- Generate a CA certificate.
- Ensure that you have configured Cisco Identity Services Engine (ISE) Release 2.0.
- Ensure that both the participating devices, the CA server, and Cisco Identity Services Engine (ISE) are synchronized using Network Time Protocol (NTP). If time is not synchronized on all your devices, certificates will not be validated.

Restrictions for MACsec Encryption

• MACsec configuration is not supported on EtherChannel ports. Instead, MACsec configuration can be applied on the individual member ports of an EtherChannel. To remove MACsec configuration, you must first unbundle the member ports from the EtherChannel, and then remove it from the individual member ports.

- MACsec Key Agreement (MKA) is not supported with high availability.
- MACsec with MKA is supported only on point-to-point links.
- GCM-AES-256 and XPN cipher suites (GCM-AES-XPN-128 and GCM-AES-XPN-256) are supported only with Network Advantage license.
- The MACsec Cipher announcement is not supported for MACsec Extended Packet Numbering (XPN) Ciphers and switch-to-switch MACsec connections.
- MACsec XPN Cipher Suites are not supported in switch-to-host MACsec connections.
- MACsec XPN Cipher Suites do not provide confidentiality protection with a confidentiality offset, and these together are not supported in switch-to-switch MACsec connections.
- As per IEEE standards, the maximum value of replay window is 2³⁰⁻¹ for MACsec XPN Cipher Suites. Even if you configure a higher value than this, it will be restricted to 2³⁰⁻¹ only.
- Certificate-based MACsec is supported only if the access-session is configured as closed or in multiple-host mode. None of the other configuration modes are supported.
- If the **dot1q tag vlan native** command is configured globally, the dot1x reauthentication will fail on trunk ports.
- Catalyst 9600 Switches (Dual-Supervisor and StackWise Virtual) does not support MACsec Key Agreement (MKA) with high availability.
- MACsec is not supported with Multicast VPN (mVPN).
- MACsec switch-to-host connections are not supported on Software-Defined Access deployments.
- should-secure access mode is supported on switch-to-switch ports only using PSK authentication. It is
 not supported on dot1x sessions and Cisco TrustSec Security Association Protocol (SAP) configuration.
- The **should-secure** access mode is not supported on the C9600-LC-40YL4CD line card if used with the Cisco Catalyst 9600 Series Supervisor 2 Module.
- Access control options are only applicable to uplink ports. The options are not applicable to downlink
 ports and supervisor ports.

Information About MACsec Encryption

The following sections provide information about MACsec encryption.

Recommendations for MACsec Encryption

This section list the recommendations for configuring MACsec encryption:

- Use the confidentiality (encryption) offset as 0 in switch-to-host connections.
- Use Bidirectional Forwarding and Detection (BFD) timer value as 750 milliseconds for 10Gbps ports and 1.25 seconds for any port with speed above 10Gbps.

- Execute the **shutdown** command, and then the **no shutdown** command on a port, after changing any MKA policy or MACsec configuration for active sessions, so that the changes are applied to active sessions.
- Use Extended Packet Numbering (XPN) Cipher Suite for port speeds of 40Gbps and above.
- Set the connectivity association key (CAK) rekey overlap timer to 30 seconds or more.
- Do not use Cisco TrustSec Security Association Protocol (SAP) MACsec encryption for port speeds above 10Gbps.
- Do not enable both Cisco TrustSec SAP and uplink MKA at the same time on any interface.
- We recommend that you use MACsec MKA encryption.

MACsec Encryption Overview

MACsec is the IEEE 802.1AE standard for authenticating and encrypting packets between two MACsec-capable devices. Catalyst switches support 802.1AE encryption with MACsec Key Agreement (MKA) on switch-to-host links for encryption between the switch and host device. The switch also supports MACsec encryption for switch-to-switch (inter-network device) security using both Cisco TrustSec Network Device Admission Control (NDAC), Security Association Protocol (SAP) and MKA-based key exchange protocol.

Note

When switch-to-switch MACSec is enabled, all traffic is encrypted, except the EAP-over-LAN (EAPOL) packets.

Link layer security can include both packet authentication between switches and MACsec encryption between switches (encryption is optional). Link layer security is supported on SAP-based MACsec.

Table 20: MACsec Support on Switch Ports

Connections	MACsec Support
Switch-to-Host	MACsec MKA Encryption
Switch-to-Switch	MACsec MKA encryption (recommended)
	Cisco TrustSec SAP

Cisco TrustSec and Cisco SAP are meant only for switch-to-switch links and are not supported on switch ports connected to end hosts, such as PCs or IP phones. MKA is supported on switch-to-host facing links as well as switch-to-switch links. Host-facing links typically use flexible authentication ordering for handling heterogeneous devices with or without IEEE 802.1x, and can optionally use MKA-based MACsec encryption. Cisco NDAC and SAP are mutually exclusive with Network Edge Access Topology (NEAT), which is used for compact switches to extend security outside the wiring closet.

Media Access Control Security and MACsec Key Agreement

MACsec, defined in 802.1AE, provides MAC-layer encryption over wired networks by using out-of-band methods for encryption keying. The MACsec Key Agreement (MKA) Protocol provides the required session

keys and manages the required encryption keys. MKA and MACsec are implemented after successful authentication using the certificate-based MACsec or Pre Shared Key (PSK) framework.

A switch using MACsec accepts either MACsec or non-MACsec frames, depending on the policy associated with the MKA peer. MACsec frames are encrypted and protected with an integrity check value (ICV). When the switch receives frames from the MKA peer, it decrypts them and calculates the correct ICV by using session keys provided by MKA. The switch compares that ICV to the ICV within the frame. If they are not identical, the frame is dropped. The switch also encrypts and adds an ICV to any frames sent over the secured port (the access point used to provide the secure MAC service to a MKA peer) using the current session key.

The MKA Protocol manages the encryption keys used by the underlying MACsec protocol. The basic requirements of MKA are defined in 802.1x-REV. The MKA Protocol extends 802.1x to allow peer discovery with confirmation of mutual authentication and sharing of MACsec secret keys to protect data exchanged by the peers.

The EAP framework implements MKA as a newly defined EAP-over-LAN (EAPOL) packet. EAP authentication produces a master session key (MSK) shared by both partners in the data exchange. Entering the EAP session ID generates a secure connectivity association key name (CKN). The switch acts as the authenticator for both switch-to-switch and switch-to-host; and acts as the key server for switch-to-host. It generates a random secure association key (SAK), which is sent to the client partner. The client is never a key server and can only interact with a single MKA entity, the key server. After key derivation and generation, the switch sends periodic transports to the partner at a default interval of 2 seconds.

The packet body in an EAPOL Protocol Data Unit (PDU) is referred to as a MACsec Key Agreement PDU (MKPDU). MKA sessions and participants are deleted when the MKA lifetime (6 seconds) passes with no MKPDU received from a participant. For example, if a MKA peer disconnects, the participant on the switch continues to operate MKA until 6 seconds have elapsed after the last MKPDU is received from the MKA peer.

Note Integrity check value (ICV) indicator in MKPDU is optional. ICV is not optional when the traffic is encrypted.

MKA Policies

You apply a defined MKA policy to an interface to enable MKA on the interface. Removing the MKA policy disables MKA on that interface. You can configure these options:

- Policy name, not to exceed 16 ASCII characters.
- Confidentiality (encryption) offset of 0, 30, or 50 bytes for each physical interface.

Note Confidentiality offset of 50 bytes with MACsec XPN Cipher Suites is not supported.

Definition of Policy-Map Actions

This section describes the policy-map actions and its definition:

- Activate: Applies a service template to the session.
- Authenticate: Starts authentication of the session.

- Authorize: Explicitly authorizes a session.
- Set-domain: Explicitly sets the domain of a client.
- Terminate: Terminates the method that is running, and deletes all the method details associated with the session.
- Deactivate: Removes the service-template applied to the session. If not applied, no action is taken.
- Set-timer: Starts a timer and gets associated with the session. When the timer expires, any action that needs to be started can be processed.
- Authentication-restart: Restarts authentication.
- Clear-session: Deletes a session.
- Pause: Pauses authentication.

Rest of the actions as self-explanatory and are associated with authentication.

Virtual Ports

Use virtual ports for multiple secured connectivity associations on a single physical port. Each connectivity association (pair) represents a virtual port. In switch-to-switch, you can have only one virtual port per physical port. In switch-to-host, you can have a maximum of two virtual ports per physical port, of which one virtual port can be part of a data VLAN; the other must externally tag its packets for the voice VLAN. You cannot simultaneously host secured and unsecured sessions in the same VLAN on the same port. Because of this limitation, 802.1x multiple authentication mode is not supported.

The exception to this limitation is in multiple-host mode when the first MACsec supplicant is successfully authenticated and connected to a hub that is connected to the switch. A non-MACsec host connected to the hub can send traffic without authentication because it is in multiple-host mode. We do not recommend using multi-host mode because after the first successful client, authentication is not required for other clients.

Virtual ports represent an arbitrary identifier for a connectivity association and have no meaning outside the MKA Protocol. A virtual port corresponds to a separate logical port ID. Valid port IDs for a virtual port are 0x0002 to 0xFFFF. Each virtual port receives a unique secure channel identifier (SCI) based on the MAC address of the physical interface concatenated with a 16-bit port ID.

MKA Statistics

Some MKA counters are aggregated globally, while others are updated both globally and per session. You can also obtain information about the status of MKA sessions. See Example: Displaying MKA Information, on page 282 for further information.

Key Lifetime and Hitless Key Rollover

A MACsec key chain can have multiple pre-shared keys (PSK) each configured with a key id and an optional lifetime. A key lifetime specifies at which time the key expires. In the absence of a lifetime configuration, the default lifetime is unlimited. When a lifetime is configured, MKA rolls over to the next configured pre-shared key in the key chain after the lifetime is expired. Time zone of the key can be local or UTC. Default time zone is UTC.

You can Key rolls over to the next key within the same key chain by configuring a second key in the key chain and configuring a lifetime for the first key. When the lifetime of the first key expires, it automatically

rolls over to the next key in the list. If the same key is configured on both sides of the link at the same time, then the key rollover is hitless, that is, key rolls over without traffic interruption.

On all participating devices, the MACsec key chain must be synchronised by using Network Time Protocol (NTP) and the same time zone must be used. If all the participating devices are not synchronized, the connectivity association key (CAK) rekey will not be initiated on all the devices at the same time.

The lifetime of the keys need to be overlapped in order to achieve hitless key rollover.

Replay Protection Window Size

Replay protection is a feature provided by MACsec to counter replay attacks. Each encrypted packet is assigned a unique sequence number and the sequence is verified at the remote end. Frames transmitted through a Metro Ethernet service provider network are highly susceptible to reordering due to prioritization and load balancing mechanisms used within the network.

A replay window is necessary to support the use of MACsec over provider networks that reorder frames. Frames within the window can be received out of order, but are not replay protected. The default window size is 0, which enforces strict reception ordering. The replay window size can be configured in the range of 0 to 2^{32} - 1. In case of XPN cipher suite, maximum replay window size is 2^{30} - 1, and if a higher window size is configured, the window size gets restricted to 2^{30} - 1. If the cipher suite is changed to a non-XPN cipher suite, then there is no restriction and the configured window size is used.

MACsec, MKA, and 802.1x Host Modes

You can use MACsec and the MKA Protocol with 802.1x single-host mode, multi-host mode, or Multi Domain Authentication (MDA) mode. Multiple authentication mode is not supported.

Single-Host Mode

The figure shows how a single EAP authenticated session is secured by MACsec by using MKA

Figure 12: MACsec in Single-Host Mode with a Secured Data Session

Multiple Host Mode

In standard (not 802.1x REV) 802.1x multiple-host mode, a port is open or closed based on a single authentication. If one user, the primary secured client services client host, is authenticated, the same level of network access is provided to any host connected to the same port. If a secondary host is a MACsec supplicant, it cannot be authenticated and traffic would not flow. A secondary host that is a non-MACsec host can send traffic to the network without authentication because it is in multiple-host mode. The figure shows MACsec in Standard Multiple-Host Unsecure Mode.

Figure 13: MACsec in Multiple-Host Mode - Unsecured

Multiple-Domain Mode

In standard (not 802.1x REV) 802.1x multiple-domain mode, a port is open or closed based on a single authentication. If the primary user, a PC on data domain, is authenticated, the same level of network access is provided to any domain connected to the same port. If a secondary user is a MACsec supplicant, it cannot be authenticated and traffic would no flow. A secondary user, an IP phone on voice domain, that is a non-MACsec host, can send traffic to the network without authentication because it is in multiple-domain mode.

Access Control Option for Smoother Migration

When MACsec is enabled on an interface, the entire interface traffic is secured by default. MACsec does not allow any unencrypted packets to be transmitted or received from the same physical interface. However, to enable MACsec on selected subinterfaces, an additional Cisco-proprietary extension has been implemented to allow unencrypted packets to be transmitted or received from the same physical interface.

Use the **macsec access-control** {**must-secure** | **should-secure**} command to control the behavior of unencrypted packets.

Certificate-Based MACsec Encryption

Using certificate-based MACsec encryption, you can configure MACsec MKA between device switch-to-switch ports. Certificate-based MACsec encryption allows mutual authentication and obtains an MSK (master session key) from which the connectivity association key (CAK) is derived for MKA operations. Device certificates are carried, using certificate-based MACsec encryption, for authentication to the AAA server.

MACsec Connections Across Intermediate Switches

Prior to Cisco IOS XE Gibraltar 16.10.1, MACsec connection between end devices which have WAN MACsec configured with the intermediate switches as the Cisco Catalyst 9000 Series Switches was not supported. The encrypted packets were dropped if WAN MACsec was configured on the end devices with MACsec not configured on the intermediate switches. With the ClearTag feature implemented on the ASIC, the switch forwards the encrypted packet without parsing the MACsec header. Below topology displays how the encrypted packets are forwarded through the intermediate switches with L2 switching.

Figure 14: Topology for ClearTag MACsec : MACsec Not Configured on the Intermediate Switches

Limitations for MACsec Connections Across Intermediate Switches

- Hop-by-hop MACsec encryption with Catalyst 9000 Series switches as intermediate switches where WAN MACsec is configured on the routers is not supported.
- WAN MACsec configured on the routers with intermediate switches as the Catalyst 9000 Series switches is not supported on Layer 3 VPNs.
- WAN MACsec configured on the routers with intermediate switches as the Catalyst 9000 Series switches show Cisco Discovery Protocol neighbors only in should-secure mode.

Switch-to-switch MKA MACsec Must Secure Policy

Starting with Cisco IOS XE Fuji 16.8.1a, must-secure support is enabled on both the ingress and the egress. Must-secure is supported for MKA and SAP. With must-secure enabled, only EAPoL traffic will not be encrypted. The rest of the traffic will be encrypted. Unencrypted packets are dropped.

Note Must-secure mode is enabled by default.

Prior to Cisco IOS XE Fuji 16.8.1a, should-secure was supported for MKA and SAP. With should-secure enabled, if the peer is configured for MACsec, the data traffic is encrypted, otherwise it is sent in clear text.

MACsec Extended Packet Numbering (XPN)

Every MACsec frame contains a 32-bit packet number (PN), and it is unique for a given Security Association Key (SAK). Upon PN exhaustion (after reaching 75% of 2^{31} - 1), SAK rekey takes place to refresh the data plane keys. For high capacity links such as 40 Gb/s, PN exhausts within a few seconds, and frequent SAK rekey to the control plane is required. When XPN is used, the PN of the MACsec frame is a 64-bit value, after reaching 75% of th of 2^{63} - 1, it will require several years to exhaust the PN; this ensures that frequent SAK rekey does not happen on high speed links. The XPN feature in MKA/MACsec eliminates the need for frequent SAK rekey that may occur in high capacity links. XPN is a mandatory requirement for FIPS/CC compliance on high speed links such as 40 Gb/s, and so on.

Note MACsec XPN is supported only on the switch-to-switch ports.

The following rekey is possible in XPN:

- Volume-based Rekey—To ensure that frequent SAK rekey does not happen, you can configure XPN using the GCM-AES-XPN-128 or GCM-AES-XPN-256 cipher suites under the defined MKA policy; these cipher suites allow more than 2³² frames to be protected with a single SAK. XPN supports a 64-bit value for the PN. The MACsec frame contains only the lowest 32 bits and the most significant 32 bits would be maintained by the peer itself, both the sending and the receiving peers. The most significant 32 bits of the PN is incremented at the receiving end when the MSB (most significant bits) of LAPN (lowest acceptable packet number) for the respective peer is set, and the MSB of the PN value received in the MACsec frame is 0. Thus, both the sending and the receiving peer maintain the same PN value without changing the MACsec frame structure.
- **Time-based Rekey**—To set the SAK rekey manually, timer-based rekey is supported where you have the provision to start re-keying SAK at a given interval. Use the **sak rekey interval** *time-interval* command in MKA policy configuration mode to configure the SAK rekey interval for a defined MKA policy applied to the interface.

MKA/MACsec for Port Channel

MKA/MACsec can be configured on the port members of a port channel. MKA/MACsec is agnostic to the port channel since the MKA session is established between the port members of a port channel.

Note Etherchannel links that are formed as part of the port channel can either be congruent or disparate i.e. the links can either be MACsec-secured or non-MACsec-secured. MKA session between the port members is established even if a port member on one side of the port channel is not configured with MACsec.

It is recommended that you enable MKA/MACsec on all the member ports for better security of the port channel.

MACsec Cipher Announcement

Cipher Announcement allows the supplicant and the authenticator to announce their respective MACsec Cipher Suite capabilities to each other. Both the supplicant and the authenticator calculate the largest common supported MACsec Cipher Suite and use the same as the keying material for the MKA session.

How to Configure MACsec Encryption

The following sections provide information about the various tasks that comprise MACsec encryption.

Configuring MKA and MACsec

By default, MACsec is disabled. No MKA policies are configured.

Configuring an MKA Policy

Beginning in privileged EXEC mode, follow these steps to create an MKA Protocol policy. Note that MKA also requires that you enable 802.1x.

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	

	Command or Action	Purpose
Step 3	<pre>mka policy policy-name Example: Device(config)# mka policy mka_policy</pre>	Identifies an MKA policy, and enters MKA policy configuration mode. The maximum policy name length is 16 characters. Note The default MACsec cipher suite in the MKA policy will always be "GCM-AES-128". If the device supports both "GCM-AES-128" and "GCM-AES-256" ciphers, it is highly recommended to define and use a user defined MKA policy to include both 128 and 256 bits ciphers or only 256 bits cipher, as may be required.
Step 4	key-server priority Example: Device(config-mka-policy)# key-server priority 200	Configures MKA key server options and set priority (between 0-255).NoteWhen value of key server priority is set to 255, the peer can not become the key server. The key server priority value is valid only for MKA PSK; and not for MKA EAPTLS.
Step 5	include-icv-indicator Example: Device(config-mka-policy)# include-icv-indicator	Enables the ICV indicator in MKPDU. Use the no form of this command to disable the ICV indicator.
Step 6	<pre>macsec-cipher-suite {gcm-aes-128 gcm-aes-256} Example: Device (config-mka-policy) # macsec-cipher-suite gcm-aes-128</pre>	Configures a cipher suite for deriving SAK with 128-bit or 256-bit encryption.
Step 7	<pre>confidentiality-offset offset-value Example: Device(config-mka-policy)# confidentiality-offset 0</pre>	Set the confidentiality (encryption) offset for each physical interface.NoteOffset Value can be 0, 30 or 50. If you are using Anyconnect on the client, it is recommended to use Offset 0.
Step 8	ssci-based-on-sci Example: Device(config-mka-policy)# ssci-based-on-sci	(Optional) Computes Short Secure Channel Identifier (SSCI) value based on Secure Channel Identifier (SCI) value. The higher the SCI value, the lower is the SSCI value.

	Command or Action	Purpose
Step 9	end	Exit enters MKA policy configuration mode
	Example:	and returns to privileged EXEC mode.
	<pre>Device(config-mka-policy)# end</pre>	
Step 10	show mka policy	Displays MKA policy configuration
	Example:	information.
	Device# show mka policy	

Configuring Switch-to-host MACsec Encryption

Follow these steps to configure MACsec on an interface with one MACsec session for voice and one for data:

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter the password if prompted.
	Device> enable	
Step 2	configure terminal	Enters the global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface type number	Identifies the MACsec interface, and enters
	Example:	interface configuration mode. The interface must be a physical interface.
	Device(config)# interface	must de la physical interface.
	GigabitEthernet 1/0/1	
Step 4	switchport access vlanvlan-id	Configures the access VLAN for the port.
	Example:	
	<pre>Device(config-if)# switchport access vlan 1</pre>	
Step 5	switchport mode access	Configures the interface as an access port.
	Example:	
	Device(config-if)# switchport mode	
	access	
Step 6	macsec	Enables 802.1ae MACsec on the interface. The
	Example:	macsec command enables MKA MACsec on
	Device(config-if)# macsec	switch-to-host links only.
Step 7	authentication event linksec fail action	(Optional) Specifies that the switch processes
	authorize vlan vlan-id	authentication link-security failures resulting
	Example:	from unrecognized user credentials by

	Command or Action	Purpose
	Device (config-if) # authentication event linksec fail action authorize vlan 1	authorizing a restricted VLAN on the port afte a failed authentication attempt.
Step 8	authentication host-mode multi-domain Example: Device(config-if)# authentication host-mode multi-domain	Configures authentication manager mode on the port to allow both a host and a voice device to be authenticated on the 802.1x-authorized port. If not configured, the default host mode is single.
Step 9	authentication linksec policy must-secure Example: Device(config-if)# authentication linksec policy must-secure	Sets the LinkSec security policy to secure th session with MACsec if the peer is available If not set, the default is <i>should secure</i> .
Step 10	authentication port-control auto Example: Device(config-if)# authentication port-control auto	Enables 802.1x authentication on the port. The port changes to the authorized or unauthorized state based on the authentication exchange between the switch and the client.
Step 11	<pre>authentication periodic Example: Device(config-if)# authentication periodic</pre>	(Optional) Enables or disables re-authentication for this port .
Step 12	authentication timer reauthenticate Example: Device(config-if)# authentication timer reauthenticate	(Optional) Enters a value between 1 and 6553. (in seconds). Obtains re-authentication timeou value from the server. Default re-authentication time is 3600 seconds.
Step 13	authentication violation protect Example: Device(config-if)# authentication violation protect	Configures the port to drop unexpected incoming MAC addresses when a new devic connects to a port or when a device connects to a port after the maximum number of device are connected to that port. If not configured, the default is to shut down the port.
Step 14	<pre>mka policy policy-name Example: Device(config-if)# mka policy mka_policy</pre>	Applies an existing MKA protocol policy to the interface, and enable MKA on the interface If no MKA policy was configured (by entering the mka policy global configuration command)
Step 15	<pre>dot1x pae authenticator Example: Device(config-if)# dot1x pae authenticator</pre>	Configures the port as an 802.1x port access entity (PAE) authenticator.
Step 16	spanning-tree portfast Example:	Enables spanning tree Port Fast on the interface in all its associated VLANs. When the Port Fast feature is enabled, the interface changes

	Command or Action	Purpose
	<pre>Device(config-if)# spanning-tree portfast</pre>	directly from a blocking state to a forwarding state without making the intermediate spanning-tree state changes
Step 17	end Example: Device(config)# end	Exits interface configuration mode and returns to privileged EXEC mode.
Step 18	<pre>show authentication session interface interface-id details Example: Device# show authentication session interface GigabitEthernet 1/0/1</pre>	Verifies the details of the security status of the authorized session.
Step 19	show macsec interface interface-id Example: Device# show macsec interface GigabitEthernet 1/0/1	Verifies the MACsec status on the interface.
Step 20	show mka sessions Example: Device# show mka sessions	Verifies the established MKA sessions.

Configuring MKA MACsec using PSK

Configuring MACsec MKA using PSK

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	key chain key-chain-name macsec	Configures a key chain and enters the key chain
	Example:	configuration mode.
	Device(config)# key chain keychain1 macsec	

	Command or Action	Purpose	
Step 4	<pre>key hex-string Example: Device(config-key-chain)# key 1000</pre>	Configures a unique identifier for each key in the keychain and enters the keychain's key configuration mode.	
		Note For 128-bit encryption, use any value between 1 and 32 hex digit key-string. For 256-bit encryption, use 64 hex digit key-string.	
Step 5	cryptographic-algorithm {aes-128-cmac aes-256-cmac}	Set cryptographic authentication algorithm with 128-bit or 256-bit encryption.	
	Example:		
	Device(config-key-chain)# cryptographic-algorithm aes-128-cmac		
Step 6	key-string { [0/6/7] pwd-string pwd-string}Example:	Sets the password for a key string. Only hex characters must be entered.	
	Device(config-key-chain)# key-string 12345678901234567890123456789012		
Step 7	lifetime local [start timestamp {hh::mm::ss day month year}] [duration seconds end timestamp {hh::mm::ss day month year}]	Sets the lifetime of the pre shared key.	
	Example:		
	Device(config-key-chain)# lifetime local 12:12:00 July 28 2016 12:19:00 July 28 2016		
Step 8	end	Exits key chain configuration mode and returns	
	Example:	to privileged EXEC mode.	
	Device(config-key-chain)# end		

Configuring MACsec MKA on an Interface Using PSK

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	

	Command or Action	Purpose
Step 3	interface type number	Enters interface configuration mode.
	Example:	
	<pre>Device(config-if)# interface GigabitEthernet 0/0/0</pre>	
Step 4	macsec access-control {must-secure should-secure}	(Optional) Controls the behavior of unencrypted packets.
	Example:	• should-secure: Allows unencrypted
	<pre>Device(config-if) # macsec access-control should-secure</pre>	packets from the physical interface or subinterfaces to be transmitted or received.
		• must-secure : Does not allow unencrypted packets from physical interface or subinterfaces to be transmitted or received. All such packets are dropped, except for MKA control protocol packets.
Step 5	macsec network-link	Enables MACsec on the interface.
	Example:	
	<pre>Device(config-if) # macsec network-link</pre>	
Step 6	mka policy policy-name	Configures an MKA policy.
	Example:	
	Device(config-if)# mka policy mka_policy	
Step 7	mka pre-shared-key key-chain key-chain name	Configures an MKA pre-shared-key key-chain name.
	Example:	
	Device(config-if)# mka pre-shared-key key-chain key-chain-name	
Step 8	macsec replay-protection window-size <i>frame</i> number	Sets the MACsec window size for replay protection.
	Example:	
	<pre>Device(config-if)# macsec replay-protection window-size 10</pre>	
Step 9	end	Exits interface configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-if)# end	

What to do next

It is not recommended to change the MKA policy on an interface with MKA PSK configured when the session is running. However, if a change is required, you must reconfigure the policy as follows:

- 1. Disable the existing session by removing macsec network-link configuration on each of the participating node using the **no macsec network-link** command
- 2. Configure the MKA policy on the interface on each of the participating node using the **mka policy policy-name** command.
- 3. Enable the new session on each of the participating node by using the macsec network-link command.

Configuring Certificate-Based MACsec Encryption

To configure MACsec with MKA on point-to-point links, perform these tasks:

- Configure Certificate Enrollment
 - · Generate Key Pairs
 - Configure SCEP Enrollment
 - Configure Certificates Manually
- Configure an Authentication Policy
- Configure certificate-based MACsec encryption Profiles and IEEE 802.1x Credentials
- · Configure MKA MACsec using certificate-based MACsec encryption on Interfaces

Generating Key Pairs

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	crypto key generate rsa label label-name general-keys modulus size	Generates a RSA key pair for signing and encryption.
	Example: Device(config)# crypto key generate rsa label general-keys modulus 2048	You can also assign a label to each key pair using the label keyword. The label is referenced by the trustpoint that uses the key pair. If you do not assign a label, the key pair is automatically labeled <default-rsa-key>. If you do not use additional keywords this command generates one general purpose RSA key pair. If the modulus is not specified, the default key modulus of 1024 is used. You can</default-rsa-key>

Procedure

	Command or Action	Purpose
		specify other modulus sizes with the modulus keyword.
Step 4	end	Exits global configuration mode and returns to
	Example:	privileged EXEC mode.
	Device(config)# end	
Step 5	show authentication session interface interface-id	Verifies the authorized session security status.
	Example:	
	Device# show authentication session interface gigabitethernet 0/1/1	

Configuring Enrollment using SCEP

Simple Certificate Enrollment Protocol (SCEP) is a Cisco-developed enrollment protocol that uses HTTP to communicate with the certificate authority (CA) or registration authority (RA). SCEP is the most commonly used method for sending and receiving requests and certificates.

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	crypto pki trustpoint server name	Declares the trustpoint and a given name and
	Example:	enters ca-trustpoint configuration mode.
	Device(config)# crypto pki trustpoint ka	
Step 4	enrollment url url name pem	Specifies the URL of the CA on which your
	Example:	device should send certificate requests.
	<pre>Device(ca-trustpoint)# enrollment url http://url:80</pre>	An IPv6 address can be added in the URL enclosed in brackets. For example: http:// [2001:DB8:1:1::1]:80.
		The pem keyword adds privacy-enhanced mail (PEM) boundaries to the certificate request.
Step 5	rsakeypair label	Specifies which key pair to associate with the
	Example:	certificate.

	Command or Action	Purpose
	<pre>Device(ca-trustpoint)# rsakeypair exampleCAkeys</pre>	Note The rsakeypair name must match the trust-point name.
Step 6	<pre>serial-number none Example: Device(ca-trustpoint)# serial-number none</pre>	The none keyword specifies that a serial number will not be included in the certificate request.
Step 7	<pre>ip-address none Example: Device(ca-trustpoint)# ip-address none</pre>	The none keyword specifies that no IP address should be included in the certificate request.
Step 8	<pre>revocation-check crl Example: Device(ca-trustpoint)# revocation-check crl</pre>	Specifies CRL as the method to ensure that the certificate of a peer has not been revoked.
Step 9	auto-enroll percent regenerate Example: Device(ca-trustpoint)# auto-enroll 90 regenerate	Enables auto-enrollment, allowing the client to automatically request a rollover certificate from the CA.
		If auto-enrollment is not enabled, the client must be manually re-enrolled in your PKI upon certificate expiration.
		By default, only the Domain Name System (DNS) name of the device is included in the certificate.
		Use the percent argument to specify that a new certificate will be requested after the percentage of the lifetime of the current certificate is reached.
		Use the regenerate keyword to generate a new key for the certificate even if a named key already exists.
		If the key pair being rolled over is exportable, the new key pair will also be exportable. The following comment will appear in the trustpoint configuration to indicate whether the key pair is exportable: "! RSA key pair associated with trustpoint is exportable."
		It is recommended that a new key pair be generated for security reasons.
Step 10	exit Example:	Exits ca-trustpoint configuration mode and returns to global configuration mode.
	Device(ca-trustpoint)# exit	

	Command or Action	Purpose
Step 11	crypto pki authenticate name	Retrieves the CA certificate and authenticates it.
	Example:	
	Device(config)# crypto pki authenticate myca	
Step 12	end	Exits global configuration mode and returns to privileged EXEC mode.
	Example:	
	Device(config)# end	
Step 13	show crypto pki certificate trustpoint name	Displays information about the certificate for the trust point.
	Example:	
	Device# show crypto pki certificate ka	

Configuring Enrollment Manually

If your CA does not support SCEP or if a network connection between the router and CA is not possible. Perform the following task to set up manual certificate enrollment:

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	crypto pki trustpoint server name	Declares the trustpoint and a given name and enters ca-trustpoint configuration mode.
	Example:	
	Device# crypto pki trustpoint ka	
Step 4	enrollment url url-name	Specifies the URL of the CA on which your device should send certificate requests.
	Example:	
	Device(ca-trustpoint)# enrollment url http://url:80	An IPv6 address can be added in the URL enclosed in brackets. For example: http:// [2001:DB8:1:1::1]:80.
		The pem keyword adds privacy-enhanced mail (PEM) boundaries to the certificate request.
Step 5	rsakeypair label	Specifies which key pair to associate with the certificate.
	Example:	

	Command or Action	Purpose
	Device(ca-trustpoint)# rsakeypair exampleCAkeys	
Step 6	<pre>serial-number none Example: Device(ca-trustpoint)# serial-number none</pre>	Specifies that serial numbers will not be included in the certificate request.
Step 7	<pre>ip-address none Example: Device(ca-trustpoint)# ip-address none</pre>	The none keyword specifies that no IP address should be included in the certificate request.
Step 8	<pre>revocation-check crl Example: Device(ca-trustpoint)# revocation-check crl</pre>	Specifies CRL as the method to ensure that the certificate of a peer has not been revoked.
Step 9	exit Example: Device(ca-trustpoint)# exit	Exits ca-trustpoint configuration mode and returns to global configuration mode.
Step 10	crypto pki authenticate name Example: Device(config)# crypto pki authenticate myca	Retrieves the CA certificate and authenticates it.
Step 11	crypto pki enroll name Example: Device(config)# crypto pki enroll myca	Generates certificate request and displays the request for copying and pasting into the certificate server. Enter enrollment information when you are prompted. For example, specify whether to include the device FQDN and IP address in the certificate request. You are also given the choice about displaying the certificate request to the console terminal. The base-64 encoded certificate with or without PEM headers as requested is displayed
Step 12	crypto pki import name certificate Example: Device(config) # crypto pki import myca certificate	without PEM headers as requested is displayed. Imports a certificate via TFTP at the console terminal, which retrieves the granted certificate. The device attempts to retrieve the granted certificate via TFTP using the same filename used to send the request, except the extension is changed from ".req" to ".crt". For usage key certificates, the extensions "-sign.crt" and "-encr.crt" are used.

	Command or Action	Purpose
		The device parses the received files, verifies the certificates, and inserts the certificates into the internal certificate database on the switch.
		Note Some CAs ignore the usage key information in the certificate request and issue general purpose usage certificates. If your CA ignores the usage key information in the certificate request, only import the general purpose certificate. The router will not use one of the two key pairs generated.
Step 13	end Example: Device(config)# end	Exits global configuration mode and returns to privileged EXEC mode.
Step 14	show crypto pki certificate trustpoint name Example: Device# show crypto pki certificate ka	Displays information about the certificate for the trust point.

Configuring Switch-to-switch MACsec Encryption

To apply MACsec MKA using certificate-based MACsec encryption to interfaces, perform the following task:

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface type number	Identifies the MACsec interface, and enters
	Example:	interface configuration mode. The interface must be a physical interface.
	Device(config)# interface gigabitethernet 0/2/1	must be a physical interface.
<u> </u>		
Step 4	macsec network-link	Enables MACsec on the interface.
	Example:	

	Command or Action	Purpose
	Device(config-if)# macsec network-link	
Step 5	authentication periodic	Enables reauthentication for this port.
	Example:	
	<pre>Device(config-if)# authentication periodic</pre>	
Step 6	authentication timer reauthenticate interval	Sets the reauthentication interval.
	Example:	
	<pre>Device(config-if)# authentication timer reauthenticate interval</pre>	
Step 7	access-session host-mode multi-host	Allows hosts to gain access to the interface.
	Example:	
	<pre>Device(config-if) # access-session host-mode multi-host</pre>	
Step 8	access-session closed	Prevents preauthentication access on the
	Example:	interface.
	Device(config-if)# access-session closed	
Step 9	access-session port-control auto	Sets the authorization state of a port.
	Example:	
	<pre>Device(config-if)# access-session port-control auto</pre>	
Step 10	dot1x pae both	Configures the port as an 802.1X port access
	Example:	entity (PAE) supplicant and authenticator.
	Device(config-if)# dot1x pae both	
Step 11	dot1x credentials profile	Assigns a 802.1x credentials profile to the
	Example:	interface.
	<pre>Device(config-if)# dot1x credentials profile</pre>	
Step 12	end	Exits interface configuration mdoe and returns
	Example:	to privileged EXEC mode.
	<pre>Device(config-if)# end</pre>	
Step 13	show macsec interface interface-id	Displays MACsec details for the interface.
	Example:	
	Device# show macsec interface	
	GigabitEthernet 1/0/1	

Configuring MACsec XPN

Configuring an MKA Policy for XPN

Follow these steps to configure XPN in an MKA policy:

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	mka policy policy-name	Identifies an MKA policy, and enters MKA
	Example:	policy configuration mode. The maximum policy name length is 16 characters.
	Device(config)# mka policy mka_policy	Note The default MACsec cipher suite in the MKA policy will always be "GCM-AES-128". If the device supports both "GCM-AES-128" and "GCM-AES-256" ciphers, it is highly recommended to define and use a user defined MKA policy to include both 128 and 256 bits ciphers or only 256 bits cipher, as may be required.
Step 4	macsec-cipher-suite { gcm-aes-128 gcm-aes-256 gcm-aes-xpn-128 gcm-aes-xpn-256}	Configures cipher suite for deriving SAK with 128-bit and 256-bit encryption for XPN.
	Example:	
	Device(config-mka-policy)# macsec-cipher-suite gcm-aes-xpn-256	
Step 5	sak-rekey interval time-interval	(Optional) Configures the SAK rekey interval
	Example:	(in seconds). The range is from 30 to 65535. By default, the SAK rekey interval occurs
	Device(config-mka-policy)# sak-rekey	automatically depending on the interface speed
	interval 50	Use the no form of this command to stop the SAK rekey timer.
Step 6	end	Exits MKA policy configuration mode and
	Example:	returns to privileged EXEC mode.

 Command or Action	Purpose
Device(config-mka-policy)# end	

Applying the XPN MKA Policy to an Interface

To apply the XPN MKA policy to an interface, perform the following task:

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface interface-name	Identifies the MACsec interface, and enters
	Example:	interface configuration mode. The interface
	Device(config) # interface gigabitethernet 1/0/1	must be a physical interface.
Step 4	mka policy policy-name	Applies the XPN MKA protocol policy to the
	Example:	interface.
	Device(config-if)# mka policy mka-xpn-policy	
Step 5	end	Exits interface configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-if) # end	

Configuring MKA/MACsec for Port Channel

Configuring MKA/MACsec for Port Channel using PSK

Beginning in privileged EXEC mode, follow these steps to configure MKA policies on an interface using a Pre-Shared Key (PSK).

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	

	Command or Action	Purpose
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface interface-id	Enters interface configuration mode.
	Example:	
	Device(config-if)# interface gigabitethernet 1/0/3	
Step 4	macsec network-link	Enables MACsec on the interface. Supports
	Example:	layer 2 and layer 3 port channels.
	<pre>Device(config-if) # macsec network-link</pre>	
Step 5	mka policy policy-name	Configures an MKA policy.
	Example:	
	Device(config-if) # mka policy mka_policy	
Step 6	mka pre-shared-key key-chain key-chain name	Configures an MKA pre-shared key key-chain name.
	Example:	Note The MKA pre-shared key can be
	Device(config-if)# mka pre-shared-key key-chain key-chain-name	configured either on the physical interface or the subinterface but not on both.
Step 7	macsec replay-protection window-size <i>frame</i> number	Sets the MACsec window size for replay protection.
	Example:	
	<pre>Device(config-if)# macsec replay-protection window-size 0</pre>	
Step 8	channel-group channel-group-number mode{auto desirable} {active passive} {on}	Configures the port in a channel group and sets the mode.
	Example:	Note You cannot configure ports in a
	<pre>Device(config-if)# channel-group 3 mode auto active on</pre>	channel group without configuring MACsec on the interface. You must configure the commands in Step 3, 4, 5 and 6 before this step.
		The channel-number range is from 1 to 4096. The port channel associated with this channel group is automatically created if the port channel does not already exist. For mode, select one of the following keywords:
		• auto : Enables PAgP only if a PAgP device is detected. This places the port into a passive negotiating state, in which the port

	Command or Action	Purpose
		responds to PAgP packets it receives but does not start PAgP packet negotiation.
		NoteThe auto keyword is not supported when EtherChannel members are from different switches in the switch stack.
		• desirable : Unconditionally enables PAgP. This places the port into an active negotiating state, in which the port starts negotiations with other ports by sending PAgP packets.
		NoteThe desirable keyword is not supported when EtherChannel members are from different switches in the switch stack.
		• on : Forces the port to channel without PAgP or LACP. In the on mode, an EtherChannel exists only when a port group in the on mode is connected to another port group in the on mode.
		• active: Enables LACP only if an LACP device is detected. It places the port into an active negotiating state, in which the port starts negotiations with other ports by sending LACP packets.
		• passive : Enables LACP on the port and places it into a passive negotiating state in which the port responds to LACP packets that it receives, but does not start LACP packet negotiation.
tep 9	end Example:	Exits interface configuration mode and returns to privileged EXEC mode.
	<pre>Example: Device(config-if)# end</pre>	to priviles

Configuring Port Channel Logical Interfaces for Layer 2 EtherChannels

To create a port channel interface for a Layer 2 EtherChannel, perform this task:

Command or Action	Purpose
enable	Enables privileged EXEC mode.
Example:	• Enter your password if prompted.
Device> enable	
configure terminal	Enters global configuration mode.
Example:	
Device# configure terminal	
interface port-channel channel-group-number	Creates the port channel interface, and enters
Example:	interface configuration mode.
Device(config)# interface port-channel 1	Note Use the no form of this command to delete the port channel interface.
switchport	Switches an interface that is in Layer 3 mode
Example:	into Layer 2 mode for Layer 2 configuration.
Device(config-if)# switchport	
switchport mode {access trunk}	Assigns all ports as static-access ports in the
Example:	same VLAN, or configure them as trunks.
Device(config-if)# switchport mode access	
end	Exits interface configuration mode and returns
Example:	to privileged EXEC mode.
Device(config-if)# end	
Examp	

Procedure

Configuring Port Channel Logical Interfaces for Layer 3 EtherChannels

To create a port channel interface for a Layer 3 EtherChannel, perform this task:

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	

	Command or Action	Purpose
Step 3	interface interface-id	Enters interface configuration mode.
	Example:	
	Device(config)# interface gigabitethernet 1/0/2	
Step 4	no switchport	Switches an interface that is in Layer 2 mode
	Example:	into Layer 3 mode for Layer 3 configuration.
	Device(config-if) # no switchport	
Step 5	ip address ip-address subnet-mask	Assigns an IP address and subnet mask to the
	Example:	EtherChannel.
	Device(config-if)# ip address 10.2.2.3 255.255.255.254	
Step 6	end	Exits interface configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-if)# end	

Configuring MACsec Cipher Announcement

The following sections provide information about the various tasks to configure MACsec cipher announcement.

Configuring an MKA Policy for Secure Announcement

Beginning in privileged EXEC mode, follow these steps to create an MKA Protocol policy to enable secure announcement in MKPDUs. By default, secure announcements are disabled.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	mka policy policy-name	Identifies an MKA policy and enters MKA
	Example:	policy configuration mode. The maximum
	Device(config)# mka policy mka_policy	policy name length is 16 characters.

Procedure

	Command or Action	Purpose	
		NoteThe default MACsec cipher suite in the MKA policy is GCM-AES-128. If the device supports both GCM-AES-128 and GCM-AES-256 ciphers, we recommend that you define and use a user-defined MKA policy to include both 128 and 256 bits ciphers or only 256 bits cipher, as may be required.	
Step 4	key-server <i>priority</i>	Configures MKA key server options and sets priority between 0-255.	
	<pre>Example: Device(config-mka-policy)# key-server priority 200</pre>	Note When value of key server priority is set to 255, the peer cannot become the key server. The key server priority value is valid only for MKA PSK. This does not apply to MKA EAP-TLS.	
Step 5	<pre>send-secure-announcements Example: Device(config-mka-policy)# send-secure-announcements</pre>	Enables sending of secure announcements. Us the no form of the command to disable sendir of secure announcements. By default, secure announcements are disabled.	
Step 6	<pre>macsec-cipher-suite {gcm-aes-128 gcm-aes-256} Example: Device(config-mka-policy)# macsec-cipher-suite gcm-aes-128</pre>	Configures cipher suite for deriving SAK with 128-bit or 256-bit encryption.	
Step 7	<pre>end Example: Device(config-mka-policy)# end</pre>	Exits MKA policy configuration mode and returns to privileged EXEC mode.	
Step 8	show mka policy Example: Device# show mka policy	Displays MKA policies.	

Configuring Secure Announcement Globally

Beginning in privileged EXEC mode, follow these steps to enable secure announcement globally across all the MKA policies.

	Command or Action	Purpose	
Step 1	enable	Enables privileged EXEC mode.	
	Example:	Enter your password, if prompted.	
	Device> enable		
Step 2	configure terminal	Enters global configuration mode.	
	Example:		
	Device# configure terminal		
Step 3	mka defaults policy	Enables sending of secure announcements i MKPDUs across MKA policies. By default	
	send-secure-announcements		
	Example:	secure announcements are disabled.	
	<pre>Device(config)# mka defaults policy send-secure-announcements</pre>		
Step 4	end	Exits global configuration mode and returns to	
	Example:	privileged EXEC mode.	
	Device(config)# end		

Procedure

Configuring EAPOL Announcements on an Interface

Beginning in privileged EXEC mode, follow these steps to configure EAPOL Announcement on an interface.

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example: Device> enable	Enter your password, if prompted.
Step 2	configure terminal	Enters global configuration mode.
	Example: Device# configure terminal	
Step 3	interface interface-id	Identifies the MACsec interface, and enters
	<pre>Example: Device(config)# interface gigabitethernet 1/0/1</pre>	interface configuration mode. The interface must be a physical interface.
Step 4	<pre>eapol annoucement Example: Device(config-if)# eapol announcement</pre>	Enables EAPOL announcements. Use the no form of the command to disable EAPOL announcements. By default, EAPOL announcements are disabled.

	Command or Action	Purpose
Step 5	end	Exits interface configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-if)# configure terminal	

Configuring Cisco TrustSec MACsec

Configuring Cisco TrustSec Switch-to-Switch Link Security in Manual Mode

Before you begin

When manually configuring Cisco TrustSec on an interface, consider these usage guidelines and restrictions:

- If no SAP parameters are defined, Cisco TrustSec encapsulation or encryption is not performed.
- If you select GCM as the SAP operating mode, you must have a MACsec Encryption software license from Cisco. If you select GCM without the required license, the interface is forced to a link-down state.
- These protection levels are supported when you configure SAP pairwise master key (sap pmk):
 - SAP is not configured: no protection.
 - sap mode-list gcm-encrypt gmac no-encap: protection desirable but not mandatory.
 - **sap mode-list gcm-encrypt gmac**: confidentiality preferred and integrity required. The protection is selected by the supplicant according to supplicant preference.
 - sap mode-list gmac: integrity only.
 - sap mode-list gcm-encrypt: confidentiality required.
 - sap mode-list gmac gcm-encrypt: integrity required and preferred, confidentiality optional.
- Before changing the configuration from MKA to Cisco TrustSec SAP and vice versa, we recommend that you remove the interface configuration.

Beginning in privileged EXEC mode, follow these steps to manually configure Cisco TrustSec on an interface to another Cisco TrustSec device:

Procedure

	Command or Action	Purpose
Step 1	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 2	interface interface-id	Configures an interface, and enters interface
	Example:	configuration mode.
	Device(config)# interface tengigabitethernet 1/1/2	

	Command or Action	Purpose		
Step 3	<pre>cts manual Example: Device(config-if)# cts manual</pre>	Enters Cisco TrustSec manual configuration mode.		
Step 4	<pre>sap pmk key [mode-list mode1 [mode2 [mode3 [mode4]]]] Example: Device(config-if-cts-manual)# sap pmk 1234abcdef mode-list gcm-encrypt no-encap</pre>	 (Optional) Configures the SAP pairwise master key (PMK) and operation mode. SAP is disabled by default in Cisco TrustSec manual mode. <i>key</i>: A hexadecimal value with an even number of characters and a maximum length of 32 characters. The SAP operation mode options: gcm-encrypt: Authentication and encryption Note Select this mode for MACsec authentication and encryption if your software license supports MACsec encryption. gmac: Authentication, no encryption 		
		• no-encap : No encapsulation		
Step 5	<pre>no propagate sgt Example: Device(config-if-cts-manual) # no propagate sgt</pre>	Use the no form of this command when the peer is incapable of processing a SGT. The no propagate sgt command prevents the interface from transmitting the SGT to the peer.		
Step 6	<pre>exit Example: Device(config-if-cts-manual)# exit</pre>	Exits Cisco TrustSec 802.1x interface configuration mode.		
Step 7	end Example: Device(config-if)# end	Returns to privileged EXEC mode.		
Step 8	<pre>show cts interface [interface-id brief summary]</pre>	(Optional) Verify the configuration by displaying TrustSec-related interface characteristics.		
Step 9	copy running-config startup-config Example: Device# copy running-config startup-config	(Optional) Saves your entries in the configuration file.		

Configuration Examples for MACsec Encryption

The following sections provide configuration examples for MACsec encryption.

Example: Configuring MKA and MACsec

This example shows how to create an MKA policy:

```
Device> enable
Device# configure terminal
Device(config)# mka policy mka_policy
Device(config-mka-policy)# key-server priority 200
Device(config-mka-policy)# macsec-cipher-suite gcm-aes-128
Device(config-mka-policy)# confidentiality-offset 30
Device(config-mka-policy)# ssci-based-on-sci
Device(config-mka-policy)#end
```

This example shows how to configure MACsec on an interface:

```
Device> enable
Device# configure terminal
Device (config) # interface GigabitEthernet 1/0/1
Device(config-if)# switchport access vlan 1
Device (config-if) # switchport mode access
Device(config-if) # macsec
Device (config-if) # authentication event linksec fail action authorize vlan 1
Device(config-if) # authentication host-mode multi-domain
Device(config-if)# authentication linksec policy must-secure
Device(config-if) # authentication port-control auto
Device(config-if) # authentication periodic
Device(config-if)# authentication timer reauthenticate
Device(config-if)# authentication violation protect
Device (config-if) # mka policy mka policy
Device (config-if) # dot1x pae authenticator
Device(config-if)# spanning-tree portfast
Device (config-if) # end
```

Example: Configuring MACsec MKA using PSK

This example shows how to configure MACsec MKA using PSK.

```
Device> enable
Device# configure terminal
Device(config)# key chain keychain1 macsec
Device(config-keychain)# key 1000
Device(config-keychain-key)# cryptographic-algorithm aes-128-cmac
Device(config-keychain-key)# key-string 12345678901234567890123456789012
Device(config-keychain-key)# lifetime local 12:12:00 July 28 2016 12:19:00 July 28 2016
Device(config-keychain-key)# end
```

This example shows how to configure MACsec MKA on an interface using PSK.

```
Device> enable
Device# configure terminal
Device(config)# interface GigabitEthernet 0/0/0
Device(config-if)# mka policy mka_policy
Device(config-if)# mka pre-shared-key key-chain key-chain-name
```

Device(config-if)# macsec replay-protection window-size 10
Device(config-if)# end

MKA-PSK: CKN Behavior Change

Starting Cisco IOS XE Fuji 16.8.1 release, for MKA PSK sessions, the CKN uses exactly the same string as the CKN which is configured as the hex-string for the key, instead of the fixed 32 bytes.

```
Device> enable
Device# configure terminal
Device(config)# key chain abc macsec
Device(config-keychain)# key 11
Device(config-keychain-key)# cryptographic-algorithm aes-128-cmac
Device(config-keychain-key)# key-string 12345678901234567890123456789013
Device(config-keychain-key)# lifetime local 12:21:00 Sep 9 2015 infinite
Device(config-keychain-key)# end
```

The following is sample output of the **show mka session** command for the above configuration:

```
Device# show mka session
```

```
Total MKA Sessions..... 1
Secured Sessions... 1
Pending Sessions... 0
Interface
              Local-TxSCI
                                   Policy-Name
                                                    Inherited
                                                                       Kev-Server
Port-ID
              Peer-RxSCI
                                   MACsec-Peers
                                                    Status
                                                                       CKN
Et.0/0
              aabb.cc00.6600/0002
                                                      NO
                                       icv
                                                                        NO
2
              aabb.cc00.6500/0002 1
                                                                        11
                                                                             *Note that the
                                                    Secured
CKN key-string is exactly the same that has been configured for the key as hex-string.*
```

In case of interoperability between two images, where one having the CKN behavior change, and one without the CKN behavior change, the hex-string for the key must be a 64-character hex-string with zero padded for it to work on a device that has an image with the CKN behavior change. See the examples below:

Configuration without CKN key-string behavior change:

```
Device# configure terminal
Device(config)# key chain abc macsec
Device(config-keychain)# key 11
Device(config-keychain-key)# cryptographic-algorithm aes-128-cmac
Device(config-keychain-key)# key-string 12345678901234567890123456789013
Device(config-keychain-key)# lifetime local 12:21:00 Sep 9 2015 infinite
Device(config-keychain-key)# end
```

Configuration with CKN key-string behavior change:

Example: Configuring MACsec MKA Using Certificate-Based MACsec Encryption

This example shows how to configure MACsec MKA using certificate-based MACsec encryption:

```
Device> enable
Device# configure terminal
Device(config)# interface Gigabitethernet 1/0/1
Device(config-if)# macsec network-link
Device(config-if)# authentication periodic
Device(config-if)# authentication timer reauthenticate interval
Device(config-if)# access-session host-mode multi-domain
Device(config-if)# access-session closed
Device(config-if)# access-session port-control auto
Device(config-if)# dot1x pae both
Device(config-if)# dot1x credentials profile
Device(config-if)# dot1x supplicant eap profile profile_eap_tls
Device(config-if)# end
```

Example: Configuring MACsec XPN

This example shows how to configure MACsec MKA XPN policy:

```
Device> enable
Device# configure terminal
Device(config)# mka policy mka-xpn-policy
Device(config-mka-policy)# macsec-cipher-suite gcm-aes-xpn-256
Device(config-mka-policy)# end
```

This example shows how to apply MACsec MKA XPN policy to an interface:

```
Device> enable
Device# configure terminal
Device(config)#interface Fo 1/0/1
Device(config-if)# mka policy mka-xpn-policy
Device(config-if)# end
```

The following is a sample output of the **show mka sessions details** command with 128-bit XPN Cipher Suite configured:

```
Device# show mka sessions details

Example: Configuring MACsec MKA for Port Channel using PSK

Etherchannel Mode — Static/On

The following is sample configuration on Device 1 and Device 2 with EtherChannel Mode on:

```
Device> enable
Device# configure terminal
Device (config) # key chain KC macsec
Device(config-key-chain) # key 1000
Device(config-key-chain) # cryptographic-algorithm aes-128-cmac
Device (config-key-chain) # key-string FC8F5B10557C192F03F60198413D7D45
Device (config-key-chain) # exit
Device (config) # mka policy POLICY
Device(config-mka-policy)# key-server priority 0
Device(config-mka-policy) # macsec-cipher-suite gcm-aes-128
Device(config-mka-policy) # confidentiality-offset 0
Device(config-mka-policy)# exit
Device (config) # interface gigabitethernet 1/0/1
Device(config-if) # channel-group 2 mode on
Device(config-if)# macsec network-link
Device(config-if) # mka policy POLICY
Device (config-if) # mka pre-shared-key key-chain KC
Device (config-if) # exit
Device(config)# interface gigabitethernet 1/0/2
Device(config-if) # channel-group 2 mode on
Device(config-if) # macsec network-link
Device (config-if) # mka policy POLICY
Device(config-if) # mka pre-shared-key key-chain KC
Device(config-if)# end
```

Layer 2 EtherChannel Configuration

Device 1

```
Device> enable
Device# configure terminal
Device(config)# interface port-channel 2
Device(config-if)# switchport
Device(config-if)# switchport mode trunk
Device(config-if)# no shutdown
Device(config-if)# end
```

Device 2

```
Device> enable
Device# configure terminal
Device(config)# interface port-channel 2
Device(config-if)# switchport
Device(config-if)# switchport mode trunk
Device(config-if)# no shutdown
Device(config-if)# end
```

The following is sample output from theshow etherchannel summary command:

```
Flags: D - down
                    P - bundled in port-channel
        I - stand-alone s - suspended
        H - Hot-standby (LACP only)
        R - Layer3
                   S - Layer2
        U - in use
                        f - failed to allocate aggregator
        M - not in use, minimum links not met
        u - unsuitable for bundling
        w - waiting to be aggregated
        d - default port
        A - formed by Auto LAG
 Number of channel-groups in use: 1
 Number of aggregators:
                                  1
 Group Port-channel Protocol
                                  Ports
                                   2
        Po2(RU)
                                  Te1/0/1(P) Te1/0/2(P)
Layer 3 EtherChannel Configuration
Device 1
Device> enable
Device# configure terminal
Device(config) # interface port-channel 2
Device(config-if)# no switchport
Device(config-if) # ip address 10.25.25.3 255.255.255.0
```

Device(config-if) # no shutdown
Device(config-if) # end

Device 2

```
Device> enable
Device# configure terminal
Device(config)# interface port-channel 2
Device(config-if)# no switchport
Device(config-if)# ip address 10.25.25.4 255.255.0
Device(config-if)# no shutdown
Device(config-if)# end
```

The following is sample output from the **show etherchannel summary** command:

```
Flags: D - down
                    P - bundled in port-channel
      I - stand-alone s - suspended
      H - Hot-standby (LACP only)
      R - Layer3 S - Layer2

Displaying Active MKA Sessions

The following shows all the active MKA sessions.

```
Device# show mka sessions interface Tel/0/1
```

Interface	Local-TxSCI	Policy-Name	Inherited	
Key-Server				
Port-ID	Peer-RxSCI	MACsec-Peers	Status	CKN

Te1/0/1	00a3.d144.3364/0025 POLICY	NO	NO
37 1000	701f.539b.b0c6/0032 1	Secured	

Example: Configuring MACsec Cipher Announcement

This example shows how to configure MKA policy for Secure Announcement:

```
Device> enable
Device# configure terminal
Device(config)# mka policy mka_policy
Device(config-mka-policy)# key-server 2
Device(config-mka-policy)# send-secure-announcements
Device(config-mka-policy)# macsec-cipher-suite gcm-aes-128confidentiality-offset 0
Device(config-mka-policy)# end
```

This example shows how to configure Secure Announcement globally:

```
Device> enable
Device# configure terminal
Device(config)# mka defaults policy send-secure-announcements
Device(config)# end
```

This example shows how to configure EAPoL Announcements on an interface:

```
Device> enable
Device# configure terminal
Device(config)# interface GigabitEthernet 1/0/1
Device(config-if)# eapol announcement
Device(config-if)# end
```

The following is a sample output for **show running-config interface** *interface-name* command with EAPoL announcement enabled.

```
Device# show running-config interface GigabitEthernet 1/0/1
```

```
switchport mode access
macsec
access-session host-mode multi-host
access-session closed
access-session port-control auto
dot1x pae authenticator
dot1x timeout quiet-period 10
dot1x timeout tx-period 5
dot1x timeout supp-timeout 10
dot1x supplicant eap profile peap
eapol announcement
spanning-tree portfast
service-policy type control subscriber Dot1X
```

The following is a sample output of the **show mka sessions interface** *interface-name* **detail** command with secure announcement disabled.

```
Device# show mka sessions interface GigabitEthernet 1/0/1 detail
```

Feature History for MACsec Encryption

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.11.1	MACsec Encryption	MACsec is the IEEE 802.1AE standard for authenticating and encrypting packets between two MACsec-capable devices. Catalyst switches support 802.1AE encryption with MACsec Key Agreement (MKA) encryption between the switch and host device.
	MKA with High Availability	MKA with high availability is supported.
Cisco IOS XE Cupertino 17.7.1	MACsec Access Control Option	MACsec access control option allows unencrypted packets to be transmitted or received from the same physical interface.
Cisco IOS XE Cupertino 17.7.1	MACsec Encryption	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

Configuring Secure Shell

• Configuring Secure Shell, on page 291

Configuring Secure Shell

The Secure Shell (SSH) feature is an application and a protocol that provides a secure replacement to the Berkeley r-tools. The protocol secures sessions using standard cryptographic mechanisms, and the application can be used similarly to the Berkeley rexec and rsh tools. Two versions of SSH are available: SSH Version 1 and SSH Version 2. Unless otherwise noted, the term "SSH" denotes "SSH Version 1" only. For information about SSH Version 2, see the "Secure Shell Version 2 Support" feature module.

Prerequisites for Configuring Secure Shell

Note

Unless otherwise noted, the term "SSH" denotes "SSH Version 1" only.

- For SSH to work, the switch needs an Rivest, Shamir, and Adleman (RSA) public/private key pair. This is the same with Secure Copy Protocol (SCP), which relies on SSH for its secure transport.
- Download the required image on the device. The Secure Shell (SSH) server requires an IPsec (Data Encryption Standard [DES] or 3DES) encryption software image; the SSH client requires an IPsec (DES or 3DES) encryption software image.)
- Configure a hostname and host domain for your device by using the **hostname** and **ip domain name** commands in global configuration mode.
- Generate a Rivest, Shamir, and Adleman (RSA) key pair for your device. This key pair automatically enables SSH and remote authentication when the **crypto key generate rsa** command is entered in global configuration mode.

Note

To delete the RSA key pair, use the **crypto key zeroize rsa** global configuration command. Once you delete the RSA key pair, you automatically disable the SSH server.

- Configure user authentication for local or remote access. You can configure authentication with or without authentication, authorization, and accounting (AAA).
- The Secure Shell (SSH) server requires an IPsec (Data Encryption Standard [DES] or 3DES) encryption software image; the SSH client requires an IPsec (DES or 3DES) encryption software image.)

Restrictions for Configuring Secure Shell

Note

Unless otherwise noted, the term "SSH" denotes "SSH Version 1" only.

- The Secure Shell (SSH) server and SSH client are supported on Data Encryption Standard (DES) (56-bit) and 3DES (168-bit) data encryption software images only. In DES software images, DES is the only encryption algorithm available. In 3DES software images, both DES and 3DES encryption algorithms are available.
- Execution shell is the only application supported.
- The login banner is not supported in Secure Shell Version 1. It is supported in Secure Shell Version 2.
- The SFTP server is not supported.

Information About Configuring Secure Shell

Secure Shell (SSH) is a protocol that provides a secure, remote connection to a device. SSH provides more security for remote connections than Telnet does by providing strong encryption when a device is authenticated. This software release supports SSH Version 2 (SSHv2).

SSH Server

Note Unless otherwise noted, the term "SSH" denotes "SSH Version 1" only.

The Secure Shell (SSH) Server feature enables an SSH client to make a secure, encrypted connection to a Cisco device. This connection provides functionality that is similar to that of an inbound Telnet connection. Before SSH, security was limited to Telnet security. SSH allows a strong encryption to be used with the Cisco software authentication. The SSH server in Cisco software works with publicly and commercially available SSH clients.

SSH Integrated Client

Note Unless otherwise noted, the term "SSH" denotes "SSH Version 1" only.

The Secure Shell (SSH) Integrated Client feature is an application that runs over the SSH protocol to provide device authentication and encryption. The SSH client enables a Cisco device to make a secure, encrypted connection to another Cisco device or to any other device running the SSH server. This connection provides

functionality similar to that of an outbound Telnet connection except that the connection is encrypted. With authentication and encryption, the SSH client allows for secure communication over an unsecured network.

The SSH client in Cisco software works with publicly and commercially available SSH servers. The SSH client supports the ciphers of Data Encryption Standard (DES), 3DES, and password authentication. User authentication is performed like that in the Telnet session to the device. The user authentication mechanisms supported for SSH are RADIUS, TACACS+, and the use of locally stored usernames and passwords.

Note The SSH client functionality is available only when the SSH server is enabled.

RSA Authentication Support

Rivest, Shamir, and Adleman (RSA) authentication available in Secure Shell (SSH) clients is not supported on the SSH server for Cisco software by default. For more information about RSA authentication support, see the "Configuring a Device for SSH Version 2 Using RSA Pairs" section of the "Secure Shell Version 2 Support" module.

SSH Servers, Integrated Clients, and Supported Versions

The Secure Shell (SSH) Integrated Client feature is an application that runs over the SSH protocol to provide device authentication and encryption. The SSH client enables a Cisco device to make a secure, encrypted connection to another Cisco device or to any other device running the SSH server. This connection provides functionality similar to that of an outbound Telnet connection except that the connection is encrypted. With authentication and encryption, the SSH client allows for secure communication over an unsecured network.

The SSH server and SSH integrated client are applications that run on the switch. The SSH server works with the SSH client supported in this release and with non-Cisco SSH clients. The SSH client works with publicly and commercially available SSH servers. The SSH client supports the ciphers of Data Encryption Standard (DES), 3DES, and password authentication.

Note The SSH client functionality is available only when the SSH server is enabled.

User authentication is performed like that in the Telnet session to the device. SSH also supports the following user authentication methods:

- TACACS+
- RADIUS
- Local authentication and authorization

SSH Configuration Guidelines

Follow these guidelines when configuring the switch as an SSH server or SSH client:

- An RSA key pair generated by a SSHv1 server can be used by an SSHv2 server, and the reverse.
- If the SSH server is running on an active switch and the active switch fails, the new active switch uses the RSA key pair generated by the previous active switch.

- If you get CLI error messages after entering the **crypto key generate rsa** global configuration command, an RSA key pair has not been generated. Reconfigure the hostname and domain, and then enter the **crypto key generate rsa** command.
- When generating the RSA key pair, the message No host name specified might appear. If it does, you must configure a hostname by using the **hostname** command in global configuration mode.
- When generating the RSA key pair, the message No domain specified might appear. If it does, you must configure an IP domain name by using the **ip domain name** command in global configuration mode.
- When configuring the local authentication and authorization authentication method, make sure that AAA is disabled on the console.

How to Configure Secure Shell

Setting Up the Device to Run SSH

Follow the procedure given below to set up your device to run SSH:

Before you begin

Configure user authentication for local or remote access. This step is required.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	hostname hostname	Configures a hostname and IP domain name for
	Example:	your device.
	Device(config)# hostname your_hostname	Note Follow this procedure only if you are configuring the device as an SSH server.
Step 4	ip domain name domain_name	Configures a host domain for your device.
	Example:	
	Device(config)# ip domain name your_domain	
Step 5	crypto key generate rsa	Enables the SSH server for local and remote
	Example:	authentication on the device and generates an RSA key pair. Generating an RSA key pair for
	Device(config)# crypto key generate rsa	

	Command or Action	Purpose
		We recommend that a minimum modulus size of 1024 bits.
		When you generate RSA keys, you are prompted to enter a modulus length. A longer modulus length might be more secure, but it takes longer to generate and to use.
		Note Follow this procedure only if you are configuring the device as an SSH server.
Step 6	exit Example: Device(config)# exit	Exits global configuration mode and returns to privileged EXEC mode.
Step 7	<pre>show ip ssh Example: Device# show ip ssh</pre>	(Optional) Verifies that the SSH server is enabled and displays the version and configuration data for the SSH connection.

Configuring an SSH Server

Note

Unless otherwise noted, the term "SSH" denotes "SSH Version 1" only.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	<pre>ip ssh {time-out seconds authentication-retries integer}</pre>	Configures Secure Shell (SSH) control parameters.
	Example:	Note This command can also be used
	Device(config)# ip ssh time-out 30	to establish the number of password prompts provided to the user. The number is the lower of the following two values:

	Command or Action	Purpose
		• Value proposed by the client using the ssh • o numberofpasswordprompt command.
		• Value configured on the device using the ip ssh authentication-retries <i>integer</i> command, plus one.
Step 4	ip ssh rekey {time time volume volume} Example:	(Optional) Configures a time-based rekey or a volume-based rekey for SSH.
Cton F	Device (config) # ip ssh rekey time 108	Enite alabel configuration mode and activate to
Step 5	exit Example: Device (config) # exit	Exits global configuration mode and returns to privileged EXEC mode.
Step 6	show ip ssh	(Optional) Verifies that the SSH server is enabled and displays the version and configuration data for the SSH connection.
	Example: Device# show ip ssh	

Invoking an SSH Client

Note Unless otherwise noted, the term "SSH" denotes "SSH Version 1" only.

Perform this task to invoke the Secure Shell (SSH) client. The SSH client runs in user EXEC mode and has no specific configuration tasks.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	ssh - l username -vrf vrf-name ip-address	Invokes the SSH client to connect to an IP host
	Example:	or address in the specified virtual routing and forwarding (VRF) instance.
	Device# ssh -1 user1 -vrf vrf1 192.0.2.1	for warding (VICF) installee.

Configuration Examples for Secure Shell

Example: Configuring an SSH Server

Note

Unless otherwise noted, the term "SSH" denotes "SSH Version 1" only.

The following is an example of the Secure Shell (SSH) control parameters configured for the server. In this example, the timeout interval of 30 seconds has been specified. This timeout interval is used during the SSH negotiation phase.

Device> enable Device# configure terminal Device(config)# ip ssh timeout 30 Device(config)# end

Example: Invoking an SSH Client

Ø

Note

te Unless otherwise noted, the term "SSH" denotes "SSH Version 1" only.

In the following example, the Secure Shell (SSH) client has been invoked to connect to IP address 192.0.2.1 in the specified virtual routing and forwarding (VRF) instance:

```
Device> enable
Device# ssh -1 user1 -vrf vrf1 192.0.2.1
```

Example: Verifying SSH

e Unless otherwise noted, the term "SSH" denotes "SSH Version 1" only.

To verify that the Secure Shell (SSH) server is enabled and to display the version and configuration data for your SSH connection, use the **show ip ssh** command. The following example shows that SSH is enabled:

Device# show ip ssh

SSH Enabled - version 1.5 Authentication timeout: 120 secs; Authentication retries: 3

The following example shows that SSH is disabled:

Device# show ip ssh

%SSH has not been enabled

To verify the status of your SSH server connections, use the **show ssh** command. The following example shows the SSH server connections on the device when SSH is enabled:

Device# show ssh

```
Connection Version Encryption State Username
0 1.5 3DES Session Started guest
```

The following example shows that SSH is disabled:

Device# show ssh

%No SSH server connections running.

Feature History for Configuring Secure Shell

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Everest 16.11.1	Secure Shell	SSH is a protocol that provides a secure, remote connection to a device. SSH provides more security for remote connections than Telnet does by providing strong encryption when a device is authenticated
Cisco IOS XE Cupertino 17.7.1	Secure Shell	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

Secure Shell Version 2 Support

The Secure Shell Version 2 Support feature allows you to configure Secure Shell (SSH) Version 2. (SSH Version 1 support was implemented in an earlier Cisco software release.) SSH runs on top of a reliable transport layer and provides strong authentication and encryption capabilities. The only reliable transport that is defined for SSH is TCP. SSH provides a means to securely access and securely execute commands on another computer over a network. The Secure Copy Protocol (SCP) feature that is provided with SSH allows for the secure transfer of files.

- Prerequisites for Secure Shell Version 2 Support, on page 299
- Restrictions for Secure Shell Version 2 Support, on page 300
- Information About Secure Shell Version 2 Support, on page 300
- How to Configure Secure Shell Version 2 Support, on page 303
- Configuration Examples for Secure Shell Version 2 Support, on page 314
- Additional References for Secure Shell Version 2 Support, on page 318
- Feature History for Secure Shell Version 2 Support, on page 319

Prerequisites for Secure Shell Version 2 Support

- Before configuring SSH, ensure that the required image is loaded on your device. The SSH server requires you to have a k9 (Triple Data Encryption Standard [3DES]) software image depending on your release.
- You have to use a SSH remote device that supports SSH Version 2 and connect to a Cisco device.
- SCP relies on authentication, authorization, and accounting (AAA) to function correctly. Therefore, AAA must be configured on the device to enable the secure copy protocol on the SSH Server.

Note The SSH Version 2 server and the SSH Version 2 client are supported on your Cisco software, depending on your release. (The SSH client runs both the SSH Version 1 protocol and the SSH Version 2 protocol. The SSH client is supported in k9 images depending on your release.)

Restrictions for Secure Shell Version 2 Support

- Secure Shell (SSH) servers and SSH clients are supported in Triple Data Encryption Standard (3DES) software images.
- Execution Shell, remote command execution, and Secure Copy Protocol (SCP) are the only applications supported.
- Rivest, Shamir, and Adleman (RSA) key generation is an SSH server-side requirement. Devices that act as SSH clients need not generate RSA keys.
- The RSA key pair size must be greater than or equal to 768 bits.
- The following features are not supported:
 - Port forwarding
 - Compression

Information About Secure Shell Version 2 Support

Secure Shell Version 2

The Secure Shell Version 2 Support feature allows you to configure SSH Version 2.

The configuration for the SSH Version 2 server is similar to the configuration for SSH Version 1. The **ip** ssh version command defines the SSH version to be configured. If you do not configure this command, SSH by default runs in compatibility mode; that is, both SSH Version 1 and SSH Version 2 connections are honored.

Note

SSH Version 1 is a protocol that has never been defined in a standard. If you do not want your device to fall back to the undefined protocol (Version 1), you should use the **ip ssh version** command and specify Version 2.

The **ip** ssh rsa keypair-name command enables an SSH connection using the Rivest, Shamir, and Adleman (RSA) keys that you have configured. Previously, SSH was linked to the first RSA keys that were generated (that is, SSH was enabled when the first RSA key pair was generated). This behavior still exists, but by using the **ip** ssh rsa keypair-name command, you can overcome this behavior. If you configure the **ip** ssh rsa keypair-name command with a key pair name, SSH is enabled if the key pair exists or SSH will be enabled if the key pair is generated later. If you use this command to enable SSH, you are not forced to configure a hostname and a domain name, which was required in SSH Version 1 of the Cisco software.

Note

The login banner is supported in SSH Version 2, but it is not supported in Secure Shell Version 1.

Secure Shell Version 2 Enhancements

The SSH Version 2 Enhancements feature includes a number of additional capabilities such as supporting Virtual Routing and Forwarding (VRF)-Aware SSH, SSH debug enhancements, and Diffie-Hellman (DH) group exchange support.

Note The VRF-Aware SSH feature is supported depending on your release.

The Cisco SSH implementation has traditionally used 768-bit modulus, but with an increasing need for higher key sizes to accommodate DH Group 14 (2048 bits) and Group 16 (4096 bits) cryptographic applications, a message exchange between the client and the server to establish the favored DH group becomes necessary. The **ip ssh dh min size** command configures the modulus size on the SSH server. In addition to this, the **ssh** command was extended to add VRF awareness to the SSH client-side functionality through which the VRF instance name in the client is provided with the IP address to look up the correct routing table and establish a connection.

Debugging was enhanced by modifying SSH debug commands. The **debug ip ssh** command was extended to simplify the debugging process. Before the simplification of the debugging process, this command printed all debug messages related to SSH regardless of what was specifically required. The behavior still exists, but if you configure the **debug ip ssh** command with a keyword, messages are limited to information specified by the keyword.

Secure Shell Version 2 Enhancements for RSA Keys

Cisco SSH Version 2 supports keyboard-interactive and password-based authentication methods. The SSH Version 2 Enhancements for RSA Keys feature also supports RSA-based public key authentication for the client and the server.

User authentication: RSA-based user authentication uses a private/public key pair associated with each
user for authentication. The user must generate a private/public key pair on the client and configure a
public key on the Cisco SSH server to complete the authentication.

An SSH user trying to establish credentials provides an encrypted signature using the private key. The signature and the user's public key are sent to the SSH server for authentication. The SSH server computes a hash over the public key provided by the user. The hash is used to determine if the server has a matching entry. If a match is found, an RSA-based message verification is performed using the public key. Hence, the user is authenticated or denied access based on the encrypted signature.

• Server authentication: While establishing an SSH session, the Cisco SSH client authenticates the SSH server by using the server host keys available during the key exchange phase. SSH server keys are used to identify the SSH server. These keys are created at the time of enabling SSH and must be configured on the client.

For server authentication, the Cisco SSH client must assign a host key for each server. When the client tries to establish an SSH session with a server, the client receives the signature of the server as part of the key exchange message. If the strict host key checking flag is enabled on the client, the client checks if it has the host key entry corresponding to the server. If a match is found, the client tries to validate the signature by using the server host key. If the server is successfully authenticated, the session establishment continues; otherwise, it is terminated and displays a "Server Authentication Failed" message.

 Note
 • Storing public keys on a server up

- Storing public keys on a server uses memory; therefore, the number of public keys configurable on an SSH server is restricted to ten users, with a maximum of two public keys per user.
 - RSA-based user authentication is supported by the Cisco server, but Cisco clients cannot propose public key as an authentication method. If the Cisco server receives a request from an open SSH client for RSA-based authentication, the server accepts the authentication request.
 - For server authentication, configure the RSA public key of the server manually and configure the ip ssh stricthostkeycheck command on the Cisco SSH client.

SSH And Switch Access

Secure Shell (SSH) is a protocol that provides a secure, remote connection to a device. SSH provides more security for remote connections than Telnet does by providing strong encryption when a device is authenticated. This software release supports SSH Version 2 (SSHv2).

SSH functions the same in IPv6 as in IPv4. For IPv6, SSH supports IPv6 addresses and enables secure, encrypted connections with remote IPv6 nodes over an IPv6 transport.

SNMP Trap Generation

Depending on your release, Simple Network Management Protocol (SNMP) traps are generated automatically when an SSH session terminates if the traps have been enabled and SNMP debugging has been enabled.

Note

When you configure the **snmp-server host** command, the IP address must be the address of the PC that has the SSH (telnet) client and that has IP connectivity to the SSH server.

You must also enable SNMP debugging using the **debug snmp packet** command to display the traps. The trap information includes information such as the number of bytes sent and the protocol that was used for the SSH session.

SSH Keyboard Interactive Authentication

The SSH Keyboard Interactive Authentication feature, also known as Generic Message Authentication for SSH, is a method that can be used to implement different types of authentication mechanisms. Basically, any currently supported authentication method that requires only user input can be performed with this feature. The feature is automatically enabled.

The following methods are supported:

- Password
- SecurID and hardware tokens printing a number or a string in response to a challenge sent by the server
- Pluggable Authentication Module (PAM)
- S/KEY (and other One-Time-Pads)

How to Configure Secure Shell Version 2 Support

Configuring a Device for SSH Version 2 Using a Hostname and Domain Name

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	hostname name	Configures a hostname for your device.
	Example:	
	Device(config) # hostname catalyst9k	
Step 4	ip domain name name	Configures a domain name for your device.
	Example:	
	<pre>catalyst9k(config)# ip domain name example.com</pre>	
Step 5	crypto key generate rsa	Enables the SSH server for local and remote
	Example:	authentication.
	<pre>catalyst9k(config)# crypto key generate rsa</pre>	
Step 6	ip ssh [time-out seconds	(Optional) Configures SSH control variables
	authentication-retries integer]	on your device.
	Example:	
	<pre>catalyst9k(config) # ip ssh time-out 120</pre>	
Step 7	ip ssh version [1 2]	(Optional) Specifies the version of SSH to be
	Example:	run on your device.
	<pre>catalyst9k(config)# ip ssh version 1</pre>	
Step 8	exit	Exits global configuration mode and enters
	Example:	privileged EXEC mode.
	catalyst9k(config)# exit	• Use no hostname command to return to the default host.

Configuring a Device for SSH Version 2 Using RSA Key Pairs

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	ip ssh rsa keypair-name keypair-name	Specifies the RSA key pair to be used for SSH
	Example:	Note A Cisco device can have many
	<pre>Device(config)# ip ssh rsa keypair-name sshkeys</pre>	RSA key pairs.
Step 4	crypto key generate rsa usage-keys label key-label modulus modulus-size	Enables the SSH server for local and remote authentication on the device.
	Example:	• For SSH Version 2, the modulus size mus
	Device(config)# crypto key generate rsa usage-keys label sshkeys modulus 768	be at least 768 bits.
		Note To delete the RSA key pair, use the crypto key zeroize rsa command. When you delete the RSA key pair, you automatically disable the SSH server.
Step 5	ip ssh [time-out seconds authentication-retries integer]	Configures SSH control variables on your device.
	Example:	
	Device(config) # ip ssh time-out 12	
Step 6	ip ssh version 2	Specifies the version of SSH to be run on the
	Example:	device.
	Device(config)# ip ssh version 2	
Step 7	exit	Exits global configuration mode and enters
	Example:	privileged EXEC mode.
	Device(config)# exit	

Configuring the Cisco SSH Server to Perform RSA-Based User Authentication

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	hostname name	Specifies the hostname.
	Example:	
	Device(config)# hostname host1	
Step 4	ip domain name name	Defines a default domain name that the Cisco
	Example:	software uses to complete unqualified
	hostl(config)# ip domain name namel	hostnames.
Step 5	crypto key generate rsa	Generates RSA key pairs.
	Example:	
	<pre>host1(config)# crypto key generate rsa</pre>	
Step 6	ip ssh pubkey-chain	Configures SSH-RSA keys for user and server
	Example: host1(config)# ip ssh pubkey-chain	authentication on the SSH server and enters public-key configuration mode.
		• The user authentication is successful if
		the RSA public key stored on the server
		is verified with the public or the private
		key pair stored on the client.
Step 7	username username	Configures the SSH username and enters
	Example:	public-key user configuration mode.
	<pre>host1(conf-ssh-pubkey)# username user1</pre>	
Step 8	key-string	Specifies the RSA public key of the remote
	Example:	peer and enters public-key data configuration mode.
	<pre>host1(conf-ssh-pubkey-user)# key-string</pre>	
		Note You can obtain the public key value from an open SSH client;
		that is, from the .ssh/id_rsa.pub file.

Security Configuration Guide, Cisco IOS XE Cupertino 17.7.x (Catalyst 9600 Switches)

I

	Command or Action	Purpose
Step 9	<pre>key-hash key-type key-name Example: host1(conf-ssh-pubkey-data)# key-hash ssh-rsa key1</pre>	 (Optional) Specifies the SSH key type and version. The key type must be ssh-rsa for the configuration of private public key pairs. This step is optional only if the key-string command is configured. You must configure either the key-string command or the key-hash command. Note You can use a hashing software to compute the hash of the public key string, or you can also copy the hash value from another Cisco device. Entering the public key data using the key-string command is the preferred way to enter the public key data for the first time.
Step 10	<pre>end Example: host1(conf-ssh-pubkey-data)# end</pre>	 Exits public-key data configuration mode and returns to privileged EXEC mode. Use no hostname command to return to the default host.

Configuring the Cisco IOS SSH Client to Perform RSA-Based Server Authentication

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	hostname name	Specifies the hostname.
	Example:	
	Device(config)# hostname host1	

I

	Command or Action	Purpose
Step 4	<pre>ip domain name name Example: host1(config)# ip domain name name1</pre>	Defines a default domain name that the Cisco software uses to complete unqualified hostnames.
Step 5	crypto key generate rsa Example: host1(config)# crypto key generate rsa	Generates RSA key pairs.
Step 6	<pre>ip ssh pubkey-chain Example: host1(config)# ip ssh pubkey-chain</pre>	Configures SSH-RSA keys for user and server authentication on the SSH server and enters public-key configuration mode.
Step 7	<pre>server server-name Example: host1(conf-ssh-pubkey)# server server1</pre>	Enables the SSH server for public-key authentication on the device and enters public-key server configuration mode.
Step 8	<pre>key-string Example: host1(conf-ssh-pubkey-server)# key-string</pre>	Specifies the RSA public-key of the remote peer and enters public key data configuration mode.NoteYou can obtain the public key value from an open SSH client; that is, from the .ssh/id_rsa.pub file.
Step 9	<pre>exit Example: host1(conf-ssh-pubkey-data)# exit</pre>	Exits public-key data configuration mode and enters public-key server configuration mode.
Step 10	<pre>key-hash key-type key-name Example: hostl(conf-ssh-pubkey-server)# key-hash ssh-rsa key1</pre>	 (Optional) Specifies the SSH key type and version. The key type must be ssh-rsa for the configuration of private/public key pairs. This step is optional only if the key-string command is configured. You must configure either the key-string command or the key-hash command.

	Command or Action	Purpose
		Note You can use a hashing software to compute the hash of the public key string, or you can copy the hash value from another Cisco device. Entering the public key data using the key-string command is the preferred way to enter the public key data for the first time.
Step 11	end Example:	Exits public-key server configuration mode and returns to privileged EXEC mode.
	host1(conf-ssh-pubkey-server)# end	
Step 12	configure terminal	Enters global configuration mode.
	Example: host1# configure terminal	
Step 13	ip ssh stricthostkeycheck	Ensures that server authentication takes place.
	Example: host1(config)# ip ssh stricthostkeycheck	 The connection is terminated in case of a failure. Use no hostname command to return to the default host.
Step 14	end Example: hostl(config)# end	Exits global configuration mode and returns to privileged EXEC mode.

Starting an Encrypted Session with a Remote Device

Note The device with which you want to connect must support a Secure Shell (SSH) server that has an encryption algorithm that is supported in Cisco software. Also, you need not enable your device. SSH can be run in disabled mode.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	

	Command or Action	Purpose
Step 2	ssh [-v {1 2} -c {aes128-ctr aes192-ctr	Starts an encrypted session with a remote
-	aes256-ctr aes128-cbc 3des aes192-cbc	networking device.
	aes256-cbc } -1 user-id -1 user-id:vrf-name	-
	number ip-address ip-address -1	
	user-id:rotary number ip-address -m	
	{hmac-md5-128 hmac-md5-96	
	hmac-sha1-160 hmac-sha1-96} -o	
	numberofpasswordprompts <i>n</i> -p <i>port-num</i>]	
	{ <i>ip-addr</i> <i>hostname</i> } [command -vrf]	
	Example:	
	Device# ssh -v 2 -c aes256-ctr -m	
	hmac-sha1-96 -1 user2 10.76.82.24	

Verifying the Status of the Secure Shell Connection

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	show ssh	Displays the status of SSH server connections.
	Example:	
	Device# show ssh	
Step 3	exit	Exits privileged EXEC mode and returns to user
	Example:	EXEC mode.
	Device# exit	

The following sample output from the **show ssh** command displays status of various SSH Version 1 and Version 2 connections for Version 1 and Version 2 connections:

Device# show ssh						
ConnectionVersion EncryptionStateUsername01.53DESSession startedlab						
Connection	Version	Mode	Encryption	Hmac	State	
Username						
1	2.0	IN	aes128-cbc	hmac-md5	Session starte	ed lab
1	2.0	OUT	aes128-cbc	hmac-md5	Session starte	ed lab

The following sample output from the **show ssh** command displays status of various SSH Version 1 and Version 2 connections for a Version 2 connection with no Version 1 connection:

Device# show ssh Connection Version Mode Encryption Hmac State Username 1 2.0 IN aes128-cbc hmac-md5 Session started lab 1 2.0 OUT aes128-cbc hmac-md5 Session started lab %No SSHv1 server connections running.

The following sample output from the **show ssh** command displays status of various SSH Version 1 and Version 2 connections for a Version 1 connection with no Version 2 connection:

```
Device# show ssh

Connection Version Encryption State Username

0 1.5 3DES Session started lab

%No SSHv2 server connections running.
```

Verifying the Secure Shell Version 2 Status

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	show ip ssh	Displays the version and configuration data for
	Example:	SSH.
	Device# show ip ssh	
Step 3	exit	Exits privileged EXEC mode and returns to user
	Example:	EXEC mode.
	Device# exit	

Examples

The following sample output from the **show ip ssh** command displays the version of SSH that is enabled, the authentication timeout values, and the number of authentication retries for Version 1 and Version 2 connections:

```
Device# show ip ssh
SSH Enabled - version 1.99
Authentication timeout: 120 secs; Authentication retries: 3
```

The following sample output from the **show ip ssh** command displays the version of SSH that is enabled, the authentication timeout values, and the number of authentication retries for a Version 2 connection with no Version 1 connection:

```
Device# show ip ssh
SSH Enabled - version 2.0
Authentication timeout: 120 secs; Authentication retries: 3
```

The following sample output from the **show ip ssh** command displays the version of SSH that is enabled, the authentication timeout values, and the number of authentication retries for a Version 1 connection with no Version 2 connection:

```
Device# show ip ssh

3d06h: %SYS-5-CONFIG_I: Configured from console by console

SSH Enabled - version 1.5

Authentication timeout: 120 secs; Authentication retries: 3
```

Monitoring and Maintaining Secure Shell Version 2

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	debug ip ssh	Enables debugging of SSH.
	Example:	
	Device# debug ip ssh	
Step 3	debug snmp packet	Enables debugging of every SNMP packet sent
	Example:	or received by the device.
	Device# debug snmp packet	

Example

The following sample output from the **debug ip ssh** command shows the connection is an SSH Version 2 connection:

Device# debug ip ssh

```
00:33:55: SSH1: starting SSH control process
00:33:55: SSH1: sent protocol version id SSH-1.99-Cisco-1.25

Configuration Examples for Secure Shell Version 2 Support

Example: Configuring Secure Shell Version 2

Device> enable
Device# configure terminal
Device(config)# ip ssh version 2
Device(config)# end

Example: Configuring Secure Shell Versions 1 and 2

Device> enable Device# configure terminal Device(config)# no ip ssh version Device(config)# end

Example: Starting an Encrypted Session with a Remote Device

```
Device> enable
Device# ssh -v 2 -c aes256-cbc -m hmac-shal-160 -l shaship 10.76.82.24
Device# exit
```

Example: Setting an SNMP Trap

The following example shows how to set an SNMP trap is set. The trap notification is generated automatically when the SSH session terminates. In the example, 10.1.1.1 is the IP address of the SSH client.

```
Device> enable
Device# configure terminal
Device(config)# snmp-server trap link switchover
Device(config)# snmp-server host 10.1.1.1 public tty
Device(config)# end
```

Examples: SSH Keyboard Interactive Authentication

Example: Enabling Client-Side Debugs

The following example shows that the client-side debugs are turned on, and the maximum number of prompts is six (three for the SSH keyboard interactive authentication method and three for the password authentication method).

```

```

Example: Enabling ChPass with a Blank Password Change

In the following example, the ChPass feature is enabled, and a blank password change is accomplished using the SSH Keyboard Interactive Authentication method. A TACACS+ access control server (ACS) is used as the back-end AAA server.

```
Device> enable
Device1# ssh -1 cisco 10.1.1.3
Password:
Old Password: cisco
New Password: cisco123
Re-enter New password: cisco123
Device2> exit
```

[Connection to 10.1.1.3 closed by foreign host]

Example: Enabling ChPass and Changing the Password on First Login

In the following example, the ChPass feature is enabled and TACACS+ ACS is used as the back-end server. The password is changed on the first login using the SSH keyboard interactive authentication method.

```
Device1> enable
Device1# ssh -1 cisco 10.1.1.3
Password: cisco
Your password has expired.
Enter a new one now.
New Password: cisco123
Re-enter New password: cisco123
Device2> exit
[Connection to 10.1.1.3 closed by foreign host]
Device1# ssh -1 cisco 10.1.1.3
Password:ciscol
Your password has expired.
Enter a new one now.
New Password: cisco
Re-enter New password: ciscol2
The New and Re-entered passwords have to be the same.
Try again.
New Password: cisco
Re-enter New password: cisco
```

Device2>

Example: Enabling ChPass and Expiring the Password After Three Logins

In the following example, the ChPass feature is enabled and TACACS+ ACS is used as the back-end AAA server. The password expires after three logins using the SSH keyboard interactive authentication method.

```
Device# ssh -l cisco. 10.1.1.3
Password: cisco
Device2> exit
[Connection to 10.1.1.3 closed by foreign host]
Device1# ssh -l cisco 10.1.1.3
Password: cisco
Device2> exit
Device1# ssh -l cisco 10.1.1.3
Password: cisco
Device2> exit
[Connection to 10.1.1.3 closed by foreign host]
```

```
Devicel# ssh -1 cisco 10.1.1.3
Password: cisco
Your password has expired.
Enter a new one now.
New Password: cisco123
Re-enter New password: cisco123
```

Device2>

Example: SNMP Debugging

The following is sample output from the **debug snmp packet** command. The output provides SNMP trap information for an SSH session.

```
Device1# debug snmp packet
SNMP packet debugging is on
Device1# ssh -1 lab 10.0.0.2
Password:
Device2# exit
[Connection to 10.0.0.2 closed by foreign host]
Device1#

Feature History for Secure Shell Version 2 Support

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Everest 16.11.1	Secure Shell Version 2 Support	The Secure Shell Version 2 Support feature allows you to configure Secure Shell (SSH) Version 2 (SSH Version 1 support was implemented in an earlier Cisco IOS software release). SSH runs on top of a reliable transport layer and provides strong authentication and encryption capabilities. SSH version 2 also supports AES counter-based encryption mode.
Cisco IOS XE Cupertino 17.7.1	Secure Shell Version 2 Support	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

SSH Support Over IPv6

Secure Shell (SSH) provides support for IPv6 addresses that enable a Cisco device to accept and establish secure, encrypted connections with remote IPv6 nodes over an IPv6 transport.

- Prerequisites for SSH Support over IPv6, on page 321
- Information About SSH Support over IPv6, on page 321
- How to Configure SSH Support over IPv6, on page 322
- Configuration Examples for SSH Support over IPv6, on page 323
- Additional References for SSH Support over IPv6, on page 323
- Feature History for SSH Support over IPv6, on page 323

Prerequisites for SSH Support over IPv6

- An IPsec (Data Encryption Standard [DES] or 3DES) encryption software image is loaded on your device. IPv6 transport for the SSH server and SSH client requires an IPsec encryption software image.
- A hostname and host domain are configured for your device.
- A Rivest, Shamir, and Adelman (RSA) key pair, which automatically enables SSH, is generated for your device.
- A user authentication mechanism for local or remote access is configured on your device.
- To authenticate SSH clients, configure TACACS+ or RADIUS over an IPv4 transport and then connect to an SSH server over an IPv6 transport.

The basic restrictions for SSH over an IPv4 transport apply to SSH over an IPv6 transport. The use of locally stored usernames and passwords is the only user authentication mechanism supported by SSH over an IPv6 transport. TACACS+ and RADIUS user authentication mechanisms are not supported over an IPv6 transport.

Information About SSH Support over IPv6

SSH over an IPv6 Transport

Secure shell (SSH) SSH in IPv6 functions the same and offers the same benefits as SSH in IPv4. The SSH server feature enables an SSH client to make a secure, encrypted connection to a Cisco device, and the SSH

client feature enables a Cisco device to make a secure, encrypted connection to another Cisco device or to any other device running an SSH server. IPv6 enhancements to SSH consist of support for IPv6 addresses that enable a Cisco device to accept and establish secure, encrypted connections with remote IPv6 nodes over an IPv6 transport.

How to Configure SSH Support over IPv6

Enabling SSH on an IPv6 Device

This task is optional. If you do not configure SSH parameters, then the default values will be used.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	ip ssh [timeout seconds	Configures SSH control variables on your
	authentication-retries integer]	device.
	Example:	
	Device (config) # IP ssh timeout 100 authentication-retries 2	
Step 4	exit	Exits global configuration mode, and returns to
	Example:	privileged EXEC mode.
	Device(config)# exit	
Step 5	ssh $[-v \{1 2\} c \{3des aes128-cbc $ aes192-cbc aes256-cbc } -l userid -luserid:vrfname number ip-address ip-address -l userid:rotary number ip-address -m{ hmac-md5 hmac-md5-96 hmac-sha1 hmac-sha1-96 } -onumberofpasswordprompts $n -p$ port-num] { ip-addr hostname }[command -vrf]	Starts an encrypted session with a remote networking device.
	Example:	
	Device# ssh -1 userid1 2001:db8:2222:1044::72	

L

Configuration Examples for SSH Support over IPv6

Example: Enabling SSH on an IPv6 Device

Device# configure terminal
Device(config)# ip ssh
Device(config)# exit
Device# ssh -1 userid1 2001:db8:2222:1044::72

Configuring SSH File Transfer Protocol

Secure Shell (SSH) includes support for SSH File Transfer Protocol (SFTP), which is a new standard file transfer protocol introduced in SSHv2. This feature provides a secure and authenticated method for copying device configuration or device image files.

- Prerequisites for SSH File Transfer Protocol, on page 325
- Restrictions for SSH File Transfer Protocol, on page 325
- Information About SSH Support over IPv6, on page 326
- How to Configure SSH File Transfer Protocol, on page 326
- Configuration Examples for SSH Support over IPv6, on page 327
- Additional References for SSH File Transfer Protocol, on page 328
- Feature History for SSH File Transfer Protocol, on page 328

Prerequisites for SSH File Transfer Protocol

- SSH must be enabled.
- The ip ssh source-interface interface-type interface-number command must be configured.

Restrictions for SSH File Transfer Protocol

- The SFTP server is not supported.
- SFTP boot is not supported.
- The sftp option in the install add command is not supported.

Information About SSH Support over IPv6

SSH File Transfer Protocol Overview

The SFTP client functionality is provided as part of the SSH component and is always enabled on the corresponding device. Therefore, any SFTP server user with the appropriate permission can copy files to and from the device.

An SFTP client is VRF-aware; you can configure the secure FTP client to use the virtual routing and forwarding (VRF) associated with a particular source interface during connection attempts.

How to Configure SSH File Transfer Protocol

The following sections provide information about the various tasks that comprise an SFTP configuration.

Configuring SFTP

Perform the following steps:

Before you begin

To configure a Cisco device for SFTP client-side functionality, the **ip** ssh source-interface *interface-type interface-number* command must be configured first.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	ip ssh source-interface <i>interface-type interface-number</i>	Defines the source IP for the SSH session.
	Example:	
	Device(config)# ip ssh source-interface GigabitEthernet 1/0/1	
Step 4	exit	Exits global configuration mode and returns to
	Example:	privileged EXEC mode.
	Device(config)# exit	

	Command or Action	Purpose
Step 5	show running-config Example:	(Optional) Displays the SFTP client-side functionality.
	Device# show running-config	
Step 6	debug ip sftp	(Optional) Enables SFTP debugging.
	Example:	
	Device# debug ip sftp	

Performing an SFTP Copy Operation

SFTP copy takes the IP or hostname of the corresponding server if Domain Name System (DNS) is configured. To perform SFTP copy operations, use the following commands in privileged EXEC mode:

Command	Purpose
Device# copy ios-file-system:file sftp://user:pwd@server-ip//filepath	Copies a file from the local Cisco IOS file system to the server.
Or Device# copy ios-file-system: sftp:	Specify the username, password, IP address, and filepath of the server.
Device# copy sftp://user:pwd@server-ip //filepath ios-file-system:file	Copies the file from the server to the local Cisco IOS file system.
Or Device# copy sftp: ios-file-system:	Specify the username, password, IP address, and filepath of the server.

Configuration Examples for SSH Support over IPv6

Example: Configuring SSH File Transfer Protocol

The following example shows how to configure the client-side functionality of SFTP:

```
Device> enable
Device# configure terminal
Device(config)# ip ssh source-interface gigabitethernet 1/0/1
Device(config)# exit
```

X.509v3 Certificates for SSH Authentication

• X.509v3 Certificates for SSH Authentication, on page 329

X.509v3 Certificates for SSH Authentication

The X.509v3 Certificates for SSH Authentication feature uses the X.509v3 digital certificates in server and user authentication at the secure shell (SSH) server side.

This module describes how to configure server and user certificate profiles for a digital certificate.

Prerequisites for X.509v3 Certificates for SSH Authentication

• The X.509v3 Certificates for SSH Authentication feature introduces the **ip ssh server algorithm authentication** command to replace the **ip ssh server authenticate user** command. If you use the **ip ssh server authenticate user** command, the following deprecation message is displayed.

Warning: SSH command accepted but this CLI will be deprecated soon. Please move to new CLI "ip ssh server algorithm authentication". Please configure "default ip ssh server authenticate user" to make the CLI ineffective.

Use the **default ip ssh server authenticate user** command to remove the **ip ssh server authenticate user** command from effect. The IOS secure shell (SSH) server then starts using the **ip ssh server algorithm authentication** command.

Restrictions for X.509v3 Certificates for SSH Authentication

- The X.509v3 Certificates for SSH Authentication feature implementation is applicable only on the Cisco IOS XE secure shell (SSH) server side.
- The SSH server supports only the x509v3-ssh-rsa algorithm-based certificate for server and user authentication.

Information About X.509v3 Certificates for SSH Authentication

The following section provides information about digital certificates, and server and user authentication.

Digital Certificates

The validity of the authentication depends upon the strength of the linkage between the public signing key and the identity of the signer. Digital certificates in the X.509v3 format (RFC5280) are used to provide identity management. A chain of signatures by a trusted root certification authority and its intermediate certificate authorities binds a given public signing key to a given digital identity.

Public key infrastructure (PKI) trustpoint helps manage the digital certificates. The association between the certificate and the trustpoint helps track the certificate. The trustpoint contains information about the certificate authority (CA), different identity parameters, and the digital certificate. Multiple trustpoints can be created to associate with different certificates.

Server and User Authentication using X.509v3

For server authentication, the Cisco IOS XE secure shell (SSH) server sends its own certificate to the SSH client for verification. This server certificate is associated with the trustpoint configured in the server certificate profile (ssh-server-cert-profile-server configuration mode).

For user authentication, the SSH client sends the user's certificate to the SSH server for verification. The SSH server validates the incoming user certificate using public key infrastructure (PKI) trustpoints configured in the server certificate profile (ssh-server-cert-profile-user configuration mode).

By default, certificate-based authentication is enabled for server and user at the SSH server end.

How to Configure X.509v3 Certificates for SSH Authentication

The following section provides information about how to configure X.509v3 Certificates for SSH Authentication.

Configuring the SSH Server to Use Digital Certificates for Server Authentication

To configure the SSH server to use digital certificates for server authentication, perform this procedure:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	ip ssh server algorithm hostkey {x509v3-ssh-rsa [ssh-rsa] ssh-rsa [x509v3-ssh-rsa]}	Defines the order of host key algorithms. Only the configured algorithm is negotiated with the secure shell (SSH) client.
	Example:	

	Command or Action	Purpose	
	Device(config)# ip ssh server algorithm hostkey x509v3-ssh-rsa	Note The IOS SSH server must have at least one configured host key algorithm:	
		 ssh-rsa: public key based authentication 	
		• x509v3-ssh-rsa: certificate-based authentication	
Step 4	ip ssh server certificate profile	Configures server certificate profile and user	
	Example:	certificate profile and enters SSH certificate profile configuration mode.	
	Device(config)# ip ssh server certificate profile		
Step 5	server	Configures server certificate profile and enters	
	Example:	SSH server certificate profile server	
	Device(ssh-server-cert-profile)# server	configuration mode.	
Step 6	trustpoint sign PKI-trustpoint-name	Attaches the public key infrastructure (PKI)	
	Example:	trustpoint to the server certificate profile. The SSH server uses the certificate associated with	
	<pre>Device(ssh-server-cert-profile-server)# trustpoint sign trust1</pre>	this PKI trustpoint for server authentication.	
Step 7	ocsp-response include	(Optional) Sends the Online Certificate Status	
	Example:	Protocol (OCSP) response or OCSP staplin along with the server certificate.	
	Device(ssh-server-cert-profile-server)#		
	ocsp-response include	Note By default the no form of this command is configured and no OCSP response is sent along with the server certificate.	
Step 8	end	Exits SSH server certificate profile server	
	Example:	configuration mode and returns to privileged EXEC mode.	
	Device(ssh-server-cert-profile-server)#		
	end		

Configuring the SSH Server to Verify Digital Certificates for User Authentication

To configure the SSH Server to use digital certificates for user authentication, perform this procedure:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.

	Command or Action	Purpose
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	ip ssh server algorithm authentication {publickey keyboard password}	Defines the order of user authentication algorithms. Only the configured algorithm is negotiated with the secure shell (SSH) client.
	Example: Device(config)# ip ssh server algorithm authentication publickey	Note The COLL company these of
		• To use the certificate method for user authentication, the publickey keyword must be configured.
		• The ip ssh server algorithm authentication command replaces the ip ssh server authenticate user command.
Step 4	ip ssh server algorithm publickey {x509v3-ssh-rsa [ssh-rsa] ssh-rsa [x509v3-ssh-rsa]}	Defines the order of public key algorithms. Onl the configured algorithm is accepted by the SSI client for user authentication.
	Example: Device(config)# ip ssh server algorithm publickey x509v3-ssh-rsa	Note The SSH client must have at least one configured public key algorithm:
		• ssh-rsa: public-key-based authentication
		• x509v3-ssh-rsa: certificate-based authentication
Step 5	ip ssh server certificate profile	Configures server certificate profile and user certificate profile and enters SSH certificate
	<pre>Example: Device(config)# ip ssh server certificate profile</pre>	profile configuration mode.
Step 6	user	Configures user certificate profile and enters
	Example:	SSH server certificate profile user configuration mode.

	Command or Action	Purpose
Step 7	<pre>trustpoint verify PKI-trustpoint-name Example: Device(ssh-server-cert-profile-user)# trustpoint verify trust2</pre>	Configures the public key infrastructure (PKI)trustpoint that is used to verify the incoming user certificate.NoteConfigure multiple trustpoints by executing the same command multiple times. A maximum of 10 trustpoints can be configured.
Step 8	<pre>ocsp-response required Example: Device(ssh-server-cert-profile-user)# ocsp-response required</pre>	 (Optional) Mandates the presence of the Online Certificate Status Protocol (OCSP) response with the incoming user certificate. Note By default the no form of this command is configured and the user certificate is accepted without an OCSP response.
Step 9	<pre>end Example: Device(ssh-server-cert-profile-user)# end</pre>	Exits SSH server certificate profile user configuration mode and returns to privileged EXEC mode.

Configuring Trustpoint Authentication and Creating Device Certificate

To configure trustpoint authentication and create device certificate, perform this procedure:

Note

- We recommend that you use a new RSA keypair name for the newly configured PKI certificate. If you want to reuse an existing RSA keypair name (that is associated with an old certificate) for a new PKI certificate, do either of the following:
 - Do not regenerate a new RSA keypair with an existing RSA keypair name, reuse the existing RSA keypair name. Regenerating a new RSA keypair with an existing RSA keypair name will make all the certificates associated with the existing RSA keypair invalid.
 - Manually remove the old PKI certificate configurations first, before reusing the existing RSA keypair name for the new PKI certificate.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	

	Command or Action	Purpose
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	crypto pki trustpoint name	Declares the trustpoint and a given name and
	Example:	enters ca-trustpoint configuration mode.
	Device(config)# crypto pki trustpoint trust1	
Step 4	enrollment url url	Specifies the URL of the CA on which your
	Example:	device should send certificate requests.
	<pre>Device(ca-trustpoint)# enrollment url http://10.1.1.10:80</pre>	
Step 5	revocation-check none	Specifies that certificate checking is ignored.
	Example:	
	<pre>Device(ca-trustpoint)# revocation-check none</pre>	
Step 6	rsakeypair key-label [key-size [encryption-key-size]]	(Optional) Specifies which key pair to associate with the certificate.
	Example: Device(ca-trustpoint)# rsakeypair trust1 2048	A key pair with the <i>key-label</i> argument will be generated during enrollment if it does not already exist or if the auto-enroll regenerate command was issued.
		Specify the <i>key-size</i> argument for generating the key, and specify the <i>encryption-key-size</i> argument to request separate encryption, signature keys, and certificates. The <i>key-size</i> argument range is from 512 to 4096. The key-size and encryption-key-size must be the same size. Length of less than 2048 is not recommended.
		Note If this command is not enabled, the FQDN key pair is used.
Step 7	exit	Exits ca-trustpoint configuration mode and
	Example:	returns to global configuration mode.
	Device(ca-trustpoint)# exit	
Step 8	crypto pki authenticate <i>name</i> Example:	Retrieves the CA certificate and authenticates it. Check the certificate fingerprint if prompted.
	Device (config) # crypto pki authenticate trust1	Note This command is optional if the CA certificate is already loaded into the configuration.

	Command or Action	Purpose
Step 9	crypto pki enroll name Example: Device (config) # crypto pki enroll trust1	Certificate request is sent to the certificate server and the server issues the ID or device certificate. You are prompted for enrollment information, such as whether to include the device FQDN and IP address in the certificate request.
Step 10	<pre>show crypto pki certificates Example: Device(config) # show crypto pki certificates verbose trust1</pre>	(Optional) Displays information about your certificates, including any rollover certificates.

What to do next

For more information on how to install the certificate using other enrollment options, see Deploying RSA Keys Within a PKI.

Verifying Configuration for Server and User Authentication Using Digital Certificates

To verify configuration for server and user Authentication using digital certificates, perform this procedure:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	show ip ssh	Displays the currently configured authentication
	Example:	methods. To confirm the use of certificate-based
	Device# show ip ssh	authentication, ensure that the x509v3-ssh-rsa algorithm is the configured host key algorithm.
	SSH Enabled - version 1.99 Authentication methods:publickey,keyboard-interactive,password Authentication Publickey Algorithms:x509v3-ssh-rsa,ssh-rsa Hostkey Algorithms:x509v3-ssh-rsa,ssh-rsa Authentication timeout: 120 secs; Authentication retries: 3 Minimum expected Diffie Hellman key size : 1024 bits	

Procedure

Configuration Examples for X.509v3 Certificates for SSH Authentication

The following section provides examples for user and server authentication using digital certificates.

Example: Configuring the SSH Server to Use Digital Certificates for Server Authentication

This example shows how to configure the SSH Server to use digital certificates for server authentication.

```
Device> enable
Device# configure terminal
Device(config)# ip ssh server algorithm hostkey x509v3-ssh-rsa
Device(config)# ip ssh server certificate profile
Device(ssh-server-cert-profile)# server
Device(ssh-server-cert-profile-server)# trustpoint sign trust1
Device(ssh-server-cert-profile-server)# end
```

Example: Configuring the SSH Server to Verify Digital Certificates for User Authentication

This example shows how to configure the SSH server to verify user's digital certificate for user authentication.

```
Device> enable
Device# configure terminal
Device(config)# ip ssh server algorithm authentication publickey
Device(config)# ip ssh server algorithm publickey x509v3-ssh-rsa
Device(config)# ip ssh server certificate profile

Feature History for X.509v3 Certificates for SSH Authentication

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.11.1	X.509v3 Certificates for SSH Authentication	The X.509v3 Certificates for SSH Authentication feature uses the X.509v3 digital certificates in server and user authentication at the SSH server side.
Cisco IOS XE Cupertino 17.7.1	X.509v3 Certificates for SSH Authentication	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

SSH Algorithms for Common Criteria Certification

Restriction for SSH Algorithms for Common Criteria Certification

Starting from Cisco IOS XE Amsterdam 17.1.1, SHA1 is not supported.

Information About SSH Algorithms for Common Criteria Certification

This section provides information about the Secure Shell (SSH) Algorithms for Common Criteria Certification, the Cisco IOS SSH Server Algorithms and Cisco IOS SSH Client Algorithms.

SSH Algorithms for Common Criteria Certification

A Secure Shell (SSH) configuration enables a Cisco IOS SSH server and client to authorize the negotiation of only those algorithms that are configured from the allowed list. If a remote party tries to negotiate using only those algorithms that are not part of the allowed list, the request is rejected and the session is not established.

Cisco IOS SSH Server Algorithms

Cisco IOS secure shell (SSH) servers support the encryption algorithms (Advanced Encryption Standard Counter Mode [AES-CTR], AES Cipher Block Chaining [AES-CBC], Triple Data Encryption Standard [3DES]) in the following order:

Supported Default Encryption Order:

1. aes128-gcm

- 2. aes256-gcm
- 3. aes128-ctr
- 4. aes192-ctr
- 5. aes256-ctr

Supported Non-Default Encrytion Order:

- **1.** aes128-cbc
- 2. aes192-cbc
- 3. aes256-cbc
- **4.** 3des

Cisco IOS SSH clients support the Message Authentication Code (MAC) algorithms in the following order: Supported Default HMAC order:

- 1. hmac-sha2-256
- 2. hmac-sha2-512

Cisco IOS SSH clients support only one host key algorithm and do not need a CLI configuration.

Supported Default Host Key order:

- 1. x509v3-ssh-rsa
- 2. ssh-rsa

Cisco IOS SSH Client Algorithms

Cisco IOS secure shell (SSH) clients support the encryption algorithms (Advanced Encryption Standard counter mode [AES-CTR], AES Cipher Block Chaining [AES-CBC], Triple Data Encryption Standard [3DES]) in the following order:

Supported Default Encryption Order:

- 1. aes128-gcm
- 2. aes256-gcm
- 3. aes128-ctr
- 4. aes192-ctr
- 5. aes256-ctr

Supported Non-Default Encrytion Order:

- 1. aes128-cbc
- 2. aes192-cbc
- 3. aes256-cbc

4. 3des

Cisco IOS SSH clients support the Message Authentication Code (MAC) algorithms in the following order: Supported Default HMAC order:

- 1. hmac-sha2-256
- 2. hmac-sha2-512

Cisco IOS SSH clients support only one host key algorithm and do not need a CLI configuration. Supported Default Host Key order:

- 1. x509v3-ssh-rsa
- 2. ssh-rsa

How to Configure SSH Algorithms for Common Criteria Certification

This section provides information on how to configure and troubleshoot:

- · Encryption key algorithm for a Cisco IOS SSH server and client
- MAC algorithm for a Cisco IOS SSH server and client
- · Host Key algorithm for a Cisco IOS SSH server

Configuring an Encryption Key Algorithm for a Cisco IOS SSH Server and Client

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	ip ssh {server client} algorithm encryption {aes128-gcm aes256-gcm aes128-ctr aes192-ctr aes256-ctr aes128cbc aes192-cbs 3des}	Defines the order of encryption algorithms in the SSH server and client. This order is presented during algorithm negotiation. Note The Cisco IOS SSH server and
	Example:	client must have at least one configured encryption algorithm

	Command or Action	Purpose	rpose
	Device(config)# ip ssh server algorithm encryption aes128-gcm aes256-gcm aes128-ctr aes192-ctr aes256-ctr aes128-cbc aes192-cbc aes256-cbc 3des Device(config)# ip ssh client algorithm encryption aes128-gcm aes256-gcm aes128-ctr aes192-ctr aes256-ctr aes128-cbc aes192-cbc aes256-cbc 3des	Note To disable one algorithm from previously configured algorith list, use the no form of this	 previously configured algori list, use the no form of this command. To disable more to one algorithm, use the no for this command multiple times different algorithm names. te For a default configuration, the default form of this commands shown below: Device (config) # ip ssh se algorithm encryption aes128-gcm aes256-gcm aes128-ctr aes192-ctr aes256-ctr aes128-cbc
Step 4	end Example:	Exits global configuration mode and return privileged EXEC mode.	
	Device(config)# end		

Troubleshooting Tips

If you try to disable the last encryption algorithm in the configuration, the following message is displayed and the command is rejected:

 $\ensuremath{\$}$ SSH command rejected: All encryption algorithms cannot be disabled

Configuring a MAC Algorithm for a Cisco IOS SSH Server and Client

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	

	Command or Action	Purpose
Step 3	ip ssh {server client} algorithm mac {hmac-sha2-256-etm hmac-sha2-512-etm hmac-sha2-256 hmac-sha2-512 } Example:	Defines the order of MAC (Message Authentication Code) algorithms in the SSH server and client. This order is presented during algorithm negotiation.
	Device(config)# ip ssh server algorithm mac hmac-sha2-256-etm hmac-sha2-512-etm hmac-sha2-256 hmac-sha2-512	Note The Cisco IOS SSH server and client must have at least one configured Hashed Message Authentication Code (HMAC) algorithm.
	Device(config)# ip ssh client algorithm mac hmac-sha2-256-etm hmac-sha2-512-etm hmac-sha2-256 hmac-sha2-512	
		Note For default configuration, use the default form of this command as shown below:
		Device(config)# ip ssh serve: algorithm mac hmac-sha2-256-etm hmac-sha2-512-etm hmac-sha2-256 hmac-sha2-512
Step 4	end Example:	Exits global configuration mode and returns to privileged EXEC mode.
	Device(config)# end	

Troubleshooting Tips

If you try to disable the last MAC algorithm in the configuration, the following message is displayed and the command is rejected:

% SSH command rejected: All mac algorithms cannot be disabled

Configuring a Host Key Algorithm for a Cisco IOS SSH Server

	Command or Action	Purpose	
Step 1	enable	Enables privileged EXEC mode.	
	Example:	Enter your password if prompted.	
	Device> enable		
Step 2	configure terminal	Enters global configuration mode.	
	Example:		
	Device# configure terminal		
Step 3	ip ssh server algorithm hostkey {x509v3-ssh-rsa rsa-sha2-512 rsa-sha2-256ssh-rsa}	Defines the order of host key algorithms. O the configured algorithm is negotiated with Cisco IOS secure shell (SSH) client.	
	Example: Device(config)# ip ssh server algorithm hostkey x509v3-ssh-rsa rsa-sha2-512 rsa-sha2-256 ssh-rsa	Note The Cisco IOS SSH server mu have at least one configured ho key algorithm:	
		• x509v3-ssh-rsa—X.509v3 certificate-based authentication	3
		• ssh-rsa—Public-key-base authentication	ed
		Note To disable one algorithm from the previously configured algorithe list, use the no form of this command. To disable more that one algorithm, use the no form this command multiple times we different algorithm names.	nm an 1 of
		Note For default configuration, use t default form of this command shown below:	
		Device(config)# ip ssh ser algorithm hostkey x509v3-ssh-rsa rsa-sha2-51 rsa-sha2-256 ssh-rsa	
Step 4	end	Exits global configuration mode and return	is to
	Example:	privileged EXEC mode.	

Command or Action	Purpose
Device(config)# end	

Troubleshooting Tips

If you try to disable the last host key algorithm in the configuration, the following message is displayed and the command is rejected:

```
% SSH command rejected: All hostkey algorithms cannot be disabled
```

Configuration Examples For SSH Algorithms for Common Criteria Certification

This section provides configuration examples for SSH algorithms for common certification.

Example: Configuring Encryption Key Algorithms for a Cisco IOS SSH Server

```
Device> enable
Device# configure terminal
Device(config)# ip ssh server algorithm encryption aes128-ctr aes192-ctr aes256-ctr aes128-cbc
aes192-cbc aes256-cbc 3des
Device(config)# end
```

Example: Configuring Encryption Key Algorithms for a Cisco IOS SSH Client

Device> enable
Device# configure terminal
Device(config)# ip ssh client algorithm encryption aes128-ctr aes192-ctr aes256-ctr aes128-cbc
 aes192-cbc aes256-cbc 3des

Device(config)# end

Example: Configuring MAC Algorithms for a Cisco IOS SSH Server

```
Device> enable
Device# configure terminal
Device(config)# ip ssh server algorithm mac hmac-sha2-256-etm hmac-sha2-512-etm hmac-sha2-256
hmac-sha2-512
Device(config)# end
```

Example: Configuring Host Key Algorithms for a Cisco IOS SSH Server

Device> enable
Device# configure terminal
Device(config)# ip ssh server algorithm hostkey x509v3-ssh-rsa rsa-sha2-512 rsa-sha2-256
ssh-rsaa
Device(config)# end

Verifying SSH Algorithms for Common Criteria Certification

Procedure

Step 1 enable

Enables privileged EXEC mode.

• Enter your password if prompted.

Example:

Device> enable

Step 2 show ip ssh

Displays configured Secure Shell (SSH) encryption, host key, and Message Authentication Code (MAC) algorithms.

Example:

The following sample output from the **show ip ssh** command shows the encryption algorithms configured in the default order:

Device# show ip ssh

```
Encryption Algorithms: aes128-ctr aes192-ctr aes256-ctr aes128-cbc aes192-cbc aes256-cbc 3des
```

The following sample output from the **show ip ssh** command shows the MAC algorithms configured in the default order:

Device# show ip ssh

MAC Algorithms: hmac-sha2-256, hmac-sha2-512

The following sample output from the **show ip ssh** command shows the host key algorithms configured in the default order:

Device# show ip ssh

Hostkey Algorithms: x509v3-ssh-rsa, ssh-rsa

Feature History for Secure Shell Algorithms for Common Criteria Certification

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Everest 16.5.1a	Secure Shell Algorithms for Common Criteria Certification	The SSH Algorithms for Common Criteria Certification feature provides the list and order of the algorithms that are allowed for Common Criteria Certification. This module describes how to configure the encryption, Message Authentication Code (MAC), and host key algorithms for a secure shell (SSH) server and client so that SSH connections can be limited on the basis of the allowed algorithms list.
Cisco IOS XE Cupertino 17.7.1	Secure Shell Algorithms for Common Criteria Certification	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

Configuring Secure Socket Layer HTTP

- Information About Secure Socket Layer HTTP, on page 347
- How to Configure Secure Socket Layer HTTP, on page 350
- Monitoring Secure HTTP Server and Client Status, on page 356
- Additional References for Secure Socket Layer HTTP, on page 357

Information About Secure Socket Layer HTTP

Secure HTTP Servers and Clients Overview

On a secure HTTP connection, data to and from an HTTP server is encrypted before being sent over the Internet. HTTP with SSL encryption provides a secure connection to allow such functions as configuring a switch from a Web browser. Cisco's implementation of the secure HTTP server and secure HTTP client uses an implementation of SSL Version 3.0 with application-layer encryption. HTTP over SSL is abbreviated as HTTPS; the URL of a secure connection begins with https:// instead of http://.

The primary role of the HTTP secure server (the switch) is to listen for HTTPS requests on a designated port (the default HTTPS port is 443) and pass the request to the HTTP 1.1 Web server. The HTTP 1.1 server processes requests and passes responses (pages) back to the HTTP secure server, which, in turn, responds to the original request.

The primary role of the HTTP secure client (the web browser) is to respond to Cisco IOS application requests for HTTPS User Agent services, perform HTTPS User Agent services for the application, and pass the response back to the application.

Certificate Authority Trustpoints

Certificate authorities (CAs) manage certificate requests and issue certificates to participating network devices. These services provide centralized security key and certificate management for the participating devices. Specific CA servers are referred to as *trustpoints*.

When a connection attempt is made, the HTTPS server provides a secure connection by issuing a certified X.509v3 certificate, obtained from a specified CA trustpoint, to the client. The client (usually a Web browser), in turn, has a public key that allows it to authenticate the certificate.

For secure HTTP connections, we highly recommend that you configure a CA trustpoint. If a CA trustpoint is not configured for the device running the HTTPS server, the server certifies itself and generates the needed RSA key pair. Because a self-certified (self-signed) certificate does not provide adequate security, the connecting client generates a notification that the certificate is self-certified, and the user has the opportunity to accept or reject the connection. This option is useful for internal network topologies (such as testing).

If you do not configure a CA trustpoint, when you enable a secure HTTP connection, either a temporary or a persistent self-signed certificate for the secure HTTP server (or client) is automatically generated.

- If the switch is not configured with a hostname and a domain name, a temporary self-signed certificate is generated. If the switch reboots, any temporary self-signed certificate is lost, and a new temporary new self-signed certificate is assigned.
- If the switch has been configured with a host and domain name, a persistent self-signed certificate is generated. This certificate remains active if you reboot the switch or if you disable the secure HTTP server so that it will be there the next time you re-enable a secure HTTP connection.

Note The certificate authorities and trustpoints must be configured on each device individually. Copying them from other devices makes them invalid on the switch.

When a new certificate is enrolled, the new configuration change is not applied to the HTTPS server until the server is restarted. You can restart the server using the **reload** command. On restarting the server, the switch starts using the new certificate.

If a self-signed certificate has been generated, this information is included in the output of the **show running-config** privileged EXEC command. This is a partial sample output from that command displaying a self-signed certificate.

```
Device# show running-config
Building configuration...
<output truncated>
crypto pki trustpoint TP-self-signed-3080755072
enrollment selfsigned
subject-name cn=IOS-Self-Signed-Certificate-3080755072

```

<output truncated>

You can remove this self-signed certificate by disabling the secure HTTP server and entering the **no crypto pki trustpoint TP-self-signed-30890755072** global configuration command. If you later re-enable a secure HTTP server, a new self-signed certificate is generated.

Note The values that follow *TP self-signed* depend on the serial number of the device.

You can use the **ip http secure-client-auth** command (optional) to allow the HTTPS server to request an X.509v3 certificate from the client. Authenticating the client provides more security than server authentication by itself.

Note

Beginning from Cisco IOS XE Amsterdam 17.3.x, CA's self-signed root certificate must be configured for successful authentication of the client.

CipherSuites

A CipherSuite specifies the encryption algorithm and the digest algorithm to use on a SSL connection. When connecting to the HTTPS server, the client Web browser offers a list of supported CipherSuites, and the client and server negotiate the best encryption algorithm to use from those on the list that are supported by both. For example, Netscape Communicator 4.76 supports U.S. security with RSA Public Key Cryptography, MD2, MD5, RC2-CBC, RC4, DES-CBC, and DES-EDE3-CBC.

For the best possible encryption, you should use a client browser that supports 128-bit encryption, such as Microsoft Internet Explorer Version 5.5 (or later) or Netscape Communicator Version 4.76 (or later). The SSL_RSA_WITH_DES_CBC_SHA CipherSuite provides less security than the other CipherSuites, as it does not offer 128-bit encryption.

The more secure and more complex CipherSuites require slightly more processing time. This list defines the CipherSuites supported by the switch and ranks them from fastest to slowest in terms of router processing load (speed):

- 1. SSL_RSA_WITH_DES_CBC_SHA—RSA key exchange (RSA Public Key Cryptography) with DES-CBC for message encryption and SHA for message digest
- SSL_RSA_WITH_NULL_SHA key exchange with NULL for message encryption and SHA for message digest (only for SSL 3.0).
- **3.** SSL_RSA_WITH_NULL_MD5 key exchange with NULL for message encryption and MD5 for message digest (only for SSL 3.0).
- SSL_RSA_WITH_RC4_128_MD5—RSA key exchange with RC4 128-bit encryption and MD5 for message digest
- SSL_RSA_WITH_RC4_128_SHA—RSA key exchange with RC4 128-bit encryption and SHA for message digest
- SSL_RSA_WITH_3DES_EDE_CBC_SHA—RSA key exchange with 3DES and DES-EDE3-CBC for message encryption and SHA for message digest
- 7. SSL_RSA_WITH_AES_128_CBC_SHA—RSA key exchange with AES 128-bit encryption and SHA for message digest (only for SSL 3.0).
- 8. SSL_RSA_WITH_AES_256_CBC_SHA—RSA key exchange with AES 256-bit encryption and SHA for message digest (only for SSL 3.0).

- **9.** SSL_RSA_WITH_DHE_AES_128_CBC_SHA—RSA key exchange with AES 128-bit encryption and SHA for message digest (only for SSL 3.0).
- **10.** SSL_RSA_WITH_DHE_AES_256_CBC_SHA—RSA key exchange with AES 256-bit encryption and SHA for message digest (only for SSL 3.0).

Note The latest versions of Chrome do not support the four original cipher suites, thus disallowing access to both web GUI and guest portals.

RSA (in conjunction with the specified encryption and digest algorithm combinations) is used for both key generation and authentication on SSL connections. This usage is independent of whether or not a CA trustpoint is configured.

Default SSL Configuration

The following guidelines apply to the default SSL configuration:

- The standard HTTP server is enabled.
- SSL is enabled.
- No CA trustpoints are configured.
- · No self-signed certificates are generated.

SSL Configuration Guidelines

When SSL is used in a switch cluster, the SSL session terminates at the cluster commander. Cluster member switches must run standard HTTP.

Before you configure a CA trustpoint, you should ensure that the system clock is set. If the clock is not set, the certificate is rejected due to an incorrect date.

In a switch stack, the SSL session terminates at the active switch.

How to Configure Secure Socket Layer HTTP

Configuring a CA Trustpoint

For secure HTTP connections, we recommend that you configure an official CA trustpoint. A CA trustpoint is more secure than a self-signed certificate.

Beginning in privileged EXEC mode, follow these steps to configure a CA Trustpoint:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.

	Command or Action	Purpose	
	Example:	Enter your password, if prompted.	
	Device> enable		
Step 2	configure terminal	Enters global configuration mode.	
	Example:		
	Device# configure terminal		
Step 3	hostname hostname	Specifies the hostname of the switch (required	
	Example:	only if you have not previously configure hostname). The hostname is required for	
	Device (config) # hostname your_hostname	security keys and certificates.	
Step 4	ip domain name domain-name	Specifies the IP domain name of the switch	
	Example:	(required only if you have not previously	
	Device(config)# ip domain name	configured an IP domain name). The domain name is required for security keys and	
	your_domain	certificates.	
Step 5	crypto key generate rsa	(Optional) Generates an RSA key pair. RSA	
	Example:	key pairs are required before you can obtain a certificate for the switch. RSA key pairs are	
	Device(config)# crypto key generate rsa		
		command to regenerate the keys, if needed.	
Step 6	crypto ca trustpoint name	Specifies a local configuration name for the	
	Example:	CA trustpoint and enter CA trustpoint configuration mode.	
	Device(config)# crypto ca trustpoint your_trustpoint		
Step 7	enrollment url url	Specifies the URL to which the switch should	
	Example:	send certificate requests.	
	<pre>Device(ca-trustpoint)# enrollment url http://your_server:80</pre>		
Step 8	enrollment http-proxy host-name	(Optional) Configures the switch to obtain	
	port-number	certificates from the CA through an HTTP proxy server.	
	Example: Device(ca-trustpoint)# enrollment	• For <i>host-name</i> , specify the proxy server	
	http-proxy your_host 49	used to get the CA.	
		• For <i>port-number</i> , specify the port number used to access the CA.	
Step 9	crl query url	Configures the switch to request a certificate	
	Example:	revocation list (CRL) to ensure that the	
	Device(ca-trustpoint)# crl query ldap://your_host:49	certificate of the peer has not been revoked.	

	Command or Action	Purpose
Step 10	<pre>primary name Example: Device(ca-trustpoint)# primary your_trustpoint</pre>	 (Optional) Specifies that the trustpoint should be used as the primary (default) trustpoint for CA requests. For <i>name</i>, specify the trustpoint that you just configured.
Step 11	<pre>exit Example: Device(ca-trustpoint)# exit</pre>	Exits CA trustpoint configuration mode and return to global configuration mode.
Step 12	crypto ca authentication name Example: Device(config)# crypto ca authentication your_trustpoint	Authenticates the CA by getting the public key of the CA. Use the same name used in Step 5.
Step 13	crypto ca enroll name Example: Device(config)# crypto ca enroll your_trustpoint	Obtains the certificate from the specified CA trustpoint. This command requests a signed certificate for each RSA key pair.
Step 14	end Example: Device(config)# end	Exits global configuration mode and returns to privileged EXEC mode.

Configuring the Secure HTTP Server

Beginning in privileged EXEC mode, follow these steps to configure a secure HTTP server:

Before you begin

If you are using a certificate authority for certification, you should use the previous procedure to configure the CA trustpoint on the switch before enabling the HTTP server. If you have not configured a CA trustpoint, a self-signed certificate is generated the first time that you enable the secure HTTP server. After you have configured the server, you can configure options (path, access list to apply, maximum number of connections, or timeout policy) that apply to both standard and secure HTTP servers.

To verify the secure HTTP connection by using a Web browser, enter https://URL, where the URL is the IP address or hostname of the server switch. If you configure a port other than the default port, you must also specify the port number after the URL. For example:

Note AES256_SHA2 is not supported.

https://209.165.129:1026

or

https://host.domain.com:1026

The existing **ip http access-class** *access-list-number* command for specifying the access-list(Only IPv4 ACLs) is going to be deprecated. You can still use this command to specify an access list to allow access to the HTTP server. Two new commands have been introduced to enable support for specifying IPv4 and IPv6 ACLs. These are **ip http access-class ipv4** *access-list-name* | *access-list-number* for specifying IPv4 ACLs and **ip http access-class ipv6** *access-list-name* for specifying IPv6 ACLs. We recommend using the new CLI to avoid receiving warning messages.

Note the following considerations for specifying access-lists:

• If you specify an access-list that does not exist, the configuration takes place but you receive the below warning message:

ACL being attached does not exist, please configure it

• If you use **ip http access-class ipv4** *access-list-name* | *access-list-number* or **ip http access-class ipv6** *access-list-name*, and an access-list was already configured using **ip http access-class**, the below warning message appears:

Removing ip http access-class <access-list-number>

ip http access-class *access-list-number* and **ip http access-class ipv4** *access-list-name* | *access-list-number* share the same functionality. Each command overrides the configuration of the previous command. The following combinations between the configuration of the two commands explain the effect on the running configuration:

- If **ip http access-class** *access-list-number* is already configured and you try to configure using **ip http access-class ipv4** *access-list-number* command, the configuration of **ip http access-class** *access-list-number* will be removed and the configuration of **ip http access-class ipv4** *access-list-number* will be added to the running configuration.
- If **ip http access-class** *access-list-number* is already configured and you try to configure using **ip http access-class ipv4** *access-list-name* command, the configuration of **ip http access-class** *access-list-number* will be removed and the configuration of **ip http access-class ipv4** *access-list-name* will be added to the running configuration.
- If **ip http access-class ipv4** *access-list-number* is already configured and you try to configure using **ip http access-class** *access-list-name*, the configuration of **ip http access-class ipv4** *access-list-number* will be removed from configuration and the configuration of **ip http access-class** *access-list-name* will be added to the running configuration.
- If **ip http access-class ipv4** *access-list-name* is already configured and you try to configure using **ip http access-class** *access-list-number*, the configuration of **ip http access-class ipv4** *access-list-name* will be removed from the configuration and the configuration of **ip http access-class** *access-list-number* will be added to the running configuration.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	

	Command or Action	Purpose	
Step 2	<pre>show ip http server status Example: Device# show ip http server status</pre>	(Optional) Displays the status of the HTTP server to determine if the secure HTTP server feature is supported in the software. You should see one of these lines in the output:	
		HTTP secure server capability: Present Or HTTP secure server capability: Not present	
Step 3	configure terminal	Enters global configuration mode.	
	Example: Device# configure terminal		
Step 4	<pre>ip http secure-server Example: Device(config)# ip http secure-server</pre>	Enables the HTTPS server if it has been disabled. The HTTPS server is enabled by default.	
Step 5	<pre>ip http secure-port port-number Example: Device (config) # ip http secure-port 443</pre>	(Optional) Specifies the port number to be us for the HTTPS server. The default port num is 443. Valid options are 443 or any number in the range 1025 to 65535.	
Step 6	<pre>ip http secure-ciphersuite {[3des-ede-cbc-sha] [rc4-128-md5] [rc4-128-sha] [des-cbc-sha]} Example: Device(config) # ip http secure-ciphersuite rc4-128-md5</pre>	(Optional) Specifies the CipherSuites (encryption algorithms) to be used for encryption over the HTTPS connection. If you do not have a reason to specify a particularly CipherSuite, you should allow the server and client to negotiate a CipherSuite that they both support. This is the default.	
Step 7	<pre>ip http secure-client-auth Example: Device(config)# ip http secure-client-auth</pre>	(Optional) Configures the HTTP server to request an X.509v3 certificate from the clien for authentication during the connection process. The default is for the client to reques a certificate from the server, but the server does not attempt to authenticate the client.	
Step 8	<pre>ip http secure-trustpoint name Example: Device(config)# ip http secure-trustpoint your_trustpoint</pre>	Specifies the CA trustpoint to use to get an X.509v3 security certificate and to authenticate the client certificate connection.NoteUse of this command assumes you have already configured a CA trustpoint according to the	
Step 9	ip http path <i>path-name</i> Example:	(Optional) Sets a base HTTP path for HTML files. The path specifies the location of the	

	Command or Action	Purpose	
	<pre>Device(config)# ip http path /your_server:80</pre>	HTTP server files on the local system (usually located in system flash memory).	
Step 10	<pre>ip http access-class { ipv4 {access-list-number access-list-name} ipv6 {access-list-name} }</pre>	(Optional)Specifies an access list to use to allow access to the HTTP server.	
	Example: Device(config)# ip http access-class ipv4 4		
Step 11	<pre>ip http max-connections value Example: Device(config)# ip http max-connections 4</pre>	(Optional) Sets the maximum number of concurrent connections that are allowed to the HTTP server. We recommend that the value be at least 10 and not less. This is required for the UI to function as expected.	
Step 12	ip http timeout-policy idle seconds life seconds requests value Example:	(Optional) Specifies how long a connection to the HTTP server can remain open under the defined circumstances:	
	Device(config)# ip http timeout-policy idle 120 life 240 requests 1	• idle: the maximum time period when no data is received or response data cannot be sent. The range is 1 to 600 seconds. The default is 180 seconds (3 minutes).	
		• life : the maximum time period from the time that the connection is established. The range is 1 to 86400 seconds (24 hours). The default is 180 seconds.	
		• requests : the maximum number of requests processed on a persistent connection. The maximum value is 86400. The default is 1.	
Step 13	end Example: Device (config) #end	Exits global configuration mode and returns to privileged EXEC mode.	

Configuring the Secure HTTP Client

Beginning in privileged EXEC mode, follow these steps to configure a secure HTTP client:

Before you begin

The standard HTTP client and secure HTTP client are always enabled. A certificate authority is required for secure HTTP client certification. This procedure assumes that you have previously configured a CA trustpoint on the switch. If a CA trustpoint is not configured and the remote HTTPS server requires client authentication, connections to the secure HTTP client fail.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	ip http client secure-trustpoint name	(Optional) Specifies the CA trustpoint to be
	Example:	used if the remote HTTP server requests client authentication. Using this command assumes
	<pre>Device(config)# ip http client secure-trustpoint your_trustpoint</pre>	that you have already configured a CA trustpoint by using the previous procedure. The command is optional if client authentication is
		not needed or if a primary trustpoint has been configured.
Step 4	ip http client secure-ciphersuite	(Optional) Specifies the CipherSuites
	{[3des-ede-cbc-sha] [rc4-128-md5] [rc4-128-sha] [des-cbc-sha]}	(encryption algorithms) to be used for encryption over the HTTPS connection. If you
		do not have a reason to specify a particular
	Example:	CipherSuite, you should allow the server and
	Device(config)# ip http client secure-ciphersuite rc4-128-md5	client to negotiate a CipherSuite that they both support. This is the default.
Step 5	end	Exits global configuration mode and returns to
	Example:	privileged EXEC mode.
	Device(config) # end	

Procedure

Monitoring Secure HTTP Server and Client Status

To monitor the SSL secure server and client status, use the privileged EXEC commands in the following table.

Table 21: Commands for Displaying the SSL Secure Server and Client Status

Command	Purpose
show ip http client secure status	Shows the HTTP secure client configuration.
show ip http server secure status	Shows the HTTP secure server configuration.
show running-config	Shows the generated self-signed certificate for secure HTTP connections.

Feature History for Secure Socket Layer HTTP

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.11.1	Secure Socket Layer HTTP	Cisco's implementation of the secure HTTP server and secure HTTP client uses an implementation of SSL Version 3.0 with application-layer encryption. On a secure HTTP connection, data to and from an HTTP server is encrypted before being sent over the Internet.
Cisco IOS XE Cupertino 17.7.1	Secure Socket Layer HTTP	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

Restrictions for IPv4 Access Control Lists

General Network Security

The following are restrictions for configuring network security with ACLs:

- Not all commands that accept a numbered ACL accept a named ACL. ACLs for packet filters and route filters on interfaces can use a name. VLAN maps also accept a name.
- A standard ACL and an extended ACL cannot have the same name.
- Though visible in the command-line help strings, **appletalk** is not supported as a matching condition for the **deny** and **permit** MAC access-list configuration mode commands.
- ACLs cannot be configured on management ports.
- On Cisco Catalyst 9600 Series Supervisor 2 Module only a maximum of 126 IPv4 ACL IDs in ingress, and a maximum of 14 IPv4 ACL IDs in egress are supported.

In ingress, a maximum of 16 ACL IDs are shared among other features such as Security and QoS ACLs, while one ACL ID is shared among PBR and EPC ACLs each. In egress, a maximum of one ACL ID is shared among Security and EPC ACLs each.

- IPv4 ACL and IPv4 object group-based ACL logging is supported on Cisco Catalyst 9600 Series Supervisor 2 Module.
- Time-based ACL is supported on Cisco Catalyst 9600 Series Supervisor 2 Module.
- ACL modification when ACL is applied is supported on Cisco Catalyst 9600 Series Supervisor 2 Module.
- ACL wildcard is not supported in downstream client policy.

- When you apply a scale ACL to an interface that does not program TCAM for a protocol and the ACLs that have been unloaded, it can impact the existing normal movement of traffic for other protocols. The restriction is applicable to IPv4, IPv6, and MAC address traffic.
- TCAM optimization is not supported on Cisco Catalyst 9600 Series Supervisor 2 Module.
- IPv4 ACLs are supported only on Layer 3 ports on Cisco Catalyst 9600 Series Supervisor 2 Module.
- Router ACL is enforced on all types of traffic, including CPU generated traffic.
- ACL logging in the egress direction are not supported for packets that are generated from the control plane of the device.
- Time-to-live (TTL) classification is not supported on ACLs.
- If a downloadable ACL contains any type of duplicate entries, the entries are not auto merged. As a result, the 802.1X session authorization fails. Ensure that the downloadable ACL is optimized without any duplicate entries, for example port-based and name-based entries for the same port.
- Egress ACL lookup is not supported for injected traffic that is forwarded by the software.
- ACLs support only Layer 3 interfaces (such as routed interfaces and VLAN interfaces), port channel interface, and sub-interfaces.

There is no support on Layer 2 interfaces on Cisco Catalyst 9600 Series Supervisor 2 Module.

- Multicast control packets are not filtered by ACL on Cisco Catalyst 9600 Series Supervisor 2 Module
- On Cisco Catalyst 9600 Series Supervisor 2 Module, per-ACE statistics is supported only for deny ACEs. Per-ACE statistics is not supported for Permit ACEs. If the same ACL is applied to multiple ports, then the deny counters is cumulative for all the ports on which the ACL is attached.
- On Cisco Catalyst 9600 Series Supervisor 2 Module, when an ACL is applied to the port-channel which
 consists of active and standby interfaces (StackWise Virtual platform), the ACL gets programmed in the
 TCAM of both active and standby switches. In case of scaled ACL configuration, make sure there is
 enough TCAM space available in both active and standby switches before applying the ACL.
- On Cisco Catalyst 9600 Series Supervisor 2 Module, TCAM entries of an ACL attached to a Layer 3 port-channel or member port are deleted when the Layer 3 port-channel or member port is shut down. Make sure the Layer 3 port-channel or member port is up before attaching the ACL.
- On Cisco Catalyst 9600 Series Supervisor 2 Module, security ACL is not supported for MPLS tagged traffic.

IPv4 ACL Network Interfaces

The following restrictions apply to IPv4 ACLs to network interfaces:

- When controlling access to an interface, you can use a named or numbered ACL.
- If you apply an ACL to a Layer 2 interface that is a member of a VLAN, the Layer 2 (port) ACL takes precedence over an input Layer 3 ACL applied to the VLAN interface or a VLAN map applied to the VLAN.
- If you apply an ACL to a Layer 3 interface and routing is not enabled on the switch, the ACL only filters packets that are intended for the CPU, such as SNMP, Telnet, or web traffic.
- If the preauth_ipv4_acl ACL is configured to filter packets, the ACL is removed after authentication.

IPv4 ACLs

• You do not have to enable routing to apply ACLs to Layer 2 interfaces.

MAC ACLs on a Layer 2 Interface

After you create a MAC ACL, you can apply it to a Layer 2 interface to filter non-IP traffic coming in that interface. When you apply the MAC ACL, consider these guidelines:

- You can apply no more than one IP access list and one MAC access list to the same Layer 2 interface. The IP access list filters only IP packets, and the MAC access list filters non-IP packets.
- A Layer 2 interface can have only one MAC access list. If you apply a MAC access list to a Layer 2 interface that has a MAC ACL configured, the new ACL replaces the previously configured one.

Note The **mac access-group** interface configuration command is only valid when applied to a physical Layer 2 interface. You cannot use the command on EtherChannel port channels.

IP Access List Entry Sequence Numbering

• This feature does not support dynamic, reflexive, or firewall access lists.

Information About IPv4 Access Control Lists

ACL Overview

Packet filtering can help limit network traffic and restrict network use by certain users or devices. ACLs filter traffic as it passes through a device and permit or deny packets crossing specified interfaces. An ACL is a sequential collection of permit and deny conditions that apply to packets. When a packet is received on an interface, the switch compares the fields in the packet against any applied ACLs to verify that the packet has the required permissions to be forwarded, based on the criteria specified in the access lists. One by one, it tests packets against the conditions in an access list. The first match decides whether the switch accepts or rejects the packets. Because the switch rejects the packet. If there are no restrictions, the switch forwards the packet; otherwise, the switch drops the packet. The switch can use ACLs on all packets it forwards.

You configure access lists on a device to provide basic security for your network. If you do not configure ACLs, all packets passing through the switch could be allowed onto all parts of the network. You can use ACLs to control which hosts can access different parts of a network or to decide which types of traffic are forwarded or blocked at device interfaces. For example, you can allow e-mail traffic to be forwarded but not Telnet traffic.

Access Control Entries

An ACL contains an ordered list of access control entries (ACEs). Each ACE specifies *permit* or *deny* and a set of conditions the packet must satisfy in order to match the ACE. The meaning of *permit* or *deny* depends on the context in which the ACL is used.

ACL Supported Types

The device supports IP ACLs and Ethernet (MAC) ACLs:

- IP ACLs filter IPv4 traffic, including TCP, User Datagram Protocol (UDP), Internet Group Management Protocol (IGMP), and Internet Control Message Protocol (ICMP).
- Ethernet ACLs filter non-IP traffic.

This device also supports quality of service (QoS) classification ACLs.

Supported ACLs

The switch supports three types of ACLs to filter the traffic:

- Port ACLs access-control traffic entering a Layer 2 interface. You can apply port ACLs to a Layer 2 interface in each direction to each access list type—IPv4 and MAC.
- Router ACLs access-control traffic routed between VLANs and are applied to Layer 3 interfaces in a specific direction (inbound or outbound).

ACL Precedence

When VLAN maps, Port ACLs, and router ACLs are configured on the same switch, the filtering precedence, from greatest to least for ingress traffic is port ACL, VLAN map, and then router ACL. For egress traffic, the filtering precedence is router ACL, VLAN map, and then port ACL.

The following examples describe simple use cases:

- When both an input port ACL and a VLAN map are applied, incoming packets received on ports with a
 port ACL applied are filtered by the port ACL. Other packets are filtered by the VLAN map
- When an input router ACL and input port ACL exist in a switch virtual interface (SVI), incoming packets received on ports to which a port ACL is applied are filtered by the port ACL. Incoming routed IP packets received on other ports are filtered by the router ACL. Other packets are not filtered.
- When an output router ACL and input port ACL exist in an SVI, incoming packets received on the ports to which a port ACL is applied are filtered by the port ACL. Outgoing routed IP packets are filtered by the router ACL. Other packets are not filtered.
- When a VLAN map, input router ACL, and input port ACL exist in an SVI, incoming packets received on the ports to which a port ACL is applied are only filtered by the port ACL. Incoming routed IP packets received on other ports are filtered by both the VLAN map and the router ACL. Other packets are filtered only by the VLAN map.
- When a VLAN map, output router ACL, and input port ACL exist in an SVI, incoming packets received on the ports to which a port ACL is applied are only filtered by the port ACL. Outgoing routed IP packets are filtered by both the VLAN map and the router ACL. Other packets are filtered only by the VLAN map.

Port ACLs

Port ACLs are ACLs that are applied to Layer 2 interfaces on a switch. Port ACLs are supported on physical interfaces and EtherChannel interfaces but not on EtherChannel member interfaces. Port ACLs can be applied to the interface in inbound and outbound direction. The following access lists are supported:

- · Standard IP access lists using source addresses
- Extended IP access lists using source and destination addresses and optional protocol type information
- MAC extended access lists using source and destination MAC addresses and optional protocol type information

The switch examines ACLs on an interface and permits or denies packet forwarding based on how the packet matches the entries in the ACL. In this way, ACLs control access to a network or to part of a network.

Figure 15: Using ACLs to Control Traffic in a Network

This is an example of using port ACLs to control access to a network when all workstations are in the same VLAN. ACLs applied at the Layer 2 input would allow Host A to access the Human Resources network, but prevent Host B from accessing the same network. Port ACLs can only be applied to Layer 2 interfaces in the

inbound direction.

When you apply a port ACL to a trunk port, the ACL filters traffic on all VLANs present on the trunk port. When you apply a port ACL to a port with voice VLAN, the ACL filters traffic on both data and voice VLANs.

With port ACLs, you can filter IP traffic by using IP access lists and non-IP traffic by using MAC addresses. You can filter both IP and non-IP traffic on the same Layer 2 interface by applying both an IP access list and a MAC access list to the interface.

Note

You can't apply more than one IP access list and one MAC access list to a Layer 2 interface. If an IP access list or MAC access list is already configured on a Layer 2 interface and you apply a new IP access list or MAC access list to the interface, the new ACL replaces the previously configured one.

Router ACLs

You can apply router ACLs on switch virtual interfaces (SVIs), which are Layer 3 interfaces to VLANs; on physical Layer 3 interfaces; and on Layer 3 EtherChannel interfaces. You apply router ACLs on interfaces for specific directions (inbound or outbound). You can apply one router ACL in each direction on an interface.

Note On Cisco Catalyst 9600 Series Supervisor 2 Module, router ACLs are supported only on Layer 3 interfaces such as SVIs, port channel interfaces, and subinterfaces.

The switch supports these access lists for IPv4 traffic:

- Standard IP access lists use source addresses for matching operations.
- Extended IP access lists use source and destination addresses and optional protocol type information for matching operations.

As with port ACLs, the switch examines ACLs associated with features configured on a given interface. As packets enter the switch on an interface, ACLs associated with all inbound features configured on that interface are examined. After packets are routed and before they are forwarded to the next hop, all ACLs associated with outbound features configured on the egress interface are examined.

ACLs permit or deny packet forwarding based on how the packet matches the entries in the ACL, and can be used to control access to a network or to part of a network.

VLAN Maps

VLAN ACLs or VLAN maps are used to control the network traffic within a VLAN. You can apply VLAN maps to all packets that are bridged within a VLAN in the switch or switch stack. VACLs are strictly for the security packet filtering and for redirecting traffic to specific physical interfaces. VACLs are not defined by direction (ingress or egress).

All non-IP protocols are access-controlled through MAC addresses and Ethertype using MAC VLAN maps. (IP traffic is not access-controlled by MAC VLAN maps.) You can enforce VLAN maps only on packets going through the switch; you cannot enforce VLAN maps on traffic between hosts on a hub or on another switch that is connected to this switch.

With VLAN maps, forwarding of packets is permitted or denied, based on the action specified in the map.

Figure 16: Using VLAN Maps to Control Traffic

This figure shows how a VLAN map is applied to prevent a specific type of traffic from Host A in VLAN 10 from being forwarded. You can apply only one VLAN map to a VLAN.

ACEs and Fragmented and Unfragmented Traffic

IP packets can be fragmented as they cross the network. When this happens, only the fragment containing the beginning of the packet contains the Layer 4 information, such as TCP or UDP port numbers, ICMP type and code, and so on. All other fragments are missing this information.

Some access control entries (ACEs) do not check Layer 4 information and therefore can be applied to all packet fragments. ACEs that do test Layer 4 information cannot be applied in the standard manner to most of the fragments in a fragmented IP packet. When the fragment contains no Layer 4 information and the ACE tests some Layer 4 information, the matching rules are modified:

• Permit ACEs that check the Layer 3 information in the fragment (including protocol type, such as TCP, UDP, and so on) are considered to match the fragment regardless of what the missing Layer 4 information might have been.

- **Note** For TCP ACEs with L4 Ops, the fragmented packets will be dropped per RFC 1858.
 - Deny ACEs that check Layer 4 information never match a fragment unless the fragment contains Layer 4 information.

Standard and Extended IPv4 ACLs

An ACL is a sequential collection of permit and deny conditions. One by one, the device tests packets against the conditions in an access list. The first match determines whether the device accepts or rejects the packet. Because the device stops testing after the first match, the order of the conditions is critical. If no conditions match, the device denies the packet.

The software supports these types of ACLs or access lists for IPv4:

- Standard IP access lists use source addresses for matching operations.
- Extended IP access lists use source and destination addresses for matching operations and optional
 protocol-type information for finer granularity of control.

IPv4 ACL Switch Unsupported Features

The following ACL-related features are not supported:

- Non-IP protocol ACLs
- IP accounting
- Reflexive ACLs and dynamic ACLs are not supported.

Access List Numbers

The number you use to denote your ACL shows the type of access list that you are creating.

This lists the access-list number and corresponding access list type and shows whether or not they are supported in the switch. The switch supports IPv4 standard and extended access lists, numbers 1 to 199 and 1300 to 2699.

Access List Number	Туре	Supported
1–99	IP standard access list	Yes
100–199	IP extended access list	Yes
200–299	Protocol type-code access list	No
300–399	DECnet access list	No
400–499	XNS standard access list	No
500–599	XNS extended access list	No
600–699	AppleTalk access list	No
700–799	48-bit MAC address access list	No
800–899	IPX standard access list	No
900–999	IPX extended access list	No
1000–1099	IPX SAP access list	No
1100–1199	Extended 48-bit MAC address access list	No
1200–1299	IPX summary address access list	No
1300–1999	IP standard access list (expanded range)	Yes
2000–2699	IP extended access list (expanded range)	Yes

Table 22: Access List Numbers

In addition to numbered standard and extended ACLs, you can also create standard and extended named IP ACLs by using the supported numbers. That is, the name of a standard IP ACL can be 1 to 99; the name of an extended IP ACL can be 100 to 199. The advantage of using named ACLs instead of numbered lists is that you can delete individual entries from a named list.

Numbered Standard IPv4 ACLs

When creating an ACL, remember that, by default, the end of the ACL contains an implicit deny statement for all packets that it did not find a match for before reaching the end. With standard access lists, if you omit the mask from an associated IP host address ACL specification, 0.0.0.0 is assumed to be the mask.

Starting from the Cisco IOS XE Bengaluru 17.5.1 release, when using the **show ip access-list** *acl_name* or the **show run section** *acl_name* command, the ACEs are displayed in ascending order according to their sequence numbers.

After creating a numbered standard IPv4 ACL, you can apply it to VLANs, to terminal lines, or to interfaces.

Numbered Extended IPv4 ACLs

Although standard ACLs use only source addresses for matching, you can use extended ACL source and destination addresses for matching operations and optional protocol type information for finer granularity of control. When you are creating ACEs in numbered extended access lists, remember that after you create the ACL, any additions are placed at the end of the list. You cannot reorder the list or selectively add or remove ACEs from a numbered list.

The device does not support dynamic or reflexive access lists. It also does not support filtering based on the type of service (ToS) minimize-monetary-cost bit.

Some protocols also have specific parameters and keywords that apply to that protocol.

You can define an extended TCP, UDP, ICMP, IGMP, or other IP ACL. The device also supports these IP protocols:

Note ICMP echo-reply cannot be filtered. All other ICMP codes or types can be filtered.

These IP protocols are supported:

- Authentication Header Protocol (ahp)
- Encapsulation Security Payload (esp)
- Enhanced Interior Gateway Routing Protocol (eigrp)
- Generic routing encapsulation (gre)
- Internet Control Message Protocol (icmp)
- Internet Group Management Protocol (igmp)
- Any Interior Protocol (ip)
- IP in IP tunneling (ipinip)
- KA9Q NOS-compatible IP over IP tunneling (nos)
- Open Shortest Path First routing (ospf)
- Payload Compression Protocol (pcp)
- Protocol-Independent Multicast (pim)
- Transmission Control Protocol (tcp)
- User Datagram Protocol (**udp**)

Named IPv4 ACLs

You can identify IPv4 ACLs with an alphanumeric string (a name) rather than a number. You can use named ACLs to configure more IPv4 access lists in a device than if you were to use numbered access lists. If you identify your access list with a name rather than a number, the mode and command syntax are slightly different. However, not all commands that use IP access lists accept a named access list.

Note The name you give to a standard or extended ACL can also be a number in the supported range of access list numbers. That is, the name of a standard IP ACL can be 1 to 99. The advantage of using named ACLs instead of numbered lists is that you can delete individual entries from a named list.

Consider these guidelines before configuring named ACLs:

- Numbered ACLs are also available.
- A standard ACL and an extended ACL cannot have the same name.
- You can use standard or extended ACLs (named or numbered) in VLAN maps.

ACL Logging

The device software can provide logging messages about packets permitted or denied by a standard IP access list. That is, any packet that matches the ACL causes an informational logging message about the packet to be sent to the console. The level of messages logged to the console is controlled by the **logging console** commands controlling the syslog messages.

ACL logging is not supported for ACLs used with Unicast Reverse Path Forwarding (uRPF). It is only supported for router ACL.

Note Because routing is done in hardware and logging is done in software, if a large number of packets match a *permit* or *deny* ACE containing a **log** keyword, the software might not be able to match the hardware processing rate, and not all packets will be logged.

The first packet that triggers the ACL causes a logging message right away, and subsequent packets are collected over 5-minute intervals before they appear or logged. The logging message includes the access list number, whether the packet was permitted or denied, the source IP address of the packet, and the number of packets from that source permitted or denied in the prior 5-minute interval.

Note The logging facility might drop some logging message packets if there are too many to be handled or if there is more than one logging message to be handled in 1 second. This behavior prevents the device from crashing due to too many logging packets. Therefore, the logging facility should not be used as a billing tool or an accurate source of the number of matches to an access list.

Hardware and Software Treatment of IP ACLs

ACL processing is performed in hardware. If the hardware reaches its capacity to store ACL configurations, all packets on that interface are dropped.

For router ACLs, other factors can cause packets to be sent to the CPU:

- Using the log keyword
- Generating ICMP unreachable messages

When you enter the **show ip access-lists** privileged EXEC command, the match count displayed does not account for packets that are access controlled in hardware. Use the **show platform software fed switch** { *switch_num* | **active** | **standby** } **acl counters hardware** privileged EXEC command to obtain some basic hardware ACL statistics for switched and routed packets.

Router ACLs function as follows:

- The hardware controls permit and deny actions of standard and extended ACLs (input and output) for security access control.
- If **log** has not been specified, the flows that match a *deny* statement in a security ACL are dropped by the hardware if *ip unreachables* is disabled. The flows matching a *permit* statement are switched in hardware.
- Adding the **log** keyword to an ACE in a router ACL causes a copy of the packet to be sent to the CPU for logging only. If the ACE is a *permit* statement, the packet is still switched and routed in hardware.

VLAN Map Configuration Guidelines

VLAN maps are the only way to control filtering within a VLAN. VLAN maps have no direction. To filter traffic in a specific direction by using a VLAN map, you need to include an ACL with specific source or destination addresses. If there is a match clause for that type of packet (IP or MAC) in the VLAN map, the default action is to drop the packet if the packet does not match any of the entries within the map. If there is no match clause for that type of packet.

The following are the VLAN map configuration guidelines:

- If there is no ACL configured to deny traffic on an interface and no VLAN map is configured, all traffic is permitted.
- Each VLAN map consists of a series of entries. The order of entries in an VLAN map is important. A packet that comes into the device is tested against the first entry in the VLAN map. If it matches, the action specified for that part of the VLAN map is taken. If there is no match, the packet is tested against the next entry in the map.
- If the VLAN map has at least one match clause for the type of packet (IP or MAC) and the packet does not match any of these match clauses, the default is to drop the packet. If there is no match clause for that type of packet in the VLAN map, the default is to forward the packet.
- Logging is not supported for VLAN maps.
- When a device has an IP access list or MAC access list applied to a Layer 2 interface, and you apply a VLAN map to a VLAN that the port belongs to, the port ACL takes precedence over the VLAN map.

• If a VLAN map configuration cannot be applied in hardware, all packets in that VLAN are dropped.

VLAN Maps with Router ACLs

To access control both bridged and routed traffic, you can use VLAN maps only or a combination of router ACLs and VLAN maps. You can define router ACLs on both input and output routed VLAN interfaces, and you can define a VLAN map to access control the bridged traffic.

If a packet flow matches a VLAN-map deny clause in the ACL, regardless of the router ACL configuration, the packet flow is denied.

Note

When you use router ACLs with VLAN maps, packets that require logging on the router ACLs are not logged if they are denied by a VLAN map.

If the VLAN map has a match clause for the type of packet (IP or MAC) and the packet does not match the type, the default is to drop the packet. If there is no match clause in the VLAN map, and no action specified, the packet is forwarded if it does not match any VLAN map entry.

VLAN Maps and Router ACL Configuration Guidelines

These guidelines are for configurations where you need to have an router ACL and a VLAN map on the same VLAN. These guidelines do not apply to configurations where you are mapping router ACLs and VLAN maps on different VLANs.

If you must configure a router ACL and a VLAN map on the same VLAN, use these guidelines for both router ACL and VLAN map configuration:

- You can configure only one VLAN map and one router ACL in each direction (input/output) on a VLAN interface.
- Whenever possible, try to write the ACL with all entries having a single action except for the final, default action of the other type. That is, write the ACL using one of these two forms:

permit... permit... deny ip any any

or

deny... deny... permit ip any any

- To define multiple actions in an ACL (permit, deny), group each action type together to reduce the number of entries.
- Avoid including Layer 4 information in an ACL; adding this information complicates the merging process. The best merge results are obtained if the ACLs are filtered based on IP addresses (source and destination) and not on the full flow (source IP address, destination IP address, protocol, and protocol ports). It is also helpful to use *don't care* bits in the IP address, whenever possible.

If you need to specify the full-flow mode and the ACL contains both IP ACEs and TCP/UDP/ICMP ACEs with Layer 4 information, put the Layer 4 ACEs at the end of the list. This gives priority to the filtering of traffic based on IP addresses.

Time Ranges for ACLs

You can selectively apply extended ACLs based on the time of day and the week by using the **time-range** global configuration command. First, define a time-range name and set the times and the dates or the days of the week in the time range. Then enter the time-range name when applying an ACL to set restrictions to the access list. You can use the time range to define when the permit or deny statements in the ACL are in effect, for example, during a specified time period or on specified days of the week. The **time-range** keyword and argument are referenced in the named and numbered extended ACL task tables.

These are some benefits of using time ranges:

- You have more control over permitting or denying a user access to resources, such as an application (identified by an IP address/mask pair and a port number).
- You can control logging messages. ACL entries can be set to log traffic only at certain times of the day. Therefore, you can simply deny access without needing to analyze many logs generated during peak hours.

Time-based access lists trigger CPU activity because the new configuration of the access list must be merged with other features and the combined configuration loaded into the hardware memory. For this reason, you should be careful not to have several access lists configured to take affect in close succession (within a small number of minutes of each other.)

Note The time range relies on the device system clock; therefore, you need a reliable clock source. We recommend that you use Network Time Protocol (NTP) to synchronize the device clock.

IPv4 ACL Interface Considerations

For inbound ACLs, after receiving a packet, the device checks the packet against the ACL. If the ACL permits the packet, the device continues to process the packet. If the ACL rejects the packet, the device discards the packet.

For outbound ACLs, after receiving and routing a packet to a controlled interface, the device checks the packet against the ACL. If the ACL permits the packet, the device sends the packet. If the ACL rejects the packet, the device discards the packet.

By default, the input interface sends ICMP Unreachable messages whenever a packet is discarded, regardless of whether the packet was discarded because of an ACL on the input interface or because of an ACL on the output interface. ICMP Unreachables are normally limited to no more than one every one-half second per input interface, but this can be changed by using the **ip icmp rate-limit unreachable** global configuration command.

When you apply an undefined ACL to an interface, the device acts as if the ACL has not been applied to the interface and permits all packets. Remember this behavior if you use undefined ACLs for network security.

How to Configure IPv4 Access Control Lists

Configuring IPv4 ACLs

These are the steps to use IP ACLs on the switch:

Procedure

Step 1 Create an ACL by specifying an access list number or name and the access conditions.Step 2 Apply the ACL to interfaces or terminal lines. You can also apply standard and extended IP ACLs to VLAN maps.

Creating a Numbered Standard ACL

Follow these steps to create a numbered standard ACL:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	access-list access-list-number {deny permit} source source-wildcard]	Defines a standard IPv4 access list by using a source address and wildcard.
	Example: Device(config)# access-list 2 deny your_host	The <i>access-list-number</i> is a decimal number from 1 to 99 or 1300 to 1999.
		Enter deny or permit to specify whether to deny or permit access if conditions are matched.
		The <i>source</i> is the source address of the network or host from which the packet is being sent specified as:
		• The 32-bit quantity in dotted-decimal format.
		• The keyword any as an abbreviation for <i>source</i> and <i>source-wildcard</i> of 0.0.0.0

I

	Command or Action	Purpose
		255.255.255.255. You do not need to enter a source-wildcard.
		• The keyword host as an abbreviation for source and <i>source-wildcard</i> of <i>source</i> 0.0.0.0.
		(Optional) The <i>source-wildcard</i> applies wildcard bits to the source.
		Note Logging is supported only on ACLs attached to Layer 3 interfaces.
Step 4	end Example:	Exits global configuration mode and returns to privileged EXEC mode.
	Device(config)# end	

Creating a Numbered Extended ACL

Follow these steps to create a numbered extended ACL:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	access-list access-list-number {deny permit} protocol source source-wildcard destination destination-wildcard [precedence precedence] [tos tos] [fragments] [time-range time-range-name] [dscp dscp]Example:	Defines an extended IPv4 access list and the access conditions.
		The <i>access-list-number</i> is a decimal number from 100 to 199 or 2000 to 2699.
		Enter deny or permit to specify whether to deny or permit the packet if conditions are
	Device (config) # access-list 101 permit ip host 10.1.1.2 any precedence 0 tos 0	matched.
	log	Source, source-wildcard, destination, and destination-wildcard can be specified as:
		• The 32-bit quantity in dotted-decimal format.

	Command or Action	Purpose
		• The keyword any for 0.0.0.0 255.255.255.255 (any host).
		• The keyword host for a single host 0.0.0.0.
		The other keywords are optional and have these meanings:
		• precedence : Enter to match packets with a precedence level specified as a number from 0 to 7 or by name: routine (0), priority (1), immediate (2), flash (3), flash-override (4), critical (5), internet (6), network (7).
		• fragments : Enter to check non-initial fragments.
		 tos: Enter to match by type of service level, specified by a number from 0 to 15 or a name: normal (0), max-reliability (2), max-throughput (4), min-delay (8).
		• time-range: Specify the time-range name.
		• dscp : Enter to match packets with the DSCP value specified by a number from 0 to 63, or use the question mark (?) to see a list of available values.
		NoteIf you enter a dscp value, you cannot enter tos or precedence. You can enter both a tos and a precedence value with no dscp.
Step 4	access-list access-list-number {deny permit} tcp source source-wildcard [operator port]	Defines an extended TCP access list and the access conditions.
	<pre>destination destination-wildcard [operator port] [established] [precedence precedence] [tos tos] [fragments] [time-range time-range-name] [dscp dscp] [flag] Example: Device (config) # access-list 101 permit tcp any any eq 500</pre>	The parameters are the same as those described for an extended IPv4 ACL, with these exceptions:
		(Optional) Enter an <i>operator</i> and <i>port</i> to
		compare source (if positioned after <i>source</i> <i>source-wildcard</i>) or destination (if positioned after <i>destination destination-wildcard</i>) port. Possible operators include eq (equal), gt (greater than), lt (less than), neq (not equal), and range (inclusive range). Operators require a port number (range requires two port numbers separated by a space).

I

	Command or Action	Purpose
		Enter the <i>port</i> number as a decimal number (from 0 to 65535) or the name of a TCP port. Use only TCP port numbers or names when filtering TCP.
		The other optional keywords have these meanings:
		• established : Enter to match an established connection. This has the same function as matching on the ack or rst flag.
		 <i>flag</i>: Enter one of these flags to match by the specified TCP header bits: ack (acknowledge), fin (finish), psh (push), rst (reset), syn (synchronize), or urg (urgent).
Step 5	access-list access-list-number {deny permit} udp source source-wildcard [operator port]	(Optional) Defines an extended UDP access list and the access conditions.
	<pre>destination destination-wildcard [operator port] [precedence precedence] [tos tos] [fragments] [time-range time-range-name] [dscp dscp] Example: Device (config) # access-list 101 permit udp any any eq 100</pre>	The UDP parameters are the same as those described for TCP except that the [operator [port]] port number or name must be a UDP port number or name, and the flag and established keywords are not valid for UDP.
Step 6	access-list access-list-number {deny permit} icmp source source-wildcard destination	Defines an extended ICMP access list and the access conditions.
	destination-wildcard [icmp-type [[icmp-type icmp-code] [icmp-message]] [precedence precedence] [tos tos] [fragments] [time-range time-range-name] [dscp dscp] Example:	The ICMP parameters are the same as those described for most IP protocols in an extended IPv4 ACL, with the addition of the ICMP message type and code parameters. These optional keywords have these meanings:
	Device(config)# access-list 101 permit icmp any any 200	• <i>icmp-type</i> : Enter to filter by ICMP message type, a number from 0 to 255.
		• <i>icmp-code</i> : Enter to filter ICMP packets that are filtered by the ICMP message code type, a number from 0 to 255.
		• <i>icmp-message</i> : Enter to filter ICMP packets by the ICMP message type name or the ICMP message type and code name
Step 7	access-list access-list-number {deny permit} igmp source source-wildcard destination destination-wildcard [igmp-type] [precedence	(Optional) Defines an extended IGMP access list and the access conditions.

I

	Command or Action	Purpose
	precedence] [tos tos] [fragments] [time-range	±
	time-range-name] [dscp dscp]	described for most IP protocols in an extended
	Example:	IPv4 ACL, with this optional parameter.
	Device (config) # access-list 101 permit	<i>igmp-type</i> : To match IGMP message type, enter
	igmp any any 14	a number from 0 to 15, or enter the message name: dvmrp , host-query , host-report , pim , or trace .
Step 8	end	Exits global configuration mode and returns to
1	Example:	privileged EXEC mode.
	Device(config)# end	

Creating Named Standard ACLs

Follow these steps to create a standard ACL using names:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example: Device> enable	Enter your password, if prompted.
Step 2	configure terminal	Enters global configuration mode.
	Example: Device# configure terminal	
Step 3	<pre>ip access-list standard name Example: Device(config)# ip access-list standard 20</pre>	Defines a standard IPv4 access list using a name, and enter access-list configuration mode. The name can be a number from 1 to 99.
Step 4	Use one of the following: • deny {source [source-wildcard] host source any} [log] • permit {source [source-wildcard] host source any} [log] Example:	 In access-list configuration mode, specify one or more conditions denied or permitted to decide if the packet is forwarded or dropped. host <i>source</i>: A source and source wildcard of <i>source</i> 0.0.0.0. any: A source and source wildcard of
	Device(config-std-nacl) # deny 192.168.0.0 0.0.255.255 255.255.0.0 0.0.255.255 Or Device(config-std-nacl) # permit 10.108.0.0 0.0.0.0 255.255.255.0 0.0.0.0	0.0.0.0 255.255.255.255.

	Command or Action	Purpose
Step 5	end	Exits access-list configuration mode and returns
	Example:	to privileged EXEC mode.
	<pre>Device(config-std-nacl)# end</pre>	

Creating Extended Named ACLs

Follow these steps to create an extended ACL using names:

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	ip access-list extended name	Defines an extended IPv4 access list using a
	Example:	name, and enter access-list configuration mode.
	Device(config)# ip access-list extended 150	The name can be a number from 100 to 199.
Step 4	{deny permit} protocol {source [source-wildcard] host source any} {destination [destination-wildcard] host destination any} [precedence precedence] [tos tos] [established] [log] [time-range	In access-list configuration mode, specify the conditions allowed or denied. Use the log keyword to get access list logging messages, including violations. • host <i>source</i> : A source and source wildcard
	time-range-name]	of source 0.0.0.0.
	<pre>Example: Device(config-ext-nacl)# permit 0 any any</pre>	• host <i>destintation</i> : A destination and destination wildcard of <i>destination</i> 0.0.0.0.
		• any : A source and source wildcard or destination and destination wildcard of 0.0.0.0 255.255.255.255.
Step 5	end	Exits access-list configuration mode and returns
	Example:	to privileged EXEC mode.
	<pre>Device(config-ext-nacl)# end</pre>	

When you are creating extended ACLs, remember that, by default, the end of the ACL contains an implicit deny statement for everything if it did not find a match before reaching the end. For standard ACLs, if you omit the mask from an associated IP host address access list specification, 0.0.0.0 is assumed to be the mask.

After you create an ACL, any additions are placed at the end of the list. You cannot selectively add ACL entries to a specific ACL. However, you can use **no permit** and **no deny** access-list configuration mode commands to remove entries from a named ACL.

Being able to selectively remove lines from a named ACL is one reason you might use named ACLs instead of numbered ACLs.

What to do next

After creating a named ACL, you can apply it to interfaces or to VLANs .

Configuring Time Ranges for ACLs

Follow these steps to configure a time-range parameter for an ACL:

Command or Action	Purpose
enable	Enables privileged EXEC mode.
Example:	Enter your password, if prompted.
Device> enable	
configure terminal	Enters global configuration mode.
Example:	
Device# configure terminal	
time-range time-range-name	Assigns a meaningful name (for example,
Example:	<i>workhours</i>) to the time range to be created, and
Device(config)# time-range workhours	enters time-range configuration mode. The name cannot contain a space or quotation mark
	and must begin with a letter.
Use one of the following:	Specifies when the function it will be applie
• absolute [start time date] [end time date]	to is operational.
• periodic day-of-the-week hh:mm to	• You can use only one absolute statement
[day-of-the-week] hh:mm	in the time range. If you configure more
• periodic {weekdays weekend daily} hh:mm to hh:mm	than one absolute statement, only the one configured last is executed.
Example:	• You can enter multiple periodic
Device(config-time-range)# absolute start 00:00 1 Jan 2006 end 23:59 1 Jan 2006	statements. For example, you could configure different hours for weekdays and weekends.
or	weekends.
Device(config-time-range)# periodic weekdays 8:00 to 12:00	
end	Exits time-range configuration mode and returns
Example:	to privileged EXEC mode.
Device(config-time-range)# end	
	Example: Device> enable configure terminal Example: Device# configure terminal time-range time-range-name Example: Device (config) # time-range workhours Use one of the following: • absolute [start time date] [end time date] • periodic day-of-the-week hh:mm to [day-of-the-week] hh:mm • periodic {weekdays weekend daily} hh:mm to hh:mm Example: Device (config-time-range) # absolute start 00:00 1 Jan 2006 end 23:59 1 Jan 2006 or Device (config-time-range) # periodic weekdays 8:00 to 12:00 end Example:

What to do next

Repeat the steps if you have multiple items that you want in effect at different times.

Applying an IPv4 ACL to a Terminal Line

You can use numbered ACLs to control access to one or more terminal lines. You cannot apply named ACLs to lines. You must set identical restrictions on all the virtual terminal lines because a user can attempt to connect to any of them.

Follow these steps to restrict incoming and outgoing connections between a virtual terminal line and the addresses in an ACL:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	line [console vty] line-number	Identifies a specific line to configure, and enter
	Example:	in-line configuration mode.
	Device(config)# line console 0	• console : Specifies the console terminal line. The console port is DCE.
		• vty: Specifies a virtual terminal for remote console access.
		The <i>line-number</i> is the first line number in a contiguous group that you want to configure when the line type is specified. The range is from 0 to 16.
Step 4	access-class access-list-number {in out}	Restricts incoming and outgoing connections
	Example:	between a particular virtual terminal line (into
	Device(config-line)# access-class 10 in	a device) and the addresses in an access list.
Step 5	end	Exits line configuration mode and returns to
	Example:	privileged EXEC mode.
	• Device(config-line)# end	

Procedure

Applying an IPv4 ACL to an Interface

This section describes how to apply IPv4 ACLs to network interfaces.

Beginning in privileged EXEC mode, follow these steps to control access to an interface:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface interface-id	Identifies a specific interface for configuration,
	Example:	and enters interface configuration mode.
	Device(config)# interface	The interface can be a Layer 2 interface (port
	gigabitethernet1/0/1	ACL), or a Layer 3 interface (router ACL).
Step 4	ip access-group { <i>access-list-number</i> <i>name</i> }	Controls access to the specified interface.
	{ in out }	
	Example:	
	<pre>Device(config-if) # ip access-group 2 in</pre>	
Step 5	end	Exits interface configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-if)# end	

Procedure

Creating Named MAC Extended ACLs

You can filter non-IPv4 traffic on a VLAN or on a Layer 2 interface by using MAC addresses and named MAC extended ACLs. The procedure is similar to that of configuring other extended named ACLs.

Follow these steps to create a named MAC extended ACL:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	

	Command or Action	Purpose
	Device# configure terminal	
Step 3	<pre>mac access-list extended name Example: Device(config) # mac access-list extended mac1</pre>	Defines an extended MAC access list using a name.
Step 4	<pre>{deny permit} {any host source MAC address source MAC address mask} {any host destination MAC address destination MAC address mask} [type mask lsap lsap mask aarp amber dec-spanning decnet-iv diagnostic dsm etype-6000 etype-8042 lat lavc-sca mop-console mop-dump msdos mumps netbios vines-echo vines-ip xns-idp 0-65535] [cos cos] Example: Device (config-ext-macl) # deny any any decnet-iv Or Device (config-ext-macl) # permit any any</pre>	 In extended MAC access-list configuration mode, specifies to permit or deny any source MAC address, a source MAC address with a mask, or a specific host source MAC address and any destination MAC address, destination MAC address. (Optional) You can also enter these options: <i>type mask</i>—An arbitrary EtherType number of a packet with Ethernet II or SNAP encapsulation in decimal, hexadecimal, or octal with optional mask of <i>don't care</i> bits applied to the EtherType before testing for a match. Isap <i>lsap mask</i>—An LSAP number of a packet with IEEE 802.2 encapsulation in decimal, hexadecimal, or octal with optional mask of <i>don't care</i> bits. aarp amber dec-spanning decnet-iv diagnostic dsm etype-6000 etype-8042 lat lavc-sca mop-console mop-dump msdos mumps netbios vines-echo vines-ip xns-idp—A non-II protocol.
Step 5	end Example:	Exits extended MAC access-list configuration mode and returns to privileged EXEC mode.
	<pre>Device(config-ext-macl)# end</pre>	

Applying a MAC ACL to a Layer 2 Interface

Follow these steps to apply a MAC access list to control access to a Layer 2 interface:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface interface-id	Identifies a specific interface, and enters
	Example:	interface configuration mode. The interface must be a physical Layer 2 interface (port ACL).
	Device(config)# interface gigabitethernet1/0/2	must be a physical Layer 2 interface (port AC)
Step 4	<pre>mac access-group {name} {in out }</pre>	Controls access to the specified interface by
	Example:	using the MAC access list.
	Device(config-if) # mac access-group macl in	Port ACLs are supported in the outbound and inbound directions .
Step 5	end	Exits interface configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-if)# end	
Step 6	show mac access-group [interface <i>interface-id</i>]	Displays the MAC access list applied to the interface or all Layer 2 interfaces.
	Example:	
	Device# show mac access-group interface gigabitethernet1/0/2	

After receiving a packet, the device checks it against the inbound ACL. If the ACL permits it, the device continues to process the packet. If the ACL rejects the packet, the device discards it. When you apply an undefined ACL to an interface, the device acts as if the ACL has not been applied and permits all packets. Remember this behavior if you use undefined ACLs for network security.

Configuring an IPv4 ACL in Template Mode

Note

You can configure ip access-group command in the template configuration mode. You can configure the source template command only once to an interface.

Beginning in privileged EXEC mode, follow these steps to configure ACL in a template:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	ip access-list extended name	Defines an extended IPv4 access list using a
	Example:	name, and enter access-list configuration mode
	<pre>Device(config)# ip access-list extended 150</pre>	
		Enter <i>number</i> to define extended IP access-list number. The range is from 100 to 199.
		Enter <i>ext_number</i> to define extended IP access-list number. The expanded range is from 2000 to 2699.
Step 4	<pre>ip access-list extended {name number ext_number}</pre>	Defines an extended IPv4 access list using a name, and enter access-list configuration mode.
	Example:	Enter name to define access-list name.
	Device(config) # ip access-list extended 151	Enter <i>number</i> to define extended IP access-list number. The range is from 100 to 199.
		Enter <i>ext_number</i> to define extended IP access-list number. The expanded range is from 2000 to 2699.
Step 5	exit	Exits access-list configuration mode.
	Example:	
	<pre>Device(config-ext-nacl)# exit</pre>	
Step 6	template	Creates a user template and enters template
	Example:	configuration mode.
	Device# template test	
Step 7	ip access-group { <i>access-list-number</i> <i>name</i> }	Controls access to the specified interface.
-	{ in out }	Enter <i>access-list-number</i> to define the access
	Example:	list. The access list can be a number.
	<pre>Device(config-template)# ip access-group 150 in</pre>	Enter <i>name</i> to define the access list. The access list can be a name.

	Command or Action	Purpose
		Enter in to direct the access list in the incoming direction of the interface.
		Enter out to direct the access list in the outgoing direction of the interface.
Step 8	exit	Exits template configuration mode and returns
	Example:	to privileged EXEC mode.
	<pre>Device(config-template)# exit</pre>	
Step 9	interface interface-id	Identifies a specific interface for configuration,
	Example:	and enters interface configuration mode.
	Device(config)# interface gigabitethernet1/0/1	The interface can be a Layer 2 interface (port ACL), or a Layer 3 interface (router ACL).
Step 10	ip access-group { <i>access-list-number</i> <i>name</i> }	Controls access to the specified interface.
	{in out}	Enter <i>access-list-number</i> to define the access
	Example:	list. The access list can be a number.
	<pre>Device(config-if)# ip access-group 151 out</pre>	Enter <i>name</i> to define the access list. The access list can be a name.
		Enter in to direct the access list in the incoming direction of the interface.
		Enter out to direct the access list in the outgoing direction of the interface.
Step 11	source template name	Applies an interface template to a target. The
	Example:	accesss list 150 is the incoming access list that is configured.
	Device(config) # source template test	is configured.
Step 12	end	Exits global configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config)# end	

Configuring VLAN Maps

To create a VLAN map and apply it to one or more VLANs, perform these steps:

Before you begin

Create the standard or extended IPv4 ACLs or named MAC extended ACLs that you want to apply to the VLAN.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	vlan access-map name [number]	Creates a VLAN map, and give it a name and
	Example:	(optionally) a number. The number is the sequence number of the entry within the map
	Device(config) # vlan access-map map1 20	
		When you create VLAN maps with the same name, numbers are assigned sequentially in increments of 10. When modifying or deletin maps, you can enter the number of the map entry that you want to modify or delete.
		VLAN maps do not use the specific permit of deny keywords. To deny a packet by using VLAN maps, create an ACL that would matc the packet, and set the action to drop. A perm in the ACL counts as a match. A deny in the ACL means no match.
		Entering this command changes to access-ma configuration mode.
Step 4	match { ip mac } address { <i>name</i> <i>number</i> } [<i>name</i> <i>number</i>]	Match the packet (using either the IP or MAC address) against one or more standard or
	Example:	extended access lists. Note that packets are onl matched against access lists of the correct
	Device(config-access-map)# match ip address ip2	protocol type. IP packets are matched against standard or extended IP access lists. Non-IP packets are only matched against named MA extended access lists.
		Note If the VLAN map is configured with a match clause for a type of packet (IP or MAC) and the map action is drop, all packets that match the type are dropped. If the VLAN map has no match clause and the configured action is drop all IP and Layer 2 packets are dropped.
Step 5	Enter one of the following commands to specify an IP packet or a non-IP packet (with only a	Sets the action for the map entry.

I

	Command or Action	Purpose
	known MAC address) and to match the packet against one or more ACLs (standard or extended):	
	<pre>• action { forward} Device(config-access-map)# action</pre>	
	forward • action { drop}	
	Device(config-access-map)# action drop	
Step 6	<pre>exit Example: Device(config-access-map)# exit</pre>	Exits access-map configuration mode. and returns to global configuration mode.
Step 7	<pre>vlan filter mapname vlan-list list Example: Device(config)# vlan filter map1 vlan-list 20-22</pre>	Applies the VLAN map to one or more VLAN IDs. The list can be a single VLAN ID (22), a consecutive list (10-22), or a string of VLAN IDs (12, 22, 30). Spaces around the comma and hyphen are optional.
Step 8	end Example: Device (config) # end	Exits global configuration mode and returns to privileged EXEC mode.

Applying a VLAN Map to a VLAN

To apply a VLAN map to one or more VLANs, perform these steps.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	vlan filter mapname vlan-list list	Applies the VLAN map to one or more VLAN
	Example:	IDs.

	Command or Action	Purpose
	Device(config)# vlan filter map 1 vlan-list 20-22	The list can be a single VLAN ID (22), a consecutive list (10-22), or a string of VLAN IDs (12, 22, 30). Spaces around the comma and hyphen are optional.
Step 4	end	Exits global configuration mode and returns to
	<pre>Example: Device(config)# end</pre>	privileged EXEC mode.

Monitoring IPv4 ACLs

You can monitor IPv4 ACLs by displaying the ACLs that are configured on the device, and displaying the ACLs that have been applied to interfaces and VLANs.

When you use the **ip access-group** interface configuration command to apply ACLs to a Layer 2 or 3 interface, you can display the access groups on the interface. You can also display the MAC ACLs applied to a Layer 2 interface. You can use the privileged EXEC commands as described in this table to display this information.

Command	Purpose
show access-lists [number name]	Displays the contents of one or all current IP and MAC address a specific access list (numbered or named).
show ip access-lists [number name]	Displays the contents of all current IP access lists or a specific I (numbered or named).
show ip interface interface-id	Displays detailed configuration and status of an interface. If IP the interface and ACLs have been applied by using the ip access-g configuration command, the access groups are included in the d
show running-config [interface interface-id]	Displays the contents of the configuration file for the device or interface, including all configured MAC and IP access lists and groups are applied to an interface.
show mac access-group [interface interface-id]	Displays MAC access lists applied to all Layer 2 interfaces or the Layer 2 interface.

Table 23: Commands for Displaying Access Lists and Access Groups

Configuration Examples for IPv4 Access Control Lists

ACLs in a Small Networked Office

Figure 17: Using Router ACLs to Control Traffic

This shows a small networked office environment with routed Port 2 connected to Server A, containing benefits and other information that all employees can access, and routed Port 1 connected to Server B, containing

confidential payroll data. All users can access Server A, but Server B has restricted access.

Use router ACLs to do this in one of two ways:

- Create a standard ACL, and filter traffic coming to the server from Port 1.
- Create an extended ACL, and filter traffic coming from the server into Port 1.

Examples: ACLs in a Small Networked Office

This example uses a standard ACL to filter traffic coming into Server B from a port, permitting traffic only from Accounting's source addresses 172.20.128.64 to 172.20.128.95. The ACL is applied to traffic coming out of routed Port 1 from the specified source address.

```
Device> enable
Device# configure terminal
Device(config)# access-list 6 permit 172.20.128.64 0.0.0.31
Device(config)# exit
Device# show access-lists
Standard IP access list 6
    10 permit 172.20.128.64, wildcard bits 0.0.0.31
Device# configure terminal
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# ip access-group 6 out
Device(config-if)# end
```

This example uses an extended ACL to filter traffic coming from Server B into a port, permitting traffic from any source address (in this case Server B) to only the Accounting destination addresses 172.20.128.64 to 172.20.128.95. The ACL is appliDeviceed to traffic going into routed Port 1, permitting it to go only to the specified destination addresses. Note that with extended ACLs, you must enter the protocol (IP) before the source and destination information.

```
Device(config)# access-list 106 permit ip any 172.20.128.64 0.0.0.31
Device(config)# exit
Device# show access-lists
Extended IP access list 106
    10 permit ip any 172.20.128.64 0.0.0.31
Device# configure terminal
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# ip access-group 106 in
Device(config-if)# end
```

Example: Numbered ACLs

In this example, network 10.0.0.0 is a Class A network whose second octet specifies a subnet; that is, its subnet mask is 255.255.0.0. The third and fourth octets of a network 10.0.0.0 address specify a particular host. Using access list 2, the switch accepts one address on subnet 48 and reject all others on that subnet. The last line of the list shows that the switch accepts addresses on all other network 10.0.0.0 subnets. The ACL is applied to packets entering a port.

```
Device> enable
Device# configure terminal
Device(config)# access-list 2 permit 10.48.0.3
Device(config)# access-list 2 deny 10.48.0.0 0.0.255.255
Device(config)# access-list 2 permit 10.0.0.0 0.255.255.255
Device(config)# interface gigabitethernet2/0/1
Device(config-if)# ip access-group 2 in
Device(config-if)# end
```

Examples: Extended ACLs

In this example, the first line permits any incoming TCP connections with destination ports greater than 1023. The second line permits incoming TCP connections to the Simple Mail Transfer Protocol (SMTP) port of host 172.16.0.0. The third line permits incoming ICMP messages for error feedback.

```
Device> enable
Device# configure terminal
Device(config)# access-list 102 permit tcp any 172.16.0.0 0.0.255.255 gt 1023
Device(config)# access-list 102 permit tcp any host 172.16.1.2 eq 25
Device(config)# access-list 102 permit icmp any any
Device(config)# interface gigabitethernet 2/0/1
Device(config-if)# ip access-group 102 in
Device(config-if)# end
```

In this example, suppose that you have a network connected to the Internet, and you want any host on the network to be able to form TCP connections to any host on the Internet. However, you do not want IP hosts to be able to form TCP connections to hosts on your network, except to the mail (SMTP) port of a dedicated mail host.

SMTP uses TCP port 25 on one end of the connection and a random port number on the other end. The same port numbers are used throughout the life of the connection. Mail packets coming in from the Internet have a destination port of 25. Because the secure system of the network always accepts mail connections on port 25, the incoming sevices are separately controlled.

```
Device> enable
Device# configure terminal
Device(config)# access-list 102 permit tcp any 172.16.0.0 0.0.255.255 eq 23
Device(config)# access-list 102 permit tcp any 172.16.0.0 0.0.255.255 eq 25
Device(config)# interface gigabitethernet 1/0/1
Device(config-if)# ip access-group 102 in
Device(config-if)# end
```

In this example, the network is a Class B network with the address 172.16.0.0, and the mail host address is 172.16.1.2. The **established** keyword is used only for the TCP to show an established connection. A match occurs if the TCP datagram has the ACK or RST bits set, which show that the packet belongs to an existing connection. Gigabit Ethernet interface 1 is the interface that connects the device to the Internet.

```
Device> enable
Device# configure terminal
Device(config)# access-list 102 permit tcp any 172.16.0.0 0.0.255.255 established
Device(config)# access-list 102 permit tcp any host 172.16.1.2 eq 25
Device(config)# interface gigabitethernet 1/0/1
Device(config-if)# ip access-group 102 in
Device(config-if)# end
```

Examples: Named ACLs

Creating named standard and extended ACLs

This example creates a standard ACL named *internet_filter* and an extended ACL named *marketing_group*. The *internet_filter* ACL allows all traffic from the source address 10.2.3.4.

```
Device> enable
Device# configure terminal
Device(config)# ip access-list standard Internet_filter
Device(config-ext-nacl)# permit 10.2.3.4
Device(config-ext-nacl)# exit
Device(config-ext-nacl)# end
```

The *marketing_group* ACL allows any TCP Telnet traffic to the destination address and wildcard 172.16.0.0 0.0.255.255 and denies any other TCP traffic. It permits ICMP traffic, denies UDP traffic from any source to the destination address range 172.16.0.0 through 172.16.255.255 with a destination port less than 1024, denies any other IP traffic, and provides a log of the result.

```
Device> enable
Device# configure terminal
Device(config)# ip access-list extended marketing_group
Device(config-ext-nacl)# permit tcp any 172.16.0.0 0.0.255.255 eq telnet
Device(config-ext-nacl)# deny tcp any any
Device(config-ext-nacl)# permit icmp any any
Device(config-ext-nacl)# deny udp any 172.16.0.0 0.0.255.255 lt 1024
Device(config-ext-nacl)# deny ip any any log
Device(config-ext-nacl)# end
```

The *Internet_filter* ACL is applied to outgoing traffic and the *marketing_group* ACL is applied to incoming traffic on a Layer 3 port.

```
Device> enable
Device# configure terminal
Device(config)# interface gigabitethernet3/0/2
Device(config-if)# no switchport
Device(config-if)# ip address 10.0.5.1 255.255.255.0
```

```
Device(config-if)# ip access-group Internet_filter out
Device(config-if)# ip access-group marketing_group in
Device(config-if)# end
```

Deleting Individual ACEs from Named ACLs

This example shows how to delete individual ACEs from the named access list border-list:

```
Device> enable
Device# configure terminal
Device(config)# ip access-list extended border-list
Device(config-ext-nacl)# no permit ip host 10.1.1.3 any
Device(config-ext-nacl)# end
```

Examples: ACL Logging

Two variations of logging are supported on router ACLs. The **log** keyword sends an informational logging message to the console about the packet that matches the entry; the **log-input** keyword includes the input interface in the log entry.

In this example, standard named access list *stan1* denies traffic from 10.1.1.0 0.0.0.255, allows traffic from all other sources, and includes the **log** keyword.

```
Device> enable
Device# configure terminal
Device(config) # ip access-list standard stan1
Device (config-std-nacl) # deny 10.1.1.0 0.0.0.255 log
Device (config-std-nacl) # permit any log
Device(config-std-nacl)# exit
Device(config)# interface gigabitethernet1/0/1
Device(config-if) # ip access-group stan1 in
Device(config-if) # end
Device# show logging
Syslog logging: enabled (0 messages dropped, 0 flushes, 0 overruns)
    Console logging: level debugging, 37 messages logged
   Monitor logging: level debugging, 0 messages logged
   Buffer logging: level debugging, 37 messages logged
   File logging: disabled
   Trap logging: level debugging, 39 message lines logged
Log Buffer (4096 bytes):
00:00:48: NTP: authentication delay calculation problems
<output truncated>
00:09:34:%SEC-6-IPACCESSLOGS:list stan1 permitted 0.0.0.0 1 packet
00:09:59:%SEC-6-IPACCESSLOGS:list stan1 denied 10.1.1.15 1 packet
00:10:11:%SEC-6-IPACCESSLOGS:list stan1 permitted 0.0.0.0 1 packet
```

This example is a named extended access list *ext1* that permits ICMP packets from any source to 10.1.1.0 0.0.0.255 and denies all UDP packets.

```
Device> enable
Device# configure terminal
Device(config)# ip access-list extended ext1
Device(config-ext-nacl)# permit icmp any 10.1.1.0 0.0.0.255 log
Device(config-ext-nacl)# deny udp any any log
Device(config-std-nacl)# exit
Device(config)# interface gigabitethernet1/0/2
```

Device(config-if) # ip access-group ext1 in
Device(config) # end

This is a an example of a log for an extended ACL:

```
01:24:23:%SEC-6-IPACCESSLOGDP:list ext1 permitted icmp 10.1.1.15 -> 10.1.1.61 (0/0), 1
packet
01:25:14:%SEC-6-IPACCESSLOGDP:list ext1 permitted icmp 10.1.1.15 -> 10.1.1.61 (0/0), 7
packets
01:26:12:%SEC-6-IPACCESSLOGP:list ext1 denied udp 0.0.0.0(0) -> 255.255.255.255(0), 1 packet
01:31:33:%SEC-6-IPACCESSLOGP:list ext1 denied udp 0.0.0.0(0) -> 255.255.255.255(0), 8 packets
```

Note that all logging entries for IP ACLs start with %SEC-6-IPACCESSLOG with minor variations in format depending on the kind of ACL and the access entry that has been matched.

This is an example of an output message when the **log-input** keyword is entered:

```
00:04:21:%SEC-6-IPACCESSLOGDP:list inputlog permitted icmp 10.1.1.10 (Vlan1 0001.42ef.a400)
->
10.1.1.61 (0/0), 1 packet
```

A log message for the same sort of packet using the **log** keyword does not include the input interface information:

```
00:05:47:%SEC-6-IPACCESSLOGDP:list inputlog permitted icmp 10.1.1.10 -> 10.1.1.61 (0/0), 1 packet
```

Example: ACEs and Fragmented and Unfragmented Traffic

Consider access list 102, configured with these commands, applied to three fragmented packets:

```
Device> enable
Device# configure terminal
Device(config)# access-list 102 permit tcp any host 10.1.1.1 eq smtp
Device(config)# access-list 102 deny tcp any host 10.1.1.2 eq telnet
Device(config)# access-list 102 permit tcp any host 10.1.1.2
Device(config)# access-list 102 deny tcp any any
Device(config)# end
```

```
Note
```

In the first and second ACEs in the examples, the eq keyword after the destination address means to test for the TCP-destination-port well-known numbers equaling Simple Mail Transfer Protocol (SMTP) and Telnet, respectively.

- Packet A is a TCP packet from host 10.2.2.2., port 65000, going to host 10.1.1.1 on the SMTP port. If this packet is fragmented, the first fragment matches the first ACE (a permit) as if it were a complete packet because all Layer 4 information is present. The remaining fragments also match the first ACE, even though they do not contain the SMTP port information, because the first ACE only checks Layer 3 information when applied to fragments. The information in this example is that the packet is TCP and that the destination is 10.1.1.1.
- Packet B is from host 10.2.2.2, port 65001, going to host 10.1.1.2 on the Telnet port. If this packet is fragmented, the first fragment matches the second ACE (a deny) because all Layer 3 and Layer 4 information is present. The remaining fragments in the packet do not match the second ACE because they are missing Layer 4 information. Instead, they match the third ACE (a permit).

Because the first fragment was denied, host 10.1.1.2 cannot reassemble a complete packet, so packet B is effectively denied. However, the later fragments that are permitted will consume bandwidth on the network and resources of host 10.1.1.2 as it tries to reassemble the packet.

• Fragmented packet C is from host 10.2.2.2, port 65001, going to host 10.1.1.3, port ftp. If this packet is fragmented, the first fragment matches the fourth ACE (a deny). All other fragments also match the fourth ACE because that ACE does not check any Layer 4 information and because Layer 3 information in all fragments shows that they are being sent to host 10.1.1.3, and the earlier permit ACEs were checking different hosts.

Examples: Using Time Ranges with ACLs

This example shows how to verify after you configure time ranges for *workhours* and to configure January 1, 2006, as a company holiday.

```
Device# show time-range
time-range entry: new_year_day_2003 (inactive)
   absolute start 00:00 01 January 2006 end 23:59 01 January 2006
time-range entry: workhours (inactive)
   periodic weekdays 8:00 to 12:00
   periodic weekdays 13:00 to 17:00
```

To apply a time range, enter the time-range name in an extended ACL that can implement time ranges. This example shows how to create and verify extended access list 188 that denies TCP traffic from any source to any destination during the defined holiday times and permits all TCP traffic during work hours.

```
Device> enable
Device# configure terminal
Device(config)# access-list 188 deny tcp any any time-range new_year_day_2006
Device(config)# access-list 188 permit tcp any any time-range workhours
Device(config)# exit
Device# show access-lists
Extended IP access list 188
   10 deny tcp any any time-range new_year_day_2006 (inactive)
   20 permit tcp any any time-range workhours (inactive)
```

This example uses named ACLs to permit and deny the same traffic.

```
Device> enable
Device# configure terminal
Device(config)# ip access-list extended deny_access
Device(config-ext-nacl)# deny tcp any any time-range new_year_day_2006
Device(config-ext-nacl)# exit
Device(config-ext-nacl)# permit tcp any any time-range workhours
Device(config-ext-nacl)# end
Device# show ip access-lists
Extended IP access list lpip_default
    10 permit ip any any
Extended IP access list deny_access
    10 deny tcp any any time-range new_year_day_2006 (inactive)
Extended IP access list may_access
    10 permit tcp any any time-range workhours (inactive)
```

Examples: Time Range Applied to an IP ACL

This example denies HTTP traffic on IP on Monday through Friday between the hours of 8:00 a.m. and 6:00 p.m (18:00). The example allows UDP traffic only on Saturday and Sunday from noon to 8:00 p.m. (20:00).

```
Device> enable
Device# configure terminal
Device(config)# time-range no-http
Device(config)# periodic weekdays 8:00 to 18:00
Device(config)# time-range udp-yes
Device(config)# periodic weekend 12:00 to 20:00
Device(config)# ip access-list extended strict
Device(config-ext-nacl)# deny tcp any any eq www time-range no-http
Device(config-ext-nacl)# permit udp any any time-range udp-yes
Device(config-ext-nacl)# exit
Device(config)# interface gigabitethernet2/0/1
Device(config-if)# ip access-group strict in
Device(config-if)# end
```

Examples: Including Comments in ACLs

You can use the **remark** keyword to include comments (remarks) about entries in any IP standard or extended ACL. The remarks make the ACL easier for you to understand and scan. Each remark line is limited to 100 characters.

The remark can go before or after a permit or deny statement. You should be consistent about where you put the remark so that it is clear which remark describes which permit or deny statement. For example, it would be confusing to have some remarks before the associated permit or deny statements and some remarks after the associated statements.

To include a comment for IP numbered standard or extended ACLs, use the **access-list** *access-list number* **remark** *remark* global configuration command. To remove the remark, use the **no** form of this command.

In this example, the workstation that belongs to user1 is allowed access, and the workstation that belongs to user2 is not allowed access:

```
Device> enable
Device# configure terminal
Device(config)# access-list 1 remark Permit only user1 workstation through
Device(config)# access-list 1 permit 171.69.2.88
Device(config)# access-list 1 remark Do not allow user2 through
Device(config)# access-list 1 deny 171.69.3.13
Device(config)# end
```

For an entry in a named IP ACL, use the **remark** access-list configuration command. To remove the remark, use the **no** form of this command.

In this example, the subnet1 subnet is not allowed to use outbound Telnet:

```
Device> enable
Device# configure terminal
Device(config)# ip access-list extended telnetting
Device(config-ext-nacl)# remark Do not allow subnet1 subnet to telnet out
Device(config-ext-nacl)# deny tcp host 171.69.2.88 any eq telnet
Device(config-ext-nacl)# end
```

Example: Creating an ACL and a VLAN Map to Deny a Packet

This example shows how to create an ACL and a VLAN map to deny a packet. In the first map, any packets that match the *ip1* ACL (TCP packets) would be dropped. You first create the *ip1* ACL to permit any TCP packet and no other packets. Because there is a match clause for IP packets in the VLAN map, the default action is to drop any IP packet that does not match any of the match clauses.

```
Device> enable
Device# configure terminal
Device(config)# ip access-list extended ip1
Device(config-ext-nacl)# permit tcp any any
Device(config-ext-nacl)# exit
Device(config)# vlan access-map map_1 10
Device(config-access-map)# match ip address ip1
Device(config-access-map)# action drop
Device(config-access-map)# end
```

Example: Creating an ACL and a VLAN Map to Permit a Packet

This example shows how to create a VLAN map to permit a packet. ACL *ip2* permits UDP packets and any packets that match the *ip2* ACL are forwarded. In this map, any IP packets that did not match any of the previous ACLs (that is, packets that are not TCP packets or UDP packets) would get dropped.

```
Device> enable
Device# configure terminal
Device(config)# ip access-list extended ip2
Device(config-ext-nacl)# permit udp any any
Device(config-ext-nacl)# exit
Device(config)# vlan access-map map_1 20
Device(config-access-map)# match ip address ip2
Device(config-access-map)# action forward
Device(config-access-map)# exit
```

Example: Default Action of Dropping IP Packets and Forwarding MAC Packets

In this example, the VLAN map has a default action of drop for IP packets and a default action of forward for MAC packets. Used with standard ACL 101 and extended named access lists **igmp-match** and **tcp-match**, the map will have the following results:

- Forward all UDP packets
- Drop all IGMP packets
- · Forward all TCP packets
- Drop all other IP packets
- · Forward all non-IP packets

```
Device> enable
Device# configure terminal
Device(config)# access-list 101 permit udp any any
Device(config)# ip access-list extended igmp-match
Device(config-ext-nacl)# permit igmp any any
Device(config)# action forward
Device(config-ext-nacl)# permit tcp any any
Device(config-ext-nacl)# exit
Device(config)# vlan access-map drop-ip-default 10
```

```
Device(config-access-map)# match ip address 101
Device(config-access-map)# action forward
Device(config-access-map)# exit
Device(config-access-map drop-ip-default 20
Device(config-access-map)# match ip address igmp-match
Device(config-access-map)# action drop
Device(config-access-map)# exit
Device(config)# vlan access-map drop-ip-default 30
Device(config-access-map)# match ip address tcp-match
Device(config-access-map)# action forward
Device(config-access-map)# action forward
Device(config-access-map)# action forward
```

Example: Default Action of Dropping MAC Packets and Forwarding IP Packets

In this example, the VLAN map has a default action of drop for MAC packets and a default action of forward for IP packets. Used with MAC extended access lists **good-hosts** and **good-protocols**, the map will have the following results:

- Forward MAC packets from hosts 0000.0c00.0111 and 0000.0c00.0211
- Forward MAC packets with decnet-iv or vines-ip protocols
- Drop all other non-IP packets
- Forward all IP packets

```
Device> enable
Device# configure terminal
Device (config) # mac access-list extended good-hosts
Device(config-ext-macl) # permit host 000.0c00.0111 any
Device (config-ext-macl) # permit host 000.0c00.0211 any
Device(config-ext-nacl)# exit
Device (config) # action forward
Device (config-ext-macl) # mac access-list extended good-protocols
Device (config-ext-macl) # permit any any vines-ip
Device(config-ext-nacl) # exit
Device(config) # vlan access-map drop-mac-default 10
Device (config-access-map) # match mac address good-hosts
Device (config-access-map) # action forward
Device(config-access-map)# exit
Device(config) # vlan access-map drop-mac-default 20
Device(config-access-map) # match mac address good-protocols
Device (config-access-map) # action forward
Device(config-access-map)# end
```

Example: Default Action of Dropping All Packets

In this example, the VLAN map has a default action of drop for all packets (IP and non-IP). Used with access lists **tcp-match** and **good-hosts** from Examples 2 and 3, the map will have the following results:

- Forward all TCP packets
- Forward MAC packets from hosts 0000.0c00.0111 and 0000.0c00.0211
- Drop all other IP packets
- Drop all other MAC packets

```
Device> enable
Device# configure terminal
Device(config)# vlan access-map drop-all-default 10
Device(config-access-map)# match ip address tcp-match
Device(config-access-map)# action forward
Device(config-access-map)# exit
Device(config)# vlan access-map drop-all-default 20
Device(config-access-map)# match mac address good-hosts
Device(config-access-map)# action forward
Device(config-access-map)# action forward
```

Example: Using VLAN Maps in a Network

Example: Wiring Closet Configuration

Figure 18: Wiring Closet Configuration

In a wiring closet configuration, routing might not be enabled on the switch. In this configuration, the switch can still support a VLAN map and a QoS classification ACL. Assume that Host X and Host Y are in different VLANs and are connected to wiring closet switches A and C. Traffic from Host X to Host Y is eventually being routed by Switch B, a Layer 3 switch with routing enabled. Traffic from Host X to Host Y can be access-controlled at the traffic entry point, Switch A.

If you do not want HTTP traffic switched from Host X to Host Y, you can configure a VLAN map on Switch A to drop all HTTP traffic from Host X (IP address 10.1.1.32) to Host Y (IP address 10.1.1.34) at Switch A and not bridge it to Switch B.

First, define the IP access list http that permits (matches) any TCP traffic on the HTTP port.

```
Device> enable
Device# configure terminal
Device(config)# ip access-list extended http
Device(config-ext-nacl)# permit tcp host 10.1.1.32 host 10.1.1.34 eq www
Device(config-ext-nacl)# end
```

Next, create VLAN access map *map2* so that traffic that matches the *http* access list is dropped and all other IP traffic is forwarded.

```
Device> enable
Device# configure terminal
Device(config)# vlan access-map map2 10
Device(config-access-map)# match ip address http
Device(config-access-map)# action drop
Device(config-access-map)# exit
Device(config)# ip access-list extended match_all
Device(config-ext-nacl)# permit ip any any
Device(config-ext-nacl)# exit
Device(config)# vlan access-map map2 20
Device(config-access-map)# match ip address match_all
Device(config-access-map)# action forward
Device(config-access-map)# end
```

Then, apply VLAN access map *map2* to VLAN 1.

```
Device> enable
Device# configure terminal
Device(config)# vlan filter map2 vlan 1
Device(config)# end
```

Example: Restricting Access to a Server on Another VLAN

Figure 19: Restricting Access to a Server on Another VLAN

You can restrict access to a server on another VLAN. For example, server 10.1.1.100 in VLAN 10 needs to have access denied to these hosts:

- Hosts in subnet 10.1.2.0/8 in VLAN 20 should not have access.
- Hosts 10.1.1.4 and 10.1.1.8 in VLAN 10 should not have access.

Example: Denying Access to a Server on Another VLAN

This example shows how to deny access to a server on another VLAN by creating the VLAN map SERVER 1 that denies access to hosts in subnet 10.1.2.0.8, host 10.1.1.4, and host 10.1.1.8 and permits other IP traffic. The final step is to apply the map SERVER1 to VLAN 10.

Define the IP ACL that will match the correct packets.

```
Device> enable
Device# configure terminal
Device(config)# ip access-list extended SERVER1 ACL
```

```
Device(config-ext-nacl)# permit ip 10.1.2.0 0.0.0.255 host 10.1.1.100
Device(config-ext-nacl)# permit ip host 10.1.1.4 host 10.1.1.100
Device(config-ext-nacl)# permit ip host 10.1.1.8 host 10.1.1.100
Device(config-ext-nacl)# end
```

Define a VLAN map using this ACL that will drop IP packets that match SERVER1_ACL and forward IP packets that do not match the ACL.

```
Device> enable
Device# configure terminal
Device(config)# vlan access-map SERVER1_MAP
Device(config-access-map)# match ip address SERVER1_ACL
Device(config-access-map)# action drop
Device(config)# vlan access-map SERVER1_MAP 20
Device(config-access-map)# action forward
Device(config-access-map)# end
```

Apply the VLAN map to VLAN 10.

```
Device> enable
Device# configure terminal
Device(config)# vlan filter SERVER1_MAP vlan-list 10
Device(config)# end
```

Feature History for IPv4 Access Control Lists

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.11.1	IPv4 Access Control Lists	This chapter describes how to configure network security on the switch by using ACLs. Packet filtering can help limit network traffic and restrict network use by certain users or devices. ACLs filter traffic as it passes through device and permit or deny packets crossing specified interfaces.
Cisco IOS XE Bengaluru 17.5.1	ACL template support for IPv4	Interface template allows you to configure multiple commands and associate it with an interface. The ip access-group command is used to apply an IPv4 access list under template mode of configuration.
Cisco IOS XE Cupertino 17.7.1	IPv4 Access Control Lists	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

IPv6 ACLs

Restrictions for IPv6 ACLs

IPv6 supports only named ACLs. With IPv4 ACLs, you can configure standard and extended numbered IP ACLs, named IP ACLs, and MAC ACLs.

The switch supports most Cisco IOS-supported IPv6 ACLs with some exceptions:

- The switch does not support matching on these keywords: **flowlabel**, **routing header**, and **undetermined-transport**.
- The switch does not support reflexive ACLs (the reflect keyword).
- The vrf-also keyword is mutually exclusive of IPv6 access-class line command.
- The switch does not apply MAC-based ACLs on IPv6 frames.
- When configuring an ACL, there is no restriction on keywords that are entered in the ACL, regardless of whether they are supported or not on the platform. When you apply the ACL to an interface that requires hardware forwarding (physical ports or SVIs), the switch checks to determine whether ACL can be supported on the interface or not. If the ACL is not supported on the interface, the ACL is rejected.
- If an ACL is applied to an interface and you attempt to add an access control entry (ACE) with an unsupported keyword, the switch does not allow the ACE to be added to the ACL that is currently attached to the interface.
- When you apply a scale ACL to an interface that does not program TCAM for a protocol and the ACLs that have been unloaded, it can impact the existing normal movement of traffic for other protocols. The restriction is applicable to IPv4, IPv6, and MAC address traffic.
- TCAM optimization is not supported on Cisco Catalyst 9600 Series Supervisor 2 Module.
- Time-to-live (TTL) classification is not supported on ACLs.

 On Cisco Catalyst 9600 Series Supervisor 2 Module, only a maximum of 126 IPv6 ACL IDs in ingress, and a maximum of 14 IPv6 ACL IDs in egress are supported.

In ingress, a maximum of 16 ACL IDs are shared among other features such as Security and QoS ACLs, while 1 ACL ID is shared among PBR and EPC ACLs each. While in egress, a maximum of 1 ACL ID is shared among Security and EPC ACLs each.

- ACL for IPv6 next-header and fragmentation is not supported on Cisco Catalyst 9600 Series Supervisor 2 Module.
- Modification of an ACL when it is applied, is supported on Cisco Catalyst 9600 Series Supervisor 2 Module.
- Time-based ACL is supported on Cisco Catalyst 9600 Series Supervisor 2 Module.
- If a downloadable ACL contains any type of duplicate entries, the entries are not auto merged. As a result, the 802.1X session authorization fails. Ensure that the downloadable ACL is optimized without any duplicate entries, for example port-based and name-based entries for the same port.
- Egress ACL lookup is not supported for injected traffic that is forwarded by the software.
- VLAN ACLs and Port ACLs are not supported on Cisco Catalyst 9600 Series Supervisor 2 Module.
- Multicast control packets are not filtered by ACL on Cisco Catalyst 9600 Series Supervisor 2 Module.
- ACLs support only Layer 3 interfaces (such as routed interfaces and VLAN interfaces), port channel interface, and subinterfaces.

There is no support on Layer 2 interfaces on Cisco Catalyst 9600 Series Supervisor 2 Module.

 On Cisco Catalyst 9600 Series Supervisor 2 Module, per ACE statistics is supported only for Deny ACEs. Per ACE statistics for Permit ACE is not supported. If the same ACL is applied to multiple ports, the deny counters are cumulative of all the ports on which the corresponding ACL is attached.

Information About IPv6 ACLs

The following sections provide information about IPv6 ACLs.

IPv6 ACL Overview

This topic provides an overview of IPv6 ACL.

An access control list (ACL) is a set of rules that are used to limit access to a particular interface. ACLs are configured on the device and applied to the management interface and to any of the dynamic interfaces.

You can also create a preauthentication ACL for web authentication. Such an ACL is used to allow certain types of traffic before authentication is complete.

IPv6 ACLs support the same options as IPv4 ACLs including source, destination, source, and destination ports.

Supported ACLs

The switch supports three types of ACLs to filter the traffic:

- Port ACLs access-control traffic entering a Layer 2 interface. You can apply port ACLs to a Layer 2 interface in each direction to each access list type—IPv4 and MAC.
- Router ACLs access-control traffic routed between VLANs and are applied to Layer 3 interfaces in a specific direction (inbound or outbound).

Types of ACL

The following sections provide information on the types of ACL:

Per-User IPv6 ACL

For the per-user ACL, the full access control entries (ACE) as the text strings are configured on the Cisco Secure Access Control Server (Cisco Secure ACS).

Filter ID IPv6 ACL

For the filter-Id ACL, the full ACEs and the acl name(filter-id) is configured on the device and only the filter-id is configured on the Cisco Secure ACS.

ACL Precedence

When Port ACLs, and router ACLs are configured on the same switch, the filtering precedence, from greatest to least for ingress traffic is port ACL, and then router ACL. For egress traffic, the filtering precedence is router ACL, and then port ACL.

The following examples describe simple use cases:

- When an input router ACL and input port ACL exist in a switch virtual interface (SVI), incoming packets that are received on ports to which a port ACL is applied are filtered by the port ACL. Incoming routed IP packets received on other ports are filtered by the router ACL. Other packets are not filtered.
- When an output router ACL and input port ACL exist in an SVI, incoming packets that are received on the ports to which a port ACL is applied are filtered by the port ACL. Outgoing routed IP packets are filtered by the router ACL. Other packets are not filtered.

VLAN Maps

VLAN ACLs or VLAN maps are used to control the network traffic within a VLAN. You can apply VLAN maps to all packets that are bridged within a VLAN in the switch or switch stack. VACLs are strictly for the security packet filtering and for redirecting traffic to specific physical interfaces. VACLs are not defined by direction (ingress or egress).

All non-IP protocols are access-controlled through MAC addresses and Ethertype using MAC VLAN maps. (IP traffic is not access-controlled by MAC VLAN maps.) You can enforce VLAN maps only on packets going through the switch; you cannot enforce VLAN maps on traffic between hosts on a hub or on another switch that is connected to this switch.

With VLAN maps, forwarding of packets is permitted or denied, based on the action specified in the map.

Figure 20: Using VLAN Maps to Control Traffic

This figure shows how a VLAN map is applied to prevent a specific type of traffic from Host A in VLAN 10 from being forwarded. You can apply only one VLAN map to a VLAN.

Interactions with Other Features and Switches

- If an IPv6 router ACL is configured to deny a packet, the packet is not routed. A copy of the packet is sent to the Internet Control Message Protocol (ICMP) queue to generate an ICMP unreachable message for the frame.
- If a bridged frame is to be dropped due to a port ACL, the frame is not bridged.
- You can create both IPv4 and IPv6 ACLs on a switch or switch stack, and you can apply both IPv4 and IPv6 ACLs to the same interface. Each ACL must have a unique name; an error message appears if you try to use a name that is already configured.

You use different commands to create IPv4 and IPv6 ACLs and to attach IPv4 or IPv6 ACLs to the same Layer 2 or Layer 3 interface. If you use the wrong command to attach an ACL (for example, an IPv4 command to attach an IPv6 ACL), you receive an error message.

- You cannot use MAC ACLs to filter IPv6 frames. MAC ACLs can only filter non-IP frames.
- If the hardware memory is full, packets are dropped on the interface and an unload error message is logged.

If the hardware memory is full, for any additional configured ACLs, packets are dropped to the CPU, and the ACLs are applied in software. When the hardware is full a message is printed to the console indicating the ACL has been unloaded and the packets will be dropped on the interface.

• On Cisco Catalyst 9600 Series Supervisor 2 Module, statistics for multicast and Layer 2 traffic dropped by queuing police, due to exceeded shape limit value, are not displayed in the total packet drop statistics on the interface. It displays statistics only for unicast traffic.

How to Configure an IPv6 ACL

The following sections display information on how to configure an IPv6 ACL.

Default Configuration for IPv6 ACLs

The default IPv6 ACL configuration is as follows:

```
Device# show access-lists preauth_ipv6_acl
```

```
IPv6 access list preauth_ipv6_acl (per-user)
```

```
permit udp any any eq domain sequence 10
permit tcp any any eq domain sequence 20
permit icmp any any nd-ns sequence 30
permit icmp any any nd-na sequence 40
permit icmp any any router-solicitation sequence 50
permit icmp any any router-advertisement sequence 60
permit icmp any any redirect sequence 70
permit udp any eq 547 any eq 546 sequence 80
permit udp any eq 546 any eq 547 sequence 90
deny ipv6 any any sequence 100
```

Configuring IPv6 ACLs

To filter IPv6 traffic, perform this procedure.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	<pre>ipv6 access-list {list-name log-update threshold role-based list-name}</pre>	Defines an IPv6 ACL name, and enters IPv6 access list configuration mode.
	Example:	
	<pre>Device(config)# ipv6 access-list example_acl_list</pre>	
Step 4	<pre>{deny permit} protocol {source-ipv6-prefix/ prefix-length any threshold host source-ipv6-address} [operator [port-number]] { destination-ipv6-prefix/prefix-length any host destination-ipv6-address} [operator [port-number]][dscp value] [fragments] [log] [log-input][sequence value] [time-range name] Example: Device (config-ipv6-acl) # permit tcp 2001:DB8:0300:0201::/32 eq telnet any</pre>	 For protocol, enter the name of number of an IP: ahp, esp, icmp, ipv6, pcp, stcp, tcp, or udp, or an integer in the range 0 to 255 representing an IPv6 protocol number. The <i>source-ipv6-prefix/prefix-length</i> or <i>destination-ipv6-prefix/prefix-length</i> is the source or destination IPv6 network or
		 class of networks for which to set deny of permit conditions, specified in hexadecimal and using 16-bit values between colons (see RFC 2373). Enter any as an abbreviation for the IPv6 prefix ::/0.

Command or Action	Purpose
	For host source-ipv6-address or destination-ipv6-address, enter the source or destination IPv6 host address for which to set deny or permit conditions, specified in hexadecimal using 16-bit values between colons.
	 (Optional) For operator, specify an operand that compares the source or destination ports of the specified protocol. Operands are lt (less than), gt (greater than), eq (equal), neq (not equal), and range.
	If the operator follows the <i>source-ipv6-prefix/prefix-length</i> argument, it must match the source port. If the operator follows the <i>destination-ipv6-prefix/prefix-length</i> argument, it must match the destination port.
	• (Optional) The port-number is a decimal number from 0 to 65535 or the name of a TCP or UDP port. You can use TCP port names only when filtering TCP. You can use UDP port names only when filtering UDP.
	• (Optional) Enter dscp value to match a differentiated services code point value against the traffic class value in the Traffic Class field of each IPv6 packet header. The acceptable range is from 0 to 63.
	• (Optional) Enter fragments to check noninitial fragments. This keyword is visible only if the protocol is ipv6.
	• (Optional) Enter log to cause an logging message to be sent to the console about the packet that matches the entry. Enter log-input to include the input interface in the log entry. Logging is supported only for router ACLs.
	• (Optional) Enter sequence value to specify the sequence number for the access list statement. The acceptable range is from 1 to 4,294,967,295.
	• (Optional) Enter time-range name to specify the time range that applies to the deny or permit statement.

	Command or Action	Purpose
Step 5	<pre>{deny permit} tcp {source-ipv6-prefix/prefix-length any host source-ipv6-address} [operator [port-number]] {destination-ipv6- prefix/prefix-length any host destination-ipv6-address} [operator [port-number]] [ack] [dscp value] [established] [fin] [log] [log-input] [neq {port protocol}] [psh] [range {port protocol}] [rst] [sequence value] [syn] [time-range name] [urg] Example: Device (config-ipv6-acl) # deny tcp host 2001:DB8:1::1 any log-input</pre>	 Specifies permit or deny conditions for an IPv6 ACL. Enter tcp for Transmission Control Protocol. The parameters are the same as those described in Step 3a, with these additional optional parameters: ack: Acknowledgment bit set. established: An established connection. A match occurs if the TCP datagram has the ACK or RST bits set. fin: Finished bit set; no more data from sender. neq { port protocol}: Matches only packets that are not on a given port number. psh: Push function bit set. range { port protocol}: Matches only packets in the port number range. rst: Reset bit set. syn: Synchronize bit set.
Step 6	end Example: Device(config-ipv6-acl)# end	Exits IPv6 access list configuration mode and returns to privileged EXEC mode.
Step 7	<pre>show ipv6 access-list Example: Device# show ipv6 access-list</pre>	Verifies that IPv6 ACLs are configured correctly.

Attaching an IPv6 ACL to an Interface

You can apply an ACL to outbound or inbound traffic on Layer 3 interfaces, or to inbound traffic on Layer 2 interfaces. You can also apply ACLs only to inbound management traffic on Layer 3 interfaces.

Follow these steps to control access to an interface.

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.

	Command or Action	Purpose
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface interface-id	Identifies a Layer 2 interface (for port ACLs)
	Example:	or Layer 3 interface (for router ACLs) on which
	Device(config)# interface gigabitethernet 1/0/1	to apply an access list, and enters interface configuration mode.
Step 4	no switchport	Returns the interface to the routed-interface
	Example:	status and erases all further Layer 2 configuration.
	<pre>Device(config-if) # no switchport</pre>	
Step 5	ipv6 address ipv6-address	Configures an IPv6 address on a Layer 3
	Example:	interface (for router ACLs).
	<pre>Device(config-if)# ipv6 address 2001:DB8::1</pre>	
Step 6	ipv6 traffic-filter <i>access-list-name</i> { in out }	Applies the access list to incoming or outgoing
	Example:	traffic on the interface.
	<pre>Device(config-if)# ipv6 traffic-filter acl1 in</pre>	
Step 7	end	Exits interface configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-ipv6-acl)# end	

Configuring an IPv6 ACL in Template Mode

Note You can configure **ipv6 traffic-filter** command in the template configuration mode. You can configure the **source template** command only once to an interface.

Beginning in privileged EXEC mode, follow these steps to configure ACL in a template:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	

	Command or Action	Purpose
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	<pre>ipv6 access-list {list-name log-update threshold role-based list-name}</pre>	Defines an IPv6 ACL name, and enters IPv6 access list configuration mode.
	Example:	
	Device(config) # ipv6 access-list v6acl10	
Step 4	<pre>ipv6 access-list {list-name log-update threshold role-based list-name}</pre>	Defines an IPv6 ACL name, and enters IPv6 access list configuration mode.
	Example:	
	<pre>Device(config-ipv6-acl)#ipv6 access-list v6acl11</pre>	
Step 5	exit	Exits access-list configuration mode.
	Example:	
	Device(config-ipv6-acl)# exit	
Step 6	template	Creates a user template and enters template
	Example:	configuration mode.
	Device(config)# template test	
Step 7	ipv6 traffic-filter { <i>access-list-number</i> <i>name</i> }	Controls access to the specified interface.
	{ in out }	Enter access-list-number to define the access
	<pre>Example: Device(config-template)# ipv6 traffic-filter v6acl10 in</pre>	list. The access list can be a number.
		Enter <i>name</i> to define the access list. The access list can be a name.
		Enter in to direct the access list in the incoming direction of the interface.
		Enter out to direct the access list in the outgoing direction of the interface.
Step 8	exit	Exits template configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-template)# exit	
Step 9	interface interface-id	Identifies a specific interface for configuration
	Example:	and enters interface configuration mode.
	Device(config)# interface gigabitethernet1/0/1	The interface can be a Layer 2 interface (por ACL), or a Layer 3 interface (router ACL).
Step 10	<pre>ipv6 traffic-filter {access-list-number name} {in out}</pre>	Controls access to the specified interface.

I

	Command or Action	Purpose
	Example: Device(config-if)# ipv6 traffic-filter v6acl11 out	Enter <i>access-list-number</i> to define the access list. The access list can be a number. Enter <i>name</i> to define the access list. The access list can be a name. Enter in to direct the access list in the incoming direction of the interface. Enter out to direct the access list in the outgoing direction of the interface.
Step 11	<pre>source template name Example: Device(config)# source template test</pre>	Applies an interface template to a target. The accesss list <i>v6acl10</i> is the incoming access list that is configured.
Step 12	end Example: Device(config)# end	Exits global configuration mode and returns to privileged EXEC mode.

Configuring a VLAN Map

To create a VLAN map and apply it to one or more VLANs, perform these steps:

Before you begin

Create the IPv6 ACL that you want to apply to the VLAN.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	vlan access-map name [number]	Creates a VLAN map, and enters VLAN
	Example:	access-map command mode
	Device(config)# vlan access-map map_1 20	VLAN map can have a name or (optionally) a number. The number is the sequence number of the entry within the map.
		When you create VLAN maps with the same name, numbers are assigned sequentially in increments of 10. When modifying or deleting

	Command or Action	Purpose
		maps, you can enter the number of the map entry that you want to modify or delete.
		VLAN maps do not use the specific permit or deny keywords. To deny a packet by using VLAN maps, create an ACL that would match the packet, and set the action to drop. A permit in the ACL counts as a match. A deny in the ACL means no match.
Step 4	match {ip ipv6 mac} address {name number} [name number] Example:	Matches the packet against one or more access lists. Note that packets are only matched against access lists of the correct protocol type. IP
	Device(config-access-map)# match ipv6 address ip_net	packets are matched against IP access lists. Non-IP packets are only matched against named MAC access lists.
		Note If the VLAN map is configured with a match clause for a type of packet (IP or MAC) and the map action is drop, all packets that match the type are dropped. If the VLAN map has no match clause, and the configured action is drop, all IP and Layer 2 packets are dropped.
Step 5	Enter one of the following commands to specify an IP packet or a non-IP packet (with only a known MAC address) and to match the packet against one or more ACLs:	Sets the action for the map entry.
	• action { forward}	
	Device(config-access-map)# action forward	
	• action { drop}	
	Device(config-access-map)# action drop	
Step 6	vlan filter mapname vlan-list list	Applies the VLAN map to one or more VLAN IDs.
	Example: Device(config)# vlan filter map 1 vlan-list 20-22	The list can be a single VLAN ID (22), a consecutive list (10-22), or a string of VLAN IDs (12, 22, 30). Spaces around the comma and hyphen are optional.
Step 7	end	Exits global configuration mode and returns to
	Example:	privileged EXEC mode.
	Device(config)# end	

Applying a VLAN Map to a VLAN

To apply a VLAN map to one or more VLANs, perform these steps.

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	vlan filter mapname vlan-list list	Applies the VLAN map to one or more VLAN
	Example:	IDs.
	Device(config)# vlan filter map 1 vlan-list 20-22	The list can be a single VLAN ID (22), a consecutive list (10-22), or a string of VLAN IDs (12, 22, 30). Spaces around the comma and hyphen are optional.
Step 4	end	Exits global configuration mode and returns to
	Example:	privileged EXEC mode.
	Device(config)# end	

Monitoring IPv6 ACLs

You can display information about all configured access lists, all IPv6 access lists, or a specific access list by using one or more of the privileged EXEC commands shown in the table below:

Table 24: show ACL commands

Command	Purpose
show access-lists	Displays all access lists configured on the switch.
show ipv6 access-list [access-list-name]	Displays all configured IPv6 access lists or the access list specified by name.
show vlan access-map [map-name]	Displays VLAN access map configuration.
show vlan filter [access-map access-map vlan vlan-id]	Displays the mapping between VACLs and VLANs.

Configuration Examples for IPv6 ACL

This following sections display configuration examples for IPv6 ACL.

Example: Creating an IPv6 ACL

This example configures the IPv6 access list named IPv6-ACL. The first deny entry in the list denies all packets that have a destination TCP port number greater than 5000. The second deny entry denies packets that have a source UDP port number less than 5000. The second deny also logs all matches to the console. The first permit entry in the list permits all ICMP packets. The second permit entry in the list permits all other traffic. The second permit entry is necessary because an implicit deny -all condition is at the end of each IPv6 access list.

Note

Logging is supported only on Layer 3 interfaces.

```
Device> enable
Device(config) # ipv6 access-list IPv6_ACL
Device(config-ipv6-acl) # deny tcp any any gt 5000
Device (config-ipv6-acl) # deny ::/0 lt 5000 ::/0 log
Device(config-ipv6-acl) # permit icmp any any
Device(config-ipv6-acl) # permit any any
Device(config-ipv6-acl) # end
```

Example: Displaying IPv6 ACLs

The following is a sample output from the **show access-lists** command. The output shows all access lists that are configured on the device.

```
Device# show access-lists
```

```
Extended IP access list hello
10 permit ip any any
IPv6 access list ipv6
permit ipv6 any any sequence 10
```

The following is a sample output from the **show ipv6 access-lists** command. The output shows only IPv6 access lists configured on the switch.

Device# show ipv6 access-list

```
IPv6 access list inbound
permit tcp any any eq bgp (8 matches) sequence 10
permit tcp any any eq telnet (15 matches) sequence 20
permit udp any any sequence 30
IPv6 access list outbound
deny udp any any sequence 10
deny tcp any any eq telnet sequence 20
```

Example: Displaying VLAN Access Map Configuration

The following is a sample output from the **show vlan access-map** privileged EXEC command:

```
Device# show vlan access-map
Vlan access-map "m1" 10
Match clauses:
    ipv6 address: ip2
Action: drop
```

The following is a sample output from the **show ipv6 access-lists** privileged EXEC command. The output shows only IPv6 access lists configured on the switch.

```
Device# show ipv6 access-list
```

```
IPv6 access list inbound
permit tcp any any eq bgp (8 matches) sequence 10
permit tcp any any eq telnet (15 matches) sequence 20
permit udp any any sequence 30
IPv6 access list outbound
deny udp any any sequence 10
deny tcp any any eq telnet sequence 20
```

Feature History for IPv6 ACLs

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.11.1	IPv6 ACLs	You can filter IPv6 traffic by creating IPv6 ACLs and applying them to interfaces similar to how you create and apply IPv4 named ACLs. You can also create and apply input router ACLs to filter Layer 3 management traffic.
Cisco IOS XE Gibraltar 16.11.1	IPv6 Downloadable ALCs	IPv6 dACLs are supported.
Cisco IOS XE Bengaluru 17.5.1	ACL template support for IPv6	Interface template allows you to configure multiple commands and associate it with an interface. The ipv6 traffic-filter command is used to apply an IPv6 access list under template mode of configuration.
Cisco IOS XE Cupertino 17.7.1	IPv6 ACLs	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

Object Groups for ACLs

• Object Groups for ACLs, on page 415

Object Groups for ACLs

The Object Groups for ACLs feature lets you classify users, devices, or protocols into groups and apply those groups to access control lists (ACLs) to create access control policies for those groups. This feature lets you use object groups instead of individual IP addresses, protocols, and ports, which are used in conventional ACLs. This feature allows multiple access control entries (ACEs), but now you can use each ACE to allow an entire group of users to access a group of servers or services or to deny them from doing so.

In large networks, the number of ACLs can be large (hundreds of lines) and difficult to configure and manage, especially if the ACLs frequently change. Object group-based ACLs are smaller, more readable, and easier to configure and manage than conventional ACLs, simplifying static and dynamic ACL deployments for large user access environments on Cisco IOS routers.

Cisco IOS Firewall benefits from object groups, because they simplify policy creation (for example, group A has access to group A services).

Restrictions for Object Groups for ACLs

- You can use object groups only in extended named and numbered ACLs. On Cisco Catalyst 9600 Series Supervisor 2 Module, object group are only supported in extended ACLs.
- Object group-based ACLs support only IPv4 or IPv6 addresses. On Cisco Catalyst 9600 Series Supervisor 2 Module, object group-based ACLs support both IPv4 and IPv6 addresses.
- Object group-based ACLs support only Layer 3 interfaces (such as routed interfaces and VLAN interfaces), port channel interface, and sub-interfaces.

There is no support on Layer 2 interfaces on Cisco Catalyst 9600 Series Supervisor 2 Module.

- Object group-based ACLs are not supported with IPsec.
- ACL statements using object groups will be ignored on packets that are sent to RP for processing. This is not applicable to Cisco Catalyst 9600 Series Supervisor 2 Module.
- The number of object group-based ACEs supported in an ACL varies depending on platform, subject to TCAM availability.

- On Cisco Catalyst 9600 Series Supervisor 2 Module, object group-based ACLs are supported only on ingress port. There is no support on egress direction.
- IPv6 object group-based ACLs with Log option are not supported on C9600X-SUP-2. However, IPv4 object group-based ACLs with Log option is supported.
- IPv4 object group-based ACLs for multicast packet control are not supported on Cisco Catalyst 9600 Series Supervisor 2 Module.
- IPv6 object group-based ACLs for control packet are not supported on Cisco Catalyst 9600 Series Supervisor 2 Module.
- On Cisco Catalyst 9600 Series Supervisor 2 Module, you cannot configure conventional ACEs and ACEs that refer to object groups in the same ACL.
- On Cisco Catalyst 9600 Series Supervisor 2 Module, per ACE statistics is supported only for Deny ACEs. Per ACE statistics for Permit ACE is not supported. If the same ACL is applied to multiple ports, then the deny counters are cumulative of all the ports on which the ACL is attached.

Information About Object Groups for ACLs

You can configure conventional ACEs and ACEs that refer to object groups in the same ACL.

You can use object group-based ACLs with quality of service (QoS) match criteria, Cisco IOS Firewall, Dynamic Host Configuration Protocol (DHCP), and any other features that use extended ACLs. In addition, you can use object group-based ACLs with multicast traffic.

When there are many inbound and outbound packets, using object group-based ACLs increases performance when compared to conventional ACLs. Also, in large configurations, this feature reduces the storage needed in NVRAM, because using object groups in ACEs means that you do not need to define an individual ACE for every address and protocol pairing.

Object Groups

An object group can contain a single object (such as a single IP address, network, or subnet) or multiple objects (such as a combination of multiple IP addresses, networks, or subnets).

A typical access control entry (ACE) allows a group of users to have access only to a specific group of servers. In an object group-based access control list (ACL), you can create a single ACE that uses an object group name instead of creating many ACEs (which requires each ACE to have a different IP address). A similar object group (such as a protocol port group) can be extended to provide access only to a set of applications for a user group. ACEs can have object groups for the source only, destination only, none, or both.

You can use object groups to separate the ownership of the components of an ACE. For example, each department in an organization controls its group membership, and the administrator owns the ACE itself to control which departments can contact one another.

You can use object groups in features that use Cisco Policy Language (CPL) class maps.

This feature supports two types of object groups for grouping ACL parameters: network object groups and service object groups. Use these object groups to group IP addresses, protocols, protocol services (ports), and Internet Control Message Protocol (ICMP) types.

Objects Allowed in Network Object Groups

A network object group is a group of any of the following objects:

- Any IP address—includes a range from 0.0.0.0 to 255.255.255.255 (This is specified using the **any** command.)
- Host IP addresses
- Hostnames
- · Other network object groups
- Subnets
- Host IP addresses
- · Network address of group members
- Nested object groups

Objects Allowed in Service Object Groups

A service object group is a group of any of the following objects:

- Source and destination protocol ports (such as Telnet or Simple Network Management Protocol [SNMP])
- Internet Control Message Protocol (ICMP) types (such as echo, echo-reply, or host-unreachable)
- Top-level protocols (such as Encapsulating Security Payload [ESP], TCP, or UDP)
- Other service object groups

ACLs Based on Object Groups

All features that use or reference conventional access control lists (ACLs) are compatible with object-group-based ACLs, and the feature interactions for conventional ACLs are the same with object-group-based ACLs. This feature extends the conventional ACLs to support object-group-based ACLs and also adds new keywords and the source and destination addresses and ports.

You can add, delete, or change objects in an object group membership list dynamically (without deleting and redefining the object group). Also, you can add, delete, or change objects in an object group membership list without redefining the ACL access control entry (ACE) that uses the object group. You can add objects to groups, delete them from groups, and then ensure that changes are correctly functioning within the object-group-based ACL without reapplying the ACL to the interface.

You can configure an object-group-based ACL multiple times with a source group only, a destination group only, or both source and destination groups.

You cannot delete an object group that is used within an ACL or a class-based policy language (CPL) policy.

How to Configure Object Groups for ACLs

To configure object groups for ACLs, you first create one or more object groups. These can be any combination of network object groups (groups that contain objects such as, host addresses and network addresses) or service object groups (which use operators such as **lt**, **eq**, **gt**, **neq**, and **range** with port numbers). Then, you create access control entries (ACEs) that apply a policy (such as **permit** or **deny**) to those object groups.

Creating a Network Object Group

A network object group that contains a single object (such as a single IP address, a hostname, another network object group, or a subnet) or multiple objects with a network object-group-based ACL to create access control policies for the objects.

Perform this task to create a network object group.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	object-group network object-group-name	Defines the object group name and enters
	Example:	network object-group configuration mode.
	Device(config)# object-group network my-network-object-group	
Step 4	<pre>description description-text Example: Device (config-network-group) # description</pre>	(Optional) Specifies a description of the object group.You can use up to 200 characters.
	test engineers	
Step 5	<pre>host {host-address host-name} Example: Device (config-network-group) # host 209.165.200.237</pre>	(Optional) Specifies the IP address or name of a host.If you specify a host address, you must use an IPv4 address.
Step 6	network-address {/nn network-mask}	(Optional) Specifies a subnet object.
	Example: Device(config-network-group)# 209.165.200.225 255.255.255.224	• You must specify an IPv4 address for the network address. The default network mask is 255.255.255.255.
Step 7	<pre>group-object nested-object-group-name Example: Device(config-network-group)# group-object my-nested-object-group</pre>	 (Optional) Specifies a nested (child) object group to be included in the current (parent) object group. The type of child object group must match that of the parent (for example, if you are creating a network object group, you must specify another network object group as the child).

	Command or Action	Purpose
		 You can use duplicated objects in an object group only via nesting of group objects. For example, if object 1 is in both group A and group B, you can define a group C that includes both A and B. However, you cannot include a group object that causes the group hierarchy to become circular (for example, you cannot include group A in group B and then also include group B in group A). You can use an unlimited number of levels of nested object groups (however, a maximum of two levels is recommended).
Step 8	Repeat the steps until you have specified objects on which you want to base your object group.	
Step 9	end Example: Device(config-network-group)# end	Exits network object-group configuration mode and returns to privileged EXEC mode.

Creating a Service Object Group

Use a service object group to specify TCP and/or UDP ports or port ranges. When the service object group is associated with an access control list (ACL), this service object-group-based ACL can control access to ports.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	object-group service object-group-name	Defines an object group name and enters service object-group configuration mode.
	Example:	
	Device(config)# object-group service my-service-object-group	
Step 4	description description-text	(Optional) Specifies a description of the object
-	Example:	group.
		• You can use up to 200 characters.

I

	Command or Action	Purpose
	Device(config-service-group)# description test engineers	
Step 5	<pre>protocol Example: Device(config-service-group)# ahp</pre>	(Optional) Specifies an IP protocol number of name.
Step 6	<pre>{tcp udp tcp-udp} [source {{[eq] lt gt} port1 range port1 port2}] [{[eq] lt gt} port1 range port1 port2] Example: Device (config-service-group) # tcp-udp range 2000 2005</pre>	(Optional) Specifies TCP, UDP, or both.
Step 7	<pre>icmp icmp-type Example: Device(config-service-group)# icmp conversion-error</pre>	(Optional) Specifies the decimal number or name of an Internet Control Message Protocol (ICMP) type.
Step 8	<pre>group-object nested-object-group-name Example: Device(config-service-group)# group-object my-nested-object-group</pre>	 (Optional) Specifies a nested (child) object group to be included in the current (parent) object group. The type of child object group must match that of the parent (for example, if you are creating a network object group, you must specify another network object group as the child). You can use duplicated objects in an object group only via nesting of group objects. For example, if object 1 is in both group A and group B, you can define a group C that includes both A and B. However, you cannot include a group object that causes the group hierarchy to become circular (for example, you cannot include group A in group A). You can use an unlimited number of levels of nested object groups (however, a maximum of two levels is recommended).
Step 9	Repeat the steps to specify the objects on which you want to base your object group.	-
Step 10	end Example:	Exits service object-group configuration mode and returns to privileged EXEC mode.

Command or Action	Purpose
Device(config-service-group)# end	

Creating an Object-Group-Based ACL

When creating an object-group-based access control list (ACL), configure an ACL that references one or more object groups. As with conventional ACLs, you can associate the same access policy with one or more interfaces.

You can define multiple access control entries (ACEs) that reference object groups within the same object-group-based ACL. You can also reuse a specific object group in multiple ACEs.

Perform this task to create an object-group-based ACL.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	ip access-list extended access-list-name	Defines an extended IP access list using a name
	Example:	and enters extended access-list configuration mode.
	<pre>Device(config)# ip access-list extended nomarketing</pre>	
Step 4	remark remark	(Optional) Adds a comment about the
	Example:	configured access list entry.
	Device(config-ext-nacl)# remark protect server by denying access from the	• A remark can precede or follow an access list entry.
	Marketing network	• In this example, the remark reminds the network administrator that the subsequent entry denies the Marketing network access to the interface.
Step 5	deny protocol source [source-wildcard] destination [destination-wildcard] [option	(Optional) Denies any packet that matches all conditions specified in the statement.
	option-name] [precedence precedence] [tos tos] [established] [log log-input] [time-range time-range-name] [fragments]	• Optionally use the object-group <i>service-object-group-name</i> keyword and argument as a substitute for the <i>protocol</i> .
	Example:	argument
	Device(config-ext-nacl)# deny ip 209.165.200.244 255.255.255.224 host 209.165.200.245 log	• Optionally use the object-group source-network-object-group-name

I

	Command or Action	Purpose
	<pre>Command or Action Example based on object-group: Router(config)# object-group network my_network_object_group Router(config-network-group)# exit Router(config-network-group)# host 209.165.200.245 Router(config-network-group)# exit Router(config-network-group)# exit Router(config-ext-nacl)# deny ip object-group my_other_network_object_group log</pre>	 Purpose keyword and argument as a substitute for the <i>source source-wildcard</i>. arguments Optionally use the object-group <i>destination-network-object-group-name</i> keyword and argument as a substitute for the <i>destination destination-wildcard</i>. arguments If the <i>source-wildcard</i> or <i>destination-wildcard</i> is omitted, a wildcard mask of 0.0.0 is assumed, which matches all bits of the source or destination address, respectively. Optionally use the any keyword as a substitute for the <i>source source-wildcard</i> to specify the address and wildcard of 0.0.0 255.255.255.255. Optionally use the host <i>source</i> keyword and argument to indicate a source and source wildcard of <i>source</i> 0.0.0 or the host <i>destination</i> keyword and argument to indicate a source and source wildcard of <i>destination</i> 0.0.0. In this example, packets from all sources are denied access to the destination network 209.165.200.244. Logging messages about packets permitted or denied by the access list are sent to the facility configured by the logging facility command (for example, console, terminal, or syslog). That is, any packet that matches the access list will cause an informational logging message about the packet to be sent to the configured facility. The level of messages logged to the console is controlled by the logging console command.
Step 6	<pre>remark remark Example: Device(config-ext-nacl)# remark allow</pre>	(Optional) Adds a comment about the configured access list entry.A remark can precede or follow an access
Step 7	TCP from any source to any destination permit protocol source [source-wildcard] destination [destination-wildcard] [option	list entry. Permits any packet that matches all conditions specified in the statement.

	Command or Action	Purpose
	<pre>option-name] [precedence precedence] [tos tos] [established] [log log-input] [time-range time-range-name] [fragments] Example: Device (config-ext-nacl) # permit tcp any any</pre>	 Every access list needs at least one permit statement. Optionally use the object-group service-object-group-name keyword and argument as a substitute for the protocol. Optionally use the object-group source-network-object-group-name keyword and argument as a substitute for the source source-wildcard. Optionally use the object-group destination-network-object-group-name keyword and argument as a substitute for the destination destination-wildcard. If source-wildcard or destination-wildcard is omitted, a wildcard mask of 0.0.0.0 is assumed, which matches on all bits of the source or destination address, respectively. Optionally use the anykeyword as a substitute for the source source source-wildcard to specify the address and wildcard of 0.0.0.0 255.255.255.255. In this example, TCP packets are allowed from any source to any destination. Use the log-input keyword to include input interface, source MAC address, or virtual circuit in the logging output.
Step 8	Repeat the steps to specify the fields and values on which you want to base your access list.	Remember that all sources not specifically permitted are denied by an implicit deny statement at the end of the access list.
Step 9	<pre>end Example: Device(config-ext-nacl)# end</pre>	Exits extended access-list configuration mode and returns to privileged EXEC mode.

Applying an Object Group-Based ACL to an Interface

Use the **ip access-group** command to apply an object group-based ACL to an interface. An object group-based access control list (ACL) can be used to control traffic on the interface it is applied to.

Perform this task to apply an object group-based ACL to an interface.

	Command or Action	Purpose	
Step 1	enable	Enables privileged EXEC mode.	
	Example:	Enter your password, if prompted.	
	Device> enable		
Step 2	configure terminal	Enters global configuration mode.	
	Example:		
	Device# configure terminal		
Step 3	interface type number	Specifies the interface and enters interface configuration mode.	
	Example:		
	Device(config)# interface vlan 100		
Step 4	ip access-group { <i>access-list-name</i> <i>access-list-number</i> } { in out }	Applies the ACL to the interface and specifies whether to filter inbound or outbound packets	
	Example:		
	<pre>Device(config-if)# ip access-group my-ogacl-policy in</pre>		
Step 5	end	Exits interface configuration mode and return to privileged EXEC mode.	
	Example:		
	Device(config-if)# end		

Procedure

Verifying Object Groups for ACLs

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	show object-group [object-group-name] Example: Device# show object-group my-object-group	Displays the configuration in the named or numbered object group (or in all object groups if no name is entered).
Step 3	<pre>show ip access-list [access-list-name] Example: Device# show ip access-list my-ogacl-policy</pre>	Displays the contents of the named or numbered access list or object group-based ACL (or for all access lists and object group-based ACLs if no name is entered).

Configuration Examples for Object Groups for ACLs

Example: Creating a Network Object Group

The following example shows how to create a network object group named my-network-object-group, which contains two hosts and a subnet as objects:

```
Device> enable
Device# configure terminal
Device(config)# object-group network my-network-object-group
Device(config-network-group)# description test engineers
Device(config-network-group)# host 209.165.200.237
Device(config-network-group)# host 209.165.200.241 255.255.255.224
Device(config-network-group)# end
```

The following example shows how to create a network object group named my-company-network, which contains two hosts, a subnet, and an existing object group (child) named my-nested-object-group as objects:

```
Device> enable
Device# configure terminal
Device(config)# object-group network my-company-network
Device(config-network-group)# host host1
Device(config-network-group)# host 209.165.200.242
Device(config-network-group)# 209.165.200.225 255.255.254
Device(config-network-group)# group-object my-nested-object-group
Device(config-network-group)# end
```

Example: Creating a Service Object Group

The following example shows how to create a service object group named my-service-object-group, which contains several ICMP, TCP, UDP, and TCP-UDP protocols and an existing object group named my-nested-object-group as objects:

```
Device> enable
Device# configure terminal
Device(config)# object-group service my-service-object-group
Device(config-service-group)# icmp echo
Device(config-service-group)# tcp smtp
Device(config-service-group)# tcp telnet
Device(config-service-group)# tcp source range 1 65535 telnet
Device(config-service-group)# tcp source 2000 ftp
Device(config-service-group)# udp domain
Device(config-service-group)# tcp-udp range 2000 2005
Device(config-service-group)# group-object my-nested-object-group
Device(config-service-group)# end
```

Example: Creating an Object Group-Based ACL

The following example shows how to create an object-group-based ACL that permits packets from the users in my-network-object-group if the protocol ports match the ports specified in my-service-object-group:

```
Device> enable
Device# configure terminal
Device(config)# ip access-list extended my-ogacl-policy
Device(config-ext-nacl)# permit object-group my-service-object-group object-group
my-network-object-group any
Device(config-ext-nacl)# deny tcp any any
Device(config-ext-nacl)# end
```

Applying an Object Group-Based ACL to an Interface

Use the **ip access-group** command to apply an object group-based ACL to an interface. An object group-based access control list (ACL) can be used to control traffic on the interface it is applied to.

Perform this task to apply an object group-based ACL to an interface.

Procedure

	Command or Action	Purpose	
Step 1	enable	Enables privileged EXEC mode.	
	Example:	Enter your password, if prompted.	
	Device> enable		
Step 2	configure terminal	Enters global configuration mode.	
	Example:		
	Device# configure terminal		
Step 3	interface type number	Specifies the interface and enters interface configuration mode.	
	Example:		
	Device(config)# interface vlan 100		
Step 4	ip access-group { <i>access-list-name</i> <i>access-list-number</i> } { in out }	Applies the ACL to the interface and specifies whether to filter inbound or outbound packets.	
	Example:		
	<pre>Device(config-if)# ip access-group my-ogacl-policy in</pre>		
Step 5	end	Exits interface configuration mode and returns	
	Example:	to privileged EXEC mode.	
	Device(config-if)# end		

Example: Verifying Object Groups for ACLs

Device# show object-group

The following example shows how to display all object groups:

```
Network object group auth-proxy-acl-deny-dest
host 209.165.200.235
Service object group auth-proxy-acl-deny-services
tcp eq www
tcp eq 443
Network object group auth-proxy-acl-permit-dest
209.165.200.226 255.255.255.224
209.165.200.227 255.255.255.224
209.165.200.228 255.255.255.224
209.165.200.246 255.255.255.224
209.165.200.230 255.255.255.224
209.165.200.231 255.255.255.224
209.165.200.232 255.255.255.224
209.165.200.233 255.255.255.224
```

```
209.165.200.234 255.255.255.224
Service object group auth-proxy-acl-permit-services
tcp eq www
tcp eq 443
```

The following example shows how to display information about specific object-group-based ACLs:

Device# show ip access-list my-ogacl-policy

```
Extended IP access list my-ogacl-policy
10 permit object-group eng_service any any
```

Feature History for Object Groups for ACLs

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.12.1	Object Groups for ACLs	The Object Groups for ACLs feature lets you classify users, devices, or protocols into groups and apply them to access control lists (ACLs) to create access control policies for those groups. This feature lets you use object groups instead of individual IP addresses, protocols, and ports, which are used in conventional ACLs. This feature allows multiple access control entries (ACEs), but now you can use each ACE to allow an entire group of users to access a group of servers or services or to deny them from doing so.
Cisco IOS XE Cupertino 17.7.1	Object Groups for ACLs	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

Configuring IP Source Guard

- Monitoring IP Source Guard, on page 433
- Feature History for IP Source Guard, on page 433

Information About IP Source Guard

IP Source Guard

You can use IP source guard (IPSG) to prevent traffic attacks if a host tries to use the IP address of its neighbor and you can enable IP source guard when DHCP snooping is enabled on an untrusted interface.

After IPSG is enabled on an interface, the switch blocks all IP traffic received on the interface except for DHCP packets allowed by DHCP snooping.

The switch uses a source IP lookup table in hardware to bind IP addresses to ports. For IP and MAC filtering, a combination of source IP and source MAC lookups are used. IP traffic with a source IP address in the binding table is allowed, all other traffic is denied.

The IP source binding table has bindings that are learned by DHCP snooping or are manually configured (static IP source bindings). An entry in this table has an IP address, its associated MAC address, and its associated VLAN number. The switch uses the IP source binding table only when IP source guard is enabled.

IPSG is supported only on Layer 2 ports, including access and trunk ports. You can configure IPSG with source IP address filtering or with source IP and MAC address filtering.

IP Source Guard for Static Hosts

Note Do not use IPSGfor static hosts on uplink ports or trunk ports.

IPSG for static hosts extends the IPSG capability to non-DHCP and static environments. The previous IPSG used the entries created by DHCP snooping to validate the hosts connected to a switch. Any traffic received from a host without a valid DHCP binding entry is dropped. This security feature restricts IP traffic on nonrouted Layer 2 interfaces. It filters traffic based on the DHCP snooping binding database and on manually

configured IP source bindings. The previous version of IPSG required a DHCP environment for IPSG to work.

IPSG for static hosts allows IPSG to work without DHCP. IPSG for static hosts relies on IP device tracking-table entries to install port ACLs. The switch creates static entries based on ARP requests or other IP packets to maintain the list of valid hosts for a given port. You can also specify the number of hosts allowed to send traffic to a given port. This is equivalent to port security at Layer 3.

IPSG for static hosts also supports dynamic hosts. If a dynamic host receives a DHCP-assigned IP address that is available in the IP DHCP snooping table, the same entry is learned by the IP device tracking table. In a stacked environment, when the active switch failover occurs, the IP source guard entries for static hosts attached to member ports are retained. When you enter the **show device-tracking database** EXEC command, the IP device tracking table displays the entries as ACTIVE.

Note Some IP hosts with multiple network interfaces can inject some invalid packets into a network interface. The invalid packets contain the IP or MAC address for another network interface of the host as the source address. The invalid packets can cause IPSG for static hosts to connect to the host, to learn the invalid IP or MAC address bindings, and to reject the valid bindings. Consult the vender of the corresponding operating system and the network interface to prevent the host from injecting invalid packets.

IPSG for static hosts initially learns IP or MAC bindings dynamically through an ACL-based snooping mechanism. IP or MAC bindings are learned from static hosts by ARP and IP packets. They are stored in the device tracking database. When the number of IP addresses that have been dynamically learned or statically configured on a given port reaches a maximum, the hardware drops any packet with a new IP address. To resolve hosts that have moved or gone away for any reason, IPSG for static hosts leverages IP device tracking to age out dynamically learned IP address bindings. This feature can be used with DHCP snooping. Multiple bindings are established on a port that is connected to both DHCP and static hosts. For example, bindings are stored in both the device tracking database as well as in the DHCP snooping binding database.

IP Source Guard Configuration Guidelines

• You can configure static IP bindings only on nonrouted ports. If you enter the **ip source binding** *mac-address* **vlan** *vlan-id ip-address* **interface** *interface-id* global configuration command on a routed interface, this error message appears:

Static IP source binding can only be configured on switch port.

- When IP source guard with source IP filtering is enabled on an interface, DHCP snooping must be enabled on the access VLAN for that interface.
- If you are enabling IP source guard on a trunk interface with multiple VLANs and DHCP snooping is enabled on all the VLANs, the source IP address filter is applied on all the VLANs.

Note If IP source guard is enabled and you enable or disable DHCP snooping on a VLAN on the trunk interface, the switch might not properly filter traffic.

• You can enable this feature when 802.1x port-based authentication is enabled.

How to Configure IP Source Guard

Enabling IP Source Guard

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface interface-id	Specifies the interface to be configured, and
	Example:	enters interface configuration mode.
	Device(config)# interface gigabitethernet 1/0/1	
Step 4	ip verify source [mac-check]	Enables IP source guard with source IP address
	Example:	filtering.
	<pre>Device(config-if) # ip verify source</pre>	(Optional) mac-check : Enables IP Source Guard with source IP address and MAC address filtering.
Step 5	exit	Exits interface configuration mode and returns
	Example:	to global configuration mode.
	Device(config-if)# exit	
Step 6	ip source binding mac-address vlan vlan-id	Adds a static IP source binding.
	ip-address interface interface-id	Enter this command for each static binding.
	Example:	
	Device(config)# ip source binding 0100.0230.0002 vlan 11 10.0.0.4 interface gigabitethernet1/0/1	
Step 7	end	Exits global configuration mode and reutrns to
	Example:	privileged EXEC mode.
	Device(config)# end	

Configuring IP Source Guard for Static Hosts on a Layer 2 Access Port

You must configure the **ip device tracking maximum** *limit-number* interface configuration command globally for IPSG for static hosts to work. If you only configure this command on a port without enabling IP device tracking globally or by setting an IP device tracking maximum on that interface, IPSG with static hosts rejects all the IP traffic from that interface.

	Command or Action	Purpose	
Step 1	enable	Enables privileged EXEC mode.	
	Example:	Enter your password, if prompted.	
	Device> enable		
Step 2	configure terminal	Enters global configuration mode.	
	Example:		
	Device# configure terminal		
Step 3	ip device tracking	Turns on the IP host table, and globally enables IP device tracking.	
	Example:		
	Device(config)# ip device tracking		
Step 4	interface interface-id	Enters interface configuration mode.	
	Example:		
	Device(config)# interface gigabitethernet 1/0/1		
Step 5	switchport mode access	Configures a port as access.	
	Example:		
	Device(config-if) # switchport mode access		
Step 6	switchport access vlan vlan-id	Configures the VLAN for this port.	
	Example:		
	Device(config-if)# switchport access vlam 10		
Step 7	ip verify source[tracking] [mac-check]	Enables IP source guard with source IP address	
	Example:	filtering.	
	<pre>Device(config-if) # ip verify source tracking mac-check</pre>	(Optional) tracking : Enables IP source guard for static hosts.	
		(Optional) mac-check : Enables MAC address filtering.	
		The command ip verify source tracking mac-check enables IP source guard for static hosts with MAC address filtering.	

	Command or Action	Purpose
Step 8	<pre>ip device tracking maximum number Example: Device(config-if)# ip device tracking maximum 8</pre>	Establishes a maximum limit for the number of static IPs that the IP device tracking table allows on the port. The range is 1 to 10. The maximum number is 10. Note You must configure the ip device tracking maximum <i>limit-number</i> interface configuration command.
Step 9	<pre>end Example: Device(config-if)# end</pre>	Exits interface configuration mode and returns to privileged EXEC mode.

Monitoring IP Source Guard

Table 25: Privileged EXEC show Commands

Command	Purpose
show ip verify source [interface <i>interface-id</i>]	Displays the IP source guard configuration on the switch or on a specific interface.
<pre>show ip device tracking { all interface interface-id</pre>	Displays information about the entries in the IP device tracking table.

Table 26: Interface Configuration Commands

Command	Purpose
ip verify source tracking	Verifies the data source.

Feature History for IP Source Guard

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.11.1	IP Source Guard	You can use IP source guard to prevent traffic attacks if a host tries to use the IP address of its neighbor and you can enable IP source guard when DHCP snooping is enabled on an untrusted interface.

Configuring Dynamic ARP Inspection

- Restrictions for Dynamic ARP Inspection, on page 435
- Information About Dynamic ARP Inspection, on page 436
- How to Configure Dynamic ARP Inspection, on page 440
- Monitoring DAI, on page 447
- Verifying the DAI Configuration, on page 448
- Feature History for Dynamic ARP Inspection, on page 448

Restrictions for Dynamic ARP Inspection

This section lists the restrictions and guidelines for configuring Dynamic Address Resolution Protocol (ARP) Inspection on the switch.

- Dynamic ARP inspection is an ingress security feature; it does not perform any egress checking.
- Dynamic ARP inspection is not effective for hosts connected to switches that do not support dynamic ARP inspection or that do not have this feature enabled. Because man-in-the-middle attacks are limited to a single Layer 2 broadcast domain, separate the domain with dynamic ARP inspection checks from the one with no checking. This action secures the ARP caches of hosts in the domain enabled for dynamic ARP inspection.
- Dynamic ARP inspection depends on the entries in the DHCP snooping binding database to verify IP-to-MAC address bindings in incoming ARP requests and ARP responses. Make sure to enable DHCP snooping to permit ARP packets that have dynamically assigned IP addresses.

When DHCP snooping is disabled or in non-DHCP environments, use ARP ACLs to permit or to deny packets.

• Dynamic ARP inspection is supported on access ports, trunk ports, and EtherChannel ports.

Note Do not enable Dynamic ARP inspection on RSPAN VLANs. If Dynamic ARP inspection is enabled on RSPAN VLANs, Dynamic ARP inspection packets might not reach the RSPAN destination port.

• A physical port can join an EtherChannel port channel only when the trust state of the physical port and the channel port match. Otherwise, the physical port remains suspended in the port channel. A port

channel inherits its trust state from the first physical port that joins the channel. Consequently, the trust state of the first physical port need not match the trust state of the channel.

Conversely, when you change the trust state on the port channel, the switch configures a new trust state on all the physical ports that comprise the channel.

- The rate limit is calculated separately on each switch in a switch stack. For a cross-stack EtherChannel, this means that the actual rate limit might be higher than the configured value. For example, if you set the rate limit to 30 pps on an EtherChannel that has one port on switch 1 and one port on switch 2, each port can receive packets at 29 pps without causing the EtherChannel to become error-disabled.
- The operating rate for the port channel is cumulative across all the physical ports within the channel. For example, if you configure the port channel with an ARP rate-limit of 400 pps, all the interfaces combined on the channel receive an aggregate 400 pps. The rate of incoming ARP packets on EtherChannel ports is equal to the sum of the incoming rate of packets from all the channel members. Configure the rate limit for EtherChannel ports only after examining the rate of incoming ARP packets on the channel-port members.

The rate of incoming packets on a physical port is checked against the port-channel configuration rather than the physical-ports configuration. The rate-limit configuration on a port channel is independent of the configuration on its physical ports.

If the EtherChannel receives more ARP packets than the configured rate, the channel (including all physical ports) is placed in the error-disabled state.

- Make sure to limit the rate of ARP packets on incoming trunk ports. Configure trunk ports with higher
 rates to reflect their aggregation and to handle packets across multiple dynamic ARP inspection-enabled
 VLANs. You also can use the **ip arp inspection limit none** interface configuration command to make
 the rate unlimited. A high rate-limit on one VLAN can cause a denial-of-service attack to other VLANs
 when the software places the port in the error-disabled state.
- When you enable dynamic ARP inspection on the switch, policers that were configured to police ARP traffic are no longer effective. The result is that all ARP traffic is sent to the CPU.

Information About Dynamic ARP Inspection

Understanding Dynamic ARP Inspection

ARP provides IP communication within a Layer 2 broadcast domain by mapping an IP address to a MAC address. For example, Host B wants to send information to Host A but does not have the MAC address of Host A in its ARP cache. Host B generates a broadcast message for all hosts within the broadcast domain to obtain the MAC address associated with the IP address of Host A. All hosts within the broadcast domain receive the ARP request, and Host A responds with its MAC address. However, because ARP allows a gratuitous reply from a host even if an ARP request was not received, an ARP spoofing attack and the poisoning of ARP caches can occur. After the attack, all traffic from the device under attack flows through the attacker's computer and then to the router, switch, or host.

A malicious user can attack hosts, switches, and routers connected to your Layer 2 network by poisoning the ARP caches of systems connected to the subnet and by intercepting traffic intended for other hosts on the subnet. Figure 26-1 shows an example of ARP cache poisoning.

Figure 21: ARP Cache Poisoning

Hosts A, B, and C are connected to the switch on interfaces A, B and C, all of which are on the same subnet. Their IP and MAC addresses are shown in parentheses; for example, Host A uses IP address IA and MAC address MA. When Host A needs to communicate to Host B at the IP layer, it broadcasts an ARP request for the MAC address associated with IP address IB. When the switch and Host B receive the ARP request, they populate their ARP caches with an ARP binding for a host with the IP address IA and a MAC address MA; for example, IP address IA is bound to MAC address MA. When Host B responds, the switch and Host A populate their ARP caches with a binding for a host with the IP address IB and the MAC address MB.

Host C can poison the ARP caches of the switch, Host A, and Host B by broadcasting forged ARP responses with bindings for a host with an IP address of IA (or IB) and a MAC address of MC. Hosts with poisoned ARP caches use the MAC address MC as the destination MAC address for traffic intended for IA or IB. This means that Host C intercepts that traffic. Because Host C knows the true MAC addresses associated with IA and IB, it can forward the intercepted traffic to those hosts by using the correct MAC address as the destination. Host C has inserted itself into the traffic stream from Host A to Host B, the classic *man-in-the middle*attack.

Dynamic ARP inspection is a security feature that validates ARP packets in a network. It intercepts, logs, and discards ARP packets with invalid IP-to-MAC address bindings. This capability protects the network from certain man-in-the-middle attacks.

Dynamic ARP inspection ensures that only valid ARP requests and responses are relayed. The switch performs these activities:

- Intercepts all ARP requests and responses on untrusted ports.
- Verifies that each of these intercepted packets has a valid IP-to-MAC address binding before updating the local ARP cache or before forwarding the packet to the appropriate destination.
- Drops invalid ARP packets.

Dynamic ARP inspection determines the validity of an ARP packet based on valid IP-to-MAC address bindings stored in a trusted database, the DHCP snooping binding database. This database is built by DHCP snooping if DHCP snooping is enabled on the VLANs and on the switch. If the ARP packet is received on a trusted interface, the switch forwards the packet without any checks. On untrusted interfaces, the switch forwards the packet only if it is valid.

In non-DHCP environments, dynamic ARP inspection can validate ARP packets against user-configured ARP access control lists (ACLs) for hosts with statically configured IP addresses. You define an ARP ACL by using the **arp access-list** *acl-name* global configuration command.

You can configure dynamic ARP inspection to drop ARP packets when the IP addresses in the packets are invalid or when the MAC addresses in the body of the ARP packets do not match the addresses specified in the Ethernet header. Use the **ip arp inspection validate** {[**src-mac**] [**dst-mac**] [**ip**]} global configuration command.

Interface Trust States and Network Security

Dynamic ARP inspection associates a trust state with each interface on the switch. Packets arriving on trusted interfaces bypass all dynamic ARP inspection validation checks, and those arriving on untrusted interfaces undergo the dynamic ARP inspection validation process.

In a typical network configuration, you configure all switch ports connected to host ports as untrusted and configure all switch ports connected to switches as trusted. With this configuration, all ARP packets entering the network from a given switch bypass the security check. No other validation is needed at any other place in the VLAN or in the network. You configure the trust setting by using theip arp inspection trust interface configuration command.

∕!∖

```
Caution
```

Use the trust state configuration carefully. Configuring interfaces as untrusted when they should betrusted can result in a loss of connectivity.

In the following figure, assume that both Switch A and Switch B are running dynamic ARP inspection on the VLAN that includes Host 1 and Host 2. If Host 1 and Host 2 acquire their IP addresses from the DHCP server connected to Switch A, only Switch A binds the IP-to-MAC address of Host 1. Therefore, if the interface between Switch A and Switch B is untrusted, the ARP packets from Host 1 are dropped by Switch B. Connectivity between Host 1 and Host 2 is lost.

Figure 22: ARP Packet Validation on a VLAN Enabled for Dynamic ARP Inspection

Configuring interfaces to be trusted when they are actually untrusted leaves a security hole in the network. If Switch A is not running dynamic ARP inspection, Host 1 can easily poison the ARP cache of Switch B (and Host 2, if the link between the switches is configured as trusted). This condition can occur even though Switch B is running dynamic ARP inspection.

Dynamic ARP inspection ensures that hosts (on untrusted interfaces) connected to a switch running dynamic ARP inspection do not poison the ARP caches of other hosts in the network. However, dynamic ARP inspection does not prevent hosts in other portions of the network from poisoning the caches of the hosts that are connected to a switch running dynamic ARP inspection.

In cases in which some switches in a VLAN run dynamic ARP inspection and other switches do not, configure the interfaces connecting such switches as untrusted. However, to validate the bindings of packets from nondynamic ARP inspection switches, configure the switch running dynamic ARP inspection with ARP ACLs. When you cannot determine such bindings, at Layer 3, isolate switches running dynamic ARP inspection from switches not running dynamic ARP inspection switches.

Note Depending on the setup of the DHCP server and the network, it might not be possible to validate a given ARP packet on all switches in the VLAN.

Rate Limiting of ARP Packets

The switch CPU performs dynamic ARP inspection validation checks; therefore, the number of incoming ARP packets is rate-limited to prevent a denial-of-service attack. By default, the rate for untrusted interfaces is 15 packets per second (pps). Trusted interfaces are not rate-limited. You can change this setting by using the **ip arp inspection limit** interface configuration command.

When the rate of incoming ARP packets exceeds the configured limit, the switch places the port in the error-disabled state. The port remains in that state until you intervene. You can use the **errdisable recovery** global configuration command to enable error disable recovery so that ports automatically emerge from this state after a specified timeout period.

The rate limit for an EtherChannel is applied separately to each switch in a stack. For example, if a limit of 20 pps is configured on the EtherChannel, each switch with ports in the EtherChannel can carry up to 20 pps. If any switch exceeds the limit, the entire EtherChannel is placed into the error-disabled state.

Relative Priority of ARP ACLs and DHCP Snooping Entries

Dynamic ARP inspection uses the DHCP snooping binding database for the list of valid IP-to-MAC address bindings.

ARP ACLs take precedence over entries in the DHCP snooping binding database. The switch uses ACLs only if you configure them by using the **ip arp inspection filter vlan** global configuration command. The switch first compares ARP packets to user-configured ARP ACLs. If the ARP ACL denies the ARP packet, the switch also denies the packet even if a valid binding exists in the database populated by DHCP snooping.

Logging of Dropped Packets

When the switch drops a packet, it places an entry in the log buffer and then generates system messages on a rate-controlled basis. After the message is generated, the switch clears the entry from the log buffer. Each log entry contains flow information, such as the receiving VLAN, the port number, the source and destination IP addresses, and the source and destination MAC addresses.

You use the **ip arp inspection log-buffer** global configuration command to configure the number of entries in the buffer and the number of entries needed in the specified interval to generate system messages. You specify the type of packets that are logged by using the **ip arp inspection vlan logging** global configuration command.

Default Dynamic ARP Inspection Configuration

Feature	Default Settings
Dynamic ARP inspection	Disabled on all VLANs.
Interface trust state	All interfaces are untrusted.

Note

Feature	Default Settings
Rate limit of incoming ARP packets	The rate is 15 pps on untrusted interfaces, assuming that the network is a switched network with a host connecting to as many as 15 new hosts per second.
	The rate is unlimited on all trusted interfaces.
	The burst interval is 1 second.
ARP ACLs for non-DHCP environments	No ARP ACLs are defined.
Validation checks	No checks are performed.
Log buffer	When dynamic ARP inspection is enabled, all denied or dropped ARP packets are logged.
	The number of entries in the log is 32.
	The number of system messages is limited to 5 per second.
	The logging-rate interval is 1 second.
Per-VLAN logging	All denied or dropped ARP packets are logged.

Relative Priority of ARP ACLs and DHCP Snooping Entries

Dynamic ARP inspection uses the DHCP snooping binding database for the list of valid IP-to-MAC address bindings.

ARP ACLs take precedence over entries in the DHCP snooping binding database. The switch uses ACLs only if you configure them by using the ip arp inspection filter vlan global configuration command. The switch first compares ARP packets to user-configured ARP ACLs. If the ARP ACL denies the ARP packet, the switch also denies the packet even if a valid binding exists in the database populated by DHCP snooping.

How to Configure Dynamic ARP Inspection

Configuring ARP ACLs for Non-DHCP Environments

This procedure shows how to configure dynamic ARP inspection when Switch B shown in Figure 2 does not support dynamic ARP inspection or DHCP snooping.

If you configure port 1 on Switch A as trusted, a security hole is created because both Switch A and Host 1 could be attacked by either Switch B or Host 2. To prevent this possibility, you must configure port 1 on Switch A as untrusted. To permit ARP packets from Host 2, you must set up an ARP ACL and apply it to VLAN 1. If the IP address of Host 2 is not static (it is impossible to apply the ACL configuration on Switch A) you must separate Switch A from Switch B at Layer 3 and use a router to route packets between them.

Follow these steps to configure an ARP ACL on Switch A. This procedure is required in non-DHCP environments.

I

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	arp access-list acl-name	Defines an ARP ACL, and enters ARP
	Example:	access-list configuration mode. By default, no
	Device (config) # arp access-list arpacl22	ARP access lists are defined.
		Note At the end of the ARP access list, there is an implicit deny ip any mac any command.
Step 4	permit ip host sender-ip mac host sender-mac	Permits ARP packets from the specified host
	Example:	(Host 2).
	Device(config-arp-nacl))# permit ip host 10.2.2.2 mac host 0018.bad8.3fbd	• For <i>sender-ip</i> , enter the IP address of Host 2.
		• For <i>sender-mac</i> , enter the MAC address of Host 2.
Step 5	exit	Exits ARP access-list configuration mode and
	Example:	returns to global configuration mode.
	<pre>Device(config-arp-nacl)# exit</pre>	
Step 6	ip arp inspection filter <i>arp-acl-name</i> vlan <i>vlan-range</i> [static]	Applies ARP ACL to the VLAN. By default, no defined ARP ACLs are applied to any
	Example:	VLAN.
	Device (config) # ip arp inspection filter arpacl22 vlan 1-2	• For <i>arp-acl-name</i> , specify the name of the ACL created in Step 2.
		• For <i>vlan-range</i> , specify the VLAN that the switches and hosts are in. You can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094.
		• (Optional) Specify static to treat implicit denies in the ARP ACL as explicit denies and to drop packets that do not match any previous clauses in the ACL. DHCP bindings are not used.

	Command or Action	Purpose
		If you do not specify this keyword, it means that there is no explicit deny in the ACL that denies the packet, and DHCP bindings determine whether a packet is permitted or denied if the packet does not match any clauses in the ACL.
		ARP packets containing only IP-to-MAC address bindings are compared against the ACL. Packets are permitted only if the access list permits them.
Step 7	<pre>interface interface-type interface-number Example: Device(config)# interface gigabitethernt 0/1/1</pre>	Specifies Switch A interface that is connected to Switch B, and enters interface configuration mode.
Step 8	<pre>no ip arp inspection trust Example: Device(config-if)# no ip arp inspection trust</pre>	Configures Switch A interface that is connected to Switch B as untrusted. By default, all interfaces are untrusted. For untrusted interfaces, the switch intercepts all ARP requests and responses. It verifies that the intercepted packets have valid IP-to-MAC address bindings before updating the local cache and before forwarding the packet to the appropriate destination. The switch drops invalid packets and logs them in the log buffer according to the logging configuration specified with the ip arp inspection vlan logging global configuration command.
Step 9	end Example: Device(config-if)# end	Exits interface configuration mode and returns to privileged EXEC mode.
Step 10	<pre>show arp access-list acl-name Example: Device# show arp access-list arpacl22</pre>	Displays information about the named ACLs.
Step 11	show ip arp inspection vlan vlan-range Example: Device# show ip arp inspection vlan 1-2	Displays the statistics for the selected range of VLANs.
Step 12	<pre>show ip arp inspection interfaces Example: Device# show ip arp inspection interfaces</pre>	Displays the trust state and the rate limit of ARP packets for the provided interface.

L

Configuring Dynamic ARP Inspection in DHCP Environments

Before you begin

This procedure shows how to configure dynamic ARP inspection when two switches support this feature. Host 1 is connected to Switch A, and Host 2 is connected to Switch B. Both switches are running dynamic ARP inspection on VLAN 1 where the hosts are located. A DHCP server is connected to Switch A. Both hosts acquire their IP addresses from the same DHCP server. Therefore, Switch A has the bindings for Host 1 and Host 2, and Switch B has the binding for Host 2.

Note

Dynamic ARP inspection depends on the entries in the DHCP snooping binding database to verify IP-to-MAC address bindings in incoming ARP requests and ARP responses. Make sure to enable DHCP snooping to permit ARP packets that have dynamically assigned IP addresses.

Follow these steps to configure dynamic ARP inspection. You must perform this procedure on both switches. This procedure is required.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	show cdp neighbors	Verify the connection between the switches.
	Example:	
	Device# show cdp neighbors	
Step 3	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 4	ip arp inspection vlan vlan-range	Enable dynamic ARP inspection on a
	Example:	per-VLAN basis. By default, dynamic ARP
	Device(config)# ip arp inspection vlan	inspection is disabled on all VLANs. For vlan-range, specify a single VLAN identified
	1	by VLAN ID number, a range of VLANs
		separated by a hyphen, or a series of VLANs
		separated by a comma. The range is 1 to 4094. Specify the same VLAN ID for both switches.
Step 5	Interfacetype number	Specifies the interface connected to the other
-	Example:	switch, and enter interface configuration mode.
	Device(config)# interface	
	gigabitethernet 1/0/1	

I

	Command or Action	Purpose
Step 6	ip arp inspection trust Example:	Configures the connection between the switches as trusted. By default, all interfaces are untrusted.
	<pre>Device(config-if)# ip arp inspection trust</pre>	The switch does not check ARP packets that it receives from the other switch on the trusted interface. It simply forwards the packets.
		For untrusted interfaces, the switch intercepts all ARP requests and responses. It verifies that the intercepted packets have valid IP-to-MAC address bindings before updating the local cache and before forwarding the packet to the appropriate destination. The switch drops invalid packets and logs them in the log buffer according to the logging configuration specified with the ip arp inspection vlan logging global configuration command.
Step 7	end	Exits interface configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-if)# end	
Step 8	show ip arp inspection interfaces	Verifies the dynamic ARP inspection
	Example:	configuration on interfaces.
	Device# show ip arp inspection interfaces	
Step 9	show ip arp inspection vlan vlan-range	Verifies the dynamic ARP inspection
	Example:	configuration on VLAN.
	Device# show ip arp inspection vlan 1	
Step 10	show ip dhcp snooping binding	Verifies the DHCP bindings.
	Example:	
	Device# show ip dhcp snooping binding	
Step 11	show ip arp inspection statistics vlan vlan-range	Checks the dynamic ARP inspection statistics on VLAN.
	Example:	
	Device# show ip arp inspection statistics vlan 1	

Limiting the Rate of Incoming ARP Packets

The switch CPU performs dynamic ARP inspection validation checks; therefore, the number of incoming ARP packets is rate-limited to prevent a denial- of-service attack.

When the rate of incoming ARP packets exceeds the configured limit, the switch places the port in the error-disabled state. The port remains in that state until you enable error-disabled recovery so that ports automatically emerge from this state after a specified timeout period.

Note Unless you configure a rate limit on an interface, changing the trust state of the interface also changes its rate limit to the default value for that trust state. After you configure the rate limit, the interface retains the rate limit even when its trust state is changed. If you enter the **no ip arp inspection limit** interface configuration command, the interface reverts to its default rate limit.

Follow these steps to limit the rate of incoming ARP packets. This procedure is optional.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface type number	Specifies the interface to be rate-limited, and
	Example:	enters interface configuration mode.
	Device(config)# interface gigabitethernet 0/1/2	
Step 4	ip arp inspection limit {rate pps [burst interval seconds] none}	Limits the rate of incoming ARP requests and responses on the interface. The default rate is 15 pps on untrusted interfaces and unlimited on trusted interfaces. The burst interval is 1 second.
		The keywords have these meanings:
		• For rate <i>pps</i> , specify an upper limit for the number of incoming packets processed per second. The range is 0 to 2048 pps.
		• (Optional) For burst interval seconds, specify the consecutive interval in seconds, over which the interface is monitored for a high rate of ARP packets. The range is 1 to 15.
		• For rate none , specify no upper limit for the rate of incoming ARP packets that can be processed.

	Command or Action	Purpose
Step 5	exit Example: Device(config-if)# exit	Exits interface configuration mode and returns to global configuration mode.
Step 6	Use the following commands: • errdisable detect cause arp-inspection • errdisable recovery cause arp-inspection • errdisable recovery interval interval Example: Device (config) # errdisable recovery cause arp-inspection	By default, recovery is disabled, and the recovery interval is 300 seconds.
Step 7	exit Example: Device(config)# exit	Exits global configuration mode and returns to privileged EXEC mode.

Performing Dynamic ARP Inspection Validation Checks

Dynamic ARP inspection intercepts, logs, and discards ARP packets with invalid IP-to-MAC address bindings. You can configure the switch to perform additional checks on the destination MAC address, the sender and target IP addresses, and the source MAC address.

Follow these steps to perform specific checks on incoming ARP packets. This procedure is optional.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	ip arp inspection validate {[src-mac] [dst-mac] [ip]}	Performs a specific check on incoming ARP packets. By default, no checks are performed.
	Example:	The keywords have these meanings:
	<pre>Device(config)# ip inspection validate ip</pre>	• For src-mac , check the source MAC address in the Ethernet header against the sender MAC address in the ARP body. This check is performed on both ARP

	Command or Action	Purpose
		requests and responses. When enabled, packets with different MAC addresses are classified as invalid and are dropped.
		• For dst-mac , check the destination MAC address in the Ethernet header against the target MAC address in ARP body. This check is performed for ARP responses. When enabled, packets with different MAC addresses are classified as invalid and are dropped.
		• For ip , check the ARP body for invalid and unexpected IP addresses. Addresses include 0.0.0.0, 255.255.255.255, and all IP multicast addresses. Sender IP addresses are checked in all ARP requests and responses, and target IP addresses are checked only in ARP responses.
		You must specify at least one of the keywords. Each command overrides the configuration of the previous command; that is, if a command enables src and dst mac validations, and a second command enables IP validation only, the src and dst mac validations are disabled as a result of the second command.
Step 4	exit	Exits global configuration mode and returns to
	Example:	privileged EXEC mode.
	Device(config)# exit	
Step 5	show ip arp inspection vlan vlan-range	Displays the statistics for the selected range of
	Example:	VLANs.
	Device# show ip arp insepction vlan 1-2	

Monitoring DAI

To monitor DAI, use the following commands:

Command	Description
clear ip arp inspection statistics	Clears dynamic ARP inspection statistics.

Command	Description
show ip arp inspection statistics [vlan vlan-range]	Displays statistics for forwarded, dropped, MAC validation failure, IP validation failure, ACL permitted and denied, and DHCP permitted and denied packets for the specified VLAN. If no VLANs are specified or if a range is specified, displays information only for VLANs with dynamic ARP inspection enabled (active).
clear ip arp inspection log	Clears the dynamic ARP inspection log buffer.
show ip arp inspection log	Displays the configuration and contents of the dynamic ARP inspection log buffer.

For the **show ip arp inspection statistics** command, the switch increments the number of forwarded packets for each ARP request and response packet on a trusted dynamic ARP inspection port. The switch increments the number of ACL or DHCP permitted packets for each packet that is denied by source MAC, destination MAC, or IP validation checks, and the switch increments the appropriate.

Verifying the DAI Configuration

To display and verify the DAI configuration, use the following commands:

Command	Description
show arp access-list [acl-name]	Displays detailed information about ARP ACLs.
show ip arp inspection interfaces [interface-id]	Displays the trust state and the rate limit of ARP packets for the specified interface or all interfaces.
show ip arp inspection vlan vlan-range	Displays the configuration and the operating state of dynamic ARP inspection for the specified VLAN. If no VLANs are specified or if a range is specified, displays information only for VLANs with dynamic ARP inspection enabled (active).

Feature History for Dynamic ARP Inspection

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.11.1	Dynamic ARP Inspection	ARP provides IP communication within a Layer 2 broadcast domain by mapping an IP address to a MAC address. Dynamic ARP inspection is a security feature that validates ARP packets in a network. It intercepts, logs, and discards ARP packets with invalid IP-to-MAC address bindings. This capability protects the network from certain man-in-the-middle attacks.
Cisco IOS XE Cupertino 17.7.1	Dynamic ARP Inspection	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

Configuring IPv6 First Hop Security

- Additional References for IPv6 First Hop Security, on page 485
- Feature History for IPv6 First Hop Security, on page 486

Prerequisites for IPv6 First Hop Security

You have configured the necessary IPv6 enabled SDM template.

Restrictions for IPv6 First Hop Security

The following restrictions apply when applying FHS policies to EtherChannel interfaces (Port Channels):

- A physical port with an FHS policy attached cannot join an EtherChannel group.
- An FHS policy cannot be attached to an physical port when it is a member of an EtherChannel group.

Information About IPv6 First Hop Security

IPv6 FHS is composed of the following IPv6 security features: IPv6 Snooping, IPv6 Neighbor Discovery Inspection, IPv6 Router Advertisement Guard, IPv6 DHCP Guard, IPv6 Source Guard, IPv6 Prefix Guard, IPv6 Destination Guard.

Each one of these security features addresses a different aspect of first hop security. In order to use a security feature, the corresponding policy must be configured. Policies specify a particular behavior. They must also be attached to a target, which can be a physical interface, an EtherChannel interface, or a VLAN. An IPv6 software policy database service stores and accesses these policies. When a policy is configured or modified, the attributes of the policy are stored or updated in the software policy database, and applied as specified.

In addition to the security features, the IPv6 FHS infrastructure has an IPv6 FHS Binding Table, which is a database table of IPv6 neighbors connected to the device. A binding entry includes information such as the

IP and MAC address of the host, the interface, VLAN, state of the entry etc. This database or binding table is used by other features (such as IPv6 ND Inspection) to validate the link-layer address (LLA), the IPv4 or IPv6 address, and prefix binding of the neighbors, to prevent spoofing and redirect attacks. The binding table is updated through the IPv6 Snooping feature, and through manually added static binding entries.

Ø

Note The IPv6 FHS Binding Table is supported through the Switch Integrated Security Feature (SISF) feature. For more information, see the *Configuring Switch Integrated Security Features* chapter in this guide.

IPv6 Snooping

Note The IPv6 Snooping feature is deprecated and the SISF feature replaces it and offers the same capabilities. While the IPv6 Snooping commands are still available on the CLI and the existing configuration continues to be supported, the commands will be removed from the CLI in a later release. For more information about the replacement feature, see the *Configuring Switch Integrated Security Features* chapter in this guide.

IPv6 Snooping acts as a container that enables most of the features available with FHS in IPv6 including following capabilities and functions:

- Neighbor Discovery Snooping: IPv6 Neighbor Discovery Snooping analyzes and verifies IPv6 Neighbor Discovery Protocol (NDP) traffic. During inspection, it gleans address bindings (IP, MAC, port, etc) and stores it in the binding table.
- DHCPv6 Snooping: DHCPv6 Snooping traps DHCPv6 packets between DHCPv6 Client and DHCPv6 Server. From the packets snooped, assigned addresses are learnt and stored in the binding table.
- Device tracking: IPv6 Snooping also tracks the movement of hosts from one port to another, verifies their existence using Duplicate Address Detection (DAD).
- With the IPv6 Snooping feature one can limit the number of addresses any node on the link can claim. This feature can be used to protect the switch binding table against denial of service flooding attacks.

By default, a snooping policy has a security-level of guard. When a snooping policy is configured on an access switch, external IPv6 Router Advertisement (RA) or Dynamic Host Configuration Protocol for IPv6 (DHCPv6) server packets are blocked, even though the uplink port facing the device or DHCP server or relay is configured as a trusted port. To allow IPv6 RA or DHCPv6 server messages, do the following:

- Apply an IPv6 RA-guard policy (for RA) or IPv6 DHCP-guard policy (for DHCP server messages) on the uplink port.
- Configure a snooping policy with a lower security-level, for example glean or inspect. This is a less preferable option, because the benefits of FHS features are not effective.

To use this feature, configure an IPv6 Snooping policy and attach it to a target. See Configuring an IPv6 Snooping Policy, on page 455.

IPv6 Neighbor Discovery Inspection

Note Starting with Cisco IOS XE Amsterdam 17.1.1, the IPv6 Neighbor Discovery Inspection (IPv6 ND Inspection) feature is deprecated and the SISF feature replaces it and offers the same capabilities. While the IPv6 ND Inspection commands are still available on the CLI and the existing configuration continues to be supported, the commands will be removed from the CLI in a later release. For more information about the replacement feature, see the *Configuring Switch Integrated Security Features* chapter in this guide.

The IPv6 ND Inspection feature learns and secures bindings for stateless auto-configuration addresses in Layer 2 neighbor tables. It analyzes neighbor discovery messages in order to build a trusted binding table database. IPv6 neighbor discovery messages that do not conform are dropped. An neighbor discovery message is considered trustworthy if its IPv6-to-MAC mapping is verifiable.

This feature mitigates some of the inherent vulnerabilities of the ND mechanism, such as attacks on DAD, address resolution, router discovery, and the neighbor cache.

To use this feature, configure an IPv6 ND Inspection policy and attach it to a target. See Configuring an IPv6 Neighbor Discovery Inspection Policy, on page 461.

IPv6 Router Advertisement Guard

This feature enables the network administrator to block or reject unwanted or rogue Router Advertisement (RA) guard messages that arrive at the network device platform. RAs are used by devices to announce themselves on the link. The RA Guard feature analyzes the RAs and filters out bogus RAs sent by unauthorized devices. In host mode, all router advertisement and router redirect messages are disallowed on the port. The RA guard feature compares configuration information on the Layer 2 device with the information found in the received RA frame. Once the Layer 2 device has validated the content of the RA frame and router redirect frame against the configuration, it forwards the RA to its unicast or multicast destination. If the RA frame content is not validated, the RA is dropped.

SISF-based device-tracking forwards router solicitation packets only on interfaces that have the RA guard policy configured and are also designated as router-facing interfaces. If no such interface exists, the router solicitation messages are dropped, which might delay the router discovery for onboarding hosts as they will be unable to discover the router until it sends a periodic unsolicited router advertisement.

To use this feature, configure an IPv6 RA Guard policy and attach it to a target. See Configuring an IPv6 Router Advertisement Guard Policy, on page 466.

IPv6 DHCP Guard

The IPv6 DHCP Guard feature blocks reply and advertisement messages that come from unauthorized DHCPv6 servers and relay agents. IPv6 DHCP guard can prevent forged messages from being entered in the binding table and block DHCPv6 server messages when they are received on ports that are not explicitly configured as facing a DHCPv6 server or DHCP relay.

To use this feature, configure an IPv6 DHCP Guard policy and attach it to a target. See Configuring an IPv6 DHCP Guard Policy, on page 471.

To debug DHCP guard packets, use the debug ipv6 snooping dhcp-guard privileged EXEC command.

IPv6 Source Guard

The IPv6 Source Guard feature validates the source of IPv6 traffic to prevent source address spoofing. It deals exclusively with data packet traffic. You can use this feature to deny traffic from unknown sources, traffic from sources not assigned by a DHCP server, etc.

It involves a hardware-programmed (TCAM table) filter which allows or denies traffic based on its source address. For the filter to work this way, an entry (of the source address) in the binding table is required. If the source address is in the binding table, the filter allows the packet into the network; if the address is not in the binding table, entry is denied and the packet is dropped. When an entry is removed from the binding table, the filter is also removed, and subsequent packets with that source address are dropped.

When configuring this feature, consider the following:

- The IPv6 Source Guard and Prefix Guard features are supported only in the ingress direction and not supported in the egress direction.
- You cannot use IPv6 Source Guard and Prefix Guard together. When you attach the policy to an interface, it should be "validate address" or "validate prefix" but not both.
- PVLAN and Source or Prefix Guard cannot be applied together.
- IPv6 Source Guard and Prefix Guard is supported on EtherChannels
- An IPv6 source guard policy cannot be attached to a VLAN. It is supported only at the interface level.
- When you configure IPv4 and IPv6 source guard together on an interface, it is recommended to use ip verify source mac-check command instead of ip verify source tracking mac-check command. IPv4 connectivity on a given port might break due to two different filtering rules set: one for IPv4 (IP-filter) and the other for IPv6 (IP-MAC filter).
- When IPv6 source guard is enabled on a switch port, NDP or DHCP snooping must be enabled on the interface to which the switch port belongs. Otherwise, all data traffic from this port will be blocked.
- Binding information is normally gleaned from IPv6 NDP traffic and DHCP packets. If you rely only on a DHCP server for source addresses of hosts, ensure that you also configure a data-glean recovery function to counteract a situation where entries are prematurely removed from the binding table (for various reasons) before the DHCP lease timer expires. This way, the recovery function *restores* binding entries of valid hosts and you can be sure that the IPv6 Source Guard feature allows only packets with a DHCP server-assigned source address. See Example: Using the Data-Glean Recovery Function, on page 483.

To use this feature, you must configure an IPv6 Source Guard policy and attach it to a target. See Configuring IPv6 Source Guard, on page 475.

To debug source-guard packets, use the **debug ipv6 snooping source-guard** privileged EXEC command.

IPv6 Prefix Guard

The IPv6 Prefix Guard feature works within the IPv6 Source Guard feature to enable the device to deny traffic originated from non-topologically correct addresses. IPv6 Prefix Guard is often used when IPv6 prefixes are delegated to devices (for example, home gateways) using DHCP prefix delegation. The feature discovers ranges of addresses assigned to the link and blocks any traffic sourced with an address outside this range.

In order to use this feature, you must configure an IPv6 Prefix Guard policy and attach it to a target. See Configuring IPv6 Prefix Guard, on page 478.

Note Ensure that you have read the configuration considerations listed in the **IPv6 Source Guard** section above - some of them apply to the IPv6 Prefix Guard feature as well.

IPv6 Destination Guard

The IPv6 Destination Guard feature works with IPv6 neighbor discovery to ensure that the device performs address resolution only for those addresses that are known to be active on the link. It relies on the address glean functionality to populate all destinations active on the link into the binding table and then blocks resolutions before they happen when the destination is not found in the binding table.

Note

We recommend that you apply an IPv6 Destination Guard policy on all Layer 2 VLANs with an SVI configured.

In order to use this feature, you must configure an IPv6 Destination Guard policy and attach it to a target. See Configuring an IPv6 Destination Guard Policy, on page 480.

How to Configure IPv6 First Hop Security

Configuring an IPv6 Snooping Policy

Note The IPv6 Snooping Policy feature has been deprecated. Although the commands are visible on the CLI and you can configure them, we recommend that you use the Switch Integrated Security Feature (SISF)-based Device Tracking feature instead.

Beginning in privileged EXEC mode, follow these steps to configure IPv6 Snooping Policy :

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	ipv6 snooping policy policy-name	Creates a snooping policy and enters IPv6
	Example:	snooping policy configuration mode.
	<pre>Device(config)# ipv6 snooping policy example_policy</pre>	

	Command or Action	Purpose
Step 4	<pre>{[default] [device-role {node switch}] [limit address-count value] [no] [protocol {dhcp ndp}] [security-level {glean guard inspect}] [tracking {disable [stale-lifetime</pre>	Enables data address gleaning, validates messages against various criteria, specifies the security level for messages.
	[seconds infinite] enable [reachable-lifetime [seconds infinite] }] [trusted-port] }	• (Optional) default : Sets all to default options.
	Example: Device (config-ipv6-snooping) # security-level inspect	• (Optional) device-role {node] switch}: Specifies the role of the device attached to the port. Default is node.
	Example: Device (config-ipv6-snooping) # trusted-port	• (Optional) limit address-count <i>value</i> : Limits the number of addresses allowed per target.
		• (Optional) no : Negates a command or set it to defaults.
		• (Optional) protocol { dhcp ndp }: Specifies which protocol should be redirected to the snooping feature for analysis. The default, is dhcp and ndp . To change the default, use the no protocol command.
		• (Optional) security-level {glean guard inspect}: Specifies the level of security enforced by the feature. Default is guard.
		glean : Gleans addresses from message and populates the binding table withou any verification.
		 guard: Gleans addresses and inspect messages. In addition, it rejects RA an DHCP server messages. This is the default option. inspect: Gleans addresses, validates messages for consistency and conformance, and enforces address
		 ownership. (Optional) tracking {disable enable}: Overrides the default tracking behavior and specifies a tracking option.
		• (Optional) trusted-port : Sets up a trusted port. It disables the guard on applicable targets. Bindings learned through a trusted port have preference over bindings learned through any other port. A trusted port is given preference in case of a collision while making an entry in the table.

	Command or Action	Purpose
Step 5	end	Exits IPv6 snooping policy configuration mode
	Example:	and returns to privileged EXEC mode.
	<pre>Device(config-ipv6-snooping) # end</pre>	
Step 6	show ipv6 snooping policy policy-name	Displays the snooping policy configuration.
	Example:	
	Device#show ipv6 snooping policy example_policy	

What to do next

Attach an IPv6 Snooping policy to interfaces or VLANs.

Attaching an IPv6 Snooping Policy to an Interface

Beginning in privileged EXEC mode, follow these steps to attach an IPv6 Snooping policy on an interface or VLAN:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	<pre>interface interface_type stack/module/port</pre>	Specifies an interface type and identifier and
	Example:	enters the interface configuration mode.
	Device(config)# interface gigabitethernet 1/1/4	
Step 4	switchport	Enters the Switchport mode.
	Example:	

	Command or Action	Purpose
Step 5	command of Action Device (config-if) # switchport ipv6 snooping [attach-policy policy_name [vlan_id add vlan_ids except vlan_ids none remove vlan_ids] vlan {vlan_id add vlan_ids except vlan_ids none remove vlan_ids all }] Example: Device (config-if) # ipv6 snooping	NoteTo configure Layer 2 parameters, if the interface is in Layer 3 mode, you must enter the switchport interface configuration command without any parameters to change the interface into Layer 2 mode. This shuts down the interface and then re-enables it, which might generate messages on the device to which the interface is connected. When change the interface mode from Layer 3 to Layer 2 mode, the previous configuration information related to the affected interface might be lost, and the interface is returned to its default configuration. The command prompt displays as (config-if)# in Switchport configuration mode.Attaches a custom IPv6 snooping policy to the interface, use the ipv6 snooping command without the attach-policy keyword. To attach the default policy to VLANs on the interface, use the ipv6 snooping vlan command. The default policy is, security-level guard,
	<pre>Device(config-if)# ipv6 snooping attach-policy Device(config-if)# ipv6 snooping vlan</pre>	device-role node , protocol ndp and dhcp .
	<pre>111,112 Device(config-if)# ipv6 snooping attach-policy example_policy vlan 111,112</pre>	
Step 6	end	Exits interface configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-if)# end	
Step 7	<pre>show running-config Example: Device# show running-config</pre>	Verifies that the policy is attached to the specified interface without exiting the interface configuration mode.

Attaching an IPv6 Snooping Policy to a Layer 2 EtherChannel Interface

Beginning in privileged EXEC mode, follow these steps to attach an IPv6 Snooping policy on an EtherChannel interface or VLAN:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface range interface_name	Specifies the port-channel interface name
	Example:	assigned when the EtherChannel was created Enters the interface range configuration mode
	Device(config)# interface range Port-channel 11	Tip Enter the show interfaces summary command for quick reference to interface names and
		types.
Step 4	<pre>ipv6 snooping [attach-policy policy_name [vlan {vlan_ids add vlan_ids except vlan_ids none remove vlan_ids all}] vlan [{vlan_ids add vlan_ids exceptvlan_ids none remove vlan_ids all}]</pre>	Attaches the IPv6 Snooping policy to the interface or the specified VLANs on that interface. The default policy is attached if the attach-policy option is not used.
	Example:	
	Device(config-if-range)# ipv6 snooping attach-policy example_policy	
	<pre>Device(config-if-range)# ipv6 snooping attach-policy example_policy vlan 222,223,224</pre>	
	<pre>Device(config-if-range)# ipv6 snooping vlan 222, 223,224</pre>	
Step 5	end	Exits interface range configuration mode and
	Example:	returns to privileged EXEC mode.
	<pre>Device(config-if-range) # end</pre>	
Step 6	show running-config	Confirms that the policy is attached to the
	interfaceportchannel_interface_name	specified interface.
	Example:	
	Device# show running-config interface portchannel 11	

I

Attaching an IPv6 Snooping Policy to VLANs Globally

Beginning in privileged EXEC mode, follow these steps to attach an IPv6 Snooping Policy to VLANs across multiple interfaces:

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	vlan configuration vlan_list	Specifies the VLANs to which the IPv6
	Example:	Snooping policy will be attached, and enters
	Device(config)# vlan configuration 333	the VLAN interface configuration mode.
Step 4	ipv6 snooping [attach-policy policy_name]	Attaches the IPv6 Snooping policy to the
	Example:	specified VLANs across all device interfaces.
	Device(config-vlan-config)#ipv6 snooping attach-policy example_policy	The default policy is attached if the attach-policy option is not used. The defaul policy is, security-level guard, device-role node, protocol ndp and dhcp.
Step 5	end	Exits VLAN interface configuration mode and
	Example:	returns to privileged EXEC mode.
	Device(config-vlan-config)# end	

Configuring the IPv6 Binding Table Content

Beginning in privileged EXEC mode, follow these steps to configure IPv6 Binding Table Content :

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	

	Command or Action	Purpose
Step 3	<pre>[no] ipv6 neighbor binding [vlan vlan-id {ipv6-address interface interface_type stack/module/port hw_address [reachable-lifetimevalue [seconds default infinite] [tracking { [default disable] [reachable-lifetimevalue [seconds default infinite] [enable [reachable-lifetimevalue [seconds default infinite] [retry-interval {seconds default [reachable-lifetimevalue [seconds default [infinite] }] Example: Device (config) # ipv6 neighbor binding</pre>	Adds a static entry to the binding table database.
Step 4	[no] ipv6 neighbor binding max-entries number [mac-limit number port-limit number [mac-limit number] vlan-limit number [[mac-limit number] [port-limit number [mac-limitnumber]]]]	Specifies the maximum number of entries that are allowed to be inserted in the binding table cache.
	Example: Device(config)# ipv6 neighbor binding max-entries 30000	
Step 5	<pre>ipv6 neighbor binding logging Example: Device(config)# ipv6 neighbor binding logging</pre>	Enables the logging of binding table main events.
Step 6	exit Example: Device(config)# exit	Exits global configuration mode and returns to privileged EXEC mode.
Step 7	show ipv6 neighbor bindingExample:Device# show ipv6 neighbor binding	Displays contents of a binding table.

Configuring an IPv6 Neighbor Discovery Inspection Policy

Starting with Cisco IOS XE Amsterdam 17.1.1 the IPv6 ND Inspection feature is deprecated and the SISFbased device tracking feature replaces it and offers the same capabilities. For the corresponding replacement task, see *Creating a Custom Device Tracking Policy with Custom Settings* under the *Configuring SISF-Based Device Tracking* chapter in this document.

Beginning in privileged EXEC mode, follow these steps to configure an IPv6 ND Inspection Policy:

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	ipv6 nd inspection policy policy-name	Specifies the ND inspection policy name and
	Example:	enters ND Inspection Policy configuration
	Device(config)# ipv6 nd inspection	mode.
	policy example_policy	
Step 4	device-role {host switch}	Specifies the role of the device attached to the
	Example:	port. The default is host .
	Device(config-nd-inspection)# device-role switch	
Step 5	limit address-count value	Limits the number of IPv6 addresses allowed
	Example:	to be used on the port.
	Device(config-nd-inspection)# limit address-count 1000	
Step 6	<pre>tracking {enable [reachable-lifetime {value infinite}] disable [stale-lifetime {value infinite}]}</pre>	Overrides the default tracking policy on a port.
	Example:	
	Device(config-nd-inspection)# tracking disable stale-lifetime infinite	
Step 7	trusted-port	Configures a port to become a trusted port.
	Example:	
	Device(config-nd-inspection)# trusted-port	
Step 8	validate source-mac	Checks the source media access control (MAC)
	Example:	address against the link-layer address.
	Device(config-nd-inspection)# validate source-mac	
Step 9	no {device-role limit address-count treaking trusted port volidate	Removes the current configuration of a
	<pre>tracking trusted-port validate source-mac}</pre>	parameter with the no form of the command.
	Example:	

	Command or Action	Purpose
	Device(config-nd-inspection)# no validate source-mac	
Step 10	default {device-role limit address-count tracking trusted-port validate source-mac}	Restores configuration to the default values.
	Example:	
	Device(config-nd-inspection)# default limit address-count	
Step 11	end	Exits ND Inspection Policy configuration mo and returns to privileged EXEC mode.
	Example:	
	Device(config-nd-inspection)# end	
Step 12	show ipv6 nd inspection policy policy_name	Verifies the ND inspection configuration.
	Example:	
	Device# show ipv6 nd inspection policy example_policy	

Attaching an IPv6 Neighbor Discovery Inspection Policy to an Interface

Starting with Cisco IOS XE Amsterdam 17.1.1 the IPv6 ND Inspection feature is deprecated and the SISFbased device tracking feature replaces it and offers the same capabilities. For the corresponding replacement task, see *Attaching a Device Tracking Policy to an Interface* under the *Configuring SISF-Based Device Tracking* chapter in this document.

Beginning in privileged EXEC mode, follow these steps to attach an IPv6 ND Inspection policy to an interface or VLANs on an interface :

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface interface-type interface-number	Specifies an interface type and identifier; enters
	Example:	the interface configuration mode.
	Device(config)# interface gigabitethernet 1/1/4	
Step 4	ipv6 nd inspection [attach-policy policy_name	Attaches the Neighbor Discovery Inspection
	[vlan {vlan_ids add vlan_ids except	policy to the interface or the specified VLANs

	Command or Action	Purpose
	<pre>vlan_ids none remove vlan_ids all }] vlan [{vlan_ids add vlan_ids exceptvlan_ids none remove vlan_ids all }]</pre>	on that interface. The default policy is attached if the attach-policy option is not used.
	Example:	
	<pre>Device(config-if) # ipv6 nd inspection attach-policy example_policy</pre>	
	<pre>Device(config-if)# ipv6 nd inspection attach-policy example_policy vlan 222,223,2</pre>	
	<pre>Device(config-if)# ipv6 nd inspection vlan 222, 223,224</pre>	
Step 5	end	Exits interface configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-if)# end	

Attaching an IPv6 Neighbor Discovery Inspection Policy to a Layer 2 EtherChannel Interface

Starting with Cisco IOS XE Amsterdam 17.1.1 the IPv6 ND Inspection feature is deprecated and the SISFbased device tracking feature replaces it and offers the same capabilities. For the corresponding replacement task, see *Attaching a Device Tracking Policy to an Interface* under the *Configuring SISF-Based Device Tracking* chapter in this document.

Beginning in privileged EXEC mode, follow these steps to attach an IPv6 Neighbor Discovery Inspection policy on an EtherChannel interface or VLAN:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example: Device# configure terminal	
Step 3	interface range interface_name Example:	Specifies the port-channel interface name assigned when the EtherChannel was created. Enters interface range configuration mode.
	Device(config)# interface range Port-channel 11	TipEnter the show interfaces summary command for quick reference to interface names and types.

	Command or Action	Purpose
Step 4	ipv6 nd inspection [attach-policy policy_name [vlan {vlan_ids add vlan_ids except vlan_ids none remove vlan_ids all }] vlan [{vlan_ids add vlan_ids exceptvlan_ids none remove vlan_ids all }]	Attaches the ND Inspection policy to the interface or the specified VLANs on that interface. The default policy is attached if the attach-policy option is not used.
	Example:	
	<pre>Device(config-if-range)# ipv6 nd inspection attach-policy example_policy</pre>	
	<pre>Device(config-if-range)# ipv6 nd inspection vlan 222, 223,224</pre>	
	<pre>Device(config-if-range)# ipv6 nd inspection attach-policy example_policy vlan 222,223,224</pre>	
Step 5	end	Exits interface range configuration mode and
	Example:	returns to privileged EXEC mode.
	Device(config-if-range) # end	

Attaching an IPv6 Neighbor Discovery Inspection Policy to VLANs Globally

Starting with Cisco IOS XE Amsterdam 17.1.1 the IPv6 ND Inspection feature is deprecated and the SISFbased device tracking feature replaces it and offers the same capabilities. For the corresponding replacement task, see *Attaching a Device Tracking Policy to a VLAN* under the *Configuring SISF-Based Device Tracking* chapter in this document.

Beginning in privileged EXEC mode, follow these steps to attach an IPv6 ND Inspection policy to VLANs across multiple interfaces:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	vlan configuration vlan_list	Specifies the VLANs to which the IPv6
	Example:	Snooping policy will be attached, and enters VLAN interface configuration mode.
	Device(config) # vlan configuration 334	VLAN interface configuration mode.
Step 4	ipv6 nd inspection [attach-policy	Attaches the IPv6 Neighbor Discovery policy
	[policy_name]	to the specified VLANs across all switch and

	Command or Action	Purpose
	Example: Device(config-vlan-config)#ipv6 nd inspection attach-policy example_policy	stack interfaces. The default policy is attached if the attach-policy option is not used. The default policy is, device-role host , no drop-unsecure, limit address-count disabled, sec-level minimum is disabled, tracking is disabled, no trusted-port, no validate source-mac.
Step 5	<pre>end Example: Device(config-vlan-config)# end</pre>	Exits VLAN interface configuration mode and returns to privileged EXEC mode.

Configuring an IPv6 Router Advertisement Guard Policy

Beginning in privileged EXEC mode, follow these steps to configure an IPv6 Router Advertisement policy :

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	ipv6 nd raguard policy policy-name	Specifies the RA guard policy name and enters
	Example:	RA guard policy configuration mode.
	<pre>Device(config)# ipv6 nd raguard policy example_policy</pre>	
Step 4	[no]device-role {host monitor router switch}	Specifies the role of the device attached to the port. The default is host .
	<pre>Example: Device(config-nd-raguard)# device-role switch</pre>	Note For a network with both host-facing ports and router-facing ports, along with a RA guard policy configured with device-role host on host-facing ports or vlan, it is mandatory to configure a RA guard policy with device-role router on router-facing ports to allow the RA Guard feature to work properly.

	Command or Action	Purpose
Step 5	<pre>hop-limit {maximum minimum} value Example: Device(config-nd-raguard)# hop-limit maximum 33</pre>	Enables filtering of Router Advertisement messages by the Hop Limit value. A rogue RA message may have a low Hop Limit value (equivalent to the IPv4 Time to Live) that when accepted by the host, prevents the host from generating traffic to destinations beyond the rogue RA message generator. An RA message with an unspecified Hop Limit value is blocked.
		(1–255) Range for Maximum and Minimum Hop Limit values.
		If not configured, this filter is disabled. Configure minimum to block RA messages with Hop Limit values lower than the value you specify. Configure maximum to block RA messages with Hop Limit values greater than the value you specify.
Step 6	managed-config-flag {off on}	Enables filtering of Router Advertisement
	<pre>Example: Device(config-nd-raguard)# managed-config-flag on</pre>	messages by the managed address configuration, or "M" flag field. A rouge RA message with an M field of 1 can cause a host to use a rogue DHCPv6 server. If not configured, this filter is disabled.
		On : Accepts and forwards RA messages with an M value of 1, blocks those with 0.
		Off : Accepts and forwards RA messages with an M value of 0, blocks those with 1.
Step 7	match {ipv6 access-list <i>list</i> ra prefix-list <i>list</i> }	Matches a specified prefix list or access list.
	Example:	
	<pre>Device(config-nd-raguard)# match ipv6 access-list example_list</pre>	
Step 8	other-config-flag {on off}	Enables filtering of Router Advertisement
	Example: Device(config-nd-raguard)# other-config-flag on	messages by the Other Configuration, or "O" flag field. A rouge RA message with an O field of 1 can cause a host to use a rogue DHCPv6 server. If not configured, this filter is disabled.
		On : Accepts and forwards RA messages with an O value of 1, blocks those with 0.
		Off : Accepts and forwards RA messages with an O value of 0, blocks those with 1.

	Command or Action	Purpose
Step 9	<pre>[no]router-preference maximum {high medium low} Example: Device (config-nd-raguard) # router-preference maximum high</pre>	Enables filtering of Router Advertisement messages by the router preference flag. If not configured, this filter is disabled.
		• high : Accepts RA messages with the router preference set to high, medium, or low.
		• medium: Blocks RA messages with the router preference set to high.
		• low : Blocks RA messages with the router preference set to medium and high.
Step 10	Evample:	When configured as a trusted port, all attached devices are trusted, and no further message verification is performed.
	Device(config-nd-raguard)# trusted-port	
Step 11	default {device-role hop-limit {maximum minimum} managed-config-flag match {ipv6 access-list ra prefix-list } other-config-flag router-preference maximum trusted-port}	Restores a command to its default value.
	Example:	
	Device(config-nd-raguard)# default hop-limit	
Step 12	end	Exits RA Guard policy configuration mode
	Example:	and returns to privileged EXEC mode.
	<pre>Device(config-nd-raguard)# end</pre>	
Step 13	show ipv6 nd raguard policy policy_name	(Optional) Displays the ND guard policy
	Example:	configuration.
	Device# show ipv6 nd raguard policy example_policy	

Attaching an IPv6 Router Advertisement Guard Policy to an Interface

Beginning in privileged EXEC mode, follow these steps to attach an IPv6 Router Advertisement policy to an interface or to VLANs on the interface :

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	

	Command or Action	Purpose
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface type number	Specifies an interface type and identifier; enters the interface configuration mode.
	Example:	
	Device(config)# interface gigabitethernet 1/1/4	
Step 4	ipv6 nd raguard [attach-policy policy_name [vlan {vlan_ids add vlan_ids except vlan_ids none remove vlan_ids all }] vlan [{vlan_ids add vlan_ids exceptvlan_ids none remove vlan_ids all }]	Attaches the Neighbor Discovery Inspection policy to the interface or the specified VLANs on that interface. The default policy is attached if the attach-policy option is not used.
	Example:	
	<pre>Device(config-if)# ipv6 nd raguard attach-policy example_policy</pre>	
	<pre>Device(config-if)# ipv6 nd raguard attach-policy example_policy vlan 222,223,224</pre>	
	Device(config-if)# ipv6 nd raguard vlan 222, 223,224	
Step 5	end	Exits interface configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-if)# end	

Attaching an IPv6 Router Advertisement Guard Policy to a Layer 2 EtherChannel Interface

Beginning in privileged EXEC mode, follow these steps to attach an IPv6 Router Advertisement Guard Policy on an EtherChannel interface or VLAN:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	

I

	Command or Action	Purpose
Step 3	<pre>interface range type number Example: Device(config)# interface Port-channel 11</pre>	Specifies the port-channel interface name assigned when the EtherChannel was created. Enters interface range configuration mode.TipEnter the show interfaces summary command in privileged EXEC mode for quick reference to interface names and types.
Step 4	ipv6 nd raguard [attach-policy policy_name [vlan {vlan_ids add vlan_ids except vlan_ids none remove vlan_ids all }] vlan [{vlan_ids add vlan_ids exceptvlan_ids none remove vlan_ids all }]	Attaches the RA Guard policy to the interface or the specified VLANs on that interface. The default policy is attached if the attach-policy option is not used.
	Example: Device(config-if-range)# ipv6 nd raguard attach-policy example_policy	
	<pre>Device(config-if-range)# ipv6 nd raguard attach-policy example_policy vlan 222,223,224</pre>	
	<pre>Device(config-if-range)# ipv6 nd raguard vlan 222, 223,224</pre>	
Step 5	end Example: Device (config-if-range) # end	Exits interface range configuration mode and returns to privileged EXEC mode.

Attaching an IPv6 Router Advertisement Guard Policy to VLANs Globally

Beginning in privileged EXEC mode, follow these steps to attach an IPv6 Router Advertisement policy to VLANs regardless of interface:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	vlan configuration vlan_list	Specifies the VLANs to which the IPv6 RA Guard policy will be attached, and enters VLA
	Example:	
	Device(config)# vlan configuration 335	interface configuration mode.

	Command or Action	Purpose
Step 4	<pre>ipv6 dhcp guard [attach-policy policy_name]</pre>	Attaches the IPv6 RA Guard policy to the
	Example:	specified VLANs across all switch and stack interfaces. The default policy is attached if the
	<pre>Device(config-vlan-config)# ipv6 nd raguard attach-policy example_policy</pre>	attach-policy option is not used.
•	kits VLAN interface configuration mode and	
	Example:	returns to privileged EXEC mode.
	<pre>Device(config-vlan-config) # end</pre>	

Configuring an IPv6 DHCP Guard Policy

Beginning in privileged EXEC mode, follow these steps to configure an IPv6 DHCP (DHCPv6) Guard policy:

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example: Device# configure terminal	
Step 3	<pre>ipv6 dhcp guard policy policy-name Example: Device(config) # ipv6 dhcp guard policy example_policy</pre>	Specifies the DHCPv6 Guard policy name and enters DHCPv6 Guard Policy configuration mode.
Step 4	<pre>device-role {client server} Example: Device(config-dhcp-guard)# device-role server</pre>	 (Optional) Filters out DHCPv6 replies and DHCPv6 advertisements on the port that are not from a device of the specified role. Default is client. client: Default value, specifies that the attached device is a client. Server messages are dropped on this port. server: Specifies that the attached device is a DHCPv6 server. Server messages are allowed on this port.
Step 5	match server access-list ipv6-access-list-name Example: ;;Assume a preconfigured IPv6 Access List as follows:	(Optional). Enables verification that the advertised DHCPv6 server or relay address is from an authorized server access list (The destination address in the access list is 'any').

	Command or Action	Purpose
	<pre>Device(config)# ipv6 access-list my_acls Device(config-ipv6-acl)# permit host 2001:BD8:::1 any ;;configure DCHPv6 Guard to match approved access list. Device(config-dhcp-guard)# match server access-list my_acls</pre>	An empty access list is treated as a permit all.
Step 6	<pre>match reply prefix-list ipv6-prefix-list-name Example: ;;Assume a preconfigured IPv6 prefix list as follows: Device(config)# ipv6 prefix-list my_prefix permit 2001:DB8::/64 le 128 ;; Configure DCHPv6 Guard to match prefix Device(config-dhcp-guard)# match reply prefix-list my_prefix</pre>	(Optional) Enables verification of the advertised prefixes in DHCPv6 reply messages from the configured authorized prefix list. If not configured, this check will be bypassed. An empty prefix list is treated as a permit.
Step 7	<pre>preference{ max limit min limit } Example: Device(config-dhcp-guard) # preference max 250 Device(config-dhcp-guard) #preference min 150</pre>	Configure max and min when device-role is server to filter DCHPv6 server advertisements by the server preference value. The defaults permit all advertisements. max <i>limit</i> —(0 to 255) (Optional) Enables verification that the advertised preference (in preference option) is less than the specified limit. Default is 255. If not specified, this check will be bypassed. min <i>limit</i> —(0 to 255) (Optional) Enables verification that the advertised preference (in preference option) is greater than the specified limit. Default is 0. If not specified, this check will be bypassed.
Step 8	<pre>trusted-port Example: Device(config-dhcp-guard)# trusted-port</pre>	 (Optional) trusted-port—Sets the port to a trusted mode. No further policing takes place on the port. Note If you configure a trusted port then the device-role option is not available.
Step 9	<pre>default {device-role trusted-port} Example: Device (config-dhcp-guard) # default device-role</pre>	(Optional) default —Sets a command to its defaults.

	Command or Action	Purpose
Step 10	<pre>end Example: Device(config-dhcp-guard)# end</pre>	Exits DHCPv6 Guard Policy configuration mode and returns to privileged EXEC mode.
Step 11	<pre>show ipv6 dhcp guard policy policy_name Example: Device# show ipv6 dhcp guard policy example_policy</pre>	(Optional) Displays the configuration of the IPv6 DHCP guard policy. Omitting the <i>policy_name</i> variable displays all DHCPv6 policies.

Attaching an IPv6 DHCP Guard Policy to an Interface or a VLAN on an Interface

Beginning in privileged EXEC mode, follow these steps to configure IPv6 Binding Table Content :

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface type number	Specifies an interface type and identifier, and
	Example:	enters interface configuration mode.
	Device(config)# interface gigabitethernet 1/1/4	
Step 4	ipv6 dhcp guard [attach-policy policy_name [vlan {vlan_ids add vlan_ids except vlan_ids none remove vlan_ids all }] vlan [{vlan_ids add vlan_ids exceptvlan_ids none remove vlan_ids all }]	Attaches the DHCP Guard policy to the interface or the specified VLANs on that interface. The default policy is attached if the attach-policy option is not used.
	Example:	
	Device(config-if)# ipv6 dhcp guard attach-policy example_policy	
	<pre>Device(config-if)# ipv6 dhcp guard attach-policy example_policy vlan 222,223,224</pre>	
	Device(config-if)# ipv6 dhcp guard vlan 222, 223,224	
Step 5	end	Exits interface configuration mode and returns
Example: to p	to privileged EXEC mode.	

 Command or Action	Purpose
Device(config-if)# end	

Attaching an IPv6 DHCP Guard Policy to a Layer 2 EtherChannel Interface

Beginning in privileged EXEC mode, follow these steps to attach an IPv6 DHCP Guard policy on an EtherChannel interface or VLAN:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface range Interface_name	Specify the port-channel interface name
	Example:	assigned when the EtherChannel was created Enters interface range configuration mode.
	Device (config) # interface Port-channel	
	11	TipEnter the show interfacessummary command in privileged
		EXEC mode for quick reference
		to interface names and types.
Step 4	ipv6 dhcp guard [attach-policy policy_name	Attaches the DHCP Guard policy to the
-	[vlan {vlan_ids add vlan_ids except	interface or the specified VLANs on that
	<i>vlan_ids</i> none remove <i>vlan_ids</i> all }] vlan [{ <i>vlan_ids</i> add <i>vlan_ids</i> except <i>vlan_ids</i>	interface. The default policy is attached if the attach-policy option is not used.
	none remove vlan_ids all }]	attach-policy option is not used.
	Example:	
	<pre>Device(config-if-range)# ipv6 dhcp guard attach-policy example_policy</pre>	
	<pre>Device(config-if-range)# ipv6 dhcp guard attach-policy example_policy vlan 222,223,224</pre>	
	<pre>Device(config-if-range)# ipv6 dhcp guard vlan 222, 223,224</pre>	
Step 5	end	Exits interface range configuration mode and
	Example:	returns to privileged EXEC mode.
	Device(config-if-range)# end	

Attaching an IPv6 DHCP Guard Policy to VLANs Globally

Beginning in privileged EXEC mode, follow these steps to attach an IPv6 DHCP Guard policy to VLANs across multiple interfaces:

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	vlan configuration vlan_list	Specifies the VLANs to which the IPv6
	Example:	Snooping policy will be attached, and enters
	Device (config) # vlan configuration 334	VLAN interface configuration mode.
Step 4	<pre>ipv6 dhcp guard [attach-policy policy_name]</pre>	Attaches the IPv6 Neighbor Discovery policy
	Example:	to the specified VLANs across all switch and
	Device(config-vlan-config)# ipv6 dhcp	stack interfaces. The default policy is attached if the attach-policy option is not used. The
	guard attach-policy example_policy	default policy is, device-role client , no trusted-port.
Step 5	end	Exits VLAN interface configuration mode an
	Example:	returns to privileged EXEC mode.
	Device(config-vlan-config)# end	

Configuring IPv6 Source Guard

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	

I

	Command or Action	Purpose
Step 3	<pre>ipv6 source-guard policy policy_name Example: Device(config)# ipv6 source-guard policy example_policy</pre>	Specifies the IPv6 Source Guard policy name and enters IPv6 Source Guard policy configuration mode.
Step 4	[deny global-autoconf] [permit link-local] [default{}] [exit] [no{}]	(Optional) Defines the IPv6 Source Guard policy.
	<pre>Example: Device(config-sisf-sourceguard)# deny global-autoconf</pre>	 deny global-autoconf: Denies data traffic from auto-configured global addresses. This is useful when all global addresses on a link are DHCP-assigned and the administrator wants to block hosts with self-configured addresses to send traffic. permit link-local: Allows all data traffic that is sourced by a link-local address. Note Trusted option under source guard policy is not supported.
Step 5	end Example:	Exits of IPv6 Source Guard policy configuration mode and returns to privileged EXEC mode.
	Device(config-sisf-sourceguard)# end	
Step 6	show ipv6 source-guard policy policy_name Example: Device# show ipv6 source-guard policy example policy	Shows the policy configuration and all the interfaces where the policy is applied.

What to do next

Apply the IPv6 Source Guard policy to an interface.

Attaching an IPv6 Source Guard Policy to an Interface

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	

	Command or Action	Purpose
Step 3	interface type number	Specifies an interface type and identifier; enters interface configuration mode.
	Example:	
	Device(config)# interface gigabitethernet 1/1/4	
Step 4	ipv6 source-guard [attach-policy	Attaches the IPv6 Source Guard policy to the
	<pre><policy_name>]</policy_name></pre>	interface. The default policy is attached if the attach-policy option is not used.
	Example:	attach-policy option is not used.
	<pre>Device(config-if) # ipv6 source-guard attach-policy example_policy</pre>	
Step 5	end	Exits interface configuration mode and retu to privileged EXEC mode.
	Example:	
	<pre>Device(config-if) # end</pre>	
Step 6	<pre>show ipv6 source-guard policy policy_name</pre>	Shows the policy configuration and all the
	Example:	interfaces where the policy is applied.
	Device#(config)# show ipv6 source-guard policy example_policy	

Attaching an IPv6 Source Guard Policy to a Layer 2 EtherChannel Interface

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example: Device# configure terminal	
Step 3	interface port-channel port-channel-number Example: Device(config) # interface Port-channel 4	Specifies an interface type and port number and places the switch in the port channel configuration mode.
Step 4	<pre>ipv6 source-guard [attach-policy <policy_name>] Example: Device(config-if)# ipv6 source-guard attach-policy example_policy</policy_name></pre>	Attaches the IPv6 Source Guard policy to the interface. The default policy is attached if the attach-policy option is not used.

Procedure

I

	Command or Action	Purpose
	end	Exits interface configuration mode and returns
	to privileged EXEC mode.	
	Device(config-if)# end	
Step 6	show ipv6 source-guard policy policy_name	Shows the policy configuration and all the
	Example: interfaces where the	interfaces where the policy is applied.
	Device# show ipv6 source-guard policy example_policy	

Configuring IPv6 Prefix Guard

Note To allow routing protocol control packets sourced by a link-local address when prefix guard is applied, enable the **permit link-local** command in the source-guard policy configuration mode.

	Command or Action	Purpose	
Step 1	enable	Enables privileged EXEC mode.	
	Example:	Enter your password, if prompted.	
	Device> enable		
Step 2	configure terminal	Enters global configuration mode.	
	Example:		
	Device# configure terminal		
Step 3	ipv6 source-guard policy source-guard-policy	Defines an IPv6 source-guard policy name and	
	Example:	enters switch integrated security features source-guard policy configuration mode.	
	Device(config)# ipv6 source-guard policy		
	my_snooping_policy		
Step 4	validate address	Disables the validate address feature and enables the IPv6 prefix guard feature to be	
	Example:		
	Device(config-sisf-sourceguard)# no	configured.	
	validate address		
Step 5	validate prefix	Enables IPv6 source guard to perform the IPv	
	Example:	prefix-guard operation.	
	<pre>Device(config-sisf-sourceguard) # validate prefix</pre>		

	Command or Action	Purpose
Step 6	exit	Exits switch integrated security features
	Example:	source-guard policy configuration mode and returns to privileged EXEC mode.
	<pre>Device(config-sisf-sourceguard)# exit</pre>	
Step 7	show ipv6 source-guard policy	Displays the IPv6 source-guard policy
	[source-guard-policy]	configuration.
	Example:	
	Device# show ipv6 source-guard policy	
	policy1	

Attaching an IPv6 Prefix Guard Policy to an Interface

	Command or Action	Purpose	
Step 1	enable	Enables privileged EXEC mode.	
	Example:	Enter your password, if prompted.	
	Device> enable		
Step 2	configure terminal	Enters global configuration mode.	
	Example:		
	Device# configure terminal		
Step 3	interface type number	Specifies an interface type and identifier, and	
	Example:	enters interface configuration mode.	
	Device (config) # interface gigabitethernet 1/1/4		
Step 4	ipv6 source-guard attach-policy policy_name	Attaches the IPv6 Source Guard policy to the	
	Example:	interface. The default policy is attached if the attach-policy option is not used.	
	<pre>Device(config-if)# ipv6 source-guard attach-policy example_policy</pre>		
Step 5	end	Exits interface configuration mode and returns	
	Example:	to privileged EXEC mode.	
	Device(config-if)# end		
Step 6	show ipv6 source-guard policy policy_name	Shows the policy configuration and all the interfaces where the policy is applied.	
	Example:		
	Device(config-if)# show ipv6 source-guard policy example_policy		

Procedure

I

Attaching an IPv6 Prefix Guard Policy to a Layer 2 EtherChannel Interface

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface port-channel port-channel-number	Specifies an interface type and port i
	Example:	places the switch in the port channel configuration mode.
	Device(config) # interface Port-channel	

Procedure

Step 3	<pre>interface port-channel port-channel-number Example: Device(config)# interface Port-channel 4</pre>	Specifies an interface type and port number and places the switch in the port channel configuration mode.	
Step 4	<pre>ipv6 source-guard [attach-policy <policy_name>] Example: Device(config-if)# ipv6 source-guard attach-policy example_policy</policy_name></pre>	Attaches the IPv6 Source Guard policy to the interface. The default policy is attached if the attach-policy option is not used.	
Step 5	<pre>end Example: Device(config-if)# end</pre>	Exits interface configuration mode and returns to privileged EXEC mode.	
Step 6	<pre>show ipv6 source-guard policy policy_name Example: Device(config)# show ipv6 source-guard policy example_policy</pre>	Shows the policy configuration and all the interfaces where the policy is applied.	

Configuring an IPv6 Destination Guard Policy

Beginning in privileged EXEC mode, follow these steps to configure an IPv6 destination guard policy:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	

	Command or Action	Purpose	
Step 2	configure terminal	Enters global configuration mode.	
	Example:		
	Device# configure terminal		
Step 3	ipv6 destination-guard policy policy-name	Defines the destination guard policy name and	
	Example:	enters destination-guard configuration mode.	
	<pre>Device(config)# ipv6 destination-guard policy pol1</pre>		
Step 4	enforcement {always stressed}	Sets the enforcement level for the target address.	
	Example:		
	<pre>Device(config-destguard)# enforcement always</pre>		
Step 5	exit	Exits destination-guard configuration mode and	
	Example:	returns to global configuration mode.	
	Device(config-destguard)# exit		
Step 6	interface type number	Enters interface configuration mode.	
	Example:		
	Device (config) # interface GigabitEthernet 0/0/1		
Step 7	ipv6 destination-guard attach-policy [policy-name]	Attaches a destination guard policy to an interface.	
	Example:		
	<pre>Device(config-if)# ipv6 destination-guard attach-policy pol1</pre>		
Step 8	end	Exits interface configuration mode and returns	
	Example:	to privileged EXEC configuration mode.	
	Device(config-if)# end		
Step 9	show ipv6 destination-guard policy [policy-name]	(Optional) Displays the policy configuration and all interfaces where the policy is applied.	
	Example:		
	Device# show ipv6 destination-guard policy pol1		

Configuration Examples for IPv6 First Hop Security

Example: Configuring an IPv6 DHCP Guard Policy

Example of DHCPv6 Guard Configuration

```
Device> enable
Device# configure terminal
Device(config) # ipv6 access-list acl1
Device(config-ipv6-acl)# permit host 2001:DB8:0000:
0000:0000:0000:0000:0001 any
Device(config-ipv6-acl)# exit
Device (config) # ipv6 prefix-list abc permit 2001:0DB8::/64 le 128
Device(config) # ipv6 dhcp guard policy pol1
Device (config-dhcp-quard) # device-role server
Device(config-dhcp-guard)# match server access-list acl1
Device(config-dhcp-guard) # match reply prefix-list abc
Device (config-dhcp-guard) # preference min 0
Device(config-dhcp-guard) # preference max 255
Device(config-dhcp-quard) # trusted-port
Device (config-dhcp-guard) # exit
Device (config) # interface GigabitEthernet 0/2/0
Device(config-if)# switchport
Device (config-if) # ipv6 dhcp guard attach-policy poll vlan add 1

Device(config-vlan) # ipv6 dhcp guard attach-policy pol1
Device (config-vlan) # end
```

Examples: Attaching an IPv6 Source Guard Policy to a Layer 2 EtherChannel Interface

The following example shows how to attach an IPv6 Source Guard Policy to a Layer 2 EtherChannel Interface:

```
Device> enable
Device# configure terminal
Device(config)# ipv6 source-guard policy POL
Device(config-sisf-sourceguard) # validate address
Device(config-sisf-sourceguard)# exit
Device(config)# interface Port-Channel 4
Device(config-if)# ipv6 snooping
Device(config-if)# ipv6 source-guard attach-policy POL
Device(config-if)# end
Device#
```

Examples: Attaching an IPv6 Prefix Guard Policy to a Layer 2 EtherChannel Interface

The following example shows how to attach an IPv6 Prefix Guard Policy to a Layer 2 EtherChannel Interface:

Device> enable

```
Device# configure terminal
Device(config)# ipv6 source-guard policy POL
Device (config-sisf-sourceguard)# no validate address
Device((config-sisf-sourceguard)# validate prefix
Device(config-sisf-sourceguard)# exit
Device(config)# interface Po4
Device(config-if)# ipv6 snooping
Device(config-if)# ipv6 source-guard attach-policy POL
```

```
Device(config-if) # end
```

Example: Using the Data-Glean Recovery Function

Binding entries can be removed from the binding table for various reasons: the switch may have reset, or you may have used the **clear** commands, and so on. The following example shows how you can use the data-glean recovery function to restore valid binding entries in the binding table.

The scenario used in this example involves interaction between the IPv6 Source Guard, IEEE 802.1x authentication, and SISF-based device-tracking features. Described below is the set-up we are using for this example, along with sample configuration, followed by a description of situations that can cause premature removal of valid entries from the binding table, and finally, the configuration that you must have in-place, for such entries to be restored.

The key aspects of this example set-up are outlined below:

• An IPv6 Source Guard policy is configured and attached to an interface.

This means that if the source address of an incoming packet is in the binding table, the filter allows the packet into the network. If the address is not in the binding table, entry is denied and the packet entry is dropped. When an entry is removed from the binding table, the filter is also removed, and subsequent packets from that source are dropped.

```
Device# show ipv6 source-guard policy src-guard-policy
Source guard policy src-guard-policy configuration:
validate address
Policy src-guard-policy is applied on the following targets:
Target Type Policy Feature Target range
Gi1/0/1 PORT src-guard-policy Source guard vlan all
```

A custom SISF-based device-tracking policy, which allows gleaning of only DHCP packets and not NDP
packets is attached to the same interface as the source guard policy.

This means that any host in the network can use only a DHCP-assigned IP address to communicate.

```
Device# show device-tracking policy glean only DHCP
Device-tracking policy glean only DHCP configuration:
  security-level guard
  device-role node
 NOT gleaning from Neighbor Discovery
  gleaning from DHCP6
 NOT gleaning from ARP
 NOT gleaning from DHCP4
 NOT gleaning from protocol unkn
Policy glean only DHCP is applied on the following targets:
Target
                     Type Policy
                                               Feature
                                                               Target range
Gi1/0/1
                     PORT glean_only_DHCP
                                               Device-tracking vlan all
```

• IEEE 802.1x authentication is enabled.

This means only authenticated hosts are allowed to request addresses from the DHCP server and attach themselves to the network.

Note

The following 802.1x configuration is for example purposes only.

```
<output truncated>
interface GigabitEthernet 1/0/1
description 802.1x+MAB+IPT
authentication control-direction in
authentication event server dead action authorize vlan <vlan id>
authentication event no-response action authorize vlan <vlan id>
authentication event server alive action reinitialize
authentication host-mode multi-domain
authentication port-control auto
authentication periodic
authentication timer reauthenticate server
authentication violation protect
mab
trust device cisco-phone
dot1x pae authenticator
dot1x timeout quiet-period 30
dot1x timeout server-timeout 5
dot1x timeout tx-period 1
dot1x max-req 1
dot1x max-reauth-reg 1
<output truncated>
```

Events that cause a change in the configuration occur in any typical network. For example, a host may be unplugged from one port and then plugged back into another port, or an interface may flap, or you may have configured the **shutdown**, followed by the **no shutdown** interface configuration commands. For the duration that the host is not connected, or the interface is down, the host or interface is considered "unauthenticated". Because of this absence of host or interface authentication, the corresponding binding table entry is removed from the binding table.

When such a host connects back to the network or when such an interface is restored, the client does not reinstantiate the DHCP sequence until the DHCP lease time expires. Until the DHCP sequence is reinstantiated, a valid address fails to be stored in the binding table. If the entry is not in the binding table, the IPv6 Source Guard's filter function drops all packets initiated by that host.

In order to prevent such a situation, configure the data-glean recovery function.

To configure data-glean recovery, create a custom SISF-based device-tracking policy, configure the data-glean policy parameter to recover binding information from DHCP Server, and attach it to the necessary targets.

Note When configuring data-glean recovery from DHCP, for binding information retrieval to work as expected, the DHCPv6 Leasequery configuration (as in RFC 5007), is required. Ensure that the leasequery configuration is enabled on the DHCP Server.

The following sample configuration shows how to add the required "data-glean" policy parameter to the existing custom SISF-based device-tracking policy (glean_only_DHCP), to recover binding information. It remains attached to the same target as the IPv6 Source Guard policy, that is, Gigabit Ethernet 1/0/1:

L

```
Device# configure terminal
Device(config) # device-tracking policy glean_only_DHCP
Device (config-device-tracking) # data-glean recovery dhcp
Device(config-device-tracking)# exit
Device# show device-tracking policy glean only DHCP
Device-tracking policy glean only DHCP configuration:
 security-level guard
 device-role node
 data-glean recovery dhcp
                                                <<< Recovery of binding information is
configured.
 NOT gleaning from Neighbor Discovery
 gleaning from DHCP6
 NOT gleaning from ARP
 NOT gleaning from DHCP4
 NOT gleaning from protocol unkn
Policy glean_only_DHCP is applied on the following targets:
                    Type Policy
Target
                                          Feature
                                                             Target range
                    PORT glean_only_DHCP
Gi1/0/1
                                              Device-tracking vlan all
Device# show device-tracking policies interface Gi1/0/1
Target
                    Type Policy
                                              Feature
                                                            Target range
                    PORT glean_only_DHCP
Gi1/0/1
                                               Device-tracking vlan all
Gi1/0/1
                    PORT src-guard-policy
                                              Source guard vlan all
```

With this additional configuration, valid entries are automatically restored in the binding table if they are removed prematurely.

Feature History for IPv6 First Hop Security

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.11.1	IPv6 First Hop Security	First Hop Security in IPv6 is a set of IPv6 security features, the policies of which can be attached to a physical interface, an EtherChannel interface, or a VLAN. An IPv6 software policy database service stores and accesses these policies. When a policy is configured or modified, the attributes of the policy are stored or updated in the software policy database, then applied as was specified. The IPv6 Snooping Policy feature has been
		deprecated. Although the commands are visible on the CLI and you can configure them, we recommend that you use the Switch Integrated Security Feature (SISF)-based Device Tracking feature instead.
Cisco IOS XE Amsterdam 17.1.1	IPv6 ND Inspection	Starting with this release, the IPv6 ND Inspection feature is deprecated and the SISF- based device tracking feature replaces it and offers the same capabilities. While the IPv6 ND Inspection commands are still available on the CLI and the existing configuration continues to be supported, the commands will be removed from the CLI in a later release. For more information about the replacement feature, see the <i>Configuring SISF-Based Device</i> <i>Tracking</i> chapter in this guide.
Cisco IOS XE Cupertino 17.7.1	IPv6 First Hop Security	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

Information About SISF

Overview

Switch Integrated Security Features (SISF) is a framework developed to optimize security in Layer 2 domains. It merges the IP Device Tracking (IPDT) and *certain* IPv6 first-hop security (FHS) functionality⁶, to simplify the migration from IPv4 to IPv6 stack or a dual-stack.

The SISF infrastructure provides a unified database that is used by:

- IPv6 FHS features: IPv6 Router Advertisement (RA) Guard, IPv6 DHCP Guard, Layer 2 DHCP Relay, IPv6 Duplicate Address Detection (DAD) Proxy, Flooding Suppression, IPv6 Source Guard, IPv6 Destination Guard, RA Throttler, and IPv6 Prefix Guard.
- Features like Cisco TrustSec, IEEE 802.1X, Locator ID Separation Protocol (LISP), Ethernet VPN (EVPN), and Web Authentication, which act as clients for SISF.

The following figure illustrates this:

⁶ IPv6 Snooping Policy, IPv6 FHS Binding Table Content, and IPv6 Neighbor Discovery Inspection

Figure 23: SISF Framework

Note

The terms "SISF" "device-tracking" and "SISF-based device-tracking" are used interchangeably in this document and refer to the same feature. Neither term is used to mean or should be confused with the legacy IPDT or IPv6 Snooping features.

Understanding the SISF Infrastructure

This section explains the various elements of the SISF infrastructure as shown in the Figure 23: SISF Framework, on page 488.

The Binding Table

The SISF infrastructure is built around the binding table. The binding table contains information about the hosts that are connected to the ports of a switch and the IP and MAC address of these hosts. This helps to create a physical map of all the hosts that are connected to a switch.

Each entry in a binding table provides the following information about a connected host:

- IPv4 or IPv6 address of the host.
- MAC address of the host. The same MAC address may be linked to an IPv4 and IPv6 address.
- The interface or port on the switch that the host is connected to, and the associated VLAN.
- The state of the entry, which indicates the reachability of the entry.

The following figure shows a simple network topology and a representative binding table for each access switch in the network. SW_A and SW_B are the two access switches in the network. The two access switches are connected to the same distribution switch. H1, H2, H3, H4 are the hosts.

This is an example of a distributed binding table, that is, each access switch in the network has its own table. An alternative set-up could be one centralised binding table on the distribution switch with the entries of SW_A and SW_B .

Having a distributed or a centralised binding table is a key design choice in the process of implementing SISF in your network and is covered in greater detail in the Understanding Policy Parameters, on page 494 section in this chapter.

Figure 24: Binding Table

States and Lifetime of a Binding Table Entry

The state of an entry indicates if the host is reachable or not. The stable states of a binding table entry are: REACHABLE, DOWN, and STALE. When changing from one state to another, an entry may have other temporary or transitional states such as: VERIFY, INCOMPLETE, and TENTATIVE.

How long an entry remains in a given state is determined by its lifetime and by whether or not the entry is validated successfully. The lifetime of an entry can be policy-driven or configured globally.

To configure the REACHABLE, DOWN, and STALE lifetimes, enter the following command in global configuration mode:

device-tracking binding { reachable-lifetime { seconds | infinite } | stale-lifetime { seconds | infinite } | down-lifetime { seconds | infinite } }

State: Reachable

If an entry has this state, it means the host (IP and MAC address) from which a control packet was received, is a verified and valid host. A reachable entry has a default lifetime of 5 minutes. You can also configure a duration. By configuring a reachable-lifetime, you specify how long a host can remain in a REACHABLE state, after the last incoming control packet from that host.

If an event is detected before the entry's reachable lifetime expires, then the reachable lifetime is reset.

To qualify for the REACHABLE state, a new entry goes through the process illustrated in the figure below. The switch detects an event (E), such as an incoming control packet from a connected host and creates an entry. Various events cause the creation of an entry, and these are described in the Binding Table Sources section. The creation of an entry is followed by different transient states, such as TENTATIVE or INCOMPLETE. While in a transitional state, the switch validates and confirms the integrity of the binding entry. If the entry is found to be valid, then the state changes to REACHABLE.

But if an address theft or similar event is detected, then the entry is regarded as invalid and is deleted. For example, if an attacker sends unsolicited neighbor advertisement messages with the same IP as the target IP and its (attacker's) own MAC address to redirect traffic.

Figure 25: Creation of a Reachable Entry

State: Stale

If an entry is in this state it means that the entry's reachable lifetime has expired and the corresponding host is still silent (no incoming packets from the host). A stale entry has a default lifetime of 24 hours. You can also configure a duration. An entry that remains in the STALE state beyond the stale lifetime, is deleted.

This is illustrated in the figure below which depicts the lifecycle of an entry.

Figure 26: Lifecycle of an Entry $E \longrightarrow Create \longrightarrow TENTATIVE \longrightarrow REACHABLE \longrightarrow 5_{mo} \longrightarrow STALE \longrightarrow 24_{mo}$ $DELETE \longrightarrow DELETE$ $E \longrightarrow Event Before Reachable$ Lifetime Expired

State: Down

If an entry is in this state, it means that the host's connecting interface is down. A down entry has a default lifetime of 24 hours. You can also configure a duration. An entry that remains in the DOWN state beyond the down lifetime, is deleted.

Polling a Host and Updating the Binding Table Entry

Polling is a periodic and conditional checking of the host to see the state it is in, whether it is still connected, and whether it is communicating. In addition to determining an entry's state, you can use polling to reconfirm an entry's state.

You can enable polling with the **device-tracking tracking** command in global configuration mode. After you do, you still have the flexibility to turn polling on or off for a particular interface or VLAN. For this, configure the **tracking enable** or **tracking disable** keywords in the policy (the device-tracking configuration mode). When polling is enabled, the switch polls the host at the specified interval, thus reconfirming its reachability for the duration of its reachable lifetime.

When polling is enabled, the switch sends up to three polling requests, after the reachable lifetime expires, at system-determined intervals. You can also configure this interval with the **device-tracking tracking retry-interval** *seconds* command in global configuration mode.

The figure below depicts the lifecycle of an entry where the host is polled. Default reachable and stale lifetimes, and retry intervals are used in figure:

An event (E) is detected and a REACHABLE entry is created.

If an event is detected *during* the reachable lifetime, the reachable lifetime timer is reset.

The switch sends a polling request after the reachable lifetime expires. The switch polls the host up to three times at fixed, system-determined intervals. The polling request may be in the form of a unicast Address Resolution Protocol (ARP) probe or a Neighbor Solicitation message. During this time the state of the entry changes to VERIFY. If a polling response is received (thus confirming reachability of the host), the state of the entry changes back to REACHABLE.

If the switch does not receive a polling response after three attempts, the entry changes to the STALE state. It remains in this state for 24 hours. If an event is detected during the stale lifetime, the state of the entry is changed back to REACHABLE. At expiry of the stale lifetime, the device sends one final polling to ascertain reachability. If this final polling attempt receives a reply, the state of the entry is changed back to REACHABLE. If the final polling attempt does not receive a response, the entry is deleted.

Figure 27: Lifecycle of an Entry Where the Host is Polled

Binding Table Sources

The following are the sources of information and events that cause the creation and update of a binding table entry:

- Learning events that dynamically populate the binding table:
 - Dynamic Host Configuration Protocol (DHCP) negotiation (DHCP REQUEST, and DHCP REPLY). This includes DHCPv4 and DHCPv6.
 - Address Resolution Protocol (ARP) packets.

Starting with Cisco IOS XE Amsterdam 17.3.1, ARP packets are throttled to mitigate high CPU utilization scenarios. In a five second window, a maximum of 50 ARP broadcast packets per binding entry are processed by SISF. When the limit is reached, incoming ARP packets are dropped. Note that the limit of 50 in five seconds is for each binding entry, that is, for each source IP.

- Neighbor Discovery Protocol (NDP) packets.
- Multiple Identity Association-Nontemporary Address (IA_NA) and Identity Association-Prefix Delegation (IA_PD).

In some cases, a network device can request and receive more than one IPv6 address from the DHCP server. This may be done to provide addresses to multiple clients of the device, such as when a residential gateway requests addresses to distribute to its LAN clients. When the device sends out a DHCPv6 packet, the packet includes all of the addresses that have been assigned to the device.

When SISF analyzes a DHCPv6 packet, it examines the IA_NA (Identity Association-Nontemporary Address) and IA_PD (Identity Association-Prefix Delegation) components of the packet and extracts each IPv6 address contained in the packet. SISF adds each extracted address to the binding table.

Entries created through learning events like the ones listed above are called "dynamic entries". In the output of the **show device-tracking database details** privileged EXEC command, such entries are prefixed with an abbreviation that clarifies the kind of dynamic learning event it was. For example, ARP for ARP packets, ND for NDP packets, and so on.

· Configuring static binding entries.

If there are silent but reachable hosts in the Layer 2 domain, you can create static binding entries to retain binding information even if the host becomes silent.

A static binding entry is a binding entry that is manually added to the binding table, by configuring the following command in global configuration mode:

device-tracking binding vlan vlan_id { ipv4_add ipv6_add ipv6_prefix } [interface inteface_type_no] [48-bit-hardware-address] [reachable-lifetime { seconds | default | infinite } | tracking { default | disable | enable [retry-interval { seconds | default }] } [reachable-lifetime { seconds | default | infinite }]]

In the output of the **show device-tracking database details** privileged EXEC command, static entries are prefixed with the letter "S".

You can configure a reachable lifetime for a static entry. The stale and down lifetime timer is fixed by the system as **infinite** (For an entry in the STALE or DOWN state, the output of the **show device-tracking database** command displays the *Time Left* column as "N/A"). This means that when a static entry enters the STALE or DOWN state it remains in this state, and in the binding table, indefinitely.

A static entry can be removed from the binding table only by the actions listed below. It cannot be deleted from the binding table by using **clear** commands or by any other event:

- You remove the entry by configuring the **no** form of the above command.
- A local entry replaces the static entry.

A local entry is an entry that is automatically created by the system when you configure an SVI on the device. When configuring the SVI, if you use the same IP address as the static entry then the static entry is replaced with the local entry, because the local entry has a higher priority.

This replacement of a static entry by a local entry is introduced only in Cisco IOS XE Bengaluru 17.4.1 onwards; it does not happen in earlier releases.

In the output of the **show device-tracking database details** privileged EXEC command, local entries are prefixed with the letter "L".

For more information about static binding entries, see the **device-tracking binding** command in the command reference.

Note

In addition to the primary or key events listed above, there is a specific scenario in which a ping can result in a device-tracking entry. If a sender's ARP cache or IPv6 neighbor table doesn't have the target's IP address yet, then a ping triggers an ARP packet for IPv4, or ND packet for IPv6. This can result in a device-tracking entry.

But if the target IP is already in the ARP cache or IPv6 neighbour table, no ARP or ND packet is generated when you ping - in which case SISF cannot learn the IP address.

Device-Tracking

SISF-based device-tracking is disabled by default. You can enable the feature on an interface or VLAN.

When you enable the feature, the binding table is created, followed by subsequent maintenance of the binding table.

The events listed in the Binding Table Sources, on page 492 section act as triggers for SISF-based device-tracking, to track the presence, location, and movement of hosts in the network, to populate and maintain the binding table. For example, if information about a host is learnt by means of an ARP or ND packet, every subsequent ARP or ND packet from the same host acts as an alert for SISF-based device-tracking, to refresh the entry in the binding table, thus indicating if the host is still present in the same location or has moved.

The continuous process of snooping of packets that the switch receives, extraction of device identity (MAC and IP address), and storage of information in the binding table of the switch, ensures binding integrity and maintains the reachability status of the hosts in the binding table.

For information how to enable SISF-based device-tracking, see How to Configure SISF, on page 508.

Device-Tracking Policy

A device-tracking policy is a set of rules that SISF-based device-tracking follows. The policy dictates which events will be listened to, whether a host will be probed, the wait time before the host is probed, and so on. These rules are referred to as policy parameters.

Note

The policy must be attached to an interface or VLAN. Only then is the binding table for that interface or VLAN populated - in accordance with policy parameters.

For information about the various ways in which you can create a policy, see How to Configure SISF, on page 508.

To display a policy's settings, use the **show device-tracking policy** *policy_name* command in privileged EXEC mode.

Understanding Policy Parameters

Policy parameters are the keywords available for configuration in the device-tracking configuration mode. Each policy parameter addresses one or more aspects of network security.

This section explains the purpose of *some* of the important policy parameters so you can configure your policy to better suit your requirements.

```
Device(config) # device-tracking policy example_policy
Device(config-device-tracking) # ?
device-tracking policy configuration mode:
device-role Sets the role of the device attached to the port
limit Specifies a limit
security-level setup security level
tracking Override default tracking behavior
trusted-port setup trusted port
```

For information about all the paramters displayed in the device-tracking configuration mode, see the command reference document of the corresponding release.

Glean versus Guard versus Inspect

When a packet enters the network, SISF extracts the IP and MAC address (the source of the packet) and subsequent action, is dictated by the security-level that is configured in the policy.

Glean, guard, and inspect are the options available under the security-level parameter. Glean is the least secure option, inspect, is moderately secure, and guard, is the most secure.

To configure this parameter in a policy, enter the **security-level** keyword in the device-tracking configuration mode.

Glean

When the security-level is set to **glean**, SISF extracts the IP and MAC address and enters them into the binding table, without any verification. This option therefore does not ensure binding integrity. It may for example, be suited to a set-up where client applications such as IEEE 802.1X or SANET want to only learn about the host and not rely on SISF for authentication.

The only factor that affects the addition of the binding entry for this security-level, is the address count limit. There are separate limits for the maximum number of IPs per port, IPv4 per MAC, and IPv6 per MAC. Entries are rejected once a limit is reached. For more information about this parameter, see Address Count Limits.

Starting with Cisco IOS XE Bengaluru 17.6.1, all address limits are ignored when the security-level parameter is **glean**. Binding entries of all incoming packets are added to the table.

Guard

This is the default value for the security-level parameter.

When the security-level is set to **guard**, SISF extracts and verifies the IP and MAC address of packets entering the network. The outcome of the verification determines if a binding entry is added, or updated, or if the packet is dropped and the client is rejected.

The process of verification starts with the search for a matching entry in the database. The database may be centralised or distributed. If a matching entry is not found, a new entry is added.

If a matching entry is found and the points of attachment (MAC, VLAN, or interface) are found to be the same, only the timestamp is updated. If not, the scope of verification is extended to include validation of address ownership. This may include host polling to determine if the change in the point of attachment (a different MAC, or VLAN) is valid. If the change is valid the entry is updated, or if it is a case of theft, the entry is not added to the binding table.

If a binding entry is added or updated, the corresponding client is granted access to the network. If an entry does not pass verification, the corresponding client is rejected.

Note The verification process affects the binding entry and the corresponding incoming packet.

There have been changes in the way the verification process affects the binding entry and the corresponding incoming packet. These behaviour changes have been captured chronologically:

Until Cisco IOS XE Bengaluru 17.6.x, there are differences in the way SISF handles IPv4 and IPV6 control packets. If a client is rejected (entry does not pass verification) and if the incoming control packet from that client is IPv6, the packet is dropped, but if the incoming control packet from that client is IPv4, the packet is not dropped.

Starting with Cisco IOS XE Cupertino 17.7.1, IPv4 and IPv6 packets are treated the same way when the security-level parameter is **guard**. A rejected entry means the packet is dropped regardless of whether it is IPv4 or IPv6.

Also starting with Cisco IOS XE Cupertino 17.7.1, support for the *prevention* of IPv4 spoofing was introduced. Detection and reporting of IPv4 spoofing is supported since the introductory release of SISF. Further, detection, reporting, and prevention of *IPv6 spoofing* is supported since the introductory release of SISF. See example: Example: Detecting and Preventing Spoofing, on page 524.

Inspect

Even though security-level **inspect** is available on the CLI, we recommend not using it. The **glean** and **guard** options described above address most use cases and network requirements.

Trusted-Port and Device-Role Switch

The **device-role switch** and **trusted-port** options help you design an efficient and scalable "secure zone". When used together, these two parameters help you achieve an efficient distribution of the creation of entries in the binding table. This keeps the binding tables size under control.

The **trusted-port** option: Disables the guard function on configured targets. Bindings learned through a trusted-port have preference over bindings learned through any other port. A trusted port is also given preference in case of a collision while making an entry in the table.

The **device-role** option: Indicates the type of device that is facing the port and this can be a node or a switch. To allow the creation of binding entries for a port, you configure the device as a node. To stop the creation of binding entries, you configure the device as switch.

Configuring the device as a switch is suited to multi-switch set-ups, where the possibility of large device tracking tables is very high. Here, a port facing a device (an uplink trunk port) can be configured to stop creating binding entries, and the traffic arriving at such a port can be trusted, because the switch on the other side of the trunk port will have device-tracking enabled and that will have checked the validity of the binding entry.

Note While there are scenarios where configuring only either one of these options may be suitable, the more common use case is for both the **trusted-port** and **device-role switch** options to be configured on the port - the examples below explain this in detail. Possible scenarios where only either one of these options is suited or required have also been described, at the end of this section.

To configure these parameters in a policy, enter the **trusted-port** and **device-role** keywords in the device-tracking configuration mode.

Example: Using Trusted-Port and Device-Role Switch Options in a Multi-Switch Set-Up

The following example explains how the **device-role switch** and **trusted-port** options help to design an efficient and scalable "secure zone".

In figure Figure 28: Multi-Switch Set-Ups Without Trusted-Port and Device-Role Switch Options, on page 498 below, SW_A , SW_B , and SW_C are three access switches. They are all connected to a common distribution switch. The only required configuration on the distribution switch in this scenario is to ensure that traffic of any kind is *not* blocked.

H1, H2, ...H6 are the hosts. Each switch has two directly connected hosts. All hosts are communicating with each other, that is, control packets are being transmitted. All hosts are also within the same VLAN boundary. Each switch is receiving control packets from hosts that are directly connected to it, and also from hosts that are connected to other switches. This means SW_A is receiving control packets from H1, H2, ...H6 similarly with SW_B and SW_C .

For each switch, the entries of directly connected hosts have interface or port P_1 and P_2 in the binding table. Entries originating from hosts that are connected to other switches have interface or port name P_xUP , to show that they have been learned through the uplink port (x represents the corresponding uplink port for each switch. For example, the entries that SW_A has learnt through its uplink port have interface or port name P_AUP and for SW_B it is P_BUP , and so forth.

The end result is that each switch learns and creates binding entries for all hosts in the set-up.

This scenario displays an inefficient use of the binding table, because each host is being validated multiple times, which does not make it more secure than if just one switch validates host. Secondly, entries for the same host in multiple binding tables could mean that the address count limit is reached sooner. After the limit is reached, any further entries are rejected and required entries may be missed this way.

By contrast see figure Figure 29: Multi-Switch Set-Ups With Trusted-Port and Device-Role Switch Options, on page 500 below. Here when SW_A intercepts the packet of a host that is not attached to it (say H3 which is

directly attached to SW_B), it does not create an entry because it detects that H3 is attached to a device that is configured as a switch (**device-role switch** option) and the uplink port of the switch (where the packet came from) is a trusted port (**trusted-port** option).

By creating binding entries only on switches where the host appears on an access port (port P_1 and P_2 of each switch), and not creating entries for a host that appears over an uplink port or trusted port (P_x UP), each switch in the set-up validates and makes only the required entries, thus achieving an efficient distribution of the creation of binding table entries.

A second advantage of configuring **device-role switch** and **trusted-port** options in a multi-switch scenario is that it prevents duplicate entries when a host, say H1 moves from one switch to another. H1's IP and MAC binding in the earlier location (let's say SW_A) continues to remain there until it reaches the STALE state. But if H1 moves and connects to a second switch, say SW_C , then SW_A receives a duplicate binding entry through the uplink port. In such a situation, if the uplink port of the second switch (SW_C) is configured as a trusted port, SW_A deletes its stale entry. Further, it doesn't create another new binding entry because the SW_C will already have the latest entry and this entry is trusted.

Figure 29: Multi-Switch Set-Ups With Trusted-Port and Device-Role Switch Options

Example: When Not to Use Trusted-Port and Device-Role Switch Options

While the previous example clarifies how a multi-switch set-up with distributed binding tables stands to benefit from the **device-role switch** and **trusted-port** options, it may not suit networks of the following kinds:

- · Networks where non-Cisco switches are being used
- Networks where the switch does not support the SISF-based device-tracking feature.

In both cases, we recommended that you not configure the **device-role switch** and **trusted-port** options. Further, we recommended that you maintain a centralised binding table - on the distribution switch. When you do, all the binding entries for all the hosts connected to non-Cisco switches and switches that do not support the feature, are validated by the distribution switch and still secure your network. The figure below illustrates the same.

Figure 30: Centralised Binding Table

Creating an Efficient and Scalable Secure Zone

By using the **trusted-port** and **device-role switch** options in suitable networks and leaving them out in others, you can achieve an efficient and scalable secure zone.

Secure Zone:	Secure Zone 1 - Inefficient and Unscalable Secure Zone	Secure Zone 2 - Efficient and Scalable Secure Zone When Binding Tables are Decentralized	Secure Zone 3: Efficient Secure Zone When Binding Table is Centralized
Scalability:	Unscalable; each switch has entries of all the hosts in the network	Scalable; each switch as entries of only directly connected hosts	Unscalable; the distribution switch has entries of all hosts in the network
Polling and its effect on the network: n = number of hosts m = number of switches total number of polling requests: = n X m	 18 polling requests are being sent (6 hosts x 3 switches). Each host is polled by all the switches in the network (in the absence of the trusted-port and device-role switch options). Network load is very high. 	6 polling requests are being sent (2 hosts x 1 switch for <i>each</i> switch). Minimal network load. (Polling requests are sent by the local access switches to directly connected hosts, each polling request passes through fewer points in the network.)	6 polling requests are being sent (6 hosts x 1 switch) Network load is higher than secure zone 2, but not as high as secure zone 1. (Polling requests come from the distribution switch and go through the access switch before reaching the host.)
Efficiency:	Inefficient binding table, because the binding table is duplicated on each switch.	Efficient binding table, because each host's binding information is entered only once, and in one binding table and this the binding table of the directly connected switch.	Efficient binding table, because the binding information for each host is entered only once, and this is in the central binding table, which is on the distribution switch.
Recommended Action:	Reapply suitable policies to make the secure zone like secure zone 2	None; this is an efficient and scalable secure zone.	None; this is the best possible secure zone given the type of set-up (where the other switches in the network are either non-Cisco or do not support the feature)

Secure Zones 1, 2 and 3, display three different set-ups and the secure zone that is established in each case.

Figure 31: Secure Zone 1 - Inefficient and Unscalable Secure Zone

	Binding table for S				SWA

----- Uplink port configured as trunk port

Figure 32: Secure Zone 2 - Efficient and Scalable Secure Zone When Binding Tables are Decentralized

Figure 33: Secure Zone 3: Efficient Secure Zone When Binding Table is Centralized

When to Use Only Trusted-Port or Only Device-Role Switch

Configuring only **device-role switch** is suited to situations when you want to listen but not learn entries. For example, for Duplicate Address Detection (DAD), or when you want to send IPv6 or Neighbor Solicitation (NS) message on a switch-facing port.

When you configure this option on a switch port (or interface), SISF-based device-tracking treats the port as a trunk port, implying that the port is connected to other switches. It does not matter whether the port is actually a trunk port or not. Therefore, when NS packets or queries are sent to switches in the network for new entry validation, only the secure ports (ports where the **device-role switch** is configured) receive the packet or query. This safeguards the network. If the command is not configured on any port, a general broadcast of the query is sent.

Configuring only **trusted-port** is suited to situations where an access port should be configured as a trusted port. If an access port is connected to a DHCP server or a similar service that the switch is consuming, configuring an access port as a trusted port ensures that the service is not disrupted because traffic from such a port is trusted. This also widens the secure zone, to include the access port.

Address Count Limits

The address count limit parameter specifies limits for the number of IP and MAC addresses that can be entered in a binding table. The purpose of these limits is to contain the size of the binding table based on the number of known and expected hosts, thus enabling you to take pre-emptive action against rogue hosts or IPs in the network. At a policy level there are separate limits for the number of IP addresses per port, the number of IPv4 addresses per MAC, and IPv6 addresses per MAC. You can configure or change only the number of IP addresses per port.

IP per Port

The IP per port option is the total number of IP addresses allowed for a port. The address can be IPv4 or IPv6. When the limit is reached, no further IP addresses (i.e., entries) are added to the binding table.

To configure this parameter in a policy, enter the **limit address-count** *ip-per-port* keyword in device-tracking configuration mode. If you configure a limit that is lower than the currently configured one, then the new (lower) limit is applicable only to new entries. An existing entry remains in the binding table and goes through its binding entry lifecycle.

IPv4 per MAC and IPv6 per MAC

This refers to the number of IPv4 addresses that can be mapped to one MAC address and the number of IPv6 addresses that can be mapped to one MAC address. When the limit is reached, no further entries can be added to the binding table, and traffic from new hosts will be dropped

```
Note
```

The IPv4 per MAC limit and the IPv6 per MAC limit that is effective on an interface or VLAN is as defined in the policy that is applied. If the policy does not specify a limit, this means that a limit does not exist. You cannot change or configure a limit for IPv4 per MAC or IPv6 per MAC for any kind of policy (programmatic, or custom policy, or default policy).

Enter the show device-tracking policy policy name to check if a limit exisits.

The following is sample output of a policy where an IPv4 per MAC and an IPv6 per MAC limit exists:

```
Device# show device-tracking policy LISP-DT-GUARD-VLAN
Policy LISP-DT-GUARD-VLAN configuration:
   security-level guard (*)
   <output truncated>
   limit address-count for IPv4 per mac 4 (*)
   limit address-count for IPv6 per mac 12 (*)
   tracking enable
```

<output truncated>

Address Count Limit Considerations and Interactions with Other SISF Settings

• The limits do not have a hierarchy, but the threshold that is set for each limit affects the others.

For example, if the IP per port limit is 100, and the IPv4 per MAC limit is one, the limit is reached with a single host's IPv4-MAC binding entry. No further IP entries, which are bound to the same MAC are allowed in the table even though the port has a provision for 99 more IP addresses. Similarly, if the IP per port limit is one, and the IPv4 per MAC limit is 100. The limit is reached with a single host's IPv4-MAC binding entry. No further IP entries are allowed in the table even though the MAC has a provision for 99 more IP addresses for *that* MAC.

• Address count limits and the security-level parameter.

When these two settings co-exist, note the difference in system behaviour relating to the *binding table entry* and the system behaviour relating to treatment of the *packet*:

- If the security-level parameter is set to **glean**: Starting with Cisco IOS XE Bengaluru 17.6.1, all address limits (IP per port, IPv4 per MAC, IPv6 per MAC) are ignored. In earlier releases, reaching an address count limit results in the rejection of the entry.
- If the security-level parameter is **guard**: Reaching an address count limit still results in the rejection of further entries. But the way the *packet* is treated, depends on the software version.

Starting with Cisco IOS XE Cupertino 17.7.1, IPv4 and IPv6 packets are treated the same way. This means that if the limit is reached and the security-level parameter is guard, the entry is rejected and the packet is dropped. (On the other hand, if the security-level were glean and the address limit was reached, then the limit is ignored and entries continue to be added to the table and packets continue to be allowed)

In releases earlier than Cisco IOS XE Cupertino 17.7.1, having the security-level as **guard** and reaching an address count limit means that the entry is still rejected, but the packet is allowed to enter the network if it is an IPv4 packet. If it is an IPv6 packet, then a rejected entry means the packet is dropped.

Note

If yours is an IPv4 network, and you see that hosts that could previously join the network, are no longer able to, it may be that the address count limit is reached and rejected (IPv4) binding table entries are followed by dropped packets.

· Global and policy-level limits

The limits configured with the **device-tracking binding max-entries** command are at the global level, the limits configured with the **limit address-count** command in the device-tracking configuration mode are for a policy, which is at the interface or VLAN level.

If a policy-level value *and* a globally configured value exists, the creation of binding entries is stopped when *a* limit is reached - this limit can be any one of the global values or the policy-level value.

If only globally configured values exist, the creation of binding entries is stopped when a limit is reached.

If only a policy-level value exists, the creation of binding entries is stopped when the policy-level limit is reached.

Tracking

The tracking parameter involves tracking of hosts in the network. In section Polling a Host and Updating the Binding Table Entry, on page 491 above, this is referred to as "polling". It also describes polling behaviour in detail.

To configure polling parameters at the global level, enter the **device-tracking tracking** command in global configuration mode. After you configure this command you still have the flexibility to turn polling on or off, for individual interfaces and VLANs. For this you must enable or disable polling in the policy.

To enable polling in a policy, enter the **tracking enable** keywords in the device-tracking configuration mode. By default, polling is disabled in a policy.

Guidelines for Policy Creation

• If multiple policies are available on a given target, a system-internal policy priority determines which policy takes precedence.

A manually created policy has the highest priority. When you want to override the settings of a programmatically created policy, you can create a custom policy, so it has higher priority.

• The parameters of a programmatically created policy cannot be changed. You can configure certain attributes of a custom policy.

Guidelines for Applying a Policy

- Multiple policies can be attached to the same VLAN.
- If a programmatic policy is attached to a VLAN and you want to change policy settings, create a custom device-tracking policy and attach it to the VLAN.
- When multiple policies with different priorities are attached to the same VLAN, the settings of the policy with the highest priority are effective. The exceptions here are the limit address-count for IPv4 per mac and limit address-count for IPv6 per mac settings the settings of the policy with the lowest priorty are effective.
- When a device-tracking policy is attached to an interface under a VLAN, the policy settings on the interface take precedence over those on its VLAN; exceptions here are the values for limit address-count for IPv4 per mac and limit address-count for IPv6 per mac, which are aggregated from the policy on both the interface and VLAN.
- A policy cannot be removed unless the device tracking client feature configuration is removed.

How to Configure SISF

SISF or SISF-based device-tracking, is disabled by default. You enable it by defining a device-tracking policy and attaching the policy to a specific target. The target could be an interface or a VLAN. There are multiple ways to define a policy and no single method is a preferred or recommended one - use the option that suits your requirements.

Method of Enabling SISF	Applicable Configuration Tasks	Result
Option 1 : Manually, by using interface configuration commands to create and apply the default policy to a target.	Applying the Default Device Tracking Policy to a Target, on page 510	Automatically applies the default device tracking policy to the specified target. The default policy is a built-in
		policy with default settings; you cannot change any of the attributes of the default policy. See Option 2 if you want to configure device tracking policy attributes.

Method of Enabling SISF	Applicable Configuration Tasks	Result
Option 2 : Manually, by using global configuration commands commands to create a custom policy and applying the custom policy to a target.	 Creating a Custom Device Tracking Policy with Custom Settings, on page 510 Attach the custom policy to an interface or VLAN: Attaching a Device Tracking Policy to an Interface, on page 514 OR Attaching a Device Tracking Policy to a VLAN, on page 515 	Creates a custom policy with the name and policy parameters you configure, and attaches the policy to the specified target.
Option 3 : Programmatically, by configuring the snooping command.	Enter the ip dhcp snooping vlan <i>vlan</i> command in global configuration mode. Example: Programatically Enabling SISF by Configuring DHCP Snooping, on page 519	When you configure the command, the system automatically creates policy DT-PROGRAMMATIC. Use this method if you want to enable SISF-based device tracking for these clients: IEEE 802.1X, Web authentication, Cisco TrustSec, IP Source Guard, and SANET.
Option 4: Programmatically, by configuring Locator ID Separation Protocol (LISP).Example: Programatically enabling SISF by Configuring LISP (LISP-DT-GUARD-VLAN), on page 520Example: Programatically Enabling SISF by Configuring LISP (LISP-DT-GLEAN-VLAN), on page 520		When you configure LISP, the system automatically creates policy LISP-DT-GUARD-VLAN OF LISP-DT-GLEAN-VLAN.
Option 5 : Programmatically, by configuring EVPN VLAN.	Example: Programatically Enabling SISF by Configuring EVPN on VLAN, on page 519	When you configure EVPN on VLAN, the system automatically creates policy evpn-sisf-policy.
Option 6 : By using an interface template	Using an Interface Template to Enable SISF, on page 516	By adding the policy to an interface template, you can apply the same policy to multiple targets, without having to create it separately for each target.
Option 7 : Migrating from legacy IPDT and IPv6 Snooping.	Migrating from Legacy IPDT and IPv6 Snooping to SISF-Based Device Tracking, on page 518	Convert legacy IPDT and IPv6 Snooping configuration to the SISF-based device-tracking commands.

Applying the Default Device Tracking Policy to a Target

Beginning in privileged EXEC mode, follow these steps to apply the default device tracking policy to an interface or VLAN:

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode. Enter your
	Example:	password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	Specify an interface or a VLAN	interface type number—Specifies the
	• interface type number	interface and enters interface configuration
	• vlan configuration vlan_list	mode. The device tracking policy will be attached to the specified interface.
	Example:	vlan configuration <i>vlan_list</i> —Specifies the
	Device (config) # interface gigabitethernet 1/1/4	VLANs and enters VLAN feature configuration
	0R	mode. The device tracking policy will be attached to the specified VLAN.
	Device(config) # vlan configuration 333	attached to the specified VLAN.
Step 4	device-tracking	Enables SISF-based device tracking and
	Example:	attaches the default policy it to the interface o VLAN.
	Device(config-if)# device-tracking	
	OR Device(config-vlan-config)#	The default policy is a built-in policy with default settings; none of the attributes of the
	device-tracking	default policy can be changed.
Step 5	end	Exits interface configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-if)# end	Exits VLAN feature configuration mode and
	OR Device(config-vlan-config)# end	returns to privileged EXEC mode.
Step 6	show device-tracking policy policy-name	Displays device-tracking policy configuration
	Example:	and all the targets it is applied to.
	Device# show device-tracking policy default	

Creating a Custom Device Tracking Policy with Custom Settings

Beginning in privileged EXEC mode, follow these steps to create and configure a device tracking policy:

I

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	[no] device-tracking policy policy-name	Creates the policy and enters device-tracking
	Example:	configuration mode.
	<pre>Device(config)# device-tracking policy example_policy</pre>	
Step 4	[data-glean default destination-glean device-role distribution-switch exit limit no prefix-glean protocol security-level tracking trusted-port	
	vpc]	• (Optional) data-glean—Enables learning
	<pre>Example: Device(config-device-tracking)# destination-glean log-only</pre>	of addresses from a data packet snooped from a source inside the network and populates the binding table with the data traffic source address. Enter one of these options:
		 log-only—Generates a syslog message upon data packet notificatio
		 recovery—Uses a protocol to enabl binding table recovery. Enter NDP or DHCP.
		 (Optional) default—Sets the policy attribute to its default value. You can set these policy attributes to their default values: data-glean, destination-glean, device-role, limit, prefix-glean, protocol security-level, tracking, trusted-port.
		• (Optional) destination-glean —Populate the binding table by gleaning data traffic destination address. Enter one of these options:
		 log-only—Generates a syslog message upon data packet notificatio
		 recovery—Uses a protocol to enabl binding table recovery. Enter DHCF

Procedure

Command or Action	Purpose
	• (Optional) device-role —Sets the role of the device attached to the port. It can be a node or a switch. Enter one of these options:
	 node—Configures the attached device as a node. This is the default option.
	• switch—Configures the attached device as a switch.
	• (Optional) distribution-switch —Although visible on the CLI, this option is not supported. Any configuration settings you make will not take effect.
	• exit —Exits the device-tracking policy configuration mode.
	• limit address-count—Specifies an address count limit per port. The range is 1 to 32000.
	• no —Negates the command or sets it to defaults.
	• (Optional) prefix-glean —Enables learning of prefixes from either IPv6 Router Advertisements or from DHCP-PD. You have the following option:
	• (Optional) only —Gleans only prefixes and not host addresses.
	• (Optional) protocol —Sets the protocol to glean; by default, all are gleaned. Enter one of these options:
	• arp [prefix-list <i>name</i>]—Gleans addresses in ARP packets. Optionally, enter the name of prefix-list that is to be matched.
	• dhcp4 [prefix-list name]—Glean addresses in DHCPv4 packets. Optionally, enter the name of prefix-list that is to be matched.
	• dhcp6 [prefix-list <i>name</i>]—Glean addresses in DHCPv6 packets. Optionally, enter the name of prefix-list that is to be matched.

I

Command or Action	Purpose
	• ndp [prefix-list name]—Glean addresses in NDP packets. Optionally, enter the name of prefix-list that is to be matched.
	• udp [prefix-list <i>name</i>]—Although visible on the CLI, this option is not supported. Any configuration settings you make will not take effect.
	• (Optional) security-level —Specifies the level of security enforced by the feature. Enter one of these options:
	• glean—Gleans addresses passively.
	• guard —Inspects and drops un-authorized messages. This is the default.
	• inspect —Gleans and validates messages.
	• (Optional) tracking —Specfies a tracking option. Enter one of these options:
	• disable [stale-lifetime [1-86400-seconds infinite]] —Turns of device-tracking.
	Optionally, you can enter the duration for which the entry is kept inactive before deletion, or keep it permanently inactive.
	• enable [reachable-lifetime [1-86400-seconds infinite]] —Turns on device-tracking.
	Optionally, you can enter the duration for which the entry is kept reachable, or keep it permanently reachable.
	• (Optional) trusted-port —Sets up a trusted port. Disables the guard on applicable targets. Bindings learned through a trusted port have preference over bindings learned through any other port. A trusted port is given preference in case of a collision while making an entry in the table.
	• (Optional) vpc —Although visible on the CLI, this option is not supported. Any

	Command or Action	Purpose
		configuration settings you make will not take effect.
Step 5	end	Exits device-tracking configuration mode and
	Example:	returns to privileged EXEC mode.
	<pre>Device(config-device-tracking)# end</pre>	
	Displays the device-tracking policy	
	Example:	configuration.
	Device# show device-tracking policy example_policy	

What to do next

Attach the policy to an interface or VLAN.

Attaching a Device Tracking Policy to an Interface

Beginning in privileged EXEC mode, follow these steps to attach a device tracking policy to an interface:

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3 interface	interface interface	Specifies an interface and enters interface
	Example:	configuration mode.
	Device(config-if)# interface gigabitethernet 1/1/4	
Step 4	device-tracking attach-policy policy name	Attaches the device tracking policy to the
	Example:	interface. Device tracking is also supported on EtherChannels
	Device(config-if)# device-tracking attach-policy example_policy	EmerChannels.

	Command or Action	Purpose	
		Note	SISF based device-tracking policies can be disabled only if they are custom policies. Programmatically created policies can be removed only if the corresponding device-tracking client feature configuration is removed.
Step 5	<pre>end Example: Device(config-if)# end</pre>		erface configuration mode and returns ged EXEC mode.
Step 6	<pre>show device-tracking policies [interface interface] Example: Device# show device-tracking policies interface gigabitethernet 1/1/4</pre>		policies that match the specified type and number.

Attaching a Device Tracking Policy to a VLAN

Beginning in privileged EXEC mode, follow these steps to attach a device-tracking policy to VLANs across multiple interfaces:

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	vlan configuration vlan_list	Specifies the VLANs to which the device
	Example:	tracking policy will be attached; enters the VLAN interface configuration mode.
	Device(config)# vlan configuration 333	VEAN interface configuration mode.
Step 4	device-tracking attach-policy policy_name	Attaches the device tracking policy to the
	Example:	specified VLANs across all switch interfaces

	Command or Action	Purpose	
	<pre>Device(config-vlan-config)# device-tracking attach-policy example_policy</pre>	NoteSISF based device-tracking policies can be disabled only if they are custom policies. Programmatically created policies can be removed only if the corresponding device-tracking client feature configuration is removed.	
Step 5	do show device-tracking policies vlan vlan-ID	Verifies that the policy is attached to the specified VLAN, without exiting the VLAN	
	Example:	interface configuration mode.	
	Device(config-vlan-config)# do show device-tracking policies vlan 333		
Step 6	end Example:	Exits VLAN feature configuration mode and returns to privileged EXEC mode.	
	Device(config-vlan-config)# end		

Using an Interface Template to Enable SISF

An interface template is a container of configurations or policies. It provides a mechanism to configure multiple commands at the same time and associate it with a target, such as an interface. Starting with Cisco IOS XE Amsterdam 17.3.1, you can add the **device-tracking policy***policyname* global configuration command to a template and apply it to multiple targets.

You can also apply the template through 802.1x authentication. During the 802.1x authentication process, you can dynamically assign different templates (and therefore different policies) to different interfaces.

Note

You can apply only one interface template to one port.

Before you begin

You have already created a custom policy. See Creating a Custom Device Tracking Policy with Custom Settings, on page 510.

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode. Enter your
	Example:	password if prompted.
	Device> enable	

	Command or Action	Purpose
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	template interfacetemplate_name	Creates a template with the name you specify
	Example:	and enters template configuration mode. In the accompanying example, a template called
	<pre>Device(config)# template interface template_w_sisf</pre>	"template_w_sisf" is created.
Step 4	device-tracking attach-policypolicy_name	Attaches a policy to the template. SISF-based
	Example:	device-tracking is enabled and the policy is applied wherever the template is applied.
	<pre>Device (config-template)# device-tracking attach-policy sisf_policy_for_template</pre>	
Step 5	exit	Exits the template configuration mode and
	Example:	enters the global configuration mode.
	Device (config-template)# exit	
Step 6	interface type number	Specifies an interface and enters interface
	Example:	configuration mode.
	Device (config) # interface gigabitethernet 1/1/4	
Step 7	source templatetemplate_name	Configures a static binding for an interface
	Example:	template. In the accompaying example, "template_w_sisf" is statically applied to an
	<pre>Device(config-if)# source template template_w_sisf</pre>	interface.
Step 8	end	Exits the interface configuration mode and
	Example:	enters the privileged EXEC mode.
	Device(config-if)# end	
Step 9	show running-config interface type number	Displays the contents of the running
	Example:	configuration.
	Device# show running-config interface gigabitethernet 1/1/4	
	Building configuration <output truncated=""></output>	
	Current configuration : 71 bytes	
	! interface GigabitEthernet1/1/14 source template template_w_sisf end	

Migrating from Legacy IPDT and IPv6 Snooping to SISF-Based Device Tracking

Based on the legacy configuration that exists on your device, the **device-tracking upgrade-cli** command upgrades your CLI differently. Consider the following configuration scenarios and the corresponding migration results before you migrate your existing configuration.

Note You cannot configure a mix of the old IPDT and IPv6 snooping CLI with the SISF-based device tracking CLI.

Only IPDT Configuration Exists

If your device has only IPDT configuration, running the **device-tracking upgrade-cli** command converts the configuration to use the new SISF policy that is created and attached to the interface. You can then update this SISF policy.

If you continue to use the legacy commands, this restricts you to operate in a legacy mode where only the legacy IPDT and IPv6 snooping commands are available on the device.

Only IPv6 Snooping Configuration Exists

On a device with existing IPv6 snooping configuration, the old IPv6 Snooping commands are available for further configuration. The following options are available:

- (Recommended) Use the **device-tracking upgrade-cli** command to convert all your legacy configuration to the new SISF-based device tracking commands. After conversion, only the new device tracking commands will work on your device.
- Use the legacy IPv6 Snooping commands for your future configuration and do not run the **device-tracking upgrade-cli** command. With this option, only the legacy IPv6 Snooping commands are available on your device, and you cannot use the new SISF-based device tracking CLI commands.

Both IPDT and IPv6 Snooping Configuration Exist

On a device that has both legacy IPDT configuration and IPv6 snooping configuration, you can convert legacy commands to the SISF-based device tracking CLI commands. However, note that only one snooping policy can be attached to an interface, and the IPv6 snooping policy parameters override the IPDT settings.

Note If you do not migrate to the new SISF-based commands and continue to use the legacy IPv6 snooping or IPDT commands, your IPv4 device tracking configuration information may be displayed in the IPv6 snooping commands, as the SISF-based device tracking feature handles both IPv4 and IPv6 configuration. To avoid this, we recommend that you convert your legacy configuration to SISF-based device tracking commands.

No IPDT or IPv6 Snooping Configuration Exists

If your device has no legacy IP Device Tracking or IPv6 Snooping configurations, you can use only the new SISF-based device tracking commands for all your future configuration. The legacy IPDT commands and IPv6 snooping commands are not available.

Configuration Examples for SISF

Example: Programatically Enabling SISF by Configuring DHCP Snooping

The following example shows how to configure the **ip dhcp snooping vlan** *vlan* command in global configuration mode to enable SISF-based device-tracking. When you enable SISF this way, the system creates the DT-PROGREMATIC policy.

Enter the **show device-tracking policy** *policy_name* command in privileged EXEC mode, to display the settings for a DT-PROGREMATIC policy.

```
Device> enable
Device# configure terminal
Device(config) # ip dhcp snooping vlan 10
Device (config) # end
Device# show device-tracking policy DT-PROGRAMMATIC
Policy DT-PROGRAMMATIC configuration:
 security-level glean (*)
 device-role node
 gleaning from Neighbor Discovery
 gleaning from DHCP
 gleaning from ARP
 gleaning from DHCP4
 NOT gleaning from protocol unkn
 limit address-count for IPv4 per mac 1 (*)
 tracking enable
Policy DT-PROGRAMMATIC is applied on the following targets:
Target Type Policy
                                     Feature
                                                         Target range
vlan 10 VLAN DT-PROGRAMMATIC Device-tracking vlan all
 note:
 Binding entry Down timer: 24 hours (*)
```

Example: Programatically Enabling SISF by Configuring EVPN on VLAN

When you configure EVPN, the system automatically creates programmatic policy evpn-sisf-policy. Enter the show device-tracking policy *policy_name* command in privileged EXEC mode, to display policy settings.

Device# show device-tracking policy evpn-sisf-policy

Binding entry Stale timer: 24 hours (*)

```
Policy evpn-sisf-policy configuration:
 security-level glean (*)
 device-role node
 gleaning from Neighbor Discovery
 gleaning from DHCP
 gleaning from ARP
 gleaning from DHCP4
 NOT gleaning from protocol unkn
 tracking enable
Policy evpn-sisf-policy is applied on the following targets:
                                                           Target range
Target Type Policy
                                         Feature
        VLAN evpn-sisf-policy
                                        Device-tracking vlan all
vlan 10
 note:
```

```
Binding entry Down timer: 24 hours (*)
Binding entry Stale timer: 24 hours (*)
```

Example: Programatically Enabling SISF by Configuring LISP (LISP-DT-GLEAN-VLAN)

The following is sample output of programmatic policy LISP-DT-GLEAN-VLAN.

```
Note
```

The system creates LISP-DT-GUARD-VLAN, or LISP-DT-GLEAN-VLAN, or LISP-DT-GUARD-VLAN-MULTI-IP depending on *how* LISP is configured. You cannot change this, but if required you can create a custom policy with custom settings and attach it to the required target.

To display policy settings, enter the **show device-tracking policy** *policy_name* command in privileged EXEC mode.

Device# show device-tracking policy LISP-DT-GLEAN-VLAN

```
Policy LISP-DT-GLEAN-VLAN configuration:
 security-level glean (*)
 device-role node
 gleaning from Neighbor Discovery
 gleaning from DHCP
 gleaning from ARP
 gleaning from DHCP4
 NOT gleaning from protocol unkn
 limit address-count for IPv4 per mac 4 (*)
 limit address-count for IPv6 per mac 12 (*)
 tracking enable
Policy LISP-DT-GUARD-VLAN is applied on the following targets:
Target Type Policy
                                                    Target range
                                        Feature
          VLAN LISP-DT-GLEAN-VLAN
vlan 10
                                       Device-tracking vlan all
 note:
  Binding entry Down timer: 10 minutes (*)
  Binding entry Stale timer: 30 minutes (*)
```

Example: Programatically enabling SISF by Configuring LISP (LISP-DT-GUARD-VLAN)

The following is sample output of programmatic policy LISP-DT-GUARD-VLAN.

Ŵ

```
Note
```

The system creates LISP-DT-GUARD-VLAN, or LISP-DT-GLEAN-VLAN, or LISP-DT-GUARD-VLAN-MULTI-IP depending on *how* LISP is configured. You cannot change this, but if required you can create a custom policy with custom settings and attach it to the required target.

To display policy settings, enter the **show device-tracking policy** *policy_name* command in privileged EXEC mode.

Device# show device-tracking policy LISP-DT-GUARD-VLAN

```
Policy LISP-DT-GUARD-VLAN configuration:
```

```
security-level guard (*)
  device-role node
  gleaning from Neighbor Discovery
  gleaning from DHCP
  gleaning from ARP
  gleaning from DHCP4
  NOT gleaning from protocol unkn
  limit address-count for IPv4 per mac 4 (*)
  limit address-count for IPv6 per mac 12 (*)
  tracking enable
Policy LISP-DT-GUARD-VLAN is applied on the following targets:
          Type Policy
                                                                Target range
Target
                                             Feature
                 LISP-DT-GUARD-VLAN
                                             Device-tracking vlan all
           VLAN
vlan 10
  note:
  Binding entry Down timer: 10 minutes (*)
  Binding entry Stale timer: 30 minutes (*)
```

Example: Mitigating the IPv4 Duplicate Address Problem

For an IPv4 device-tracking entry, its reachability is verified by sending an SISF probe to its end-node, which is an ARP request message. Selection of the source IP address for this ARP probe follows these rules:

- If an SVI is configured on the VLAN, the IPv4 address of the SVI is selected. Please ensure that the SVI IP address is unique in the subnet.
- If SVI does not exist and the **device-tracking tracking auto-source** [fallback *host-ip mask*] [override] command is configured, source IP is selected according to the table below.
- Otherwise, an address with all zeros (0.0.0.0) is selected.

This example shows how you can tackle the Duplicate IP Address 0.0.0.0 error message problem encountered by clients that run Microsoft Windows:

Configure the **device-tracking tracking auto-source** command in global configuration mode. This command determines the source IP and MAC address used in the Address Resolution Packet (ARP) request sent by the switch to probe a client, in order to maintain its entry in the device-tracking table. The purpose, is to avoid using 0.0.0.0 as source IP address.

Note Configure the **device-tracking tracking auto-source** command when a switch virtual interface (SVI) is not configured. You do not have to configure it when a SVI is configured with an IPv4 address on the VLAN.

Command	Action	Notes	
	(In order to select source IP and MAC address for device tracking ARP probe)		
device-tracking tracking auto-source	 Set source to VLAN SVI if present. Look for IP and MAC binding in device-tracking table from same subnet. Use 0.0.00 	We recommend that you disable device-tracking on all trunk ports to avoid MAC flapping.	

Command	Action (In order to select source IP and MAC address for device tracking ARP probe)	Notes
device-tracking tracking auto-source override	 Set source to VLAN SVI if present Use 0.0.0.0 	Not recommended when there is no SVI.
ip device tracking probe auto-source fallback 0.0.0.X 255.255.255.0	 Set source to VLAN SVI if present. Look for IP and MAC binding in device-tracking table from same subnet. Compute source IP from client IP using host bit and mask provided. Source MAC is taken from the MAC address of the switchport facing the client*. 	We recommend that you disable device-tracking on all trunk ports to avoid MAC flapping. The computed IPv4 address must not be assigned to any client or network device.
device-tracking tracking auto-source fallback 0.0.0.X 255.255.255.0 override	 Set source to VLAN SVI if present. Compute source IP from client IP using host bit and mask provided*. Source MAC is taken from the MAC address of the switchport facing the client*. 	

* Depending on the client IP address, an IPv4 address has to be reserved for the source IP.

A reserved source IPv4 address = (host-ip and mask) | client-ip

- Client IP = 192.0.2.25
- Source IP = (192.0.2.25 and 255.255.255.0) | (0.0.0.1) = 192.0.2.1

IP address 192.0.2.1 should not be assigned to any client or network device.

Example: Disabling IPv6 Device Tracking on a Target

By default, SISF-based device-tracking supports both IPv4 and IPv6. The following configuration examples show how you can disable IPv6 device-tracking where supported.

To disable device-tracking for IPv6, when a *custom* policy is attached to a target (all releases):

```
Device (config) # device-tracking policy example-policy
Device (config-device-tracking) # no protocol ndp
Device (config-device-tracking) # no protocol dhcp6
```

Device(config-device-tracking)# end
X

Note

You cannot change the settings of a programmatic policy

Example: Enabling IPv6 for SVI on VLAN (To Mitigate the Duplicate Address Problem)

For an IPv6 device-tracking entry, its reachability is verified by sending an SISF probe to its end-node, which is a neighbor solicitation message. Selection of the source IP address for this neighbor solicitation probe follows these rules:

- If an SVI is configured on the VLAN, the link-local IPv6 address of the SVI is selected. Please ensure that the SVI IP address is unique in the subnet.
- Otherwise, an address with all zeros (0:0:0:0:0:0:0:0) is selected.

When IPv6 is enabled in the network and a switched virtual interface (SVI) is configured on a VLAN, we recommend that you add the following to the SVI configuration. This enables the SVI to acquire a link-local address automatically; this address is used as the source IP address of the SISF probe, thus preventing the duplicate IP address issue.

```
Device> enable
Device# configure terminal
Device(config)# interface vlan 10
Device(config-if)# ipv6 enable
Device(config-if)# end
```

Example: Configuring a Multi-Switch Network to Stop Creating Binding Entries from a Trunk Port

In a multi-switch network, SISF-based device tracking provides the capability to distribute binding table entries between switches running the feature. Binding entries are only created on the switches where the host appears on an access port. No entry is created for a host that appears over a trunk port. This is achieved by configuring a policy with the **trusted-port** and **device-role switch** options, and attaching it to the trunk port.

Note Both, the **trusted-port**, and **device-role switch** options, must be configured in the policy.

Further, we recommended that you apply such a policy on a port facing a device, which also has SISF-based device tracking enabled.

```
Device> enable
Device# configure terminal
Device(config)# device-tracking policy example_trusted_policy
Device(config-device-tracking)# device-role switch
Device(config-device-tracking)# trusted-port
Device(config-device-tracking)# exit
Device(config)# interface gigabitethernet 1/0/25
```

```
Device(config-if)# device-tracking attach-policy example_trusted_policy
Device(config-if)# end
```

Example: Avoiding a Short Device-Tracking Binding Reachable Time

When migrating from an older release, the following configuration may be present:

device-tracking binding reachable-lifetime 10

Remove this by entering the **no** version of the command.

```
Device> enable
Device# configure terminal
Device(config)# no device-tracking binding reachable-lifetime 10
Device(config)# end
```

Example: Detecting and Preventing Spoofing

Address spoofing, is a man-in-the-middle attack that allows an attacker to intercept communication between network devices. These attacks attempt to divert traffic from its originally intended host to the attacker instead. For example, attacks are carried out by sending unsolicited Address Resolution Protocol (ARP) replies or with IPv6 Neighbor Advertisements carrying a mapping that is different from the legitimate one, such as <IPTARGET, MACTHIEF>. When the IPTARGET is of the default gateway, all traffic that is meant to leave the subnet is routed to the attacker.

The following example shows shows the required SISF configuration to enable the system to detect and prevent spoofing. It also shows the system messages that are logged when spoofing is detected, and the action that the system takes. It includes an excerpt of LISP configuration in an SDA setup for example purposes only. Actual LISP configuration may involve additional configuration.

Sample LISP configuration:

Settings of the programmatic policy:

```
Device# show device-tracking policy LISP-DT-GUARD-VLAN
Device-tracking policy LISP-DT-GUARD-VLAN configuration:
security-level guard <<< enables the detection and prevention of IPv4 and
IPv6 spoofing
device-role node
gleaning from Neighbor Discovery
gleaning from DHCP
gleaning from DHCP
gleaning from DHCP4
NOT gleaning from protocol unkn
limit address-count for IPv4 per mac 21
limit address-count for IPv6 per mac 58
origin fabric
tracking enable reachable-lifetime 240
```

The following device-tracking counters show you that packet drops have occurred. However, the drops may be caused by reasons other than address spoofing as well. Use the information in the counters along with system messages to ascertain if spoofing has occurred.

Device# show device-tracking counters vlan 11 Received messages on vlan 11 • Protocol Protocol message NDP RS[4] RA[4] NS[1777] NA[2685] DHCPv6 ARP REQ[12] REP[1012] DHCPv4 ACD&DAD --[8] Dropped messages on vlan 10 : Feature Protocol Msg [Total dropped] Device-tracking: ARP REQ [23] reason: Packet accepted but not forwarded [23] REP [450] reason: Silent drop [445] reason: Packet accepted but not forwarded [5] :

Required configuration to display system messages:

Device# device-tracking logging theft Device# device-tracking logging packet drop

While the packet drops in the device-tracking counters do not conclusively prove that spoofing has occurred, the system messages help you ascertain this.

%SISF-4-IP_THEFT: IP Theft IP=3001::5 VLAN=10 Cand-MAC=aabb.cc00.6600 Cand-I/F=Et0/0 Known MAC aabb.cc00.6900 Known I/F Et0/1 %SISF-4-IP_THEFT: IP Theft IP=FE80::A8BB:CCFF:FE00:6900 VLAN=10 Cand-MAC=aabb.cc00.6600 Cand-I/F=Et0/0 Known MAC aabb.cc00.6900 Known I/F Et0/1

In the log, verified binding information (IP, MAC address, interface or VLAN) is preceded by the term "Known". A suspicious IP address and MAC address is preceded by the term "New" or "Cand". Interface and VLAN information is also provided along with the suspiscious IP or MAC address - this helps you identify where the suspiscious traffic was seen.

For more informaton about how to intepret these system messages, in the command reference of the corresponding release, see the usage guidelines of the **device-tracking logging** command.

Feature History for SISF

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

I

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.11.1	SISF-Based Device-Tracking	This feature was introduced. SISF-Based Device-Tracking tracks the presence, location, and movement of end-nodes in the network. The feature snoops traffic received by the switch, extracts device identity (MAC and IP address), and stores them in a binding table. Other features (called device tracking clients) depend on the accuracy of this information to operate properly. Both IPv4 and IPv6 are supported. SISF-based device-tracking is disabled by default.
Cisco IOS XE Amsterdam 17.3.1	 Interface template Throttling Limit for ARP Packets 	 The option to enable SISF-Based Device-Tracking by using an interface template was introduced. You can add the device-tracking policy <i>policy_name</i> global configuration command to a template and apply it to multiple targets. ARP packets are throttled to mitigate high CPU utilization scenarios. In a five second window, a maximum of 50 ARP broadcast packets per binding entry are processed by SISF. See the <i>Binding Table Sources</i> section in this chapter for more information.
Cisco IOS XE Bengaluru 17.6.1	Change in address count limit parameter	Address count limits are ignored when the security-level parameter is glean .
Cisco IOS XE Cupertino 17.7.1	 Treatment of IPv4 and IPv6 packets ARP Protection Implementation on newer models 	Treatment of IPv4 and IPv6 packets: When the security-level parameter is guard , IPv4 and IPv6 packets entering the network, are treated the same way. Both are stopped for the duration of the verification process. ARP Protection: Support for the <i>prevention</i> of IPv4 spoofing was introduced (Detection and reporting of IPv4 spoofing is supported since the introductory release of SISF). Implementation on newer models: This feature was also implemented on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to https://cfnng.cisco.com.

Configuring IEEE 802.1x Port-Based Authentication

This chapter describes how to configure IEEE 802.1x port-based authentication. IEEE 802.1x authentication prevents unauthorized devices (clients) from gaining access to the network. Unless otherwise noted, the term *switch* refers to a standalone switch or a switch stack.

- Restrictions for IEEE 802.1x Port-Based Authentication, on page 527
- Information About IEEE 802.1x Port-Based Authentication, on page 528
- How to Configure IEEE 802.1x Port-Based Authentication, on page 560
- Configuration Examples for IEEE 802.1x Port-Based Authentication, on page 604
- Monitoring IEEE 802.1x Port-Based Authentication Statistics and Status, on page 605
- Feature History for IEEE 802.1x Port-Based Authentication, on page 606

Restrictions for IEEE 802.1x Port-Based Authentication

The following restrictions apply to IEEE 802.1X port-based authentication.

- Switchports are always unauthorized when used with private VLANs. Dynamic VLANs pushed from the Authentication, Authorization, and Accounting (AAA) server is not supported on private VLAN ports. The data client session is expected to authorize on the secondary VLAN of the private VLAN dot1x port.
- Only interface-configured private VLAN-based authorization and dynamic VLAN on a normal access VLAN port is supported.
- If the **dot1q tag vlan native** command is configured globally, the dot1x reauthentication will fail on trunk ports.
- Do not configure the same VLAN ID for both voice VLAN and access VLAN at the same time, because it may cause authentication failures.
- If a downloadable ACL contains any type of duplicate entries, the entries are not auto merged. As a result, the 802.1X session authorization fails. Ensure that the downloadable ACL is optimized without any duplicate entries, for example port-based and name-based entries for the same port.
- Port security is not supported with IEEE 802.1x port-based authentication.
- If you overwrite the running configuration of interfaces with a configuration file loaded in flash, some ports may fail to authenticate the endpoints.

• Wake-on-LAN (WoL) feature is not supported.

Information About IEEE 802.1x Port-Based Authentication

The 802.1x standard defines a client-server-based access control and authentication protocol that prevents unauthorized clients from connecting to a LAN through publicly accessible ports unless they are properly authenticated. The authentication server authenticates each client connected to a switch port before making available any services offered by the switch or the LAN.

Note

TACACS is not supported with 802.1x authentication.

Until the client is authenticated, 802.1x access control allows only Extensible Authentication Protocol over LAN (EAPOL), Cisco Discovery Protocol, and Spanning Tree Protocol (STP) traffic through the port to which the client is connected. After authentication is successful, normal traffic can pass through the port.

The table shown below lists the maximum number of session each client supports:

Client session	Maximum sessions supported
Maximum dot1x or MAB client sessions	2000
Maximum web-based authentication sessions	2000
Maximum dot1x sessions with critical-auth VLAN enabled and server re-initialized	2000
Maximum MAB sessions with various session features applied	2000
Maximum dot1x sessions with service templates or session features applied	2000

Overview of IEEE 802.1x Port-Based Authentication

The 802.1x standard defines a client-server-based access control and authentication protocol that prevents unauthorized clients from connecting to a LAN through publicly accessible ports unless they are properly authenticated. The authentication server authenticates each client connected to a switch port before making available any services offered by the switch or the LAN.

Note TACACS is not supported with 802.1x authentication.

Until the client is authenticated, 802.1x access control allows only Extensible Authentication Protocol over LAN (EAPOL), Cisco Discovery Protocol, and Spanning Tree Protocol (STP) traffic through the port to which the client is connected. After authentication is successful, normal traffic can pass through the port.

Port-Based Authentication Process

To configure IEEE 802.1X port-based authentication, you must enable authentication, authorization, and accounting (AAA) and specify the authentication method list. A method list describes the sequence and authentication method to be queried to authenticate a user.

The AAA process begins with authentication. When 802.1x port-based authentication is enabled and the client supports 802.1x-compliant client software, these events occur:

- If the client identity is valid and the 802.1x authentication succeeds, the switch grants the client access to the network.
- If 802.1x authentication times out while waiting for an EAPOL message exchange and MAC authentication bypass is enabled, the switch can use the client MAC address for authorization. If the client MAC address is valid and the authorization succeeds, the switch grants the client access to the network. If the client MAC address is invalid and the authorization fails, the switch assigns the client to a guest VLAN that provides limited services if a guest VLAN is configured.
- If the switch gets an invalid identity from an 802.1x-capable client and a restricted VLAN is specified, the switch can assign the client to a restricted VLAN that provides limited services.
- If the RADIUS authentication server is unavailable (down) and inaccessible authentication bypass is enabled, the switch grants the client access to the network by putting the port in the critical-authentication state in the RADIUS-configured or the user-specified access VLAN.

Note Inaccessible authentication bypass is also referred to as critical authentication or the AAA fail policy.

If Multi Domain Authentication (MDA) is enabled on a port, this flow can be used with some exceptions that are applicable to voice authorization.

Figure 34: Authentication Flowchart

This figure shows the authentication process.

The switch reauthenticates a client when one of these situations occurs:

- Periodic reauthentication is enabled, and the reauthentication timer expires.
 - You can configure the reauthentication timer to use a switch-specific value or to be based on values from the RADIUS server.

After 802.1x authentication using a RADIUS server is configured, the switch uses timers based on the Session-Timeout RADIUS attribute (Attribute[27]) and the Termination-Action RADIUS attribute (Attribute [29]).

The Session-Timeout RADIUS attribute (Attribute[27]) specifies the time after which reauthentication occurs. The range is 1 to 1073741823 seconds.

Note In releases prior to Cisco IOS XE Bengaluru 17.5.1, the supported timeout range is 1to 65535. seconds. While downgrading from or releases after Cisco IOS XE Bengaluru 17.5.1 set the timeout to supported values to avoid ISSD breakage.

seconds. While downgrading from or releases after Cisco IOS XE Bengaluru 17.5.1 set the timeout to supported values to avoid ISSD breakage.

The Termination-Action RADIUS attribute (Attribute [29]) specifies the action to take during reauthentication. The actions are *Initialize* and *ReAuthenticate*. When the *Initialize* action is set (the attribute value is *DEFAULT*), the 802.1x session ends, and connectivity is lost during reauthentication. When the *ReAuthenticate* action is set (the attribute value is RADIUS-Request), the session is not affected during reauthentication.

 You manually reauthenticate the client by entering the dot1x re-authenticate interface interface-id privileged EXEC command.

Port-Based Authentication Initiation and Message Exchange

During 802.1x authentication, the switch or the client can initiate authentication. If you enable authentication on a port by using the **authentication port-control auto** interface configuration command, the switch initiates authentication when the link state changes from down to up or periodically as long as the port remains up and unauthenticated. The switch sends an EAP-request/identity frame to the client to request its identity. Upon receipt of the frame, the client responds with an EAP-response/identity frame.

However, if during bootup, the client does not receive an EAP-request/identity frame from the switch, the client can initiate authentication by sending an EAPOL-start frame, which prompts the switch to request the client's identity.

Note

If 802.1x authentication is not enabled or supported on the network access device, any EAPOL frames from the client are dropped. If the client does not receive an EAP-request/identity frame after three attempts to start authentication, the client sends frames as if the port is in the authorized state. A port in the authorized state effectively means that the client has been successfully authenticated.

When the client supplies its identity, the switch begins its role as the intermediary, passing EAP frames between the client and the authentication server until authentication succeeds or fails. If the authentication succeeds, the switch port becomes authorized. If the authentication fails, authentication can be retried, the port might be assigned to a VLAN that provides limited services, or network access is not granted.

The specific exchange of EAP frames depends on the authentication method being used.

Figure 35: Message Exchange

This figure shows a message exchange initiated by the client when the client uses the One-Time-Password (OTP) authentication method with a RADIUS server.

If 802.1x authentication times out while waiting for an EAPOL message exchange and MAC authentication bypass is enabled, the switch can authorize the client when the switch detects an Ethernet packet from the client. The switch uses the MAC address of the client as its identity and includes this information in the RADIUS-access/request frame that is sent to the RADIUS server. After the server sends the switch the RADIUS-access/accept frame (authorization is successful), the port becomes authorized. If authorization fails and a guest VLAN is specified, the switch assigns the port to the guest VLAN. If the switch detects an EAPOL packet while waiting for an Ethernet packet, the switch stops the MAC authentication bypass process and starts 802.1x authentication.

Figure 36: Message Exchange During MAC Authentication Bypass

This figure shows the message exchange during MAC authentication bypass.

Port-Based Authentication Methods

Authentication method	Mode				
	Single host	Multiple host	MDA	Multip Authen	
802.1x	VLAN assignment	VLAN assignment	VLAN assignment	VLAN	
	Per-user ACL		Per-user ACL	Per-use	
	Filter-ID attribute		Filter-Id attribute	Filter-I

Table 27: 802.1x Features

⁷ Supported in Cisco IOS Release 12.2(50)SE and later.

⁸ For clients that do not support 802.1x authentication.

Per-User ACLs and Filter IDs

Note

Using role-based ACLs as Filter ID is not recommended.

More than one host can be authenticated on MDA-enabled and multiauth ports. The ACL policy applied for one host does not effect the traffic of another host. If only one host is authenticated on a multi-host port, and the other hosts gain network access without authentication, the ACL policy for the first host can be applied to the other connected hosts by specifying any in the source address.

Ports in Authorized and Unauthorized States

During 802.1x authentication, depending on the switch port state, the switch can grant a client access to the network. The port starts in the *unauthorized* state. While in this state, the port that is not configured as a voice VLAN port disallows all ingress and egress traffic except for 802.1x authentication, Cisco Discovery Protocol, and STP packets. When a client is successfully authenticated, the port changes to the *authorized* state, allowing all traffic for the client to flow normally. If the port is configured as a voice VLAN port, the port allows VoIP traffic and 802.1x protocol packets before the client is successfully authenticated.

Note Cisco Discovery Protocol bypass is not supported and may cause a port to go into err-disabled state.

If a client that does not support 802.1x authentication connects to an unauthorized 802.1x port, the switch requests the client's identity. In this situation, the client does not respond to the request, the port remains in the unauthorized state, and the client is not granted access to the network.

In contrast, when an 802.1x-enabled client connects to a port that is not running the 802.1x standard, the client initiates the authentication process by sending the EAPOL-start frame. When no response is received, the client sends the request for a fixed number of times. Because no response is received, the client begins sending frames as if the port is in the authorized state.

You control the port authorization state by using the **authentication port-control** interface configuration command and these keywords:

- **force-authorized**: Disables 802.1x authentication and causes the port to change to the authorized state without any authentication exchange required. The port sends and receives normal traffic without 802.1x-based authentication of the client. This is the default setting.
- force-unauthorized: Causes the port to remain in the unauthorized state, ignoring all attempts by the client to authenticate. The switch cannot provide authentication services to the client through the port.
- **auto**: Enables 802.1x authentication and causes the port to begin in the unauthorized state, allowing only EAPOL frames to be sent and received through the port. The authentication process begins when the link state of the port changes from down to up or when an EAPOL-start frame is received. The switch requests the identity of the client and begins relaying authentication messages between the client and the authentication server. Each client attempting to access the network is uniquely identified by the switch by using the client MAC address.

If the client is successfully authenticated (receives an Accept frame from the authentication server), the port state changes to authorized, and all frames from the authenticated client are allowed through the port. If the authentication fails, the port remains in the unauthorized state, but authentication can be retried. If the authentication server cannot be reached, the switch can resend the request. If no response is received from the server after the specified number of attempts, authentication fails, and network access is not granted.

When a client logs off, it sends an EAPOL-logoff message, causing the switch port to change to the unauthorized state.

If the link state of a port changes from up to down, or if an EAPOL-logoff frame is received, the port returns to the unauthorized state.

802.1x Host Mode

You can configure an 802.1x port for single-host or for multiple-hosts mode. In single-host mode, only one client can be connected to the 802.1x-enabled switch port. The switch detects the client by sending an EAPOL frame when the port link state changes to the up state. If a client leaves or is replaced with another client, the switch changes the port link state to down, and the port returns to the unauthorized state.

In multiple-hosts mode, you can attach multiple hosts to a single 802.1x-enabled port. In this mode, only one of the attached clients must be authorized for all clients to be granted network access. If the port becomes unauthorized (reauthentication fails or an EAPOL-logoff message is received), the switch denies network access to all of the attached clients.

In this topology, the wireless access point is responsible for authenticating the clients attached to it, and it also acts as a client to the switch.

Figure 37: Multiple Host Mode Example

Note For all host modes, the line protocol stays up before authorization when port-based authentication is configured.

The switch supports multidomain authentication (MDA), which allows both a data device and a voice device, such as an IP Phone, to connect to the same switch port.

Access Session Limit Profile

An access session limit profile will allow you to limit the number of voice and data hosts connecting to a port. An access session limit profile will have higher priority compared to any host mode configuration. When an access session limit profile is configured the host mode configuration will be ignored.

You can create an access session limit profile by using the **access-session limit profile** command in the global configuration mode. You can configure the profile to limit the number of data and voice sessions allowed per interface. The profile can be configured to allow multiple hosts and to bypass authentication based on CDP packets if CDP bypass is supported.

The access session limit profile needs to be applied at an interface level.

You can also attach the access session limit profile to an interface template.

MAC Move

When a MAC address is authenticated on one switch port, that address is not allowed on another authentication manager-enabled port of the switch. If the switch detects that same MAC address on another authentication manager-enabled port, the address is not allowed.

There are situations where a MAC address might need to move from one port to another on the same switch. For example, when there is another device (for example a hub or an IP phone) between an authenticated host and a switch port, you might want to disconnect the host from the device and connect it directly to another port on the same switch.

You can globally enable MAC move so the device is reauthenticated on the new port. When a host moves to a second port, the session on the first port is deleted, and the host is reauthenticated on the new port. MAC move is supported on all host modes. (The authenticated host can move to any port on the switch, no matter which host mode is enabled on that port.) When a MAC address moves from one port to another, the switch terminates the authenticated session on the original port and initiates a new authentication sequence on the new port. The MAC move feature applies to both voice and data hosts.

Note

In open authentication mode, a MAC address is immediately moved from the original port to the new port, with no requirement for authorization on the new port.

MAC move with port security is not supported.

MAC move from an authentication manager-enabled port to an authentication manager-disabled port on a device is enabled by default. For this to work, MAC move must be enabled globally, that is, the **authentication mac-move permit** command must be configured in legacy mode, or, the **no access-session mac-move deny** command must be configured in IBNS 2.0. When MAC move is disabled globally, MAC move is denied. To disable MAC move from an authentication manager-enabled port to an authentication manager-disabled port on a device, use the **authentication mac-move deny-uncontrolled** command.

MAC Replace

The MAC Replace feature can be configured to address the violation that occurs when a host attempts to connect to a port where another host was previously authenticated.

Note

This feature does not apply to ports in multi-auth mode, because violations are not triggered in that mode. It does not apply to ports in multiple host mode, because in that mode, only the first host requires authentication.

If you configure the **authentication violation** interface configuration command with the **replace** keyword, the authentication process on a port in multidomain mode is:

- A new MAC address is received on a port with an existing authenticated MAC address.
- The authentication manager replaces the MAC address of the current data host on the port with the new MAC address.
- The authentication manager initiates the authentication process for the new MAC address.
- If the authentication manager determines that the new host is a voice host, the original voice host is removed.

If a port is in open authentication mode, any new MAC address is immediately added to the MAC address table.

The 802.1x standard defines how users are authorized and authenticated for network access but does not keep track of network usage. 802.1x accounting is disabled by default. You can enable 802.1x accounting to monitor this activity on 802.1x-enabled ports:

- User successfully authenticates.
- User logs off.
- Link-down occurs.
- Reauthentication successfully occurs.
- Reauthentication fails.

The switch does not log 802.1x accounting information. Instead, it sends this information to the RADIUS server, which must be configured to log accounting messages.

802.1x Accounting Attribute-Value Pairs

The information sent to the RADIUS server is represented in the form of Attribute-Value (AV) pairs. These AV pairs provide data for different applications. (For example, a billing application might require information that is in the Acct-Input-Octets or the Acct-Output-Octets attributes of a RADIUS packet.)

AV pairs are automatically sent by a switch that is configured for 802.1x accounting. Three types of RADIUS accounting packets are sent by a switch:

- · START: Sent when a new user session starts
- INTERIM: Sent during an existing session for updates
- STOP: Sent when a session terminates

This table lists the AV pairs and when they are sent are sent by the switch.

Table 2	28: Ассоц	inting A	V Pairs
---------	-----------	----------	---------

Attribute Number	AV Pair Name	START	INTERIM	STOP
Attribute[1]	User-Name	Always	Always	Always
Attribute[4]	NAS-IP-Address	Always	Always	Always
Attribute[5]	NAS-Port	Always	Always	Always
Attribute[8]	Framed-IP-Address	Never	Sometimes ⁹	Sometimes
Attribute[30]	Called-Station-ID	Always	Always	Always
Attribute[31]	Calling-Station-ID	Always	Always	Always
Attribute[40]	Acct-Status-Type	Always	Always	Always
Attribute[41]	Acct-Delay-Time	Always	Always	Always

Attribute Number	AV Pair Name	START	INTERIM	STOP	
Attribute[42]	Acct-Input-Octets	Never	Always	Always	
Attribute[43]	Acct-Output-Octets	Never	Always	Always	
Attribute[47]	Acct-Input-Packets	Never	Always	Always	
Attribute[48]	Acct-Output-Packets	Never	Always	Always	
Attribute[44]	Acct-Session-ID	Always	Always	Always	
Attribute[45]	Acct-Authentic	Always	Always	Always	
Attribute[46]	Acct-Session-Time	Never	Always	Always	
Attribute[49]	Acct-Terminate-Cause	Never	Never	Always	
Attribute[61]	NAS-Port-Type	Always	Always	Always	

⁹ The Framed-IP-Address AV pair is sent when a valid static IP address is configured or w when a Dynamic Host Control Protocol (DHCP) binding exists for the host in the DHCP snooping bindings table.

802.1x Readiness Check

The 802.1x readiness check monitors 802.1x activity on all the switch ports and displays information about the devices connected to the ports that support 802.1x. You can use this feature to determine if the devices connected to the switch ports are 802.1x-capable. You use an alternate authentication such as MAC authentication bypass or web authentication for the devices that do not support 802.1x functionality.

This feature only works if the supplicant on the client supports a query with the NOTIFY EAP notification packet. The client must respond within the 802.1x timeout value.

Switch-to-RADIUS Server Communication

RADIUS security servers are identified by their hostname or IP address, hostname and specific UDP port numbers, or IP address and specific UDP port numbers. The combination of the IP address and UDP port number creates a unique identifier, which enables RADIUS requests to be sent to multiple UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service, for example, authentication, the second host entry configured acts as the fail-over backup to the first one. The RADIUS host entries are tried in the order that they were configured.

IEEE 802.1x Authentication

The following sections provide information about IEEE 802.1x authentication.

802.1x Authentication

These are the 802.1x authentication configuration guidelines:

• You must enable SISF-Based device tracking to use 802.1x authentication. By default, SISF-Based device tracking is disabled on a switch.

- When 802.1x authentication is enabled, ports are authenticated before any other Layer 2 or Layer 3 features are enabled.
- If the VLAN to which an 802.1x-enabled port is assigned changes, this change is transparent and does not affect the switch. For example, this change occurs if a port is assigned to a RADIUS server-assigned VLAN and is then assigned to a different VLAN after reauthentication.

If the VLAN to which an 802.1x port is assigned to shut down, disabled, or removed, the port becomes unauthorized. For example, the port is unauthorized after the access VLAN to which a port is assigned shuts down or is removed.

- The 802.1x protocol is supported on Layer 2 static-access ports, voice VLAN ports, and Layer 3 routed
 ports, but it is not supported on these port types:
 - Dynamic ports: A port in dynamic mode can negotiate with its neighbor to become a trunk port. If you try to enable 802.1x authentication on a dynamic port, an error message appears, and 802.1x authentication is not enabled. If you try to change the mode of an 802.1x-enabled port to dynamic, an error message appears, and the port mode is not changed.
 - EtherChannel port: Do not configure a port that is an active or a not-yet-active member of an EtherChannel as an 802.1x port. If you try to enable 802.1x authentication on an EtherChannel port, an error message appears, and 802.1x authentication is not enabled.
 - Switched Port Analyzer (SPAN) and Remote SPAN (RSPAN) destination ports: You can enable 802.1x authentication on a port that is a SPAN or RSPAN destination port. However, 802.1x authentication is disabled until the port is removed as a SPAN or RSPAN destination port. You can enable 802.1x authentication on a SPAN or RSPAN source port.
- Before globally enabling 802.1x authentication on a switch by entering the **dot1x system-auth-control** global configuration command, remove the EtherChannel configuration from the interfaces on which 802.1x authentication and EtherChannel are configured.
- Filtering of system messages related to 802.1x authentication is supported.

Note We recommend that you configure all the dependent 802.1x CLIs under the same interface or on the same template.

Port-Based Authentication Manager CLI Commands

The authentication-manager interface-configuration commands control all the authentication methods, such as 802.1x, MAC authentication bypass, and web authentication. The authentication manager commands determine the priority and order of authentication methods applied to a connected host.

The authentication manager commands control generic authentication features, such as host-mode, violation mode, and the authentication timer. Generic authentication commands include the **authentication host-mode**, **authentication violation**, and **authentication timer** interface configuration commands.

802.1x-specific commands begin with the **dot1x** keyword. For example, the **authentication port-control auto** interface configuration command enables authentication on an interface.

To disable dot1x on a switch, remove the configuration globally by using the no dot1x system-auth-control, and also remove it from all configured interfaces.

Note

If 802.1x authentication is globally disabled, other authentication methods are still enabled on that port, such as web authentication.

The **authentication manager** commands provide the same functionality as earlier 802.1x commands.

When filtering out verbose system messages generated by the authentication manager, the filtered content typically relates to authentication success. You can also filter verbose messages for 802.1x authentication and MAB authentication. There is a separate command for each authentication method:

- The **no authentication logging verbose** global configuration command filters verbose messages from the authentication manager.
- The **no dot1x logging verbose** global configuration command filters 802.1x authentication verbose messages.
- The **no mab logging verbose** global configuration command filters MAC authentication bypass (MAB) verbose messages

Default 802.1x Authentication Configuration

Table 29: Default 802.1x Authentication Configuration

Default Setting
Disabled.
Disabled (force-authorized).
The port sends and receives normal traffic without 802.1x-based authentication of the client.
Disabled.
None specified.
• 1645.
• 1646.
None specified.
Single-host mode.
Bidirectional control.
Disabled.
3600 seconds.
Twice (number of times that the switch restarts the authentication before the port changes to the unauthorized state).

L

Feature	Default Setting		
Quiet period	60 seconds (number of seconds that the switch remains in th following a failed authentication exchange with the client).		
Retransmission time	30 seconds (number of seconds that the switch should wait for an EAP request/identity frame from the client before resendin		
Maximum retransmission number	2 times (number of times that the switch will send an EAP-re frame before restarting the authentication process).		
Client timeout period	30 seconds (when relaying a request from the authentication s client, the amount of time the switch waits for a response before the request to the client.)		
Authentication server timeout period	30 seconds (when relaying a response from the client to the a server, the amount of time the switch waits for a reply before response to the server.)		
	You can change this timeout period by using the dot1x timeout sinterface configuration command.		
Inactivity timeout	Disabled.		
Guest VLAN	None specified.		
Inaccessible authentication bypass	Disabled.		
Restricted VLAN	None specified.		
Authenticator (switch) mode	None specified.		
MAC authentication bypass	Disabled.		
Voice-aware security	Disabled.		

Port-Based Authentication and Switch Stacks

If a switch is added to or removed from a switch stack, 802.1x authentication is not affected as long as the IP connectivity between the RADIUS server and the stack remains intact. This statement also applies if the stack's active switch is removed from the switch stack. Note that if the active switch fails, a member switch in the stack becomes the new active switch by using the election process, and the 802.1x authentication process continues as usual.

If IP connectivity to the RADIUS server is interrupted because the switch that was connected to the server is removed or fails, these events occur:

- Ports that are already authenticated and that do not have periodic reauthentication enabled remain in the authenticated state. Communication with the RADIUS server is not required.
- Ports that are already authenticated and that have periodic reauthentication enabled (with the **dot1x re-authentication** global configuration command) fail the authentication process when the reauthentication occurs. Ports return to the unauthenticated state during the reauthentication process. Communication with the RADIUS server is required.

For an ongoing authentication, the authentication fails immediately because there is no server connectivity.

If the switch that failed comes up and rejoins the switch stack, the authentications might or might not fail depending on the boot-up time and whether the connectivity to the RADIUS server is re-established by the time the authentication is attempted.

To avoid loss of connectivity to the RADIUS server, you should ensure that there is a redundant connection to it. For example, you can have a redundant connection to the active switch and another to a member switch, and if the active switch fails, the switch stack still has connectivity to the RADIUS server.

802.1x Authentication with VLAN Assignment

The switch supports 802.1x authentication with VLAN assignment. After successful 802.1x authentication of a port, the RADIUS server sends the VLAN assignment to configure the switch port. The RADIUS server database maintains the username-to-VLAN mappings, assigning the VLAN based on the username of the client connected to the switch port. You can use this feature to limit network access for certain users.

When a voice device is authorized and the RADIUS server returned an authorized VLAN, the voice VLAN on the port is configured to send and receive packets on the assigned voice VLAN. Voice VLAN assignment behaves the same as data VLAN assignment on multidomain authentication (MDA)-enabled ports.

When configured on the switch and the RADIUS server, 802.1x authentication with VLAN assignment has these characteristics:

- If no VLAN is supplied by the RADIUS server or if 802.1x authentication is disabled, the port is configured in its access VLAN after successful authentication. Recall that an access VLAN is a VLAN assigned to an access port. All packets sent from or received on this port belong to this VLAN.
- If 802.1x authentication is enabled but the VLAN information from the RADIUS server is not valid, authorization fails and configured VLAN remains in use. This prevents ports from appearing unexpectedly in an inappropriate VLAN because of a configuration error.

Configuration errors could include specifying a VLAN for a routed port, a malformed VLAN ID, a nonexistent or internal (routed port) VLAN ID, an RSPAN VLAN, a shut down or suspended VLAN. In the case of a multidomain host port, configuration errors can also be due to an attempted assignment of a data VLAN that matches the configured or assigned voice VLAN ID (or the reverse).

- If 802.1x authentication is enabled and all information from the RADIUS server is valid, the authorized device is placed in the specified VLAN after authentication.
- If the multiple-hosts mode is enabled on an 802.1x port, all hosts are placed in the same VLAN (specified by the RADIUS server) as the first authenticated host.
- Enabling port security does not impact the RADIUS server-assigned VLAN behavior.
- If 802.1x authentication is disabled on the port, it is returned to the configured access VLAN and configured voice VLAN.
- If an 802.1x port is authenticated and put in the RADIUS server-assigned VLAN, any change to the port access VLAN configuration does not take effect. In the case of a multidomain host, the same applies to voice devices when the port is fully authorized with these exceptions:
 - If the VLAN configuration change of one device results in matching the other device configured or assigned VLAN, then authorization of all devices on the port is terminated and multidomain host mode is disabled until a valid configuration is restored where data and voice device configured VLANs no longer match.

 If a voice device is authorized and is using a downloaded voice VLAN, the removal of the voice VLAN configuration, or modifying the configuration value to *dot1p* or *untagged* results in voice device unauthorization and the disablement of multi-domain host mode.

When the port is in the force authorized, force unauthorized, unauthorized, or shutdown state, it is put into the configured access VLAN.

To configure VLAN assignment you need to perform these tasks:

- Enable AAA authorization by using the **network** keyword to allow interface configuration from the RADIUS server.
- Enable 802.1x authentication. (The VLAN assignment feature is automatically enabled when you configure 802.1x authentication on an access port).
- Assign vendor-specific tunnel attributes in the RADIUS server. The RADIUS server must return these attributes to the switch:
 - [64] Tunnel-Type = VLAN
 - [65] Tunnel-Medium-Type = 802
 - [81] Tunnel-Private-Group-ID = VLAN name or VLAN ID
 - [83] Tunnel-Preference

Attribute [64] must contain the value *VLAN* (type 13). Attribute [65] must contain the value 802 (type 6). Attribute [81] specifies the *VLAN name* or *VLAN ID* assigned to the IEEE 802.1x-authenticated user.

802.1x Authentication with Per-User ACLs

You can enable per-user access control lists (ACLs) to provide different levels of network access and service to an 802.1x-authenticated user. When the RADIUS server authenticates a user connected to an 802.1x port, it retrieves the ACL attributes based on the user identity and sends them to the switch. The switch applies the attributes to the 802.1x port for the duration of the user session. The switch removes the per-user ACL configuration when the session is over, if authentication fails, or if a link-down condition occurs. The switch does not save RADIUS-specified ACLs in the running configuration. When the port is unauthorized, the switch removes the ACL from the port.

You can configure router ACLs and input port ACLs on the same switch. However, a port ACL takes precedence over a router ACL. If you apply input port ACL to an interface that belongs to a VLAN, the port ACL takes precedence over an input router ACL applied to the VLAN interface. Incoming packets received on the port, to which a port ACL is applied, are filtered by the port ACL. Incoming routed packets received on other ports are filtered by the router ACL. Outgoing routed packets are filtered by the router ACL. To avoid configuration conflicts, you should carefully plan the user profiles stored on the RADIUS server.

RADIUS supports per-user attributes, including vendor-specific attributes. These vendor-specific attributes (VSAs) are in octet-string format and are passed to the switch during the authentication process. The VSAs used for per-user ACLs are inacl#<*n*> for the ingress direction and outacl#<*n*> for the egress direction. MAC ACLs are supported only in the ingress direction. The switch supports VSAs only in the ingress direction. It does not support port ACLs in the egress direction on Layer 2 ports.

Use only the extended ACL syntax style to define the per-user configuration stored on the RADIUS server. When the definitions are passed from the RADIUS server, they are created by using the extended naming convention. However, if you use the Filter-Id attribute, it can point to a standard ACL.

You can use the Filter-Id attribute to specify an inbound or outbound ACL that is already configured on the switch. The attribute contains the ACL number followed by *.in* for ingress filtering or *.out* for egress filtering. If the RADIUS server does not allow the *.in* or *.out* syntax, the access list is applied to the outbound ACL by default. The user is marked unauthorized if the Filter-Id sent from the RADIUS server is not configured on the device. The Filter-Id attribute is supported only for IP ACLs numbered in the range of 1 to 199 (IP standard ACLs) and 1300 to 2699 (IP extended ACLs).

The maximum size of the per-user ACL is 4000 ASCII characters but is limited by the maximum size of RADIUS-server per-user ACLs.

You must meet the following prerequisites to configure per-user ACLs:

- Enable AAA authentication.
- Enable AAA authorization by using the **network** keyword to allow interface configuration from the RADIUS server.
- Enable 802.1x authentication.
- Configure the user profile and VSAs on the RADIUS server.
- Configure the 802.1x port for single-host mode.

Note Per-user ACLs are supported only in single-host mode.

802.1x Authentication with Downloadable ACLs and Redirect URLs

You can download ACLs and redirect URLs from a RADIUS server to the switch during 802.1x authentication or MAC authentication bypass of the host. You can also download ACLs during web authentication. A downloadable ACL is also referred to as a *dACL*.

If more than one host is authenticated and the host is in single-host, MDA, or multiple-authentication mode, the switch changes the source address of the ACL to the host IP address.

You can apply the ACLs and redirect URLs to all the devices connected to the 802.1x-enabled port.

If no ACLs are downloaded during 802.1x authentication, the switch applies the static default ACL on the port to the host. On a voice VLAN port configured in multi-auth or MDA mode, the switch applies the ACL only to the phone as part of the authorization policies.

The limit for dACL with stacking is 64 ACEs per dACL per port. The limit without stacking is the number of available TCAM entries which varies based on the other ACL features that are active.

The 802.1x and MAB authentication methods support two authentication modes, *open* and *closed*. If there is no static ACL on a port in *closed* authentication mode:

- When the first host authenticates, the authorization policy is applied without IP address insertion.
- When a second host is detected, the policies for the first host are refreshed, and policies for the first and subsequent sessions are enforced with IP address insertion.

If there is no static ACL on a port in open authentication mode:

· Policies are enforced with IP address insertion to prevent security breaches.

To control access for hosts with no authorization policy, you can configure a directive. The supported values for the directive are *open* and *default*. When you configure the *open* directive, all traffic is allowed. The *default* directive subjects traffic to the access provided by the port. You can configure the directive either in the user profile on the AAA server or on the switch. To configure the directive on the AAA server, use the **authz-directive =<open/default>** global command. To configure the directive on the switch, use the **epm access-control open** global configuration command.

Note The default value of the directive is *default*.

For a URL redirect ACL:

- Packets that match a permit access control entry (ACE) rule are sent to the CPU for forwarding to the AAA server.
- Packets that match a deny ACE rule are forwarded through the switch.
- Packets that match neither the permit ACE rule or deny ACE rule are processed by the next dACL, and
 if there is no dACL, the packets hit the implicit-deny ACL and are dropped.

VLAN ID-Based MAC Authentication

You can use VLAN ID-based MAC authentication if you wish to authenticate hosts based on a static VLAN ID instead of a downloadable VLAN. When you have a static VLAN policy configured on your switch, VLAN information is sent to an IAS (Microsoft) RADIUS server along with the MAC address of each host for authentication. The VLAN ID configured on the connected port is used for MAC authentication. By using VLAN ID-based MAC authentication with an IAS server, you can have a fixed number of VLANs in the network.

The feature also limits the number of VLANs monitored and handled by STP. The network can be managed as a fixed VLAN.

IEEE 802.1x Authentication with MAC Authentication Bypass

You can configure the switch to authorize clients based on the client MAC address by using the MAC authentication bypass feature. For example, you can enable this feature on IEEE 802.1x ports connected to devices such as printers.

If IEEE 802.1x authentication times out while waiting for an EAPOL response from the client, the switch tries to authorize the client by using MAC authentication bypass.

When the MAC authentication bypass feature is enabled on an IEEE 802.1x port, the switch uses the MAC address as the client identity. The authentication server has a database of client MAC addresses that are allowed network access. After detecting a client on an IEEE 802.1x port, the switch waits for an Ethernet packet from the client. The switch sends the authentication server a RADIUS-access/request frame with a username and password based on the MAC address. If authorization succeeds, the switch grants the client access to the network. If authorization fails, the switch assigns the port to the guest VLAN if one is configured. This process works for most client devices; however, it does not work for clients that use an alternate MAC address format. You can configure how MAB authentication is performed for clients with MAC addresses that deviate from the standard format or where the RADIUS configuration requires the user name and password to differ.

If an EAPOL packet is detected on the interface during the lifetime of the link, the switch determines that the device connected to that interface is an 802.1x-capable supplicant and uses 802.1x authentication (not MAC

authentication bypass) to authorize the interface. EAPOL history is cleared if the interface link status goes down.

If the switch already authorized a port by using MAC authentication bypass and detects an IEEE 802.1x supplicant, the switch does not unauthorize the client connected to the port. When reauthentication occurs, the switch uses the authentication or reauthentication methods configured on the port, if the previous session ended because the Termination-Action RADIUS attribute value is DEFAULT.

Clients that were authorized with MAC authentication bypass can be reauthenticated. The reauthentication process is the same as that for clients that were authenticated with IEEE 802.1x. During reauthentication, the port remains in the previously assigned VLAN. If reauthentication is successful, the switch keeps the port in the same VLAN. If reauthentication fails, the switch assigns the port to the guest VLAN, if one is configured.

If reauthentication is based on the Session-Timeout RADIUS attribute (Attribute[27]) and the Termination-Action RADIUS attribute (Attribute [29]) and if the Termination-Action RADIUS attribute (Attribute [29]) action is *Initialize* (the attribute value is *DEFAULT*), the MAC authentication bypass session ends, and connectivity is lost during reauthentication. If MAC authentication bypass is enabled and the IEEE 802.1x authentication times out, the switch uses the MAC authentication bypass feature to initiate re-authorization. For more information about these AV pairs, see RFC 3580, "IEEE 802.1X Remote Authentication Dial In User Service (RADIUS) Usage Guidelines."

MAC authentication bypass interacts with the features:

- IEEE 802.1x authentication: You can enable MAC authentication bypass only if 802.1x authentication is enabled on the port .
- Guest VLAN: If a client has an invalid MAC address identity, the switch assigns the client to a guest VLAN if one is configured.
- Restricted VLAN: This feature is not supported when the client connected to an IEEE 802.lx port is authenticated with MAC authentication bypass.
- · Port security
- Voice VLAN
- Private VLAN: You can assign a client to a private VLAN.
- Network Edge Access Topology (NEAT): MAB and NEAT are mutually exclusive. You cannot enable MAB when NEAT is enabled on an interface, and you should not enable NEAT when MAB is enabled on an interface.

MAC Authentication Bypass Configuration Guidelines

These are the MAC authentication bypass configuration guidelines:

- Unless otherwise stated, the MAC authentication bypass guidelines are the same as the 802.1x authentication guidelines.
- If you disable MAC authentication bypass from a port after the port has been authorized with its MAC address, the port state is not affected.
- If the port is in the unauthorized state and the client MAC address is not the authentication-server database, the port remains in the unauthorized state. However, if the client MAC address is added to the database, the switch can use MAC authentication bypass to re-authorize the port.
- If the port is in the authorized state, the port remains in this state until re-authorization occurs.

• You can configure a timeout period for hosts that are connected by MAC authentication bypass but are inactive. The range is 1to 65535 seconds.

802.1x Multiple Authentication Mode

Multiple-authentication (multiauth) mode allows multiple authenticated clients on the data VLAN and voice VLAN. Each host is individually authenticated. There is no limit to the number of data or voice device that can be authenticated on a multiauthport.

If a hub or access point is connected to an 802.1x-enabled port, each connected client must be authenticated. For non-802.1x devices, you can use MAC authentication bypass or web authentication as the per-host authentication fallback method to authenticate different hosts with different methods on a single port.

You can assign a RADIUS-server-supplied VLAN in multi-auth mode, under the following conditions:

- The host is the first host authorized on the port, and the RADIUS server supplies VLAN information
- Subsequent hosts are authorized with a VLAN that matches the operational VLAN.
- A host is authorized on the port with no VLAN assignment, and subsequent hosts either have no VLAN assignment, or their VLAN information matches the operational VLAN.
- The first host authorized on the port has a group VLAN assignment, and subsequent hosts either have no VLAN assignment, or their group VLAN matches the group VLAN on the port. Subsequent hosts must use the same VLAN from the VLAN group as the first host. If a VLAN list is used, all hosts are subject to the conditions specified in the VLAN list.
- After a VLAN is assigned to a host on the port, subsequent hosts must have matching VLAN information or be denied access to the port.
- The behavior of the critical-auth VLAN is not changed for multi-auth mode. When a host tries to authenticate and the server is not reachable, all authorized hosts are reinitialized in the configured VLAN.

Multi-auth Per User VLAN assignment

The Multi-auth Per User VLAN assignment feature allows you to create multiple operational access VLANs based on VLANs assigned to the clients on the port that has a single configured access VLAN. The port configured as an access port where the traffic for all the VLANs associated with data domain is not dot1q tagged, and these VLANs are treated as native VLANs.

The number of hosts per multi-auth port is 8, however there can be more hosts.

The following scenarios are associated with the multi-auth Per User VLAN assignments:

Scenario One

When a hub is connected to an access port, and the port is configured with an access VLAN (V0).

The host (H1) is assigned to VLAN (V1) through the hub. The operational VLAN of the port is changed to V1. This behaviour is similar on a single-host or multi-domain-auth port.

When a second host (H2) is connected and gets assigned to VLAN (V2), the port will have two operational VLANs (V1 and V2). If H1 and H2 sends untagged ingress traffic, H1 traffic is mapped to VLAN (V1) and H2 traffic to VLAN (V2), all egress traffic going out of the port on VLAN (V1) and VLAN (V2) are untagged.

If both the hosts, H1 and H2 are logged out or the sessions are removed due to some reason then VLAN (V1) and VLAN (V2) are removed from the port, and the configured VLAN (V0) is restored on the port.

Scenario Two

When a hub is connected to an access port, and the port is configured with an access VLAN (V0). The host (H1) is assigned to VLAN (V1) through the hub. The operational VLAN of the port is changed to V1.

When a second host (H2) is connected and gets authorized without explicit vlan policy, H2 is expected to use the configured VLAN (V0) that is restored on the port. A ll egress traffic going out of two operational VLANs, VLAN (V0) and VLAN (V1) are untagged.

If host (H2) is logged out or the session is removed due to some reason then the configured VLAN (V0) is removed from the port, and VLAN (V1) becomes the only operational VLAN on the port.

Scenario Three

When a hub is connected to an access port in open mode, and the port is configured with an access VLAN (V0).

The host (H1) is assigned to VLAN (V1) through the hub. The operational VLAN of the port is changed to V1. When a second host (H2) is connected and remains unauthorized, it still has access to operational VLAN (V1) due to open mode.

If host H1 is logged out or the session is removed due to some reason, VLAN (V1) is removed from the port and host (H2) gets assigned to VLAN (V0).

Note

The combination of Open mode and VLAN assignment has an adverse affect on host (H2) because it has an IP address in the subnet that corresponds to VLAN (V1).

Limitation in Multi-Auth Per User VLAN assignment

In the Multi-Auth Per User VLAN Assignment feature, egress traffic from multiple VLANs are untagged on a port where the hosts receive traffic that is not meant for them. This can be a problem with broadcast and multicast traffic.

- **IPv4 ARPs**: Hosts receive ARP packets from other subnets. This is a problem if two subnets in different Virtual Routing and Forwarding (VRF) tables with overlapping IP address range are active on the port. The host ARP cache may get invalid entries.
- **IPv6 Control Packets**: In IPv6 deployments, Router Advertisements (RA) are processed by hosts that are not supposed to receive them. When a host from one VLAN receives RA from a different VLAN, the host assign incorrect IPv6 address to itself. Such a host is unable to get access to the network.

The workaround is to enable the IPv6 first hop security so that the broadcast ICMPv6 packets are converted to unicast and sent out from multi-auth enabled ports. The packet is replicated for each client in multi-auth port belonging to the VLAN and the destination MAC is set to an individual client. Ports having one VLAN, ICMPv6 packets broadcast normally.

• **IP Multicast**: Multicast traffic destined to a multicast group gets replicated for different VLANs if the hosts on those VLANs join the multicast group. When two hosts in different VLANs join a multicast group (on the same multi-auth port), two copies of each multicast packet are sent out from that port.

that fail authentication access to the guest VLAN.

unauthorized state, and 802.1x authentication restarts.

When you enable a guest VLAN on an 802.1x port, the switch assigns clients to a guest VLAN when the switch does not receive a response to its EAP request/identity frame or when EAPOL packets are not sent by the client.

You can configure a guest VLAN for each 802.1x port on the switch to provide limited services to clients, such as downloading the 802.1x client. These clients might be upgrading their system for 802.1x authentication,

and some hosts, such as Windows 98 systems, might not be IEEE 802.1x-capable.

The switch maintains the EAPOL packet history. If an EAPOL packet is detected on the interface during the lifetime of the link, the switch determines that the device connected to that interface is an IEEE 802.1x-capable supplicant, and the interface does not change to the guest VLAN state. EAPOL history is cleared if the interface link status goes down. If no EAPOL packet is detected on the interface, the interface changes to the guest VLAN state.

If the switch is trying to authorize an 802.1x-capable voice device and the AAA server is unavailable, the authorization attempt fails, but the detection of the EAPOL packet is saved in the EAPOL history. When the AAA server becomes available, the switch authorizes the voice device. However, the switch no longer allows other devices access to the guest VLAN. To prevent this situation, use one of these command sequences:

- Enter the **authentication event no-response action authorize vlan** *vlan-id* interface configuration command to allow access to the guest VLAN.
- Enter the **shutdown** interface configuration command followed by the **no shutdown** interface configuration command to restart the port.

If devices send EAPOL packets to the switch during the lifetime of the link, the switch no longer allows clients

Note If an EAPOL packet is detected after the interface has changed to the guest VLAN, the interface reverts to an

Any number of 802.1x-incapable clients are allowed access when the switch port is moved to the guest VLAN. If an 802.1x-capable client joins the same port on which the guest VLAN is configured, the port is put into the unauthorized state in the user-configured access VLAN, and authentication is restarted.

Guest VLANs are supported on 802.1x ports in single host, multiple host, multi-auth and multi-domain modes.

You can configure any active VLAN except an RSPAN VLAN, a private VLAN, or a voice VLAN as an 802.1x guest VLAN. The guest VLAN feature is not supported on internal VLANs (routed ports) or trunk ports; it is supported only on access ports.

The switch supports MAC authentication bypass. When MAC authentication bypass is enabled on an 802.1x port, the switch can authorize clients based on the client MAC address when IEEE 802.1x authentication times out while waiting for an EAPOL message exchange. After detecting a client on an 802.1x port, the switch waits for an Ethernet packet from the client. The switch sends the authentication server a RADIUS-access/request frame with a username and password based on the MAC address. If authorization succeeds, the switch grants the client access to the network. If authorization fails, the switch assigns the port to the guest VLAN if one is specified.

802.1x Authentication with Guest VLAN

802.1x Authentication with Restricted VLAN

You can configure a restricted VLAN (also referred to as an *authentication failed VLAN*) for each IEEE 802.1x port on a switch stack or a switch to provide limited services to clients that cannot access the guest VLAN. These clients are 802.1x-compliant and cannot access another VLAN because they fail the authentication process. A restricted VLAN allows users without valid credentials in an authentication server (typically, visitors to an enterprise) to access a limited set of services. The administrator can control the services available to the restricted VLAN.

Note

You can configure a VLAN to be both the guest VLAN and the restricted VLAN if you want to provide the same services to both types of users.

Without this feature, the client attempts and fails authentication indefinitely, and the switch port remains in the spanning-tree blocking state. With this feature, you can configure the switch port to be in the restricted VLAN after a specified number of authentication attempts (the default value is 3 attempts).

The authenticator counts the failed authentication attempts for the client. When this count exceeds the configured maximum number of authentication attempts, the port moves to the restricted VLAN. The failed attempt count increments when the RADIUS server replies with either an *EAP failure* or an empty response without an EAP packet. When the port moves into the restricted VLAN, the failed attempt counter resets.

Users who fail authentication remain in the restricted VLAN until the next reauthentication attempt. A port in the restricted VLAN tries to reauthenticate at configured intervals (the default is 60 seconds). If reauthentication fails, the port remains in the restricted VLAN. If reauthentication is successful, the port moves either to the configured VLAN or to a VLAN sent by the RADIUS server. You can disable reauthentication. If you do this, the only way to restart the authentication process is for the port to receive a *link down* or *EAP logoff* event. We recommend that you keep reauthentication enabled if a client might connect through a hub. When a client disconnects from the hub, the port might not receive the *link down* or *EAP logoff* event.

After a port moves to the restricted VLAN, a simulated EAP success message is sent to the client. This prevents clients from indefinitely attempting authentication. Some clients (for example, devices running Windows XP) cannot implement DHCP without EAP success.

Restricted VLANs are supported on 802.1x ports in all host modes and on Layer 2 ports.

You can configure any active VLAN except an RSPAN VLAN, a primary private VLAN, or a voice VLAN as an 802.1x restricted VLAN. The restricted VLAN feature is not supported on internal VLANs (routed ports) or trunk ports; it is supported only on access ports.

Other security port features such as dynamic ARP Inspection, DHCP snooping, and IP source guard can be configured independently on a restricted VLAN.

802.1x Authentication with Inaccessible Authentication Bypass

Use the inaccessible authentication bypass feature, also referred to as *critical authentication* or the AAA fail *policy*, when the switch cannot reach the configured RADIUS servers and new hosts cannot be authenticated. You can configure the switch to connect those hosts to *critical ports*.

When a new host tries to connect to the critical port, that host is moved to a user-specified access VLAN, the *critical VLAN*. The administrator gives limited authentication to the hosts.

When the switch tries to authenticate a host connected to a critical port, the switch checks the status of the configured RADIUS server. If a server is available, the switch can authenticate the host. However, if all the

RADIUS servers are unavailable, the switch grants network access to the host and puts the port in the *critical-authentication* state, which is a special case of the authentication state.

Ŋ

Note If *critical authentication* is configured on interface, then vlan used for critical authorization (*critical vlan*) should be active on the switch. If the *critical vlan* is inactive (or) down, *critical authentication* session will keep trying to enable inactive vlan and fail repeatedly. This can lead to large amount of memory holding.

Inaccessible Authentication Bypass Support on Multiple-Authentication Ports

When a port is configured on any host mode and the AAA server is unavailable, the port is then configured to multi-host mode and moved to the critical VLAN. To support this inaccessible bypass on multiple-authentication (multiauth) ports, use the **authentication event server dead action reinitialize vlan** *vlan-id* command. When a new host tries to connect to the critical port, that port is reinitialized and all the connected hosts are moved to the user-specified access VLAN.

This command is supported on all host modes.

Inaccessible Authentication Bypass Authentication Results

The behavior of the inaccessible authentication bypass feature depends on the authorization state of the port:

- If the port is unauthorized when a host connected to a critical port tries to authenticate and all servers are unavailable, the switch puts the port in the critical-authentication state in the RADIUS-configured or user-specified access VLAN.
- If the port is already authorized and reauthentication occurs, the switch puts the critical port in the critical-authentication state in the current VLAN, which might be the one previously assigned by the RADIUS server.
- If the RADIUS server becomes unavailable during an authentication exchange, the current exchange times out, and the switch puts the critical port in the critical-authentication state during the next authentication attempt.

You can configure the critical port to reinitialize hosts and move them out of the critical VLAN when the RADIUS server is again available. When this is configured, all critical ports in the critical-authentication state are automatically reauthenticated.

Inaccessible Authentication Bypass Feature Interactions

Inaccessible authentication bypass interacts with these features:

- Guest VLAN: Inaccessible authentication bypass is compatible with guest VLAN. When a guest VLAN is enabled on 8021.x port, the features interact as follows:
 - If at least one RADIUS server is available, the switch assigns a client to a guest VLAN when the switch does not receive a response to its EAP request/identity frame or when EAPOL packets are not sent by the client.
 - If all the RADIUS servers are not available and the client is connected to a critical port, the switch authenticates the client and puts the critical port in the critical-authentication state in the RADIUS-configured or user-specified access VLAN.
 - If all the RADIUS servers are not available and the client is not connected to a critical port, the switch might not assign clients to the guest VLAN if one is configured.

- If all the RADIUS servers are not available and if a client is connected to a critical port and was previously assigned to a guest VLAN, the switch keeps the port in the guest VLAN.
- Restricted VLAN: If the port is already authorized in a restricted VLAN and the RADIUS servers are unavailable, the switch puts the critical port in the critical-authentication state in the restricted VLAN.
- 802.1x accounting: Accounting is not affected if the RADIUS servers are unavailable.
- Private VLAN: You can configure inaccessible authentication bypass on a private VLAN host port. The access VLAN must be a secondary private VLAN.
- Voice VLAN: Inaccessible authentication bypass is compatible with voice VLAN, but the RADIUS-configured or user-specified access VLAN and the voice VLAN must be different.
- Remote Switched Port Analyzer (RSPAN): Do not configure an RSPAN VLAN as the RADIUS-configured or user-specified access VLAN for inaccessible authentication bypass.

In a switch stack:

When a member switch is added to the stack, the active switch sends the member switch the server status.

VLAN Assignment, Guest VLAN, Restricted VLAN, and Inaccessible Authentication Bypass

These are the configuration guidelines for VLAN assignment, guest VLAN, restricted VLAN, and inaccessible authentication bypass:

- When 802.1x authentication is enabled on a port, you cannot configure a port VLAN that is equal to a voice VLAN.
- You can configure any VLAN except an RSPAN VLAN or a voice VLAN as an 802.1x guest VLAN. The guest VLAN feature is not supported on internal VLANs (routed ports) or trunk ports; it is supported only on access ports.
- After you configure a guest VLAN for an 802.1x port to which a DHCP client is connected, you might need to get a host IP address from a DHCP server. You can change the settings for restarting the 802.1x authentication process on the switch before the DHCP process on the client times out and tries to get a host IP address from the DHCP server. Decrease the settings for the 802.1x authentication process (authentication timer inactivity and authentication timer reauthentication interface configuration commands). The amount to decrease the settings depends on the connected 802.1x client type.
- When configuring the inaccessible authentication bypass feature, follow these guidelines:
 - The feature is supported on 802.1x port in single-host mode and multihosts mode.
 - If the client is running Windows XP and the port to which the client is connected is in the critical-authentication state, Windows XP might report that the interface is not authenticated.
 - If the Windows XP client is configured for DHCP and has an IP address from the DHCP server, receiving an EAP-Success message on a critical port might not re-initiate the DHCP configuration process.
 - You can configure the inaccessible authentication bypass feature and the restricted VLAN on an 802.1x port. If the switch tries to reauthenticate a critical port in a restricted VLAN and all the RADIUS servers are unavailable, switch changes the port state to the critical authentication state and remains in the restricted VLAN.

• You can configure any VLAN except an RSPAN VLAN or a voice VLAN as an 802.1x restricted VLAN. The restricted VLAN feature is not supported on internal VLANs (routed ports) or trunk ports; it is supported only on access ports.

802.1x Critical Voice VLAN

When an IP phone connected to a port is authenticated by the Cisco Identity Services Engine (ISE), the phone is put into the voice domain. If the ISE is not reachable, the switch cannot determine if the device is a voice device. If the server is unavailable, the phone cannot access the voice network and therefore cannot operate.

For data traffic, you can configure inaccessible authentication bypass, or critical authentication, to allow traffic to pass through on the native VLAN when the server is not available. If the RADIUS authentication server is unavailable (down) and inaccessible authentication bypass is enabled, the switch grants the client access to the network and puts the port in the critical-authentication state in the RADIUS-configured or the user-specified access VLAN. When the switch cannot reach the configured RADIUS servers and new hosts cannot be authenticated, the switch connects those hosts to critical ports. A new host trying to connect to the critical port is moved to a user-specified access VLAN, the critical VLAN, and granted limited authentication.

Note

Dynamic assignment of critical voice VLAN is not supported with nested service templates. It causes the device to switch between VLANs continuously in a loop.

You can enter the **authentication event server dead action authorize voice** interface configuration command to configure the critical voice VLAN feature. When the ISE does not respond, the port goes into critical authentication mode. When traffic coming from the host is tagged with the voice VLAN, the connected device (the phone) is put in the configured voice VLAN for the port. The IP phones learn the voice VLAN identification through Cisco Discovery Protocol (Cisco devices) or through LLDP or DHCP.

You can configure the voice VLAN for a port by entering the **switchport voice vlan** *vlan-id* interface configuration command.

This feature is supported in multidomain and multi-auth host modes. Although you can enter the command when the switch in single-host or multi-host mode, the command has no effect unless the device changes to multidomain or multi-auth host mode.

IEEE 802.1x Authentication with Voice VLAN Ports

A voice VLAN port is a special access port associated with two VLAN identifiers:

- VVID to carry voice traffic to and from the IP phone. The VVID is used to configure the IP phone connected to the port.
- PVID to carry the data traffic to and from the workstation connected to the switch through the IP phone. The PVID is the native VLAN of the port.

The IP phone uses the VVID for its voice traffic, regardless of the authorization state of the port. This allows the phone to work independently of IEEE 802.1x authentication.

In single-host mode, only the IP phone is allowed on the voice VLAN. In multiple-hosts mode, additional clients can send traffic on the voice VLAN after a supplicant is authenticated on the PVID. When multiple-hosts mode is enabled, the supplicant authentication affects both the PVID and the VVID.

A voice VLAN port becomes active when there is a link, and the device MAC address appears after the first Cisco Discovery Protocol message from the IP phone. Cisco IP phones do not relay Cisco Discovery Protocol

messages from other devices. As a result, if several IP phones are connected in series, the switch recognizes only the one directly connected to it. When IEEE 802.1x authentication is enabled on a voice VLAN port, the switch drops packets from unrecognized IP phones more than one hop away.

When IEEE 802.1x authentication is enabled on a switch port, you can configure an access port VLAN that is also a voice VLAN.

When IP phones are connected to an 802.1x-enabled switch port that is in single host mode, the switch grants the phones network access without authenticating them. We recommend that you use multidomain authentication (MDA) on the port to authenticate both a data device and a voice device, such as an IP phone

Note

If you enable IEEE 802.1x authentication on an access port on which a voice VLAN is configured and to which a Cisco IP Phone is connected, the Cisco IP phone loses connectivity to the switch for up to 30 seconds.

Flexible Authentication Ordering

You can use flexible authentication ordering to configure the order of methods that a port uses to authenticate a new host. The IEEE 802.1X Flexible Authentication feature supports three authentication methods:

- dot1X: IEEE 802.1X authentication is a Layer 2 authentication method.
- mab: MAC-Authentication Bypass is a Layer 2 authentication method.
- webauth: Web authentication is a Layer 3 authentication method.

Using this feature, you can control which ports use which authentication methods, and you can control the failover sequencing of methods on those ports. For example, MAC authentication bypass and 802.1x can be the primary or secondary authentication methods, and web authentication can be the fallback method if either or both of those authentication attempts fail.

The IEEE 802.1X Flexible Authentication feature supports the following host modes:

- multi-auth: Multiauthentication allows one authentication on a voice VLAN and multiple authentications on the data VLAN.
- multi-domain: Multidomain authentication allows two authentications: one on the voice VLAN and one on the data VLAN.

Open1x Authentication

Open1x authentication allows a device access to a port before that device is authenticated. When open authentication is configured, a new host can pass traffic according to the access control list (ACL) defined on the port. After the host is authenticated, the policies configured on the RADIUS server are applied to that host.

You can configure open authentication with these scenarios:

- Single-host mode with open authentication—Only one user is allowed network access before and after authentication.
- MDA mode with open authentication—Only one user in the voice domain and one user in the data domain are allowed.
- Multiple-hosts mode with open authentication-Any host can access the network.

• Multiple-authentication mode with open authentication–Similar to MDA, except multiple hosts can be authenticated.

Note If open authentication is configured, it takes precedence over other authentication controls. This means that if you use the **authentication open** interface configuration command, the port will grant access to the host irrespective of the **authentication port-control** interface configuration command.

Multidomain Authentication

The switch supports multidomain authentication (MDA), which allows both a data device and voice device, such as an IP phone, to authenticate on the same switch port. The port is divided into a data domain and a voice domain.

Note For all host modes, the line protocol stays up before authorization when port-based authentication is configured.

MDA does not enforce the order of device authentication. However, for best results, we recommend that a voice device is authenticated before a data device on an MDA-enabled port.

Follow these guidelines for configuring MDA:

- You must configure a switch port for MDA.
- You must configure the voice VLAN for the IP phone when the host mode is set to multidomain.
- Voice VLAN assignment on an MDA-enabled port is supported.
- To authorize a voice device, the AAA server must be configured to send a Cisco Attribute-Value (AV) pair attribute with a value of *device-traffic-class=voice*. Without this value, the switch treats the voice device as a data device.

- **Note** When traffic-class=voice is downloaded from AAA servers as a service-template, a session will be created in DATA domain instead of VOICE domain.
 - The guest VLAN and restricted VLAN features only apply to the data devices on an MDA-enabled port. The switch treats a voice device that fails authorization as a data device.
 - If more than one device attempts authorization on either the voice or the data domain of a port, it is error disabled.
 - Until a device is authorized, the port drops its traffic. Non-Cisco IP phones or voice devices are allowed into both the data and voice VLANs. The data VLAN allows the voice device to contact a DHCP server to obtain an IP address and acquire the voice VLAN information. After the voice device starts sending on the voice VLAN, its access to the data VLAN is blocked.
 - A voice device MAC address that is binding on the data VLAN is not counted towards the port security MAC address limit.

- MDA can use MAC authentication bypass as a fallback mechanism to allow the switch port to connect to devices that do not support IEEE 802.1x authentication.
- When a *data* or a *voice* device is detected on a port, its MAC address is blocked until authorization succeeds. If the authorization fails, the MAC address remains blocked for 5 minutes.
- If more than five devices are detected on the *data* VLAN or more than one voice device is detected on the *voice* VLAN while a port is unauthorized, the port is error disabled.
- When a port host mode is changed from single- or multihost to multidomain mode, an authorized data device remains authorized on the port. However, a Cisco IP phone that has been allowed on the port voice VLAN is automatically removed and must be reauthenticated on that port.
- Active fallback mechanisms such as guest VLAN and restricted VLAN remain configured after a port changes from single- or multihost mode to multidomain mode.
- Switching a port host mode from multidomain to single- or multihost mode removes all authorized devices from the port.
- If a data domain is authorized first and placed in the guest VLAN, non-IEEE 802.1x-capable voice devices need to tag their packets on the voice VLAN to trigger authentication.
- We do not recommend per-user ACLs with an MDA-enabled port. An authorized device with a per-user ACL policy might impact traffic on both the voice and data VLANs of the port. If used, only one device on the port should enforce per-user ACLs.

802.1x Supplicant and Authenticator Switches with Network Edge Access Topology

The Network Edge Access Topology (NEAT) feature extends identity to areas outside the wiring closet (such as conference rooms). This allows any type of device to authenticate on the port.

- 802.1x switch supplicant: You can configure a switch to act as a supplicant to another switch by using the 802.1x supplicant feature. This configuration is helpful in a scenario, where, for example, a switch is outside a wiring closet and is connected to an upstream switch through a trunk port. A switch configured with the 802.1x switch supplicant feature authenticates with the upstream switch for secure connectivity. Once the supplicant switch authenticates successfully the port mode changes from access to trunk in an authenticator switch. In a supplicant switch you must manually configure trunk when enabling CISP.
- If the access VLAN is configured on the authenticator switch, it becomes the native VLAN for the trunk port after successful authentication.

In the default state, when you connect a supplicant switch to an authenticator switch that has BPDU guard enabled, the authenticator port could be error-disabled if it receives a Spanning Tree Protocol (STP) bridge protocol data unit (BPDU) packets before the supplicant switch has authenticated. You can control traffic exiting the supplicant port during the authentication period. Entering the **dot1x supplicant controlled transient** global configuration command temporarily blocks the supplicant port during authentication to ensure that the authenticator port does not shut down before authentication completes. If authentication fails, the supplicant port opens. Entering the **no dot1x supplicant controlled transient** global configuration command opens the supplicant port during the authentication period. This is the default behavior.

We strongly recommend using the **dot1x supplicant controlled transient**command on a supplicant switch when BPDU guard is enabled on the authenticator switch port with the **spanning-tree bpduguard enable** interface configuration command.

Note If you globally enable BPDU guard on the authenticator switch by using the **spanning-tree portfast bpduguard default** global configuration command, entering the **dot1x supplicant controlled transient** command does not prevent the BPDU violation.

You can enable MDA or multiauth mode on the authenticator switch interface that connects to one more supplicant switches. Multihost mode is not supported on the authenticator switch interface.

When you reboot an authenticator switch with single-host mode enabled on the interface, the interface may move to err-disabled state before authentication. To recover from err-disabled state, flap the authenticator port to activate the interface again and initiate authentication.

Use the **dot1x supplicant force-multicast** global configuration command on the supplicant switch for Network Edge Access Topology (NEAT) to work in all host modes.

- Host Authorization: Ensures that only traffic from authorized hosts (connecting to the switch with supplicant) is allowed on the network. The switches use Client Information Signalling Protocol (CISP) to send the MAC addresses connecting to the supplicant switch to the authenticator switch.
- Auto enablement: Automatically enables trunk configuration on the authenticator switch, allowing user traffic from multiple VLANs coming from supplicant switches. Configure the cisco-av-pair as *device-traffic-class=switch* at the ISE. (You can configure this under the *group* or the *user* settings.)

Figure 38: Authenticator and Supplicant Switch using CISP

1	Workstations (clients)	2	Supplicant switch (outside wiring closet)
3	Authenticator switch	4	Cisco ISE
5	Trunk port		

Note The **switchport nonegotiate** command is not supported on supplicant and authenticator switches with NEAT. This command should not be configured at the supplicant side of the topology. If configured on the authenticator side, the internal macros will automatically remove this command from the port.

802.1x User Distribution

You can configure 802.1x user distribution to load-balance users with the same group name across multiple different VLANs.

The VLANs are either supplied by the RADIUS server or configured through the switch CLI under a VLAN group name.

- Configure the RADIUS server to send more than one VLAN name for a user. The multiple VLAN names can be sent as part of the response to the user. The 802.1x user distribution tracks all the users in a particular VLAN and achieves load balancing by moving the authorized user to the least populated VLAN.
- Configure the RADIUS server to send a VLAN group name for a user. The VLAN group name can be sent as part of the response to the user. You can search for the selected VLAN group name among the VLAN group names that you configured by using the switch CLI. If the VLAN group name is found, the corresponding VLANs under this VLAN group name are searched to find the least populated VLAN. Load balancing is achieved by moving the corresponding authorized user to that VLAN.

Whenever the RADIUS server sends a VLAN group name in the attribute as a result of authorization, the least populated VLAN out of the group is assigned to the end-user. In case of reauthentication (authentication session present) and CoA (session alive), the same VLAN is kept even if it is not the least populated VLAN in the group.

Note

The RADIUS server can send the VLAN information in any combination of VLAN-IDs, VLAN names, or VLAN groups.

802.1x User Distribution Configuration Guidelines

- Confirm that at least one VLAN is mapped to the VLAN group.
- You can map more than one VLAN to a VLAN group.
- You can modify the VLAN group by adding or deleting a VLAN.
- When you clear an existing VLAN from the VLAN group name, none of the authenticated ports in the VLAN are cleared, but the mappings are removed from the existing VLAN group.
- If you clear the last VLAN from the VLAN group name, the VLAN group is cleared.
- You can clear a VLAN group even when the active VLANs are mapped to the group. When you clear a VLAN group, none of the ports or users that are in the authenticated state in any VLAN within the group are cleared, but the VLAN mappings to the VLAN group are cleared.

Network Admission Control Layer 2 IEEE 802.1x Validation

The switch supports the Network Admission Control (NAC) Layer 2 IEEE 802.1x validation, which checks the antivirus condition or *posture* of endpoint systems or clients before granting the devices network access. With NAC Layer 2 IEEE 802.1x validation, you can do these tasks:

• Download the Session-Timeout RADIUS attribute (Attribute[27]) and the Termination-Action RADIUS attribute (Attribute[29]) from the authentication server.

- Set the number of seconds between reauthentication attempts as the value of the Session-Timeout RADIUS attribute (Attribute[27]) and get an access policy against the client from the RADIUS server.
- Set the action to be taken when the switch tries to reauthenticate the client by using the Termination-Action RADIUS attribute (Attribute[29]). If the value is the *DEFAULT* or is not set, the session ends. If the value is RADIUS-Request, the reauthentication process starts.
- Set the list of VLAN number or name or VLAN group name as the value of the Tunnel Group Private ID (Attribute[81]) and the preference for the VLAN number or name or VLAN group name as the value of the Tunnel Preference (Attribute[83]). If you do not configure the Tunnel Preference, the first Tunnel Group Private ID (Attribute[81]) attribute is picked up from the list.
- View the NAC posture token, which shows the posture of the client, by using the **show authentication** privileged EXEC command.
- Configure secondary private VLANs as guest VLANs.

Configuring NAC Layer 2 IEEE 802.1x validation is similar to configuring IEEE 802.1x port-based authentication except that you must configure a posture token on the RADIUS server.

Voice Aware 802.1x Security

Note

e To use voice aware IEEE 802.1x authentication, the switch must be running the LAN base image.

You use the voice aware 802.1x security feature to configure the switch to disable only the VLAN on which a security violation occurs, whether it is a data or voice VLAN. In previous releases, when an attempt to authenticate the data client caused a security violation, the entire port shut down, resulting in a complete loss of connectivity.

You can use this feature in IP phone deployments where a PC is connected to the IP phone. A security violation found on the data VLAN results in the shutdown of only the data VLAN. The traffic on the voice VLAN flows through the switch without interruption.

Common Session ID

Authentication manager uses a single session ID (referred to as a common session ID) for a client no matter which authentication method is used. This ID is used for all reporting purposes, such as the show commands and MIBs. The session ID appears with all per-session syslog messages.

The session ID includes:

- The IP address of the Network Access Device (NAD)
- A monotonically increasing unique 32 bit integer
- The session start time stamp (a 32 bit integer)

This example shows how the session ID appears in the output of the show authentication command. The session ID in this example is 16000005000000B288508E5:

```
Device# show authentication sessions
Interface MAC Address Method Domain Status Session ID
```

Fa4/0/4 0000.0000.0203 mab DATA Authz Success 16000005000000B288508E5

This is an example of how the session ID appears in the syslog output. The session ID in this example is also160000050000000B288508E5:

1w0d: %AUTHMGR-5-START: Starting 'mab' for client (0000.0000.0203) on Interface Fa4/0/4 AuditSessionID 16000005000000B288508E5 1w0d: %MAB-5-SUCCESS: Authentication successful for client (0000.0000.0203) on Interface Fa4/0/4 AuditSessionID 16000005000000B288508E5 1w0d: %AUTHMGR-7-RESULT: Authentication result 'success' from 'mab' for client (0000.0000.0203) on Interface Fa4/0/4 AuditSessionID 16000005000000B288508E5

The session ID is used by the NAD, the AAA server, and other report-analyzing applications to identify the client. The ID appears automatically. No configuration is required.

Maximum Number of Allowed Devices Per Port

This is the maximum number of devices allowed on an 802.1x-enabled port:

- In single-host mode, only one device is allowed on the access VLAN. If the port is also configured with a voice VLAN, an unlimited number of Cisco IP phones can send and receive traffic through the voice VLAN.
- In multidomain authentication (MDA) mode, one device is allowed for the access VLAN, and one IP phone is allowed for the voice VLAN.
- In multihost mode, only one 802.1x supplicant is allowed on the port, but an unlimited number of non-802.1x hosts are allowed on the access VLAN. An unlimited number of devices are allowed on the voice VLAN.

How to Configure IEEE 802.1x Port-Based Authentication

Configuring 802.1x Authentication

To allow per-user ACLs or VLAN assignment, you must enable AAA authorization to configure the switch for all network-related service requests.

This is the 802.1x AAA process:

Before you begin

To configure 802.1x port-based authentication, you must enable authentication, authorization, and accounting (AAA) and specify the authentication method list. A method list describes the sequence and authentication method to be queried to authenticate a user.

- **Step 1** A user connects to a port on the switch.
- **Step 2** Authentication is performed.

Step 3	VLAN assignment is enabled, as appropriate, based on the RADIUS server configuration.	
Step 4	The switch sends a start message to an accounting server.	
Step 5	Re-authentication is performed, as necessary.	
Step 6	The switch sends an interim accounting update to the accounting server that is based on the result of reauthentication.	
Step 7	The user disconnects from the port.	
Step 8	The switch sends a stop message to the accounting server.	

Configuring 802.1x Port-Based Authentication

Perform these steps to configure 802.1x port-based authentication:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	aaa new-model	Enables AAA.
	Example:	
	Device(config)# aaa new-model	
Step 4	aaa authentication dot1x {default} method1	Creates an 802.1x authentication method list.
	Example: Device(config)# aaa authentication dot1x	To create a default list that is used when a named list is <i>not</i> specified in the authentication command, use the default
	default group radius	keyword followed by the method that is to be used in default situations. The default method list is automatically applied to all ports.
		For <i>method1</i> , enter the group radius keywords to use the list of all RADIUS servers for authentication.

Procedure

	Command or Action	Purpose
		Note Though other keywords are visible in the command-line help string, only the group radius keywords are supported.
Step 5	dot1x system-auth-control Example: Device (config) # dot1x system-auth-control	Enables 802.1x authentication globally on the switch.
Step 6	aaa authorization network {default} group radius Example: Device(config)# aaa authorization network default group radius	(Optional) Configures the switch to use user-RADIUS authorization for all network-related service requests, such as per-user ACLs or VLAN assignment.
Step 7	radius server server name Example: Device(config)# radius server rsim address ipv4 124.2.2.12	(Optional) Specifies the IP address of the RADIUS server.
Step 8	address {ipv4 ipv6} ip address Example: Device(config-radius-server)# address ipv4 10.0.1.12	Configures the IP address for the RADIUS server.
Step 9	key string Example: Device(config-radius-server)# key rad123	(Optional) Specifies the authentication and encryption key used between the switch and the RADIUS daemon running on the RADIUS server.
Step 10	exit Example: Device(config-radius-server)# exit	Exits the RADIUS server mode and enters the global configuration mode.
Step 11	interface interface-id Example:	Specifies the port connected to the client that is to be enabled for IEEE 802.1x

	Command or Action	Purpose
	Device(config)# interface gigabitethernet 1/0/2	authentication, and enter interface configuration mode.
Step 12	switchport mode access Example:	(Optional) Sets the port to access mode only if you configured the RADIUS server in Step 6 and Step 7.
	<pre>Device(config-if)# switchport mode access</pre>	
Step 13	authentication port-control auto Example:	Enables 802.1x authentication on the port.
	Device(config-if)# authentication port-control auto	
Step 14	dot1x pae authenticator Example: Device(config-if)# dot1x pae	Sets the interface Port Access Entity to act only as an authenticator and ignore messages meant for a supplicant.
Step 15	authenticator	Exits interface configuration mode and returns
otep 15	Example: Device(config-if)# end	to privileged EXEC mode.

Configuring Periodic Reauthentication

You can enable periodic 802.1x client reauthentication and specify how often it occurs. If you do not specify a time period before enabling reauthentication, the number of seconds between attempts is 3600.

Follow these steps to enable periodic reauthentication of the client and to configure the number of seconds between reauthentication attempts. This procedure is optional.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	

	Command or Action	Purpose
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface interface-id	Specifies the port to be configured, and enter
	Example:	interface configuration mode.
	Device(config)# interface gigabitethernet 2/0/1	
Step 4	authentication periodic Example:	Enables periodic reauthentication of the client, which is disabled by default.
	Device(config-if)# authentication periodic	Note The default value is 3600 seconds. To change the value of the reauthentication timer or to have the switch use a RADIUS-provided session timeout, enter the authentication timer reauthenticate command.
Step 5	authentication timer {{[inactivity reauthenticate restart unauthorized]}	Sets the number of seconds between reauthentication attempts.
	{value}} Example:	The authentication timer keywords have these meanings:
	Device(config-if)# authentication timer reauthenticate 180	• inactivity : Interval in seconds after which if there is no activity from the client then it is unauthorized
		• reauthenticate : Time in seconds after which an automatic reauthentication attempt is initiated
		• restart <i>value</i> : Interval in seconds after which an attempt is made to authenticate an unauthorized port
		• unauthorized <i>value</i> : Interval in seconds after which an unauthorized session will get deleted
		This command affects the behavior of the switch only if periodic reauthentication is enabled.
Step 6	end	Exits interface configuration mode and returns to privileged EXEC mode.

 Command or Action	Purpose
Device(config-if)# end	

Configuring 802.1x Violation Modes

You can configure an 802.1x port so that it shuts down, generates a syslog error, or discards packets from a new device when:

- A device connects to an 802.1x-enabled port
- The maximum number of allowed about devices have been authenticated on the port

Beginning in privileged EXEC mode, follow these steps to configure the security violation actions on the switch:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	aaa new-model	Enables AAA.
	Example:	
	Device(config)# aaa new-model	
Step 4	aaa authentication dot1x {default} method1	Creates an 802.1x authentication method list.
	Example: Device(config)# aaa authentication dot1x default group radius	To create a default list that is used when a named list is <i>not</i> specified in the authentication command, use the default keyword followed by the method that is to be used in default situations. The default method list is automatically applied to all ports.
		For <i>method1</i> , enter the group radius keywords to use the list of all RADIUS servers for authentication.

	Command or Action	Purpose
Step 5	interface interface-type interface-number Example:	Specifies the port connected to the client that is to be enabled for IEEE 802.1x authentication, and enter interface configuration mode.
	Device(config)# interface gigabitethernet 1/0/4	
Step 6	switchport mode access	Sets the port to access mode.
	Example:	
	Device(config-if)# switchport mode access	
Step 7	authentication violation {shutdown restrict protect replace}	Configures the violation mode. The keywords have these meanings:
	Example:	• shutdown: Error disable the port.
	Device(config-if)# authentication violation restrict	• restrict: Generate a syslog error.
		• protect : Drop packets from any new device that sends traffic to the port.
		• replace : Removes the current session and authenticates with the new host.
Step 8	end	Exits interface configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-if)# end	

Changing the Quiet Period

When the switch cannot authenticate the client, the switch remains idle for a set period of time and then tries again. The **authentication timer restart** interface configuration command controls the idle period. A failed authentication of the client might occur because the client provided an invalid password. You can provide a faster response time to the user by entering a number smaller than the default.

Beginning in privileged EXEC mode, follow these steps to change the quiet period. This procedure is optional.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.

	Command or Action	Purpose
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface interface-id	Specifies the port to be configured, and enters
	Example:	interface configuration mode.
	Device(config)# interface gigabitethernet 2/0/1	
Step 4	authentication timer restart seconds	Sets the number of seconds that the switch
	Example:	remains in the quiet state following a failed authentication exchange with the client.
	Device(config-if)# authentication timer restart 30	The range is 1 to 1073741823 seconds; the default is 60.
Step 5	end	Exits interface configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-if)# end	
Step 6	show authentication sessions interface interface-id	Verifies your entries.
	Example:	
	Device# show authentication sessions interface gigabitethernet2/0/1	
Step 7	copy running-config startup-config	(Optional) Saves your entries in the
	Example:	configuration file.
	Device# copy running-config startup-config	

Changing the Switch-to-Client Retransmission Time

The client responds to the EAP-request/identity frame from the switch with an EAP-response/identity frame. If the switch does not receive this response, it waits a set period of time (known as the retransmission time) and then resends the frame.

You should change the default value of this command only to adjust for unusual circumstances such as unreliable links or specific behavioral problems with certain clients and authentication servers.

Beginning in privileged EXEC mode, follow these steps to change the amount of time that the switch waits for client notification. This procedure is optional.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface interface-id	Specifies the port to be configured, and enters
	Example:	interface configuration mode.
	Device(config)# interface gigabitethernet2/0/1	
Step 4	authentication timer reauthenticate seconds	Sets the number of seconds that the switch waits
	Example:	for a response to an EAP-request/identity frame from the client before resending the request.
	Device(config-if)# authentication timer reauthenticate 60	The range is 1 to 1073741823 seconds; the default is 5.
Step 5	end	Exits interface configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-if)# end	
Step 6	show authentication sessions interface interface-id	Verifies your entries.
	Example:	
	Device# show authentication sessions interface gigabitethernet 2/0/1	

	Command or Action	Purpose
Step 7	copy running-config startup-config	(Optional) Saves your entries in the
	Example:	configuration file.
	Device# copy running-config startup-config	

Setting the Switch-to-Client Frame-Retransmission Number

In addition to changing the switch-to-client retransmission time, you can change the number of times that the switch sends an EAP-request/identity frame (assuming no response is received) to the client before restarting the authentication process.

Note You should change the default value of this command only to adjust for unusual circumstances such as unreliable links or specific behavioral problems with certain clients and authentication servers.

Beginning in privileged EXEC mode, follow these steps to set the switch-to-client frame-retransmission number. This procedure is optional.

P	ro	се	dι	ire	

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device># enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface interface-id	Specifies the port to be configured, and enters
	Example:	interface configuration mode.
	Device(config)# interface gigabitethernet2/0/1	
Step 4	dot1x max-reauth-req count	Sets the number of times that the switch sends
	Example:	an EAP-request/identity frame to the client before restarting the authentication process. The
	Device(config-if) # dotlx max-reauth-req	range is 1 to 10; the default is 2.

	Command or Action	Purpose
	5	
Step 5	end Example:	Exits interface configuration mode and returns to privileged EXEC mode.
	Device(config-if)# end	

Configuring Host Mode

Beginning in privileged EXEC mode, follow these steps to allow multiple hosts (clients) on an IEEE 802.1x-authorized port that has the **authentication port-control** interface configuration command set to **auto**. Use the **multi-domain** keyword to configure and enable multidomain authentication (MDA), which allows both a host and a voice device, such as an IP phone (Cisco or non-Cisco), on the same switch port. This procedure is optional.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface interface-id	Specifies the port to which multiple hosts are
-	Example:	indirectly attached, and enters interface configuration mode.
	Device (config) # interface gigabitethernet 2/0/1	
Step 4	authentication host-mode [multi-auth multi-domain multi-host single-host]	Allows multiple hosts (clients) on an 802.1x-authorized port.
	Example:	The keywords have these meanings:
	<pre>Device(config-if)# authentication host-mode multi-host</pre>	• multi-auth : Allow multiple authenticated clients on both the voice VLAN and data VLAN.

	Command or Action	Purpose
		Note The multi-auth keyword is only available with the authentication host-mode command.
		• multi-host : Allow multiple hosts on an 802.1x-authorized port after a single host has been authenticated.
		• multi-domain : Allow both a host and a voice device, such as an IP phone (Cisco or non-Cisco), to be authenticated on an IEEE 802.1x-authorized port.
		Note You must configure the voice VLAN for the IP phone when the host mode is set to multi-domain .
		Make sure that the authentication port-control interface configuration command is set to auto for the specified interface.
Step 5	end Example:	Exits interface configuration mode and returns to privileged EXEC mode.
	Device(config-if)# end	

Enabling MAC Move

MAC move allows an authenticated host to move from one port on the device to another.

Beginning in privileged EXEC mode, follow these steps to globally enable MAC move on the device. This procedure is optional.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	

	Command or Action	Purpose
	Device# configure terminal	
Step 3	<pre>authentication mac-move permit Example: Device(config)# authentication mac-move permit</pre>	Enables MAC move on the device. Default is deny. In Session Aware Networking mode, the default CLI is access-session mac-move deny . To enable Mac Move in Session Aware Networking, use the no access-session mac-move global configuration command. In legacy mode (IBNS 1.0), default value for mac-move is deny and in C3PL mode (IBNS 2.0) default value is permit .
Step 4	end Example: Device(config)# end	Exits global configuration mode and returns to privileged EXEC mode.

Disabling MAC Move

Beginning in privileged EXEC mode, follow these steps to disable MAC move from an authentication manager-enabled port to an authentication manager-disabled port on a device. This procedure is optional.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device# enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	authentication mac-move deny-uncontrolled	Disables MAC move to an authentication manager-disabled port on the device.
	Device(config)# authentication mac-move deny-uncontrolled	To disable Mac move in session-aware networking, use the access-session mac-move deny-uncontrolled global configuration command.

Command or Action	Purpose
end	Returns to privileged EXEC mode.
Example:	
Device(config)# end	
	end Example:

Enabling MAC Replace

MAC replace allows a host to replace an authenticated host on a port.

Beginning in privileged EXEC mode, follow these steps to enable MAC replace on an interface. This procedure is optional.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface interface-id Example:	Specifies the port to be configured, and enters interface configuration mode.
	Devic(config)# interface gigabitethernet2/0/2	
Step 4	authentication violation {protect replace restrict shutdown} Example:	Use the replace keyword to enable MAC replace on the interface. The port removes the current session and initiates authentication with the new host.
	Device(config-if)# authentication violation replace	The other keywords have these effects: • protect: the port drops packets with unexpected MAC addresses without generating a system message.
		• restrict: violating packets are dropped by the CPU and a system message is generated.

	Command or Action	Purpose
		• shutdown : the port is error disabled when it receives an unexpected MAC address.
Step 5	end Example:	Exits interface configuration mode and returns to privileged EXEC mode.
	Device(config-if)# end	

Configuring 802.1x Accounting

Enabling AAA system accounting with 802.1x accounting allows system reload events to be sent to the accounting RADIUS server for logging. The server can then infer that all active 802.1x sessions are closed.

Note

Cisco IOS XE Everest 16.6.x, periodic AAA accounting updates are not supported. The switch does not send periodic interim accounting records to the accounting server. Periodic AAA accounting updates are available in Cisco IOS XE Fuji 16.9.x and later releases.

Because RADIUS uses the unreliable UDP transport protocol, accounting messages might be lost due to poor network conditions. If the switch does not receive the accounting response message from the RADIUS server after a configurable number of retransmissions of an accounting request, this system message appears:

Accounting message %s for session %s failed to receive Accounting Response.

When the stop message is not sent successfully, this message appears:

00:09:55: %RADIUS-4-RADIUS DEAD: RADIUS server 172.20.246.201:1645,1646 is not responding.

Note You must configure the RADIUS server to perform accounting tasks, such as logging start, stop, and interim-update messages and time stamps. To turn on these functions, enable logging of "Update/Watchdog packets from this AAA client" in your RADIUS server Network Configuration tab. Next, enable "CVS RADIUS Accounting" in your RADIUS server System Configuration tab.

Beginning in privileged EXEC mode, follow these steps to configure 802.1x accounting after AAA is enabled on your switch. This procedure is optional.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.

	Command or Action	Purpose
	Device> enable	
Step 2	configure terminal Example:	Enters global configuration mode.
	Device# configure terminal	
Step 3	interface interface-id	Specifies the port to be configured, and enters interface configuration mode.
	Example: Device(config)# interface gigabitethernet 1/0/3	
Step 4	aaa accounting dot1x default start-stop group radius	Enables 802.1x accounting using the list of all RADIUS servers.
	Example:	
	Device(config-if)# aaa accounting dot1x default start-stop group radius	
Step 5	aaa accounting system default start-stop group radius	(Optional) Enables system accounting (using the list of all RADIUS servers) and generates
	Example:	system accounting reload event messages when the switch reloads.
	Device(config-if)# aaa accounting system default start-stop group radius	
Step 6	end	Exits interface configuration mode and returns
	Example:	to privileged EXEC mode.

Configuring 802.1x Readiness Check

The 802.1x readiness check monitors 802.1x activity on all the switch ports and displays information about the devices connected to the ports that support 802.1x. You can use this feature to determine if the devices connected to the switch ports are 802.1x-capable.

The 802.1x readiness check is allowed on all ports that can be configured for 802.1x. The readiness check is not available on a port that is configured as **dot1x force-unauthorized**.

Follow these steps to enable the 802.1x readiness check on the switch:

Before you begin

Follow these guidelines to enable the readiness check on the switch:

- The readiness check is typically used before 802.1x is enabled on the switch.
- If you use the **dot1x test eapol-capable** privileged EXEC command without specifying an interface, all the ports on the switch stack are tested.
- When you configure the **dot1x test eapol-capable** command on an 802.1x-enabled port, and the link comes up, the port queries the connected client about its 802.1x capability. When the client responds with a notification packet, it is 802.1x-capable. A syslog message is generated if the client responds within the timeout period. If the client does not respond to the query, the client is not 802.1x-capable. No syslog message is generated.
- The readiness check can be sent on a port that handles multiple hosts (for example, a PC that is connected to an IP phone). A syslog message is generated for each of the clients that respond to the readiness check within the timer period.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	dot1x test eapol-capable [interface interface-id]	Enables the 802.1x readiness check on the switch.
	Example:	(Optional) For <i>interface-id</i> specify the port on
	Device# dot1x test eapol-capable interface gigabitethernet1/0/13 DOT1X_PORT_EAPOL_CAPABLE:DOT1X: MAC 00-01-02-4b-f1-a3 on gigabitethernet1/0/13 is EAPOL capable	which to check for IEEE 802.1x readiness.
		Note If you omit the optional interface keyword, all interfaces on the switch are tested.
Step 3	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 4	dot1x test timeout timeout	(Optional) Configures the timeout used to wait
	Example:	for EAPOL response. The range is from 1 to 65535 seconds. The default is 10 seconds.
	Device(config) # dot1x test timeout 54	
Step 5	end	Exits global configuration mode and returns to
	Example:	privileged EXEC mode.

Command or Action	Purpose
Device(config)# end	

Configuring Switch-to-RADIUS Server Communication

Follow these steps to configure the RADIUS server parameters:

Procedure

	Command or Action	Purpose	
Step 1	enable	Enables privileged EXEC mode.	
	Example:	• Enter your password if prompted.	
	Device> enable		
Step 2	configure terminal	Enters global configuration mode.	
	Example:		
	Device# configure terminal		
Step 3	ip radius source-interface vlan vlan interface number	Specifies that the RADIUS packets have the IP address of the indicated interface.	
	Example:		
	Device(config)# ip radius source-interface vlan 80		
Step 4	radius server server name	(Optional) Specifies the IP address of the	
	Example:	RADIUS server.	
	Device(config)# radius server rsim address ipv4 172.16.0.1		
Step 5	address {ipv4 ipv6} ip address	Configures the IP address for the RADIUS	
	Example:	server.	
	Device(config-radius-server)# address ipv4 10.0.1.2 auth-port 1550 acct-port 1560		
Step 6	key string	(Optional) Specifies the authentication and	
-	Example:	encryption key used between the switch and the	

	Command or Action	Purpose
	Device(config-radius-server)# key rad123	RADIUS daemon running on the RADIUS server.
Step 7	exit Example:	Exits the RADIUS server mode and enters the global configuration mode.
	Device(config-radius-server)# exit	
Step 8	radius-server dead-criteria tries num-tries Example: Device(config)# radius-server dead-criteria tries 30	Specifies the number of unanswered sent messages to a RADIUS server before considering the server to be inactive. The range of <i>num-tries</i> is 1 to 100.
Step 9	end Example: Device(config)# end	Exits global configuration mode and returns to privileged EXEC mode.

Setting the Reauthentication Number

You can also change the number of times that the device restarts the authentication process before the port changes to the unauthorized state.

Note You should change the default value of this command only to adjust for unusual circumstances such as unreliable links or specific behavioral problems with certain clients and authentication servers.

Beginning in privileged EXEC mode, follow these steps to set the reauthentication number. This procedure is optional.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	

	Command or Action	Purpose
	Device# configure terminal	
Step 3	interface interface-id Example: Device# interface gigabitethernet2/0/1	Specifies the port to be configured, and enters interface configuration mode.
Step 4	<pre>switchport mode access Example: Device(config-if)# switchport mode access</pre>	Sets the port to access mode only if you previously configured the RADIUS server.
Step 5	<pre>dot1x max-req count Example: Device(config-if)# dot1x max-req 4</pre>	Sets the number of times that the device restarts the authentication process before the port changes to the unauthorized state. The range is 0 to 10; the default is 2.
Step 6	<pre>end Example: Device(config-if)# end</pre>	Exits interface configuration mode and returns to privileged EXEC mode.

Configuring a Guest VLAN

When you configure a guest VLAN, clients that are not 802.1x-capable are put into the guest VLAN when the server does not receive a response to its EAP request/identity frame. Clients that are 802.1x-capable but that fail authentication are not granted network access. The switch supports guest VLANs in single-host or multiple-hosts mode.

Beginning in privileged EXEC mode, follow these steps to configure a guest VLAN. This procedure is optional.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	

	Command or Action	Purpose
	Device# configure terminal	
Step 3	<pre>interface interface-id Example: Device(config)# interface gigabitethernet 2/0/2</pre>	Specifies the port to be configured, and enters interface configuration mode.
Step 4	<pre>dot1x port-control auto Example: Device(config-if)# dot1x port-control auto</pre>	Enables 802.1x authentication on the port.
Step 5	authentication event no-response action authorize vlan <i>vlan-id</i> Example: Device(config-if)# authentication event no-response action authorize vlan 2	Specifies an active VLAN as an 802.1x guest VLAN. The range is 1 to 4094. You can configure any active VLAN except an internal VLAN (routed port), an RSPAN VLAN or a voice VLAN as an 802.1x guest VLAN.
Step 6	<pre>end Example: Device(config-if)# end</pre>	Exits interface configuration mode and returns to privileged EXEC mode.

Configuring a Restricted VLAN

When you configure a restricted VLAN on a device, clients that are IEEE 802.1x-compliant are moved into the restricted VLAN when the authentication server does not receive a valid username and password. The device supports restricted VLANs only in single-host mode.

Beginning in privileged EXEC mode, follow these steps to configure a restricted VLAN. This procedure is optional.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	

I

	Command or Action	Purpose
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface interface-id	Specifies the port to be configured, and enters
	Example:	interface configuration mode.
	Device(config)# interface gigabitethernet 2/0/2	
Step 4	authentication port-control auto	Enables 802.1x authentication on the port.
	Example:	
	Device(config-if)# authentication port-control auto	
Step 5	authentication event fail action authorize vlan vlan-id	Specifies an active VLAN as an 802.1x restricted VLAN. The range is 1 to 4094.
	Example:	You can configure any active VLAN except an
	Device(config-if)# authentication event fail action authorize vlan 2	internal VLAN (routed port), an RSPAN VLAN or a voice VLAN as an 802.1x restricted VLAN.
Step 6	end	Exits interface configuration mode and returns
-	Example:	to privileged EXEC mode.
	Device(config-if)# end	

Configuring the Number of Authentication Attempts on a Restricted VLAN

You can configure the maximum number of authentication attempts allowed before a user is assigned to the restricted VLAN by using the **authentication event fail retry** *retry count* interface configuration command. The range of allowable authentication attempts is 1 to 3. The default is 3 attempts.

Beginning in privileged EXEC mode, follow these steps to configure the maximum number of allowed authentication attempts. This procedure is optional.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.

I

	Command or Action	Purpose
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface interface-id	Specifies the port to be configured, and enters
	Example:	interface configuration mode.
	Device(config)# interface gigabitethernet 2/0/3	
Step 4	authentication port-control auto	Enables 802.1x authentication on the port.
	Example:	
	Device (config-if) # authentication port-control auto	
Step 5	authentication event fail action authorize vlan vlan-id	Specifies an active VLAN as an 802.1x restricted VLAN. The range is 1 to 4094.
	Example:	You can configure any active VLAN except an
	Device(config-if)# authentication event fail action authorize vlan 8	internal VLAN (routed port), an RSPAN VLAN or a voice VLAN as an 802.1x restricted VLAN.
Step 6	authentication event fail retry retry count	Specifies a number of authentication attempts
	Example:	before a port moves to the auth fail VLAN.
	Device(config-if)# authentication event fail retry 2	
Step 7	end	Exits interface configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-if)# end	

Configuring 802.1x Inaccessible Authentication Bypass with Critical Voice VLAN

Beginning in privileged EXEC mode, follow these steps to configure critical voice VLAN on a port and enable the inaccessible authentication bypass feature.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	aaa new-model	Enables AAA.
	Example:	
	Device(config)# aaa new-model	
Step 4	radius-server dead-criteria {time seconds }	Sets the conditions that determine when a RADIUS server is considered un-available or
	[tries number] Example:	down (dead).
	Device(config)# radius-server dead-criteria time 20 tries 10	• time : 1 to 120 seconds. The switch dynamically determines a default <i>seconds</i> value between 10 and 60.
		• number : 1 to 100 tries. The switch dynamically determines a default tries <i>number</i> between 10 and 100.
Step 5	radius-serverdeadtimeminutes	(Optional) Sets the number of minutes during
	Example:	which a RADIUS server is not sent requests. The range is from 0 to 1440 minutes (24
	Device(config)# radius-server deadtime 60	hours). The default is 0 minutes.
Step 6	radius server server name	(Optional) Specifies the IP address of the
	Example:	RADIUS server.
	Device(config)# radius server rsim	

	Command or Action	Purpose
	address ipv4 124.2.2.12	
Step 7	address {ipv4 ipv6} ip address auth-port port_number acct-port port_number Example: Device(config-radius-server)# address ipv4 10.0.1.2 auth-port 1550 acct-port 1560	Configures the IP address for the RADIUS server.
Step 8	<pre>key string Example: Device(config-radius-server)# key rad123</pre>	(Optional) Specifies the authentication and encryption key used between the switch and the RADIUS daemon running on the RADIUS server.
Step 9	<pre>exit Example: Device(config-radius-server)# exit</pre>	Exits the RADIUS server mode and enters the global configuration mode.
Step 10	<pre>dot1x critical {eapol recovery delay milliseconds} Example: Device(config)# dot1x critical eapol Device(config)# dot1x critical recovery delay 2000</pre>	 (Optional) Configure the parameters for inaccessible authentication bypass: eapol: Specify that the switch sends an EAPOL-Success message when the switch successfully authenticates the critical port. recovery delaymilliseconds: Set the recovery delay period during which the switch waits to re-initialize a critical port when a RADIUS server that was unavailable becomes available. The range is from 1 to 10000 milliseconds (a port can be re-initialized every second).
Step 11	<pre>interface interface-id Example: Device (config) # interface gigabitethernet 1/0/1</pre>	Specify the port to be configured, and enters interface configuration mode.
Step 12	authentication event server dead action {authorize reinitialize} vlan vlan-id] Example:	Use these keywords to move hosts on the port if the RADIUS server is unreachable:

	Command or Action	Purpose
	Device(config-if)# authentication event server dead action reinitialicze vlan 20	• authorize : Move any new hosts trying to authenticate to the user-specified critical VLAN.
		• reinitialize : Move all authorized hosts on the port to the user-specified critical VLAN.
Step 13	switchport voice vlan vlan-id	Specifies the voice VLAN for the port. The
	Example:	voice VLAN cannot be the same as the critical data VLAN configured in Step 6.
	<pre>Device(config-if) # switchport voice vlan</pre>	
Step 14	authentication event server dead action authorize voice	Configures critical voice VLAN to move data traffic on the port to the voice VLAN if the
	Example:	RADIUS server is unreachable.
	<pre>Device(config-if)# authentication event server dead action authorize voice</pre>	
Step 15	end	Exits interface configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-if)# end	
Step 16	show authentication interface interface-id	(Optional) Verify your entries.
	Example:	
	Device(config-if)# show authentication interface gigabitethernet 1/0/1	

Example

To return to the RADIUS server default settings, use the **no radius-server dead-criteria**, the **no radius-server deadtime**, and the **no radius server** global configuration commands. To disable inaccessible authentication bypass, use the **no authentication event server dead action** interface configuration command. To disable critical voice VLAN, use the no **authentication event server dead action authorize voice** interface configuration command.

Configuring MAC Authentication Bypass

Beginning in privileged EXEC mode, follow these steps to enable MAC authentication bypass. This procedure is optional.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface interface-id	Specifies the port to be configured, and enters
	Example:	interface configuration mode.
	Device(config)# interface gigabitethernet 2/0/1	
Step 4	authentication port-control auto	Enables 802.1x authentication on the port.
	Example:	
	Device(config-if)# authentication port-control auto	
Step 5	mab [eap]	Enables MAC authentication bypass.
	Example:	(Optional) Use the eap keyword to configure
	Device(config-if)# mab	the device to use EAP for authorization.
Step 6	end	Exits interface configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-if)# end	

Configuring 802.1x User Distribution

Beginning in privileged EXEC mode, follow these steps to configure a VLAN group and to map a VLAN to it:

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	vlan group vlan-group-name vlan-list vlan-list Example:	Configures a VLAN group, and maps a single VLAN or a range of VLANs to it.
	Device(config)# vlan group eng-dept vlan-list 10	
Step 4	no vlan group <i>vlan-group-name</i> vlan-list <i>vlan-list</i>	Clears the VLAN group configuration or elements of the VLAN group configuration.
	Example:	
	Device(config)# no vlan group eng-dept vlan-list 10	
Step 5	end	Exits global configuration mode and returns to
	Example:	privileged EXEC mode.
	Device(config)# end	

Configuring NAC Layer 2 802.1x Validation

You can configure NAC Layer 2 802.1x validation, which is also referred to as 802.1x authentication with a RADIUS server.

Beginning in privileged EXEC mode, follow these steps to configure NAC Layer 2 802.1x validation. The procedure is optional.

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface interface-id	Specifies the port to be configured, and enters
	Example:	interface configuration mode.
	<pre>Device(config)# interface gigabitethernet2/0/3</pre>	
Step 4	switchport mode access	Sets the port to access mode only if you
	Example:	configured the RADIUS server.
	Device(config-if)# switchport mode access	
Step 5	authentication event no-response action authorize vlan <i>vlan-id</i>	Specifies an active VLAN as an 802.1x guest VLAN. The range is 1 to 4094.
	Example:	You can configure any active VLAN except an
	Device(config-if)# authentication event no-response action authorize vlan 8	internal VLAN (routed port), an RSPAN VLAN, or a voice VLAN as an 802.1x guest VLAN.
Step 6	authentication periodic	Enables periodic reauthentication of the client,
	Example:	which is disabled by default.
	<pre>Device(config-if)# authentication periodic</pre>	
Step 7	authentication timer reauthenticate	Sets reauthentication attempt for the client (set
	Example:	to one hour).
	<pre>Device(config-if)# authentication timer reauthenticate</pre>	This command affects the behavior of the switch only if periodic reauthentication is enabled.

	Command or Action	Purpose
Step 8	end	Exits interface configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-if)# end	
Step 9	show authentication sessions interface interface-id	Displays information about current Auth Manager sessions on the interface.
	Example:	
	Device# show authentication sessions interface gigabitethernet2/0/3	

Configuring an Authenticator Switch with NEAT

Configuring this feature requires that one switch outside a wiring closet is configured as a supplicant and is connected to an authenticator switch.

Note

- The authenticator switch interface configuration must be restored to access mode by explicitly flapping it if a line card is removed and inserted in the chassis when CISP or NEAT session is active.
- The *cisco-av-pairs* must be configured as *device-traffic-class=switch* on the ISE, which sets the interface as a trunk after the supplicant is successfully authenticated.

Beginning in privileged EXEC mode, follow these steps to configure a switch as an authenticator:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	cisp enable	Enables CISP.
	Example:	

Command or Action	Purpose
Device(config)# cisp enable	
interface interface-id	Specifies the port to be configured, and enters
Example:	interface configuration mode.
Device(config)# interface gigabitethernet 2/0/1	
switchport mode access	Sets the port mode to access .
Example:	
Device(config-if)# switchport mode access	
authentication port-control auto	Sets the port-authentication mode to auto.
Example:	
Device(config-if)# authentication port-control auto	
dot1x pae authenticator	Configures the interface as a port access entity
Example:	(PAE) authenticator.
Device(config-if)# dot1x pae authenticator	
spanning-tree portfast	Enables Port Fast on an access port connected
Example:	to a single workstation or server
<pre>Device(config-if)# spanning-tree portfast trunk</pre>	
end	Exits interface configuration mode and returns
Example:	to privileged EXEC mode.
	Device (config) # cisp enable interface interface-id Example: Device (config) # interface gigabitethernet 2/0/1 switchport mode access Example: Device (config-if) # switchport mode access authentication port-control auto Example: Device (config-if) # authentication port-control auto dot1x pae authenticator Example: Device (config-if) # dot1x pae authenticator spanning-tree portfast Example: Device (config-if) # dot1x pae authenticator spanning-tree portfast Example: Device (config-if) # spanning-tree portfast end

Configuring a Supplicant Switch with NEAT

Beginning in privileged EXEC mode, follow these steps to configure a switch as a supplicant:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	cisp enable	Enables CISP.
	Example:	
	Device(config)# cisp enable	
Step 4	dot1x credentials profile	Creates 802.1x credentials profile. This must
	Example:	be attached to the port that is configured as supplicant.
	Device(config)# dot1x credentials test	
Step 5	username suppswitch	Creates a username.
	Example:	
	Device(config)# username suppswitch	
Step 6	password password	Creates a password for the new username.
	Example:	
	Device(config)# password myswitch	
Step 7	dot1x supplicant force-multicast	Forces the switch to send only multicast
	Example:	EAPOL packets when it receives either unicast or multicast packets.
	<pre>Device(config)# dot1x supplicant force-multicast</pre>	This also allows NEAT to work on the supplicant switch in all host modes.
Step 8	interface interface-id	Specifies the port to be configured, and enters
	Example:	interface configuration mode.
	Device(config)# interface	

	Command or Action	Purpose
	gigabitethernet1/0/1	
Step 9	switchport trunk encapsulation dot1q	Sets the port to trunk mode.
	Example:	
	Device(config-if)# switchport trunk encapsulation dotlq	
Step 10	switchport mode trunk	Configures the interface as a VLAN trunk port.
	Example:	
	Device(config-if) # switchport mode trunk	
Step 11	dot1x pae supplicant	Configures the interface as a port access entit
	Example:	(PAE) supplicant.
	Device(config-if)# dot1x pae supplicant	
Step 12	dot1x credentials profile-name	Attaches the 802.1x credentials profile to the
	Example:	interface.
	Device(config-if)# dot1x credentials test	
Step 13	end	Exits interface configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-if)# end	

Configuring 802.1x Authentication with Downloadable ACLs and Redirect URLs

Note

You must configure a downloadable ACL on the ACS before downloading it to the switch.

After authentication on the port, you can use the **show ip access-list** privileged EXEC command to display the downloaded ACLs on the port.

Note The output of the **show ip access-lists interface** command does not display dACL or ACL filter IDs. This is because the ACLs are attached to the virtual ports created by multidomain authentication for each authentication session; instead of the physical interface. To display dACL or ACL filter IDs, use the **show ip access-lists** *access-list-name* command. The *access-list-name* should be taken from the **show access-session interface** *interface-name* **detail** command output. The *access-list-name* is case sensitive.

Configuring Downloadable ACLs

The policies take effect after client authentication and the client IP address addition to the IP device tracking table. The switch then applies the downloadable ACL to the port.

Beginning in privileged EXEC mode:

Before you begin

SISF-Based device tracking is a prerequisite to configuring 802.1x authentication. Ensure that you have enabled device tracking programmatically or manually. For more information, see the *Configuring SISF-Based Tracking* chapter.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	aaa new-model	Enables AAA.
	Example:	
	Device(config)# aaa new-model	
Step 4	aaa authorization network default local group radius	Sets the authorization method to local. To remove the authorization method, use the no
	Example:	aaa authorization network default local group radius command.
	Device(config)# aaa authorization network default local group radius	

	Command or Action	Purpose
Step 5	radius-server vsa send authentication	Configures the radius vsa send authentication.
	Example:	
	Device(config)# radius-server vsa send authentication	
Step 6	interface interface-id	Specifies the port to be configured, and enters interface configuration mode.
	Example:	
	Device(config)# interface gigabitethernet2/0/4	
Step 7	ip access-group acl-id in	Configures the default ACL on the port in the
	Example:	input direction.
	Device(config-if)# ip access-group default_acl in	Note The <i>acl-id</i> is an access list name or number.
Step 8	end	Exits interface configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-if)# end	

Configuring a Downloadable Policy

Before you begin

SISF-Based device tracking is a prerequisite to configuring 802.1x authentication. Ensure that you have enabled device tracking programmatically or manually.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	

I

	Command or Action	Purpose
Step 3	} { hostname any host } log	Defines the default port ACL.
		The access-list-number is a decimal number from 1 to 99 or 1300 to 1999.
	<pre>Device(config)# access-list 1 deny any log</pre>	Enter deny or permit to specify whether to deny or permit access if conditions are matched.
		The source is the source address of the network or host that sends a packet, such as this:
		• hostname : The 32-bit quantity in dotted-decimal format.
		• any : The keyword any as an abbreviation for source and source-wildcard value of 0.0.0.0 255.255.255.255. You do not need to enter a source-wildcard value.
		• host : The keyword host as an abbreviation for source and source-wildcard of source 0.0.0.0.
		(Optional) Applies the source-wildcard wildcard bits to the source.
		(Optional) Enters log to cause an informational logging message about the packet that matche the entry to be sent to the console.
Step 4	interface interface-id	Enters interface configuration mode.
	Example:	
	Device(config)# interface gigabitethernet 2/0/2	
Step 5	ip access-group acl-id in	Configures the default ACL on the port in th input direction.
	Example:	Note The <i>acl-id</i> is an access list name
	<pre>Device(config-if)# ip access-group default_acl in</pre>	or number.
Step 6	exit	Exits interface configuration mode and return
	Example:	to global configuration mode.
	Device(config-if)# exit	
Step 7	aaa new-model	Enables AAA.
	Example:	

I

	Command or Action	Purpose
	Device(config)# aaa new-model	
Step 8	aaa authorization network default group radius Example: Device(config)# aaa authorization network default group radius	Sets the authorization method to local. To remove the authorization method, use the no aaa authorization network default group radius command.
Step 9	radius-server vsa send authentication Example: Device (config) # radius-server vsa send authentication	Configures the network access server to recognize and use vendor-specific attributes.NoteThe downloadable ACL must be operational.
Step 10	end Example: Device(config)# end	Exits global configuration mode and returns to privileged EXEC mode.

Configuring VLAN ID Based MAC Authentication

Beginning in privileged EXEC mode, follow these steps:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	mab request format attribute 32 vlan access-vlan	Enables VLAN ID-based MAC authentication
	Example:	

	Command or Action	Purpose
	Device(config)# mab request format attribute 32 vlan access-vlan	
Step 4	end Example:	Exits global configuration mode and returns to privileged EXEC mode.
	Device(config)# end	

Configuring Flexible Authentication Ordering

The examples used in the instructions below changes the order of Flexible Authentication Ordering so that MAB is attempted before IEEE 802.1X authentication (dot1x). MAB is configured as the first authentication method, so MAB will have priority over all other authentication methods.

Beginning in privileged EXEC mode, follow these steps:

Command or Action	Purpose
enable	Enables privileged EXEC mode.
Example:	• Enter your password if prompted.
Device> enable	
configure terminal	Enters global configuration mode.
Example:	
Device# configure terminal	
interface interface-id	Specifies the port to be configured, and enters
Example:	interface configuration mode.
Device(config)# interface gigabitethernet 1/0/1	
switchport mode access	Sets the port to access mode only if you
Example:	previously configured the RADIUS server.
Device(config-if)# switchport mode access	
	<pre>enable Example: Device> enable configure terminal Example: Device# configure terminal interface interface-id Example: Device(config)# interface gigabitethernet 1/0/1 switchport mode access Example:</pre>

Command or Action	Purpose
authentication order [dot1x mab] {webauth}	(Optional) Sets the order of authentication methods used on a port.
Example:	
Device(config-if)# authentication order mab dot1x	
authentication priority [dot1x mab] {webauth}	(Optional) Adds an authentication method to the port-priority list.
Example:	
Device(config-if)# authentication priority mab dot1x	
end	Exits interface configuration mode and returns
Example:	to privileged EXEC mode.
Device(config-if)# end	
	authentication order [dot1x mab] {webauth} Example: Device (config-if) # authentication order mab dot1x authentication priority [dot1x mab] {webauth} Example: Device (config-if) # authentication priority mab dot1x end Example:

Configuring Open1x

Beginning in privileged EXEC mode, follow these steps to enable manual control of the port authorization state:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface interface-id	Specifies the port to be configured, and enters
	Example:	interface configuration mode.
	Device(config)# interface	

I

	Command or Action	Purpose
	gigabitethernet 1/0/1	
Step 4	<pre>switchport mode access Example: Device(config-if)# switchport mode access</pre>	Sets the port to access mode only if you configured the RADIUS server.
Step 5	authentication control-direction {both in} Example:	(Optional) Configures the port control as unidirectional or bidirectional.
	Device(config-if)# authentication control-direction both	
Step 6	authentication fallback <i>name</i> Example:	(Optional) Configures a port to use web authentication as a fallback method for clients that do not support 802.1x authentication.
	Device(config-if)# authentication fallback profile1	
Step 7	authentication host-mode [multi-auth multi-domain multi-host single-host]	(Optional) Sets the authorization manager mode on a port.
	Example: Device(config-if)# authentication host-mode multi-auth	
Step 8	authentication open Example:	(Optional) Enables or disable open access on a port.
	Device(config-if)# authentication open	
Step 9	authentication order [dot1x mab] {webauth}	(Optional) Sets the order of authentication methods used on a port.
	Example: Device(config-if)# authentication order dot1x webauth	
Step 10	authentication periodic Example:	(Optional) Enables or disable reauthentication on a port.
	Device(config-if)# authentication	

	Command or Action	Purpose
	periodic	
Step 11	authentication port-control {auto force-authorized force-un authorized}	(Optional) Enables manual control of the port authorization state.
	Example:	
	Device(config-if)# authentication port-control auto	
Step 12	end	Exits interface configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-if)# end	

Disabling 802.1x Authentication on a Port

You can disable 802.1x authentication on the port by using the no dot1x pae interface configuration command.

Beginning in privileged EXEC mode, follow these steps to disable 802.1x authentication on the port. This procedure is optional.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface interface-id	Specifies the port to be configured, and enters
	Example:	interface configuration mode.
	Device(config)# interface gigabitethernet 2/0/1	
Step 4	switchport mode access	(Optional) Sets the port to access mode only if
	Example:	you configured the RADIUS server.

I

x authentication on the port.
configuration mode and returns
XEC mode.

Resetting the 802.1x Authentication Configuration to Default Values

Beginning in privileged EXEC mode, follow these steps to reset the 802.1x authentication configuration to the default values. This procedure is optional.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface interface-id	Enters interface configuration mode, and
	Example:	specifies the port to be configured.
	Device(config)# interface gigabitethernet 1/0/2	
Step 4	dot1x default	Resets the 802.1x parameters to the default
	Example:	values.

	Command or Action	Purpose
	Device(config-if)# dot1x default	
Step 5	end Example:	Exits interface configuration mode and returns to privileged EXEC mode.
	Device(config-if)# end	

Configuring Voice-Aware 802.1x Security

You use the voice aware 802.1x security feature on the device to disable only the VLAN on which a security violation occurs, whether it is a data or voice VLAN. You can use this feature in IP phone deployments where a PC is connected to the IP phone. A security violation found on the data VLAN results in the shutdown of only the data VLAN. The traffic on the voice VLAN flows through the device without interruption.

Follow these guidelines to configure voice aware 802.1x voice security on the device:

• You enable voice aware 802.1x security by entering the **errdisable detect cause security-violation shutdown vlan** global configuration command. You disable voice aware 802.1x security by entering the **no** version of this command. This command applies to all 802.1x-configured ports in the device.

- **Note** If you do not include the **shutdown vlan** keywords, the entire port is shut down when it enters the error-disabled state.
 - If you use the **errdisable recovery cause security-violation** global configuration command to configure error-disabled recovery, the port is automatically re-enabled. If error-disabled recovery is not configured for the port, you re-enable it by using the **shutdown** and **no shutdown** interface configuration commands.
 - You can re-enable individual VLANs by using the **clear errdisable interface** *interface-id* **vlan** [*vlan-list*] privileged EXEC command. If you do not specify a range, all VLANs on the port are enabled.

Follow these steps to enable voice aware 802.1x security:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	

	Command or Action	Purpose
	Device# configure terminal	
Step 3	errdisable detect cause security-violation shutdown vlan	Shut down any VLAN on which a security violation error occurs.
	Example: Device(config)# errdisable detect cause security-violation shutdown vlan	Note If the shutdown vlan keywords are not included, the entire port enters the error-disabled state and shuts down.
Step 4	errdisable recovery cause security-violation Example: Device (config) # errdisable recovery cause	were disabled because of 802.1X security violations
Step 5	Enter the following: • shutdown • no shutdown	(Optional) Re-enables an error-disabled VLAN and clear all error-disable indications.
	Example: Device(config)# no shutdown	
Step 6	exit Example: Device(config)# exit	Exits global configuration mode and returns to privileged EXEC mode.
Step 7	clear errdisable interfaceinterface-id vlan [vlan-list] Example: Device# clear errdisable interface gigabitethernet 0/1/1 vlan vlan_list	 (Optional) Reenables individual VLANs that have been error disabled. For the <i>interface-id</i> argument, specify the port on which to reenable individual VLANs. (Optional) For the <i>vlan-list</i> argument, specify a list of VLANs to be re-enabled. If vlan-list is not specified, all VLANs are re-enabled.
Step 8	<pre>show errdisable detect Example: Device# show errdisable detect</pre>	Displays the error-disabled detection status.

Configuration Examples for IEEE 802.1x Port-Based Authentication

The following sections provide configuration examples for IEEE 802.1x port-based authentication.

Example: Configuring Inaccessible Authentication Bypass

This example shows how to configure the Inaccessible Authentication Bypass feature:

```
Device> enable
Device# configure terminal
Device(config)# radius-server dead-criteria time 30 tries 20
Device(config)# radius-server deadtime 60
Device(config)# radius server server1
Device(config-radius-server)# address ipv4 172.29.36.49 acct-port 1618 auth-port 1612
Device(config-radius-server)# key abc1234
Device(config-radius-server)# exit
Device(config)# dot1x critical eapol
Device(config)# dot1x critical recovery delay 2000
Device(config-if)# dot1x critical
Device(config-if)# dot1x critical
Device(config-if)# dot1x critical
Device(config-if)# dot1x critical recovery action reinitialize
Device(config-if)# dot1x critical vlan 20
Device(config-if)# end
```

Example: Configuring VLAN Groups

This example shows how to configure VLAN groups, map VLANs to groups, and verify VLAN group configurations and mappings to specified VLANs:

Device# show dot1x vlan-group all

Group Name	Vlans Mapped
eng-dept	10
hr-dept	20

This example shows how to add a VLAN to an existing VLAN group and to verify that the VLAN is added:

```
Device> enable
Device(config) # vlan group eng-dept vlan-list 30
Device(config) # exit
Device(config) # show vlan group eng-dept
```

Group Name

Vlans Mapped

L

eng-dept

10,30

This example shows how to remove a VLAN from a VLAN group:

```
Device> enable
Device# no vlan group eng-dept vlan-list 10
```

This example shows that when all the VLANs are cleared from a VLAN group, the VLAN group is cleared:

```
Device> enable
Device(config)# no vlan group eng-dept vlan-list 30
Vlan 30 is successfully cleared from vlan group eng-dept.
Device(config)# exit
Device# show vlan group group-name eng-dept
```

This example shows how to clear all the VLAN groups:

```
Device> enable
Device(config)# no vlan group end-dept vlan-list all
Device(config)# exit
Device# show vlan-group all
```

Monitoring IEEE 802.1x Port-Based Authentication Statistics and Status

This section list the commands to monitor IEEE 802.1x port-based authentication statistics and status.

Command	Purpose
show dot1x all statistics	Displays 802.1x statistics for all ports
show dot1x interface interface-id statistics	Displays 802.1x statistics for a specific port
show dot1x all [count details statistics summary]	Displays the 802.1x administrative and operational status for a switch
show dot1x interface interface-id	Displays the 802.1x administrative and operational status for a specific port

Table 30: Privileged EXEC show Commands

Table 31: Global Configuration Commands

Command	Purpose
no dot1x logging verbose	Filters verbose 802.1x authentication messages.

Feature History for IEEE 802.1x Port-Based Authentication

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.11.1	IEEE 802.1x Port-Based Authentication	IEEE 802.1x authentication prevents unauthorized devices (clients) from gaining access to the network.
Cisco IOS XE Amsterdam 17.2.1	Mac Move	MAC move from an authentication manager-enabled port to an authentication manager-disabled port on a device is now enabled by default.
Cisco IOS XE Amsterdam 17.2.1	Session Limit - To prevent MAC address flooding DOS attack	The access-session limit profile command was introduced to limit the number of voice and data hosts connecting to a port.
Cisco IOS XE Bengaluru 17.5.1	Session Timer Support - Authentication Timer Reauthenticate	The authentication timer reauthenticate supported time-out range was increased from 1 to 65535 seconds to 1 to 1073741823 seconds.

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

IEEE 802.1X VLAN Assignment

The IEEE 802.1X VLAN Assignment feature is automatically enabled when IEEE 802.1X authentication is configured for an access port, which allows the RADIUS server to send a VLAN assignment to the device port. This assignment configures the device port so that network access can be limited for certain users.

- Prerequisites for IEEE 802.1X VLAN Assignment, on page 607
- Restrictions for IEEE 802.1X VLAN Assignment, on page 608
- Information About IEEE 802.1X VLAN Assignment, on page 609
- How to Configure IEEE 802.1X VLAN Assignment, on page 609
- Configuration Examples for IEEE 802.1X VLAN Assignment, on page 613
- Additional References for IEEE 802.1X Port-Based Authentication, on page 614
- Feature History for IEEE 802.1X VLAN Assignment, on page 614

Prerequisites for IEEE 802.1X VLAN Assignment

The following tasks must be completed before implementing the IEEE 802.1X VLAN Assignment feature:

- IEEE 802.1X must be enabled on the device port.
- The device must have a RADIUS configuration and be connected to the Cisco secure access control server (ACS). You should understand the concepts of the RADIUS protocol and have an understanding of how to create and apply access control lists (ACLs).
- EAP support must be enabled on the RADIUS server.
- You must configure the IEEE 802.1X supplicant to send an EAP-logoff (Stop) message to the switch when the user logs off. If you do not configure the IEEE 802.1X supplicant, an EAP-logoff message is not sent to the switch and the accompanying accounting Stop message is not sent to the authentication server. See the Microsoft Knowledge Base article at the location http://support.microsoft.com and set the SupplicantMode registry to 3 and the AuthMode registry to 1.
- Authentication, authorization, and accounting (AAA) must be configured on the port for all network-related service requests. The authentication method list must be enabled and specified. A method list describes the sequence and authentication method to be queried to authenticate a user. See the IEEE 802.1X Authenticator feature module for information.
- The port must be successfully authenticated.

The IEEE 802.1X VLAN Assignment feature is available only on Cisco 89x and 88x series integrated switching routers (ISRs) that support switch ports.

The following ISR-G2 routers are supported:

- 1900
- 2900
- 3900
- 3900e

The following cards or modules support switch ports:

- Enhanced High-speed WAN interface cards (EHWICs) with ACL support:
 - EHWIC-4ESG-P
 - EHWIC-9ESG-P
 - EHWIC-4ESG
 - EHWIC-9ESG
- High-speed WAN interface cards (HWICs) without ACL support:
 - HWIC-4ESW-P
 - HWIC-9ESW-P
 - HWIC-4ESW
 - HWIC-9ES

Restrictions for IEEE 802.1X VLAN Assignment

- The IEEE 802.1X VLAN Assignment feature is available only on a switch port.
- The device port is always assigned to the configured access VLAN when any of the following conditions occurs:
 - No VLAN is supplied by the RADIUS server.
 - The VLAN information from the RADIUS server is not valid.
 - IEEE 802.1X authentication is disabled on the port.
 - The port is in the force authorized, force unauthorized, unauthorized, or shutdown state.

Note An access VLAN is a VLAN assigned to an access port. All packets sent from or received on this port belong to this VLAN.

- Assignment to the configured access VLAN prevents ports from appearing unexpectedly in an inappropriate VLAN because of a configuration error. Examples of configuration errors include the following:
 - · A nonexistent or malformed VLAN ID
 - Attempted assignment to a voice VLAN ID
- When IEEE 802.1X authentication is enabled on a port, you cannot configure a port VLAN that is equal to a voice VLAN.
- If the multihost mode is enabled on an IEEE 802.1X port, all hosts are placed in the same VLAN (specified by the RADIUS server) as the first authenticated host.
- If an IEEE 802.1X port is authenticated and put in the RADIUS server-assigned VLAN, any change to the port access VLAN configuration does not take effect.
- This feature does not support standard ACLs on the switch port.

Information About IEEE 802.1X VLAN Assignment

Configuring Authorization

The AAA authorization feature is used to determine what a user can and cannot do. When AAA authorization is enabled, the network access server uses information retrieved from the user profile that is located either in the local user database or on the security server, to configure the user's session. The user is granted access to a requested service only if the information in the user profile allows it.

IEEE 802.1X Authentication with VLAN Assignment

Device ports support IEEE 802.1X authentication with VLAN assignment. After successful IEEE 802.1X authentication of a port, the RADIUS server sends the VLAN assignment to configure the device port.

The RADIUS server database maintains the username-to-VLAN mappings, assigning the VLAN based on the username of the supplicant connected to the device port.

How to Configure IEEE 802.1X VLAN Assignment

Enabling AAA Authorization for VLAN Assignment

AAA authorization limits the services available to a user. When AAA authorization is enabled, the device uses information retrieved from the user's profile, which is in the local user database or on the security server, to configure the user's session. The user is granted access to a requested service only if the information in the user profile allows it.

Command or Action	Purpose
enable	Enables privileged EXEC mode.
Example:	• Enter your password if prompted.
Device> enable	
configure terminal	Enters global configuration mode.
Example:	
Device# configure terminal	
aaa new-model	Enables AAA.
Example:	
Device(config)# aaa new-model	
aaa authorization network radius	Configures the device for user RADIUS
	authorization for all network-related service requests. RADIUS authorization succeeds if the
Example:	user has authenticated.
Device(config)# aaa authorization network radius if-authenticated	
aaa authorization exec radius	Configures the device for user RADIUS
	authorization if the user has privileged EXEC access. RADIUS authorization succeeds if the
Example:	user has authenticated.
Device(config)# aaa authorization exec radius if-authenticated	
end	Exits global configuration mode and returns to
Example:	privileged EXEC mode.
Device(config)# end	
	enable Example: Device> enable configure terminal Example: Device# configure terminal aaa new-model Example: Device (config)# aaa new-model aaa authorization network radius if-authenticated Example: Device (config)# aaa authorization network radius if-authenticated aaa authorization exec radius if-authenticated Example: Device (config)# aaa authorization network radius if-authenticated end Example: Device (config)# aaa authorization exec radius if-authenticated

Procedure

Enabling IEEE 802.1X Authentication and Authorization

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	

I

	Command or Action	Purpose
Step 3	aaa new-model	Enables AAA.
	Example:	
	Device(config)# aaa new-model	
Step 4	aaa authentication dot1x {default <i>listname</i> }	Creates a series of authentication methods that
	method1 [method2]	are used to determine user privilege to access the privileged command level so that the
	Example:	device can communicate with the AAA server.
	Device(config)# aaa authentication dot1x default group radius	
Step 5	dot1x system-auth-control	Globally enables 802.1X port-based
	Example:	authentication.
	Device(config)# dot1x system-auth-control	
Step 6	identity profile default	Creates an identity profile and enters dot1x
	Example:	profile configuration mode.
	Device(config) # identity profile default	
Step 7	exit	Exits dot1x profile configuration mode and
	Example:	returns to global configuration mode.
	<pre>Device(config-identity-prof)# exit</pre>	
Step 8	interface type slot/port	Enters interface configuration mode and
	Example:	specifies the interface to be enabled for 802.1X authentication.
	Device(config)# interface Gigabitethernet 1/0/1	
Step 9	access-session port-control {auto force-authorized force-unauthorized}	Enables 802.1X port-based authentication on the interface.
	Example:	• auto—Enables IEEE 802.1X
	Device(config-if)# access-session port-control auto	authentication and causes the port to begin in the unauthorized state, allowing only EAPOL frames to be sent and received through the port. The authentication process begins when the link state of the port changes from down to up or when an EAPOL-start frame is received. The Device requests the identity of the supplicant and begins relaying authentication messages between the supplicant and the authentication server. Each supplicant attempting to access the network is uniquely identified by the Device by using the supplicant MAC address.

	Command or Action	Purpose
		• force-authorized-—Disables IEEE 802.1X authentication and causes the port to change to the authorized state without any authentication exchange required. The port sends and receives normal traffic without IEEE 802.1X-based authentication of the client. This is the default setting.
		• force-unauthorized —Causes the port to remain in the unauthorized state, ignoring all attempts by the supplicant to authenticate. The Device cannot provide authentication services to the supplicant through the port.
Step 10	dot1x pae [supplicant authenticator both]	Sets the Port Access Entity (PAE) type.
	<pre>Example: Device(config-if)# dot1x pae authenticator</pre>	• supplicant —The interface acts only as a supplicant and does not respond to messages that are meant for an authenticator.
		• authenticator —The interface acts only as an authenticator and does not respond to any messages meant for a supplicant.
		• both —The interface behaves both as a supplicant and as an authenticator and thus does respond to all dot1x messages.
Step 11	end	Exits interface configuration mode and enters
	Example:	privileged EXEC mode.
	Device(config-if)# end	
Step 12	show dot1x	Displays whether 802.1X authentication has
	Example:	been configured on the device.
	Device# show dot1x	

Specifying an Authorized VLAN in the RADIUS Server Database

The Internet Engineering Task Force (IETF) draft standard specifies a method for communicating vendor-specific information between the device and the RADIUS server by using the vendor-specific attribute (attribute 26). Vendor-specific attributes (VSAs) allow vendors to support their own extended attributes not suitable for general use. The Cisco RADIUS implementation supports one vendor-specific option by using the format recommended in the specification.

• You must assign the following vendor-specific tunnel attributes in the RADIUS server database. The RADIUS server must return these attributes to the device:

- [64] Tunnel-Type = VLAN
- [65] Tunnel-Medium-Type = 802
- [81] Tunnel-Private-Group-ID = VLAN name or VLAN ID

Attribute [64] must contain the value "VLAN" (type 13). Attribute [65] must contain the value "802" (type 6). Attribute [81] specifies the VLAN name or VLAN ID assigned to the IEEE 802.1X-authenticated user.

Configuration Examples for IEEE 802.1X VLAN Assignment

Example: Enabling AAA Authorization for VLAN Assignment

The following example shows how to enable AAA Authorization for VLAN assignment:

```
Device> enable
Device# configure terminal
Device(config)# aaa new-model
Device(config)# aaa authorization network radius if-authenticated
Device(config)# aaa authorization exec radius if-authenticated
Device(config)# end
```

Example: Enabling 802.1X Authentication

The following example shows how to enable 802.1X authentication on a device:

```
Device# configure terminal
Device(config)# aaa new-model
Device(config)# aaa authentication dot1x default group radius group radius
Device(config)# dot1x system-auth-control
Device(config)# interface gigabitethernet 1/0/1
Device(config-if)# dot1x port-control auto
```

The following **show dot1x** command output shows that 802.1X authentication has been configured on a device:

```
Device# show dot1x all

Web-Based Authentication

This chapter describes how to configure web-based authentication on the device. It contains these sections:

- Restrictions for Web-Based Authentication, on page 617
- Information About Web-Based Authentication, on page 617
- How to Configure Web-Based Authentication, on page 626
- Verifying Web-Based Authentication, on page 638
- Feature History for Web-Based Authentication, on page 638

Restrictions for Web-Based Authentication

A device without host switch virtual interface (SVI) does not intercept TCP SYN packets for Cisco Identity Services Engine (ISE) posture redirection.

Information About Web-Based Authentication

Web-Based Authentication Overview

Use the web-based authentication feature, known as web authentication proxy, to authenticate end users on host systems that do not run the IEEE 802.1x supplicant.

When you initiate an HTTP session, web-based authentication intercepts ingress HTTP packets from the host and sends an HTML login page to the users. The users enter their credentials, which the web-based authentication feature sends to the authentication, authorization, and accounting (AAA) server for authentication.

If authentication succeeds, web-based authentication sends a Login-Successful HTML page to the host and applies the access policies returned by the AAA server.

If authentication fails, web-based authentication forwards a Login-Fail HTML page to the user, prompting the user to retry the login. If the user exceeds the maximum number of attempts, web-based authentication forwards a Login-Expired HTML page to the host, and the user is placed on a watch list for a waiting period.

Note

HTTPS traffic interception for central web authentication redirect is not supported.

Note

You should use global parameter-map (for method-type, custom, and redirect) only for using the same web authentication methods like consent, web consent, and webauth, for all the clients and SSIDs. This ensures that all the clients have the same web-authentication method.

If the requirement is to use Consent for one SSID and Web-authentication for another SSID, then you should use two named parameter-maps. You should configure Consent in first parameter-map and configure webauth in second parameter-map.

Note

The traceback that you receive when webauth client tries to do authentication does not have any performance or behavioral impact. It happens rarely when the context for which FFM replied back to EPM for ACL application is already dequeued (possibly due to timer expiry) and the session becomes 'unauthorized'.

Based on where the web pages are hosted, the local web authention can be categorozied as follows:

- Internal—The internal default HTML pages (Login, Success, Fail, and Expire) in the controller are used during the local web authentication.
- *Customized*—The customized web pages (Login, Success, Fail, and Expire) are downloaded onto the controller and used during the local web authentication.
- External—The customized web pages are hosted on the external web server instead of using the in-built
 or custom web pages.

Based on the various web authentication pages, the types of web authentication are as follows:

- *Webauth*—This is a basic web authentication. Herein, the controller presents a policy page with the user name and password. You need to enter the correct credentials to access the network.
- *Consent or web-passthrough*—Herein, the controller presents a policy page with the Accept or Deny buttons. You need to click the Accept button to access the network.
- *Webconsent*—This is a combination of webauth and consent web authentication types. Herein, the controller presents a policy page with Accept or Deny buttons along with user name or password. You need to enter the correct credentials and click the Accept button to access the network.

Device Roles

With web-based authentication, the devices in the network have these specific roles:

- Client—The device (workstation) that requests access to the LAN and the services and responds to
 requests from the switch. The workstation must be running an HTML browser with Java Script enabled.
- Authentication server—Authenticates the client. The authentication server validates the identity of the client and notifies the switch that the client is authorized to access the LAN and the switch services or that the client is denied.
- *Switch*—Controls the physical access to the network based on the authentication status of the client. The switch acts as an intermediary (proxy) between the client and the authentication server, requesting identity information from the client, verifying that information with the authentication server, and relaying a response to the client.

Figure 39: Web-Based Authentication Device Roles

Host Detection

The switch maintains an IP device tracking table to store information about detected hosts.

For Layer 2 interfaces, web-based authentication detects IP hosts by using these mechanisms:

- ARP based trigger—ARP redirect ACL allows web-based authentication to detect hosts with a static IP address or a dynamic IP address.
- Dynamic ARP inspection
- DHCP snooping—Web-based authentication is notified when the switch creates a DHCP-binding entry for the host.

Session Creation

When web-based authentication detects a new host, it creates a session as follows:

• Reviews the exception list.

If the host IP is included in the exception list, the policy from the exception list entry is applied, and the session is established.

Reviews for authorization bypass

If the host IP is not on the exception list, web-based authentication sends a nonresponsive-host (NRH) request to the server.

If the server response is accepted, authorization is bypassed for this host. The session is established.

• Sets up the HTTP intercept ACL

If the server response to the NRH request is access rejected, the HTTP intercept ACL is activated, and the session waits for HTTP traffic from the host.

Authentication Process

When you enable web-based authentication, these events occur:

• The user initiates an HTTP session.

- The HTTP traffic is intercepted, and authorization is initiated. The switch sends the login page to the user. The user enters a username and password, and the switch sends the entries to the authentication server.
- If the authentication succeeds, the switch downloads and activates the user's access policy from the authentication server. The login success page is sent to the user.
- If the authentication fails, the switch sends the login fail page. The user retries the login. If the maximum number of attempts fails, the switch sends the login expired page, and the host is placed in a watch list. After the watch list times out, the user can retry the authentication process.
- If the authentication server does not respond to the switch, and if an AAA fail policy is configured, the switch applies the failure access policy to the host. The login success page is sent to the user.
- The switch reauthenticates a client when the host does not respond to an ARP probe on a Layer 2 interface, or when the host does not send any traffic within the idle timeout on a Layer 3 interface.
- The switch reauthenticates a client when the host does not respond to an ARP probe on a Layer 2 interface.
- The feature applies the downloaded timeout or the locally configured session timeout.
- If the terminate action is RADIUS, the feature sends a nonresponsive host (NRH) request to the server. The terminate action is included in the response from the server.
- If the terminate action is default, the session is dismantled, and the applied policy is removed.

Local Web Authentication Banner

With Web Authentication, you can create a default and customized web-browser banners that appears when you log in to a switch.

The banner appears on both the login page and the authentication-result pop-up pages. The default banner messages are as follows:

- Authentication Successful
- Authentication Failed
- Authentication Expired

The Local Web Authentication Banner can be configured in as follows:

- Legacy mode—Use the **ip admission auth-proxy-banner http** global configuration command.
- New-style mode—Use the parameter-map type webauth global banner global configuration command.

The default banner *Cisco Systems* and *Switch host-name Authentication* appear on the Login Page. *Cisco Systems* appears on the authentication result pop-up page.

Figure 40: Authentication Successful Banner

Cannot find server - Microsoft Internet Ex	plorer	- 3 🔀
File Edit View Pavorites Tools Help		1

Web Authentication Customizable Web Pages

During the web-based authentication process, the switch internal HTTP server hosts four HTML pages to deliver to an authenticating client. The server uses these pages to notify you of these four-authentication process states:

- Login—Your credentials are requested.
- Success—The login was successful.
- Fail—The login failed.
- Expire—The login session has expired because of excessive login failures.

Guidelines

- You can substitute your own HTML pages for the default internal HTML pages.
- You can use a logo or specify text in the login, success, failure, and expire web pages.
- On the banner page, you can specify text in the login page.
- The pages are in HTML.
- You must include an HTML redirect command in the success page to access a specific URL.
- The URL string must be a valid URL (for example, http://www.cisco.com). An incomplete URL might cause *page not found* or similar errors on a web browser.
- If you configure web pages for HTTP authentication, they must include the appropriate HTML commands (for example, to set the page time out, to set a hidden password, or to confirm that the same page is not submitted twice).
- The CLI command to redirect users to a specific URL is not available when the configured login form is enabled. The administrator should ensure that the redirection is configured in the web page.
- If the CLI command redirecting users to specific URL after authentication occurs is entered and then the command configuring web pages is entered, the CLI command redirecting users to a specific URL does not take effect.
- Configured web pages can be copied to the switch boot flash or flash.
- The login page can be on one flash, and the success and failure pages can be another flash (for example, the flash on the active switch or a member switch).
- You must configure all four pages.
- The banner page has no effect if it is configured with the web page.
- All of the logo files (image, flash, audio, video, and so on) that are stored in the system directory (for example, flash, disk0, or disk) and that must be displayed on the login page must use web_auth_<filename> as the file name.
- The configured authentication proxy feature supports both HTTP and SSL.

You can substitute your HTML pages for the default internal HTML pages. You can also specify a URL to which users are redirected after authentication occurs, which replaces the internal Success page.

Figure 43: Customizable Authentication Page

Customized login page	
This internet web site is provided as a public service. It is intended for use by the public for viewing and retrieving information only. Unless otherwise indicated, all information on this site is considered public information and may be copied or distributed. Wistors should know that use of this site is collected for analytical and statistical purposes, such as assessing what information is of most and least interest, determining technical design specifications, and identifying system performance or problem areas. For site security purposes and to ensure that this service remains available to all users, this system employs software programs to monitor network traffic to identify manuthorized attempts to upload or change information, or otherwise cause damage. data logs will only be used to identify individual users and their usage habits for authorized law enforcement investigations or national security purposes. These logs are scheduled for regular destruction in accordance with Company Guidelines. Neither the Government nor any agency thereof, nor any of their employees, nakes any warranty, express or implied, or assumes any legal liability or responsibility for the accuracy, completeness, or usefulness or information, apparatus, product, or process disclosed, or represents that its use would not infinge privately owned rights. Usemame: Password OK

Authentication Proxy Web Page Guidelines

When configuring customized authentication proxy web pages, follow these guidelines:

- To enable the custom web pages feature, specify all four custom HTML files. If you specify fewer than four files, the internal default HTML pages are used.
- The four custom HTML files must be present on the flash memory of the switch. The maximum size of each HTML file is 8 KB.
- Any images on the custom pages must be on an accessible HTTP server. Configure an intercept ACL within the admission rule.
- Any external link from a custom page requires configuration of an intercept ACL within the admission rule.
- To access a valid DNS server, any name resolution required for external links or images requires configuration of an intercept ACL within the admission rule.
- If the custom web pages feature is enabled, a configured auth-proxy-banner is not used.
- If the custom web pages feature is enabled, the redirection URL for successful login feature is not available.
- To remove the specification of a custom file, use the **no** form of the command.

Because the custom login page is a public web form, consider these guidelines for the page:

- The login form must accept user entries for the username and password and must show them as **uname** and **pwd**.
- The custom login page should follow best practices for a web form, such as page timeout, hidden password, and prevention of redundant submissions.

Redirection URL for Successful Login Guidelines

When configuring a redirection URL for successful login, consider these guidelines:

- If the custom authentication proxy web pages feature is enabled, the redirection URL feature is disabled and is not available in the CLI. You can perform redirection in the custom-login success page.
- If the redirection URL feature is enabled, a configured auth-proxy-banner is not used
- To remove the specification of a redirection URL, use the **no** form of the command.
- If the redirection URL is required after the web-based authentication client is successfully authenticated, then the URL string must start with a valid URL (for example, http://) followed by the URL information. If only the URL is given without http://, then the redirection URL on successful authentication might cause page not found or similar errors on a web browser.

Web-based Authentication Interactions with Other Features

Port Security

You can configure web-based authentication and port security on the same port. Web-based authentication authenticates the port, and port security manages network access for all MAC addresses, including that of the client. You can then limit the number or group of clients that can access the network through the port.

LAN Port IP

You can configure LAN port IP (LPIP) and Layer 2 web-based authentication on the same port. The host is authenticated by using web-based authentication first, followed by LPIP posture validation. The LPIP host policy overrides the web-based authentication host policy.

If the web-based authentication idle timer expires, the NAC policy is removed. The host is authenticated, and posture is validated again.

Gateway IP

You cannot configure Gateway IP (GWIP) on a Layer 3 VLAN interface if web-based authentication is configured on any of the switch ports in the VLAN.

You can configure web-based authentication on the same Layer 3 interface as Gateway IP. The host policies for both features are applied in software. The GWIP policy overrides the web-based authentication host policy.

ACLs

If you configure a VLAN ACL or a Cisco IOS ACL on an interface, the ACL is applied to the host traffic only after the web-based authentication host policy is applied.

For Layer 2 web-based authentication, it is more secure, though not required, to configure a port ACL (PACL) as the default access policy for ingress traffic from hosts connected to the port. After authentication, the web-based authentication host policy overrides the PACL. The Policy ACL is applied to the session even if there is no ACL configured on the port.

You cannot configure a MAC ACL and web-based authentication on the same interface.

You cannot configure web-based authentication on a port whose access VLAN is configured for VACL capture.

EtherChannel

You can configure web-based authentication on a Layer 2 EtherChannel interface. The web-based authentication configuration applies to all member channels.

How to Configure Web-Based Authentication

Default Web-Based Authentication Configuration

The following table shows the default web-based authentication configuration.

Table 32: Default Web-based	Authentication (Configuration
Tuble del Dellaut Treb bacca	/ achonicouron e	Johngaradion

Feature	Default Setting
AAA	Disabled
RADIUS server	None specified
• IP address	None specified
• UDP authentication port	
• Key	
Default value of inactivity timeout	3600 seconds
Inactivity timeout	Enabled

Web-Based Authentication Configuration Guidelines and Restrictions

- Web-based authentication is an ingress-only feature.
- You can configure web-based authentication only on access ports. Web-based authentication is not supported on trunk ports, EtherChannel member ports, or dynamic trunk ports.
- External web authentication, where the switch redirects a client to a particular host or web server for displaying login message, is not supported.
- You cannot authenticate hosts on Layer 2 interfaces with static ARP cache assignment. These hosts are not detected by the web-based authentication feature because they do not send ARP messages.
- By default, the IP device tracking feature is disabled on a switch. You must enable the IP device tracking feature to use web-based authentication.
- You must enable SISF-Based device tracking to use web-based authentication. By default, SISF-Based device tracking is disabled on a switch.
- You must configure at least one IP address to run the switch HTTP server. You must also configure routes to reach each host IP address. The HTTP server sends the HTTP login page to the host.

- Hosts that are more than one hop away might experience traffic disruption if an STP topology change results in the host traffic arriving on a different port. This occurs because the ARP and DHCP updates might not be sent after a Layer 2 (STP) topology change.
- Web-based authentication does not support VLAN assignment as a downloadable-host policy.
- Web-based authentication supports IPv6 in Session-aware policy mode. IPv6 Web-authentication requires at least one IPv6 address configured on the switch and IPv6 Snooping configured on the switchport.
- Web-based authentication and Network Edge Access Topology (NEAT) are mutually exclusive. You cannot use web-based authentication when NEAT is enabled on an interface, and you cannot use NEAT when web-based authentication is running on an interface.
- Identify the following RADIUS security server settings that will be used while configuring switch-to-RADIUS-server communication:
 - Host name
 - · Host IP address
 - · Host name and specific UDP port numbers
 - · IP address and specific UDP port numbers

The combination of the IP address and UDP port number creates a unique identifier, that enables RADIUS requests to be sent to multiple UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service (for example, authentication) the second host entry that is configured functions as the failover backup to the first one. The RADIUS host entries are chosen in the order that they were configured.

- When you configure the RADIUS server parameters:
 - Specify the **key** string on a separate command line.
 - For **key** *string*, specify the authentication and encryption key used between the switch and the RADIUS daemon running on the RADIUS server. The key is a text string that must match the encryption key used on the RADIUS server.
 - When you specify the **key** *string*, use spaces within and at the end of the key. If you use spaces in the key, do not enclose the key in quotation marks unless the quotation marks are part of the key. This key must match the encryption used on the RADIUS daemon.
 - You can globally configure the timeout, retransmission, and encryption key values for all RADIUS servers by using with the **radius-server** global configuration command. If you want to configure these options on a per-server basis, use the **radius-server timeout**, **radius-server transmit**, and the **radius-server key** global configuration commands.

Note

You need to configure some settings on the RADIUS server, including: the switch IP address, the key string to be shared by both the server and the switch, and the downloadable ACL (DACL). For more information, see the RADIUS server documentation.

• For a URL redirect ACL:

- Packets that match a permit access control entry (ACE) rule are sent to the CPU for forwarding to the AAA server.
- Packets that match a deny ACE rule are forwarded through the switch.
- Packets that match neither the permit ACE rule or deny ACE rule are processed by the next dACL, and if there is no dACL, the packets hit the implicit-deny ACL and are dropped.

Configuring the Authentication Rule and Interfaces

Follow these steps to configure the authentication rule and interfaces:

Before you begin

SISF-Based device tracking is a prerequisite to Web Authentication. Ensure that you have enabled device tracking programmatically or manually.

For more information, see Confguring SISF-Based Tracking.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	ip admission name name proxy http	Configures an authentication rule for web-based
	Example:	authorization.
	Device(config)# ip admission name webauth1 proxy http	
Step 4	interface type slot/port	Enters interface configuration mode and
	Example:	specifies the ingress Layer 2 or Layer 3 interface to be enabled for web-based authentication.
	Device(config)# interface gigabitethernet 1/0/1	<i>type</i> can be FastEthernet, GigabitEthernet, or TenGigabitEthernet.
Step 5	ip access-group name	Applies the default ACL.
	Example:	

	Command or Action	Purpose
	Device(config-if)# ip access-group webauthag	
Step 6	<pre>ip admission name Example: Device(config)# ip admission name</pre>	Configures an authentication rule for web-based authorization for the interface.
Step 7	exit Example: Device# exit	Exits global configuration mode and returns to privileged EXEC mode.
Step 8	<pre>show ip admission Example: Device# show ip admission</pre>	Displays the network admission cache entries and information about web authentication sessions.

Configuring AAA Authentication

If a method-list is configured under VTY lines, the corresponding method list must be added to the AAA configuration:

```
Device(config)# line vty 0 4
Device(config-line)# authorization commands 15 list1
Device(config-line)# exit
Device(config)# aaa authorization commands 15 list1 group tacacs+
```

If a method-list is not configured under VTY lines, you must add the default method list to the AAA configuration:

```
Device(config)# line vty 0 4
Device(config-line)# exit
Device(config)# aaa authorization commands 15 default group tacacs+
```

Follow these steps to configure AAA authentication:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	

	Command or Action	Purpose
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	aaa new-model	Enables AAA functionality.
	Example:	
	Device(config)# aaa new-model	
Step 4	aaa authentication login default group {tacacs+ radius}	Defines the list of authentication methods at login.
	Example:	named_authentication_list refers to any name that is not greater than 31 characters.
	Device(config)# aaa authentication login default group tacacs+	AAA_group_name refers to the server group name. You need to define the server-group server_name at the beginning itself.
Step 5	aaa authorization auth-proxy default group {tacacs+ radius}	Creates an authorization method list for web-based authorization.
	Example:	
	Device(config)# aaa authorization auth-proxy default group tacacs+	
Step 6	tacacs server server-name	Specifies an AAA server.
	Example:	
	Device(config)# tacacs server yourserver	
Step 7	address {ipv4 ipv6} ip address	Configures the IP address for the TACACS
	Example:	server.
	Device(config-server-tacacs)# address ipv4 10.0.1.12	
Step 8	key string	Configures the authorization and encryption
	Example:	key used between the switch and the TACACS server.
	Device(config-server-tacacs)# key cisco123	

	Command or Action	Purpose
Step 9	end Example:	Exits the TACACS server mode and returns to privileged EXEC mode.
	Device(config-server-tacacs)# end	

Configuring Switch-to-RADIUS-Server Communication

Follow these steps to configure the RADIUS server parameters:

Command or Action	Purpose
enable	Enables privileged EXEC mode.
Example:	• Enter your password if prompted.
Device> enable	
configure terminal	Enters global configuration mode.
Example:	
Device# configure terminal	
ip radius source-interface vlan vlan interface number	Specifies that the RADIUS packets have the IP address of the indicated interface.
Example:	
Device(config)# ip radius source-interface vlan 80	
radius server server name	(Optional) Specifies the IP address of the
Example:	RADIUS server.
Device(config)# radius server rsim address ipv4 124.2.2.12	
address {ipv4 ipv6} ip address	Configures the IP address for the RADIUS
Example:	server.
Device(config-radius-server)# address ipv4 10.0.1.2 auth-port 1550 acct-port 1560	
	<pre>enable Example: Device> enable configure terminal Example: Device# configure terminal ip radius source-interface vlan vlan interface number Example: Device(config)# ip radius source-interface vlan 80 radius server server name Example: Device(config)# radius server rsim address ipv4 124.2.2.12 address {ipv4 ipv6} ip address Example: Device(config-radius-server)# address ipv4 10.0.1.2 auth-port 1550 acct-port</pre>

	Command or Action	Purpose	
Step 6	<pre>key string Example: Device(config-radius-server)# key rad123</pre>	(Optional) Specifies the authentication and encryption key used between the switch and the RADIUS daemon running on the RADIUS server.	
Step 7	exit Example: Device(config-radius-server)# exit	Exits the RADIUS server mode and enters the global configuration mode.	
Step 8	radius-server vsa send authentication string Example: Device(config)# radius-server vsa send authentication	RADIUS server.	
Step 9	<pre>radius-server dead-criteria [time seconds] [tries num-tries] Example: Device(config)# radius-server dead-criteria tries 45</pre>	Configures the conditions that determine what a RADIUS server is considered unavailable dead.Enter time in seconds during which there is no response from RADIUS server to the device.Enter number of tries where there will be readed and the valid response from RADIUS server to the device. The range of num-tries is 1 to 100.NoteThe device will shut down if the total number of tries is set to 2 or lower when the device is part of a stack. We recommend you to enter a longer duration of time Higher value of number of tries is.	
Step 10	end Example: Device# end	Exits global configuration mode and returns to privileged EXEC mode.	

Configuring the HTTP Server

To use web-based authentication, you must enable the HTTP server within the device. You can enable the server for either HTTP or HTTPS.

Note The Apple psuedo-browser will not open if you configure only the **ip http secure-server** command. You should also configure the **ip http server** command.

Follow the procedure given below to enable the server for either HTTP or HTTPS:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	ip http server	Enables the HTTP server. The web-based
	Example:	authentication feature uses the HTTP server to communicate with the hosts for user
	Device(config)# ip http server	authentication.
Step 4	ip http secure-server	Enables HTTPS.
	Example: Device(config)# ip http secure-server	You can configure custom authentication proxy web pages or specify a redirection URL for successful login.
		NoteTo ensure secure authentication when you enter the ip http secure-server command, the login page is always in HTTPS (secure HTTP) even if the user sends an HTTP request.
Step 5	end	Exits global configuration mode and returns to
	Example:	privileged EXEC mode.
	Device# end	

Customizing the Authentication Proxy Web Pages

You can configure web authentication to display four substitute HTML pages to the user in place of the default HTML pages during web-based authentication.

Follow these steps to specify the use of your custom authentication proxy web pages:

Before you begin

Store your custom HTML files on the device flash memory.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	ip admission proxy http login page file	Specifies the location in the device memory file
	device:login-filename	system of the custom HTML file to use in place of the default login page. The <i>device:</i> is flash
	Example:	memory.
	<pre>Device(config)# ip admission proxy http login page file disk1:login.htm</pre>	
Step 4	ip admission proxy http success page file device:success-filename	Specifies the location of the custom HTML file to use in place of the default login success page.
	Example:	r and r and b and b
	<pre>Device(config)# ip admission proxy http success page file disk1:success.htm</pre>	
Step 5	ip admission proxy http failure page file <i>device:fail-filename</i>	Specifies the location of the custom HTML file to use in place of the default login failure page.
	Example:	
	<pre>Device(config)# ip admission proxy http fail page file disk1:fail.htm</pre>	

	Command or Action	Purpose
Step 6	ip admission proxy http login expired page file device:expired-filename	Specifies the location of the custom HTML file to use in place of the default login expired page.
	Example:	
	Device(config)# ip admission proxy http login expired page file disk1:expired.htm	
Step 7	end Example:	Exits global configuration mode and returns to privileged EXEC mode.
	Device# end	

Specifying a Redirection URL for a Successful Login

Follow these steps to specify a URL to which the user is redirected after authentication, effectively replacing the internal Success HTML page:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	ip admission proxy http success redirect url-string	Specifies a URL for redirection of the user in place of the default login success page.
	Example:	
	Device(config)# ip admission proxy http success redirect www.example.com	
Step 4	end	Exits global configuration mode and returns to
	Example:	privileged EXEC mode.
	Device# end	

Configuring Web-Based Authentication Parameters

Follow these steps to configure the maximum number of failed login attempts before the client is placed in a watch list for a waiting period:

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	ip admission max-login-attempts number	Sets the maximum number of failed login
	Example:	attempts. The range is 1 to 2147483647 attempts. The default is 5.
	Device(config)# ip admission max-login-attempts 10	
Step 4	exit	Exits global configuration mode and returns to
	Example:	privileged EXEC mode.
	Device# exit	

Configuring a Web-Based Authentication Local Banner

Follow these steps to configure a local banner on a switch that has web authentication configured.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	

	Command or Action	Purpose
	Device# configure terminal	
Step 3	<pre>ip admission auth-proxy-banner http [banner-text file-path] Example: Device(config) # ip admission auth-proxy-banner http C My Switch C</pre>	Enables the local banner. (Optional) Create a custom banner by entering <i>C banner-text C</i> (where <i>C</i> is a delimiting character), or <i>file-path</i> that indicates a file (for example, a logo or text file) that appears in the banner.
Step 4	end Example: Device# end	Exits global configuration mode and returns to privileged EXEC mode.

Removing Web-Based Authentication Cache Entries

Follow these steps to remove web-based authentication cache entries:

	Command or Action	Purpose	
Step 1	enable	Enables privileged EXEC mode.	
	Example:	• Enter your password if prompted.	
	Device> enable		
Step 2	clear ip auth-proxy cache {* host ip address}	Delete authentication proxy entries. Use an

Verifying Web-Based Authentication

Use the commands in this topic to display the web-based authentication settings for all interfaces or for specific ports.

Table 33: Privileged EXEC show Commands

Command	Purpose
show authentication sessions method webauth	Displays the web-based authentication settings for all interfaces for fastethernet, gigabitethernet, or tengigabitethernet
<pre>show authentication sessions interface type slot/port[details]</pre>	Displays the web-based authentication settings for the specified interface for fastethernet, gigabitethernet, or tengigabitethernet.
	In Session Aware Networking mode, use the show access-session interface command.

Feature History for Web-Based Authentication

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.11.1	Web-Based Authentication	The Web-Based Authentication feature authenticates end users on host systems that do not run the IEEE 802.1x supplicant.

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

Configuring Port-Based Traffic Control

• Port-Based Traffic Control, on page 639

Port-Based Traffic Control

Port-based traffic control is a set of Layer 2 features on the Cisco devices used to filter or block packets at the port level in response to specific traffic conditions. The following port-based traffic control features are supported:

- Storm Control
- Protected Ports
- · Port Blocking

Restrictions for Storm Control

The following restrictions are applicable for Cisco Catalyst 9600 Series Supervisor 2 Module:

- When Storm Control broadcast level is set to zero, it does not suppress the broadcast APR request completely as the minimum granularity rate limit for packet to get dropped is 250kbps.
- Storm Control is not supported on Layer 3 ports.
- When Storm Control is configured on ether channel, it will not generate notification if not load balanced.
- PPS rate limiting is not supported. Only BPS rate limiting, and percentage is supported.

Information About Port-Based Traffic Control

Storm Control

Storm control prevents traffic on a LAN from being disrupted by a broadcast, multicast, or unicast storm on one of the physical interfaces. A LAN storm occurs when packets flood the LAN, creating excessive traffic and degrading network performance. Errors in the protocol-stack implementation, mistakes in network configurations, or users issuing a denial-of-service attack can cause a storm.

Storm control (or traffic suppression) monitors packets passing from an interface to the switching bus and determines if the packet is unicast, multicast, or broadcast. The switch counts the number of packets of a specified type received within the 1-second time interval and compares the measurement with a predefined suppression-level threshold.

With the hardware rate limiter feature of the Storm Control Policer, all broadcast, multicast, and unicast packets with less than 1000 packets per second are blocked. This behavior is due to a hardware limitation on ASIC-based platforms. On these platforms, storm control will work with 1K and above packets per second, and 8K and above bits per second.

Measured Traffic Activity

Storm control uses one of these methods to measure traffic activity:

- Bandwidth as a percentage of the total available bandwidth of the port that can be used by the broadcast, multicast, or unicast traffic
- Traffic rate in packets per second at which broadcast, multicast, or unicast packets are received
- Traffic rate in bits per second at which broadcast, multicast, or unicast packets are received

With each method, the port blocks traffic when the rising threshold is reached. The port remains blocked until the traffic rate drops below the falling threshold (if one is specified) and then resumes normal forwarding. If the falling suppression level is not specified, the device blocks all traffic until the traffic rate drops below the rising suppression level. In general, the higher the level, the less effective the protection against broadcast storms.

Storm control for unicast is a combination of known unicast and unknown unicast traffic. When storm control for unicast is configured, and it exceeds the configured value, the storm will hit each type of traffic through the hardware policer. The following example describes how the unicast traffic is filtered, when the configured storm is 10%:

- Incoming traffic is unknown unicast 8% + known unicast 7%. Total of 15% storm is not filtered in hardware by the hardware policer.
- Incoming traffic is unknown unicast 11% + known unicast 7%. Total of 18% storm will hit unknown unicast traffic type, and the hardware policer will filter unknown traffic that exceeds 11%.
- Incoming traffic is unknown unicast 11% + known unicast 11%. Total of 22% storm will hit unknown unicast traffic and known unicast traffic, and the hardware policer will filter both unknown and unknown unicast traffic.

Note

Do not configure both **storm-control unicast** and **storm-control unknown unicast** commands on an interface. If you configure both these commands, it might result in the unknown unicast storm control values to be modified in the hardware.

Traffic Patterns

Broadcast traffic being forwarded exceeded the configured threshold between time intervals T1 and T2 and between T4 and T5. When the amount of specified traffic exceeds the threshold, all traffic of that kind is dropped for the next time period. Therefore, broadcast traffic is blocked during the intervals following T2 and T5. At the next time interval (for example, T3), if broadcast traffic does not exceed the threshold, it is again forwarded.

The combination of the storm-control suppression level and the 1-second time interval controls the way the storm control algorithm works. A higher threshold allows more packets to pass through. A threshold value of 100 percent means that no limit is placed on the traffic. A value of 0.0 means that all broadcast, multicast, or unicast traffic on that port is blocked.

Note Because packets do not arrive at uniform intervals, the 1-second time interval during which traffic activity is measured can affect the behavior of storm control.

You use the **storm-control** interface configuration commands to set the threshold value for each traffic type.

Storm Control Using a Hardware Rate Limiter

Traffic storm control monitors incoming traffic levels over a configured interval. However, the reaction time taken by storm control is slightly slower as it is based on statistics counters to identify a storm. With the hardware rate limiter, the action is taken at the ASIC level, and as a result, the storm control action starts immediately; as soon as the traffic rate reaches the set threshold level. The hardware rate limiter implements policers for broadcast, multicast, unicast, and unknown unicast traffic.

Protected Ports

Some applications require that no traffic be forwarded at Layer 2 between ports on the same device so that one neighbor does not see the traffic generated by another neighbor. In such an environment, the use of protected ports ensures that there is no exchange of unicast, broadcast, or multicast traffic between these ports on the device.

Protected ports have these features:

- A protected port does not forward any traffic (unicast, multicast, or broadcast) to any other port that is
 also a protected port. Data traffic cannot be forwarded between protected ports at Layer 2; only control
 traffic, such as PIM packets, is forwarded because these packets are processed by the CPU and forwarded
 in software. All data traffic passing between protected ports must be forwarded through a Layer 3 device.
- Forwarding behavior between a protected port and a nonprotected port proceeds as usual.

Protected Ports Guidelines

You can configure protected ports on a physical interface (for example, Gigabit Ethernet port 1) or an EtherChannel group (for example, port-channel 5). When you enable protected ports for a port channel, it is enabled for all ports in the port-channel group.

By default no protected ports are defined.

Port Blocking

By default, the device floods packets with unknown destination MAC addresses out of all ports. If unknown unicast and multicast traffic is forwarded to a protected port, there could be security issues. To prevent unknown unicast or multicast traffic from being forwarded from one port to another, you can block a port (protected or nonprotected) from flooding unknown unicast or multicast packets to other ports.

Note

With multicast traffic, the port blocking feature blocks only pure Layer 2 packets. Multicast packets that contain IPv4 or IPv6 information in the header are not blocked.

How to Configure Port-Based Traffic Control

Configuring Storm Control and Threshold Levels

You configure storm control on a port and enter the threshold level that you want to be used for a particular type of traffic.

However, because of hardware limitations and the way in which packets of different sizes are counted, threshold percentages are approximations. Depending on the sizes of the packets making up the incoming traffic, the actual enforced threshold might differ from the configured level by several percentage points.

Note

Storm control is supported on physical interfaces. You can also configure storm control on an EtherChannel. When storm control is configured on an EtherChannel, the storm control settings propagate to the EtherChannel physical interfaces.

Follow these steps to storm control and threshold levels:

Before you begin

Storm control is supported on physical interfaces. You can also configure storm control on an EtherChannel. When storm control is configured on an EtherChannel, the storm control settings propagate to the EtherChannel physical interfaces.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface interface-id	Specifies the interface to be configured, and
	Example:	enters interface configuration mode.
	Device(config)# interface gigabitethernet1/0/1	

I

	Command or Action	Purpose
Step 4	<pre>storm-control {broadcast multicast unicast} level {level [level-low] bps bps [bps-low] pps pps [pps-low]}</pre>	Configures broadcast, multicast, or unicast storm control. By default, storm control is disabled.
	Example: Device(config-if)# storm-control unicast level 87 65	• For <i>level</i> , specifies the rising threshold level for broadcast, multicast, or unicast traffic as a percentage (up to two decim- places) of the bandwidth. The port block traffic when the rising threshold is reache The range is 0.00 to 100.00.
		• (Optional) For <i>level-low</i> , specifies the falling threshold level as a percentage (to two decimal places) of the bandwidth This value must be less than or equal to the rising suppression value. The port forwards traffic when traffic drops belot this level. If you do not configure a falling suppression level, it is set to the rising suppression level. The range is 0.00 to 100.00.
		If you set the threshold to the maximum value (100 percent), no limit is placed of the traffic. If you set the threshold to 0.0 all broadcast, multicast, and unicast traffi on that port is blocked.
		• For bps <i>bps</i> , specifies the rising thresho level for broadcast, multicast, or unicas traffic in bits per second (up to one decimal place). The port blocks traffic when the rising threshold is reached. The range is 0.0 to 10000000000.
		• (Optional) For <i>bps-low</i> , specifies the falling threshold level in bits per second (up to one decimal place). It can be less than or equal to the rising threshold level. The port forwards traffic when traffic drops below this level. The range is 0.0 1000000000.0.
		• For pps <i>pps</i> , specifies the rising thresholevel for broadcast, multicast, or unicas traffic in packets per second (up to one decimal place). The port blocks traffic when the rising threshold is reached. The range is 0.0 to 10000000000.0.
		• (Optional) For <i>pps-low</i> , specifies the falling threshold level in packets per

I

	Command or Action	Purpose	
		second (up to one decimal place). It can be less than or equal to the rising threshold level. The port forwards traffic when traffic drops below this level. The range is 0.0 to 1000000000.0.	
		Note Cisco Catalyst 9600 Series Supervisor 2 Module do not support the pps keyword.	
		For BPS and PPS settings, you can use metric suffixes such as k, m, and g for large number thresholds.	
Step 5	storm-control action {shutdown trap}	Specifies the action to be taken when a storm	
	Example:	is detected. Once a storm is detected, the shutdown or trap action is applied on all the	
	Device(config-if)# storm-control action trap	traffic. The default is to filter out the traffic and	
		• Select the shutdown keyword to error-disable the port during a storm.	
		• Select the trap keyword to generate an SNMP trap when a storm is detected.	
Step 6	end	Exits interface configuration mode and returns	
	Example:	to privileged EXEC mode.	
	Device(config-if)# end		
Step 7	show storm-control [interface-id] [broadcast		
	multicast unicast] Example:	set on the interface for the specified traffic type. If you do not enter a traffic type, details for all traffic types (broadcast, multicast and unicast)	
	Device# show storm-control gigabitethernet1/0/1 unicast	are displayed.	

Configuring a Protected Port

Before you begin

Protected ports are not pre-defined. This is the task to configure one.

	Command or Action	Purpose	
Step 1	enable	Enables privileged EXEC mode.	

	Command or Action	Purpose
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface interface-id	Specifies the interface to be configured, and
	Example:	enters interface configuration mode.
	Device(config)# interface gigabitethernet 1/0/1	
Step 4	switchport protected	Configures the interface to be a protected port.
	Example:	
	Device(config-if)# switchport protected	
Step 5	end	Exits interface configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-if)# end	

Monitoring Protected Ports

Table 34: Commands for Displaying Protected Port Settings

Command	Purpose
show interfaces [interface-id] switchport	Displays the administrative and operational status of all sw (nonrouting) ports or the specified port, including port bloc protection settings.

Blocking Flooded Traffic on an Interface

The interface can be a physical interface or an EtherChannel group. When you block multicast or unicast traffic for a port channel, it is blocked on all ports in the port-channel group.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.

	Command or Action	Purpose
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface interface-id	Specifies the interface to be configured, and
	Example:	enter interface configuration mode.
	Device(config)# interface gigabitethernet 1/0/1	
Step 4	switchport block multicast	Blocks unknown multicast forwarding out of
	Example:	the port.
	Device(config-if)# switchport block multicast	
Step 5	switchport block unicast	Blocks unknown unicast forwarding out of the
	Example:	port.
	Device(config-if)# switchport block unicast	
Step 6	end	Exits interface configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config-if)# end	

Monitoring Port Blocking

Table 35: Commands for Displaying Port Blocking Settings

Command	Purpose
	Displays the administrative and operational status of all switch (nonrouting) ports or the specified port, including port blocking protection settings.

- Restrictions for Port Security, on page 649
- Information About Port Security, on page 650
- How to Configure Port Security, on page 654
- Configuration Examples for Port Security, on page 662
- Feature History for Port Security, on page 663

Prerequisites for Port Security

If you try to set the maximum value to a number less than the number of secure addresses already configured on an interface, the command is rejected.

Restrictions for Port Security

- The maximum number of secure MAC addresses that you can configure on a switch is set by the maximum number of available MAC addresses allowed in the system. This number is the total of available MAC addresses, including those used for other Layer 2 functions and any other secure MAC addresses configured on interfaces.
- Port Security is not supported on EtherChanel interfaces.
- Port Security is not supported on private VLAN ports.
- We recommend that you do not enable port security on an 802.1X authenticator interface.

When port-security is disabled on a port, the 802.1X sessions on the port get removed, because the aging timer and inactivity type is still configured. To ensure that the 802.1X sessions are not removed, when disabling port-security, disable the aging timer and inactivity type by removing the following commands:

- switchport port-security aging time 1
- switchport port-security aging type inactivity

If the inactivity timer is required, see the section "Enabling and Configuring Port Security Aging".

Information About Port Security

Port Security

You can use the port security feature to restrict input to an interface by limiting and identifying MAC addresses of the stations allowed to access the port. When you assign secure MAC addresses to a secure port, the port does not forward packets with source addresses outside the group of defined addresses. If you limit the number of secure MAC addresses to one and assign a single secure MAC address, the workstation attached to that port is assured the full bandwidth of the port.

If a port is configured as a secure port and the maximum number of secure MAC addresses is reached, when the MAC address of a station attempting to access the port is different from any of the identified secure MAC addresses, a security violation occurs. Also, if a station with a secure MAC address configured or learned on one secure port attempts to access another secure port, a violation is flagged.

Types of Secure MAC Addresses

The switch supports these types of secure MAC addresses:

- Static secure MAC addresses—These are manually configured by using the switchport port-security mac-address mac-address interface configuration command, stored in the address table, and added to the switch running configuration.
- Dynamic secure MAC addresses—These are dynamically configured, stored only in the address table, and removed when the switch restarts.
- Sticky secure MAC addresses—These can be dynamically learned or manually configured, stored in the address table, and added to the running configuration. If these addresses are saved in the configuration file, when the switch restarts, the interface does not need to dynamically reconfigure them.

Default MAC Address Table Settings

The following table shows the default settings for the MAC address table.

Feature	Default Setting
Aging time	300 seconds
Dynamic addresses	Automatically learned
Static addresses	None configured

Table 36: Default Settings for the MAC Address

MAC Address Table Creation

With multiple MAC addresses supported on all ports, you can connect any port on the device to other network devices. The device provides dynamic addressing by learning the source address of packets it receives on

each port and adding the address and its associated port number to the address table. As devices are added or removed from the network, the device updates the address table, adding new dynamic addresses and aging out those that are not in use.

The aging interval is globally configured. However, the device maintains an address table for each VLAN, and STP can accelerate the aging interval on a per-VLAN basis.

The device sends packets between any combination of ports, based on the destination address of the received packet. Using the MAC address table, the device forwards the packet only to the port associated with the destination address. If the destination address is on the port that sent the packet, the packet is filtered and not forwarded. The device always uses the store-and-forward method: complete packets are stored and checked for errors before transmission.

Sticky Secure MAC Addresses

You can configure an interface to convert the dynamic MAC addresses to sticky secure MAC addresses and to add them to the running configuration by enabling sticky learning. The interface converts all the dynamic secure MAC addresses, including those that were dynamically learned before sticky learning was enabled, to sticky secure MAC addresses. All sticky secure MAC addresses are added to the running configuration.

The sticky secure MAC addresses do not automatically become part of the configuration file, which is the startup configuration used each time the switch restarts. If you save the sticky secure MAC addresses in the configuration file, when the switch restarts, the interface does not need to relearn these addresses. If you do not save the sticky secure addresses, they are lost.

If sticky learning is disabled, the sticky secure MAC addresses are converted to dynamic secure addresses and are removed from the running configuration.

Security Violations

It is a security violation when one of these situations occurs:

- The maximum number of secure MAC addresses have been added to the address table, and a station whose MAC address is not in the address table attempts to access the interface.
- An address learned or configured on one secure interface is seen on another secure interface in the same VLAN.
- Running diagnostic tests with port security enabled.

You can configure the interface for one of three violation modes, based on the action to be taken if a violation occurs:

 protect—when the number of secure MAC addresses reaches the maximum limit allowed on the port, packets with unknown source addresses are dropped until you remove a sufficient number of secure MAC addresses to drop below the maximum value or increase the number of maximum allowable addresses. You are not notified that a security violation has occurred.

Note

We do not recommend configuring the protect violation mode on a trunk port. The protect mode disables learning when any VLAN reaches its maximum limit, even if the port has not reached its maximum limit.

- restrict—when the number of secure MAC addresses reaches the maximum limit allowed on the port, packets with unknown source addresses are dropped until you remove a sufficient number of secure MAC addresses to drop below the maximum value or increase the number of maximum allowable addresses. In this mode, you are notified that a security violation has occurred. An SNMP trap is sent, a syslog message is logged, and the violation counter increments.
- shutdown—a port security violation causes the interface to become error-disabled and to shut down
 immediately, and the port LED turns off. When a secure port is in the error-disabled state, you can bring
 it out of this state by entering the errdisable recovery cause *psecure-violation* global configuration
 command, or you can manually re-enable it by entering the shutdown and no shut down interface
 configuration commands. This is the default mode.
- shutdown vlan—Use to set the security violation mode per-VLAN. In this mode, the VLAN is error disabled instead of the entire port when a violation occurs

This table shows the violation mode and the actions taken when you configure an interface for port security.

Violation Mode	Traffic is forwarded <u>10</u>	Sends SNMP trap	Sends syslog message	Displays error message <u>11</u>	Violation counter increments	Shuts d
protect	No	No	No	No	No	No
restrict	No	Yes	Yes	No	Yes	No
shutdown	No	No	No	No	Yes	Yes
shutdown vlan	No	No	Yes	No	Yes	No <u>12</u>

Table 37: Security Violation Mode Actions

¹⁰ Packets with unknown source addresses are dropped until you remove a sufficient number of secure MAC addresses.

- ¹¹ The switch returns an error message if you manually configure an address that would cause a security violation.
- ¹² Shuts down only the VLAN on which the violation occurred.

Port Security Aging

You can use port security aging to set the aging time for all secure addresses on a port. Two types of aging are supported per port:

- Absolute-The secure addresses on the port are deleted after the specified aging time.
- Inactivity—The secure addresses on the port are deleted only if the secure addresses are inactive for the specified aging time.

Default Port Security Configuration

Feature	Default Setting	
Port security	Disabled on a port.	
Sticky address learning	Disabled.	
Maximum number of secure MAC addresses per port	One address	
Violation mode	Shutdown. The port shuts down when the maximum number of secure MAC addresses is exceeded.	
Port security aging	Disabled. Aging time is 0.	
	Static aging is disabled.	
	Type is absolute.	

Table 38: Default Port Security Configuration

Port Security Configuration Guidelines

- Port security can only be configured on static access ports or trunk ports. A secure port cannot be a dynamic access port.
- A secure port cannot be a destination port for Switched Port Analyzer (SPAN).
- Voice VLAN is only supported on access ports and not on trunk ports, even though the configuration is allowed.
- When you enable port security on an interface that is also configured with a voice VLAN, set the maximum
 allowed secure addresses on the port to two. When the port is connected to a Cisco IP phone, the IP
 phone requires one MAC address. The Cisco IP phone address is learned on the voice VLAN, but is not
 learned on the access VLAN. If you connect a single PC to the Cisco IP phone, no additional MAC
 addresses are required. If you connect more than one PC to the Cisco IP phone, you must configure
 enough secure addresses to allow one for each PC and one for the phone.
- When a trunk port configured with port security and assigned to an access VLAN for data traffic and to a voice VLAN for voice traffic, entering the **switchport voice** and **switchport priority extend** interface configuration commands has no effect.

When a connected device uses the same MAC address to request an IP address for the access VLAN and then an IP address for the voice VLAN, only the access VLAN is assigned an IP address.

- When you enter a maximum secure address value for an interface, and the new value is greater than the previous value, the new value overwrites the previously configured value. If the new value is less than the previous value and the number of configured secure addresses on the interface exceeds the new value, the command is rejected.
- The switch does not support port security aging of sticky secure MAC addresses.

This table summarizes port security compatibility with other port-based features.

Table 39: Port Security Compatibility with Other Switch Features

Type of Port or Feature on Port	Compatible with Port Security
DTP ¹³ port ¹⁴	No
Trunk port	Yes
Dynamic-access port $\frac{15}{2}$	No
Routed port	No
SPAN source port	Yes
SPAN destination port	No
EtherChannel	No
Tunneling port	Yes
Protected port	Yes
IEEE 802.1x port	Yes
Voice VLAN port ¹⁶	Yes
IP source guard	Yes
Dynamic Address Resolution Protocol (ARP) inspection	Yes
Flex Links	Yes

¹³ DTP=Dynamic Trunking Protocol

¹⁴ A port configured with the **switchport mode dynamic** interface configuration command.

¹⁵ A VLAN Query Protocol (VQP) port configured with the switchport access vlan dynamic interface configuration command.

¹⁶ You must set the maximum allowed secure addresses on the port to two plus the maximum number of secure addresses allowed on the access VLAN.

How to Configure Port Security

Enabling and Configuring Port Security

Before you begin

This task restricts input to an interface by limiting and identifying MAC addresses of the stations allowed to access the port:

I

	Command or Action	Purpose	
Step 1	enable	Enables privileged EXEC mode.	
	Example:	• Enter your password if prompted.	
	Device> enable		
Step 2	configure terminal	Enters global configuration mode.	
	Example:		
	Device# configure terminal		
Step 3	interface interface-id	Specifies the interface to be configured, and	
	Example:	enter interface configuration mode.	
	Device(config)# interface gigabitethernet 1/0/1		
Step 4	switchport mode {access trunk}	Sets the interface switchport mode as access	
	Example:	or trunk; an interface in the default mode (dynamic auto) cannot be configured as a	
	<pre>Device(config-if)# switchport mode access</pre>	secure port.	
Step 5	switchport voice vlan vlan-id	Enables voice VLAN on a port.	
	Example:	<i>vlan-id</i> —Specifies the VLAN to be used for voice traffic.	
	Device(config-if)# switchport voice vlam 22		
Step 6	switchport port-security	Enables port security on the interface.	
	Example:	Note Under certain conditions, when	
	<pre>Device(config-if)# switchport port-security</pre>	port security is enabled on the member ports in a switch stack, the DHCP and ARP packets would be dropped. As a workaround, shutdown the interface and then configure the no shutdown command.	
Step 7	switchport port-security [maximum value [vlan {vlan-list {access voice}}]]	(Optional) Sets the maximum number of secure MAC addresses for the interface. The	
	Example:	maximum number of secure MAC addresses that you can configure on a switch or switch	
	Device(config-if)# switchport	stack is set by the maximum number of available MAC addresses allowed in the	

I

	Command or Action	Purpose
	port-security maximum 20	system. This number is the total of available MAC addresses, including those used for other Layer 2 functions and any other secure MAC addresses configured on interfaces.
		(Optional) vlan —sets a per-VLAN maximum value
		Enter one of these options after you enter the vlan keyword:
		• <i>vlan-list</i> —On a trunk port, you can set a per-VLAN maximum value on a range of VLANs separated by a hyphen or a series of VLANs separated by commas. For nonspecified VLANs, the per-VLAN maximum value is used.
		• access —On an access port, specifies the VLAN as an access VLAN.
		• voice —On an access port, specifies the VLAN as a voice VLAN.
		Note The voice keyword is available only if a voice VLAN is configured on a port and if that port is not the access VLAN. If an interface is configured for voice VLAN, configure a maximum of two secure MAC addresses.
Step 8	<pre>switchport port-security violation {protect restrict shutdown shutdown vlan} Example: Device (config-if) # switchport port-security violation restrict</pre>	 (Optional) Sets the violation mode, the action to be taken when a security violation is detected, as one of these: protect—When the number of port secure MAC addresses reaches the maximum limit allowed on the port, packets with unknown source addresses are dropped until you remove a sufficient number of secure MAC addresses to drop below the maximum value or increase the number of maximum allowable addresses. You are not notified that a security violation has occurred.

	Command or Action	Purpose	
		Note	We do not recommend configuring the protect mode on a trunk port. The protect mode disables learning when any VLAN reaches its maximum limit even if the port has not reached its maximum limit
		MAC add on the por addresses a sufficien addresses maximum trap is ser	-When the number of secure Iresses reaches the limit allowe rt, packets with unknown source are dropped until you remove int number of secure MAC or increase the number of allowable addresses. An SNM nt, a syslog message is logged iolation counter increments.
		error-disa and the po trap is ser	n—The interface is bled when a violation occurs, ort LED turns off. An SNMP nt, a syslog message is logged iolation counter increments.
		violation the VLAN	n vlan—Use to set the securit mode per VLAN. In this mod N is error disabled instead of th t when a violation occurs.
		Note	When a secure port is in the error-disabled state, you can bring it out of this state by entering the errdisable recovery cause psecure-violation global configuration command. You can manually re-enable it by entering the shutdown and no shutdown interfac configuration commands or by using the clear errdisable interface vlam privileged EXEC command
Step 9	switchport port-security [mac-address mac-address [vlan {vlan-id {access voice}}]	the interface.	ers a secure MAC address for You can use this command to mum number of secure MAC
	Example:		ou configure fewer secure MA

I

	Command or Action	Purpose	
	<pre>port-security mac-address 00:A0:C7:12:C9:25 vlan 3 voice</pre>	addresses than the maximum, the remaining MAC addresses are dynamically learned.	
		Note If you enable sticky learning after you enter this command, the secure addresses that were dynamically learned are converted to sticky secure MAC addresses and are added to the running configuration.	
		(Optional) vlan —sets a per-VLAN maximum value.	
		Enter one of these options after you enter the vlan keyword:	
		• <i>vlan-id</i> —On a trunk port, you can specify the VLAN ID and the MAC address. If you do not specify a VLAN ID, the native VLAN is used.	
		• access—On an access port, specifies the VLAN as an access VLAN.	
		• voice —On an access port, specifies the VLAN as a voice VLAN.	
		Note The voice keyword is available only if a voice VLAN is configured on a port and if that port is not the access VLAN. If an interface is configured for voice VLAN, configure a maximum of two secure MAC addresses.	
Step 10	switchport port-security mac-address sticky Example:	(Optional) Enables sticky learning on the interface.	
	Device(config-if)# switchport port-security mac-address sticky		
Step 11	<pre>switchport port-security mac-address sticky [mac-address vlan {vlan-id {access voice}}] Example:</pre>	(Optional) Enters a sticky secure MAC address, repeating the command as many times as necessary. If you configure fewer secure MAC addresses than the maximum, the	
	Device(config-if)# switchport port-security mac-address sticky 00:A0:C7:12:C9:25 vlan voice	remaining MAC addresses are dynamically learned, are converted to sticky secure MAC addresses, and are added to the running configuration.	

	Command or Action	Purpose		
		NoteIf you do not enable sticky learning before this command is entered, an error message appears, and you cannot enter a sticky secure MAC address.		
		(Optional) vlan —sets a per-VLAN maximum value.		
		Enter one of these options after you enter the vlan keyword:		
		• <i>vlan-id</i> —On a trunk port, you can specify the VLAN ID and the MAC address. If you do not specify a VLAN ID, the native VLAN is used.		
		• access—On an access port, specifies the VLAN as an access VLAN.		
		• voice —On an access port, specifies the VLAN as a voice VLAN.		
		Note The voice keyword is available only if a voice VLAN is configured on a port and if that port is not the access VLAN.		
Step 12	end	Exits interface configuration mode and return		
	Example:	to privileged EXEC mode.		
	Device(config-if)# end			
Step 13	show port-security	Displays information about the port-security		
	Example:	settings.		

Enabling and Configuring Port Security Aging

Use this feature to remove and add devices on a secure port without manually deleting the existing secure MAC addresses and to still limit the number of secure addresses on a port. You can enable or disable the aging of secure addresses on a per-port basis.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.

	Command or Action	Purpose
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	interface interface-id	Specifies the interface to be configured, and
	Example:	enter interface configuration mode.
	Device(config)# interface gigabitethernet1/0/1	
Step 4	<pre>switchport port-security aging {static time time type {absolute inactivity}}</pre>	Enables or disable static aging for the secure port, or set the aging time or type.
	<pre>Example: Device(config-if)# switchport</pre>	Note The switch does not support por security aging of sticky secure addresses.
	port-security aging time 120	Enter static to enable aging for statically configured secure addresses on this port.
		For <i>time</i> , specifies the aging time for this por The valid range is from 0 to 1440 minutes.
		For type , select one of these keywords:
		• absolute —Sets the aging type as absolut aging. All the secure addresses on this po age out exactly after the time (minutes) specified lapses and are removed from the secure address list.
		• inactivity —Sets the aging type as inactivity aging. The secure addresses o this port age out only if there is no data traffic from the secure source addresses for the specified time period.
Step 5	end	Exits interface configuration mode and return
	Example:	to privileged EXEC mode.
	Device(config-if)# end	
Step 6	show port-security [interface interface-id] [address]	Displays information about the port-security settings on the specified interface.
	Example:	

I

 Command or Action	Purpose
Device# show port-security interface gigabitethernet1/0/1	

Changing the Address Aging Time

Follow these steps to configure the dynamic address table aging time:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	mac address-table aging-time [0 10-1000000] [routed-mac vlan vlan-id]	Sets the length of time that a dynamic entry remains in the MAC address table after the entry
	Example:	is used or updated.
	Device(config)# mac address-table aging-time 500 vlan 2	The range is 10 to 1000000 seconds. The default is 300. You can also enter 0, which disables aging. Static address entries are never aged or removed from the table.
		<i>vlan-id</i> —Valid IDs are 1 to 4094.
Step 4	end	Exits global configuration mode and returns to
	Example:	privileged EXEC mode.
	Device(config)# end	

Monitoring Port Security

This table displays port security information.

Table 40: Commands for Displaying Port Security Status and Configuration

Command	Purpose
<pre>show port-security [interface interface-id]</pre>	Displays port security settings for the device or for the specified including the maximum allowed number of secure MAC addre each interface, the number of secure MAC addresses on the int number of security violations that have occurred, and the violat
show port-security [interface interface-id] address	Displays all secure MAC addresses configured on all device in on a specified interface with aging information for each addres
show port-security interface interface-id vlan	Displays the number of secure MAC addresses configured per the specified interface.

Configuration Examples for Port Security

This example shows how to enable port security on a port and to set the maximum number of secure addresses to 50. The violation mode is the default, no static secure MAC addresses are configured, and sticky learning is enabled.

```
Device> enable
Device# configure terminal
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# switchport mode access
Device(config-if)# switchport port-security
Device(config-if)# switchport port-security maximum 50
Device(config-if)# switchport port-security mac-address sticky
Device(config-if)# end
```

This example shows how to configure a static secure MAC address on VLAN 3 on a port:

```
Device> enable
Device# configure terminal
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# switchport mode trunk
Device(config-if)# switchport port-security
Device(config-if)# switchport port-security mac-address 0000.0200.0004 vlan 3
Device(config-if)# end
```

This example shows how to enable sticky port security on a port, to manually configure MAC addresses for data VLAN and voice VLAN, and to set the total maximum number of secure addresses to 20 (10 for data VLAN and 10 for voice VLAN).

```
Device> enable
Device# configure terminal
Device(config)# interface tengigabitethernet1/0/1
Device(config-if)# switchport access vlan 21
Device(config-if)# switchport mode access
Device(config-if)# switchport voice vlan 22
Device(config-if)# switchport port-security
Device(config-if)# switchport port-security maximum 20
Device(config-if)# switchport port-security violation restrict
```

L

```
Device(config-if)# switchport port-security mac-address sticky
Device(config-if)# switchport port-security mac-address sticky 0000.0000.0002
Device(config-if)# switchport port-security mac-address 0000.0000.0003
Device(config-if)# switchport port-security mac-address sticky 0000.0000.0001 vlan voice
Device(config-if)# switchport port-security mac-address 0000.0000.0004 vlan voice
Device(config-if)# switchport port-security maximum 10 vlan access
Device(config-if)# switchport port-security maximum 10 vlan voice
Device(config-if)# switchport port-security maximum 10 vlan voice
```

Feature History for Port Security

This table provides release and related information for features explained in this module.

These features are available on all releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.11.1	Port Security	The Port Security feature restricts input to an interface by limiting and identifying MAC addresses of the stations allowed to access the port.
Cisco IOS XE Gibraltar 16.11.1	Port Security MAC Aging	When devices are added or removed from a network, the device updates the address table, adding new dynamic addresses and aging out those that are not in use.
Cisco IOS XE Cupertino 17.7.1	Port Security	Support for this feature was introduced on Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

Use Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

Configuring Control Plane Policing

- Restrictions for CoPP, on page 665
- Information About CoPP, on page 666
- How to Configure CoPP, on page 675
- Configuration Examples for CoPP, on page 678
- Monitoring CoPP, on page 683
- Feature History for CoPP, on page 683

Restrictions for CoPP

Restrictions for control plane policing (CoPP) include the following:

- Only ingress CoPP is supported. The **system-cpp-policy** policy-map is available on the control plane interface, and only in the ingress direction.
- Only the system-cpp-policy policy-map can be installed on the control plane interface.
- The system-cpp-policy policy-map and the system-defined classes cannot be modified or deleted.
- Only the **police** action is allowed under the **system-cpp-policy** policy-map. The police rate for system-defined classes must be configured only in packets per second (pps).
- One or more CPU queues are part of each class-map. Where multiple CPU queues belong to one class-map, changing the policer rate of a class-map affects all CPU queues that belong to that class-map. Similarly, disabling the policer in a class-map disables all queues that belong to that class-map. See *Table: System-Defined Values for CoPP* for information about which CPU queues belong to each class-map.
- We recommend not disabling the policer for a system-defined class map, that is, do not configure **no police rate** *rate* **pps** command. Doing so affects the overall system health in case of high traffic towards the CPU. Further, even if you disable the policer rate for a system-defined class map, the systems automatically reverts to the default policer rate after system bootup in order to protect the system bring-up process.
- The show run command does not display information about classes configured under system-cpp policy, when they are left at default values. Use the show policy-map system-cpp-policy or the show policy-map control-plane commands instead.

You can continue use the **show run** command to display information about custom policies.

- A protocol with a large number of CPU-bound packets may impact other protocols in the same class, as some of these protocols share the same policer. For example, Address Resolution Protocol (ARP) shares 4000 hardware policers with an array of host protocols like Telnet, Internet Control Message Protocol (ICMP), SSH, FTP, and SNMP in the system-cpp-police-forus class. If there is an ARP poisoning or an ICMP attack, hardware policers start throttling any incoming traffic that exceeds 4000 packets per second to protect the CPU and the overall integrity of the system. As a result, ARP and ICMP host protocols are dropped, along with any other host protocols that share the same class.
- The creation of user-defined class-maps is not supported.

Information About CoPP

This chapter describes how control plane policing (CoPP) works on your device and how to configure it.

CoPP Overview

The CoPP feature improves security on your device by protecting the CPU from unnecessary traffic and denial of service (DoS) attacks. It can also protect control traffic and management traffic from traffic drops caused by high volumes of other, lower priority traffic.

Your device is typically segmented into three planes of operation, each with its own objective:

- The data plane, to forward data packets.
- The control plane, to route data correctly.
- The management plane, to manage network elements.

You can use CoPP to protect most of the CPU-bound traffic and ensure routing stability, reachability, and packet delivery. Most importantly, you can use CoPP to protect the CPU from a DoS attack.

CoPP uses the modular QoS command-line interface (MQC) and CPU queues to achieve these objectives. Different types of control plane traffic are grouped together based on certain criteria, and assigned to a CPU queue. You can manage these CPU queues by configuring dedicated policers in hardware. For example, you can modify the policer rate for certain CPU queues (traffic-type), or you can disable the policer for a certain type of traffic.

Although the policers are configured in hardware, CoPP does not affect CPU performance or the performance of the data plane. But since it limits the number of packets going to CPU, the CPU load is controlled. This means that services waiting for packets from hardware may see a more controlled rate of incoming packets (the rate being user-configurable).

System-Defined Aspects of CoPP

When you power-up the device for the first time, the system automatically performs the following tasks:

- Looks for policy-map **system-cpp-policy**. If not found, the system creates and installs it on the control-plane.
- Creates eighteen class-maps under system-cpp-policy.

The next time you power-up the device, the system detects the policy and class maps that have already been created.

• Enables all CPU queues by default, with their respective default rate. The default rates are indicated in the table System-Defined Values for CoPP.

The **system-cpp-policy** policy map is a system-default policy map, and normally, you do not have to expressly save it to the startup configuration of the device. But, a *failed* bulk synchronization with a standby device can result in the configuration being erased from the startup configuration. In case this happens, you have to manually save the **system-cpp-policy** policy map to the startup configuration. Use the **show running-config** privileged EXEC command to verify that it has been saved:

policy-map system-cpp-policy

The following table (System-Defined Values for CoPP) lists the class-maps that the system creates when you load the device. It lists the policer that corresponds to each class-map and one or more CPU queues that are grouped under each class-map. There is a one-to-one mapping of class-maps to policers; and one or more CPU queues map to a class-map. This is followed by another table (CPU Queues and Associated Features), which lists features associated with each CPU queue.

Table 41: System-Defined Values for CoPP

Class Maps Names	Policer Index (Policer No.)	CPU queues (Queue No.)
system-cpp- police-data	WK_CPP_POLICE_DATA(0)	WK_CPU_Q_ICMP_GEN(3)
		WK_CPU_Q_BROADCAST(12)
		WK_CPU_Q_ICMP_REDIRECT(6)
system-cpp-police-l2- control	WK_CPP_POLICE_L2_ CONTROL(1)	WK_CPU_Q_L2_CONTROL(1)
system-cpp-police-routing-control	WK_CPP_POLICE_ROUTING_CONTROL(2)	WK_CPU_Q_ROUTING_CONTROL(4)
		WK_CPU_Q_LOW_LATENCY (27)
system-cpp-police-punt-webauth	WK_CPP_POLICE_PU NT_WEBAUTH(7)	WK_CPU_Q_PUNT_WEBAUTH(22)
system-cpp-police- topology-control	WK_CPP_POLICE_TOPOLOGY_CONTROL®	WK_CPU_Q_TOPOLOGY_CONTROL(15)

The following table lists the CPU queues and the feature(s) associated with each CPU queue.

Table 42: CPU Queues and Associated Features

CPU queues (Queue No.)	Feature(s)
WK_CPU_Q_DOT1X_AUTH(0)	IEEE 802.1x Port-Based Authentication

CPU queues (Queue No.)	Feature(s)
WK_CPU_Q_L2_CONTROL(1)	Dynamic Trunking Protocol (DTP)
	VLAN Trunking Protocol (VTP)
	Port Aggregation Protocol (PAgP)
	Client Information Signaling Protocol (CISP)
	Message session relay protocol
	Multiple VLAN Registration Protocol (MVRP)
	Metropolitan Mobile Network (MMN)
	Link Level Discovery Protocol (LLDP)
	UniDirectional Link Detection (UDLD)
	Link Aggregation Control Protocol (LACP)
	Cisco Discovery Protocol (CDP)
	Spanning Tree Protocol (STP)
WK_CPU_Q_FORUS_TRAFFIC(2)	Host such as Telnet, Pingv4 and Pingv6, and SNMP
	Keepalive / loopback detection
	Initiate-Internet Key Exchange (IKE) protocol (IPSec)
WK_CPU_Q_ICMP_GEN(3)	ICMP - destination unreachable
	ICMP-TTL expired

CPU queues (Queue No.)	Feature(s)
WK_CPU_Q_ROUTING_CONTROL(4)	Routing Information Protocol version 1 (RIPv1)
	RIPv2
	Interior Gateway Routing Protocol (IGRP)
	Border Gateway Protocol (BGP)
	PIM-UDP
	Virtual Router Redundancy Protocol (VRRP)
	Hot Standby Router Protocol version 1 (HSRPv1)
	HSRPv2
	Gateway Load Balancing Protocol (GLBP)
	Label Distribution Protocol (LDP)
	Web Cache Communication Protocol (WCCP)
	Routing Information Protocol next generation (RIPng)
	Open Shortest Path First (OSPF)
	Open Shortest Path First version 3(OSPFv3)
	Enhanced Interior Gateway Routing Protocol (EIGRP)
	Enhanced Interior Gateway Routing Protocol version 6 (EIGRPv6)
	DHCPv6
	Protocol Independent Multicast (PIM)
	Protocol Independent Multicast version 6 (PIMv6)
	Hot Standby Router Protocol next generation (HSRPng)
	IPv6 control
	Generic Routing Encapsulation (GRE) keepalive
	Network Address Translation (NAT) punt
	Intermediate System-to-Intermediate System (IS-IS)
WK_CPU_Q_FORUS_ADDR_RESOLUTION(5)	Address Resolution Protocol (ARP)
	IPv6 neighbor advertisement and neighbor solicitation
WK_CPU_Q_ICMP_REDIRECT(6)	Internet Control Message Protocol (ICMP) redirect

CPU queues (Queue No.)	Feature(s)
WK_CPU_Q_INTER_FED_TRAFFIC(7)	Layer 2 bridge domain inject for internal communication.
WK_CPU_Q_L2_LVX_CONT_PACK(8)	Exchange ID (XID) packet
WK_CPU_Q_EWLC_CONTROL(9)	Embedded Wirelss Controller (eWLC) [Control and Provisioning of Wireless Access Points (CAPWAP) (UDP 5246)]
WK_CPU_Q_EWLC_DATA(10)	eWLC data packet (CAPWAP DATA, UDP 5247)
WK_CPU_Q_L2_LVX_DATA_PACK(11)	Unknown unicast packet punted for map request.
WK_CPU_Q_BROADCAST(12)	All types of broadcast
WK_CPU_Q_OPENFLOW(13)	Learning cache overflow (Layer 2 + Layer 3)
WK_CPU_Q_CONTROLLER_PUNT(14)	Data - access control list (ACL) Full
	Data - IPv4 options
	Data - IPv6 hop-by-hop
	Data - out-of-resources / catch all
	Data - Reverse Path Forwarding (RPF) incomplete
	Glean packet
WK_CPU_Q_TOPOLOGY_CONTROL(15)	Spanning Tree Protocol (STP)
	Resilient Ethernet Protocol (REP)
	Shared Spanning Tree Protocol (SSTP)
WK_CPU_Q_PROTO_SNOOPING(16)	Address Resolution Protocol (ARP) snooping for Dynamic ARP Inspection (DAI)
WK_CPU_Q_DHCP_SNOOPING(17)	DHCP snooping
WK_CPU_Q_TRANSIT_TRAFFIC(18)	This is used for packets punted by NAT, which need to be handled in the software path.
WK_CPU_Q_RPF_FAILED(19)	Data – mRPF (multicast RPF) failed
WK_CPU_Q_MCAST_END_STATION_SERVICE(20)	Internet Group Management Protocol (IGMP) / Multicast Listener Discovery (MLD) control
WK_CPU_Q_LOGGING(21)	Access control list (ACL) logging
WK_CPU_Q_PUNT_WEBAUTH(22)	Web Authentication

CPU queues (Queue No.)	Feature(s)
WK_CPU_Q_HIGH_RATE_APP(23)	Wired Application Visibility and Control (WDAVC) traffic
	Network-Based Application Recognition (NBAR) traffic
WK_CPU_Q_EXCEPTION(24)	IKE indication
	IP learning violation
	IP port security violation
	IP Static address violation
	IPv6 scope check
	Remote Copy Protocol (RCP) exception
	Unicast RPF fail
WK_CPU_Q_SYSTEM_CRITICAL(25)	Media Signaling/ Wireless Proxy ARP
WK_CPU_Q_NFL_SAMPLED_DATA(26)	Netflow sampled data and Media Services Proxy (MSP)
WK_CPU_Q_LOW_LATENCY(27)	Bidirectional Forwarding Detection (BFD), Precision Time Protocol (PTP)
WK_CPU_Q_EGR_EXCEPTION(28)	Egress resolution exception
WK_CPU_Q_STACKWISE_VIRTUAL_CONTROL(29)	Front side stacking protocols, namely SVL
WK_CPU_Q_MCAST_DATA(30)	Data - (S,G) creation
	Data - local joins
	Data - PIM Registration
	Data - SPT switchover
	Data - Multicast
WK_CPU_Q_GOLD_PKT(31)	Gold

User-Configurable Aspects of CoPP

You can perform these tasks to manage control plane traffic:

Note

All system-cpp-policy configurations must be saved so they are retained after reboot.

Enable or Disable a Policer for CPU Queues

Enable a policer for a CPU queue, by configuring a policer action (in packets per second) under the corresponding class-map, within the system-cpp-policy policy-map.

Disable a policer for CPU queue, by removing the policer action under the corresponding class-map, within the system-cpp-policy policy-map.

Note

If a default policer is already present, carefully consider and control its removal; otherwise the system may see a CPU hog or other anomalies, such as control packet drops.

Change the Policer Rate

You can do this by configuring a policer rate action (in packets per second), under the corresponding class-map, within the system-cpp-policy policy-map.

Set Policer Rates to Default

Set the policer for CPU queues to their default values, by entering the **cpp system-default** command in global configuration mode.

Upgrading or Downgrading the Software Version

Software Version Upgrades and CoPP

When you upgrade the software version on your device, the system checks and make the necessary updates as required for CoPP (For instance, it checks for the system-cpp-policy policy map and creates it if missing). You may also have to complete certain tasks before or after the upgrade activity. This is to ensure that any configuration updates are reflected correctly and CoPP continues to work as expected. Depending on the method you use to upgrade the software, upgrade-related tasks may be optional or recommended in some scenarios, and mandatory in others.

The system actions and user actions for an upgrade, are described here. Also included, are any release-specific caveats.

System Actions for an Upgrade

When you upgrade the software version on your device, the system performs these actions. This applies to all upgrade methods:

- If the device did not have a system-cpp-policy policy map before upgrade, then on upgrade, the system creates a default policy map.
- If the device had a system-cpp-policy policy map before upgrade, then on upgrade, the system does not re-generate the policy.

User Actions for an Upgrade

User actions for an upgrade – depending on upgrade method:

Upgrade Method	Condition	Action Time and Action	Purpose
Regular ¹⁷	None	After upgrade (required) Enter the cpp system-default command in global configuration mode	To get the latest, default policer rates.
In-Service Software Upgrade (ISSU) ¹⁸	If there are user-defined classes in the existing software version or If there are system-defined classes in the existing software version that are deprecated in a later release (for example: system-cpp-police-control-low-priority).	Before and after upgrade (required) Enter the cpp system-default command in global configuration mode	Enter the command before upgrade, to ensure that any required system configuration is updated, ensuring smooth ISSU operation. Enter the command after upgrade for the latest, default policer rates.

 Refers to a software upgrade method that involves a reload of the switch. Can be install or bundle mode.
 ISSU is supported only from one extended maintenance release to another. For more information, see In-Service Software Upgrade (ISSU).

Software Version Downgrades and CoPP

The system actions and user actions for a downgrade, are described here.

System Actions for a Downgrade

When you downgrade the software version on your device, the system performs these actions. This applies to all downgrade methods:

• The system retains the system-cpp-policy policy map on the device, and installs it on the control plane.

User Actions for a Downgrade

User actions for a downgrade:

Upgrade Method	Condition	Action Time and Action	Purpose
Regular ¹⁹	None	No action required	Not applicable
In-Service Software Upgrade (ISSU) ²⁰	None	No action required	Not applicable

Refers to a software upgrade method that involves a reload of the switch. Can be install or bundle mode.
 ISSU downgrades are not supported.

If you downgrade the software version and then upgrade, the system action and user actions that apply are the same as those mentioned for upgrades.

How to Configure CoPP

Enabling a CPU Queue or Changing the Policer Rate

The procedure to enable a CPU queue and change the policer rate of a CPU queue is the same. Follow these steps:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	policy-map policy-map-name	Enters the policy map configuration mode.
	Example:	
	Device(config)# policy-map system-cpp-policy Device(config-pmap)#	
Step 4	class class-name Example:	Enters the class action configuration mode. Enter the name of the class that corresponds to the CPU queue you want to enable. See table
	Device(config-pmap)# class system-cpp-police-protocol-snooping Device(config-pmap-c)#	System-Defined Values for CoPP.
Step 5	police rate <i>rate</i> pps Example:	Specifies an upper limit on the number of incoming packets processed per second, for the specified traffic class.
	<pre>Device(config-pmap-c)# police rate 100 pps Device(config-pmap-c-police)#</pre>	Note The rate you specify is applied to all CPU queues that belong to the class-map you have specified.
Step 6	exit	Returns to the global configuration mode.
	Example:	
	Device(config-pmap-c-police)# exit Device(config-pmap-c)# exit	

I

	Command or Action	Purpose	
	Device(config-pmap)# exit Device(config)#		
Step 7	control-plane Example:	Enters the control plane (config-cp) configuration mode	
	Device(config)# control-plane Device(config-cp)#		
Step 8	service-policy input policy-name Example:	Installs system-cpp-policy in FED. This command is required for you to see the FED policy. Not configuring this command will lead to an error.	
	<pre>Device(config)# control-plane Device(config-cp)#service-policy input system-cpp-policy Device(config-cp)#</pre>		
Step 9	end	Returns to the privileged EXEC mode.	
	Example:		
	Device(config-cp)# end		
Step 10	show policy-map control-plane	Displays all the classes configured under system-cpp policy, the rates configured for	
	Example: Device# show policy-map control-plane	the various traffic types, and statistics	

Disabling a CPU Queue

Follow these steps to disable a CPU queue:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	policy-map policy-map-name	Enters the policy map configuration mode.
	Example:	
	Device(config)# policy-map	

	Command or Action	Purpose	
	<pre>system-cpp-policy Device(config-pmap)#</pre>		
Step 4	<pre>class class-name Example: Device(config-pmap)# class system-cpp-police-protocol-snooping Device(config-pmap-c)#</pre>	Enters the class action configuration mode. Enter the name of the class that corresponds to the CPU queue you want to disable. See the table, <i>System-Defined Values for CoPP</i> .	
Step 5	<pre>no police rate rate pps Example: Device(config-pmap-c)# no police rate 100 pps</pre>	Disables incoming packet processing for the specified traffic class.NoteThis disables all CPU queues that belong to the class-map you have specified.	
Step 6	<pre>end Example: Device(config-pmap-c)# end</pre>	Returns to the privileged EXEC mode.	
Step 7	show policy-map control-plane Example: Device# show policy-map control-plane	Displays all the classes configured under system-cpp policy and the rates configured for the various traffic types and statistics.	

Setting the Default Policer Rates for All CPU Queues

Follow these steps to set the policer rates for all CPU queues to their default rates:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	cpp system-default	Sets the policer rates for all the classes to the
	Example:	default rate.

	Command or Action	Purpose		
	Device(config)# cpp system-default Defaulting CPP : Policer rate for all classes will be set to their defaults			
Step 4	end	Returns to the privileged EXEC mode.		
	Example:			
	Device(config)# end			

Configuration Examples for CoPP

Example: Enabling a CPU Queue or Changing the Policer Rate of a CPU Queue

This example shows how to enable a CPU queue or to change the policer rate of a CPU queue. Here the **class system-cpp-police-protocol-snooping** CPU queue is enabled with the policer rate of **2000 pps**.

```
Device> enable
Device# configure terminal
Device(config) # policy-map system-cpp-policy
Device (config-pmap) # class system-cpp-police-protocol-snooping
Device (config-pmap-c) # police rate 2000 pps
Device(config-pmap-c-police)# end
Device# show policy-map control-plane
Control Plane
  Service-policy input: system-cpp-policy
    <output truncated>
    Class-map: system-cpp-police-dot1x-auth (match-any)
      0 packets, 0 bytes
      5 minute offered rate 0000 bps, drop rate 0000 bps
      Match: none
      police:
         rate 1000 pps, burst 244 packets
        conformed 0 bytes; actions:
          transmit
        exceeded 0 bytes; actions:
          drop
    Class-map: system-cpp-police-protocol-snooping (match-any)
      0 packets, 0 bytes
      5 minute offered rate 0000 bps, drop rate 0000 bps
      Match: none
      police:
          rate 2000 pps, burst 488 packets
```

```
conformed 0 bytes; actions:
    transmit
    exceeded 0 bytes; actions:
    drop
<output truncated>
Class-map: class-default (match-any)
 0 packets, 0 bytes
 5 minute offered rate 0000 bps, drop rate 0000 bps
 Match: any
```

Example: Disabling a CPU Queue

This example shows how to disable a CPU queue. Here the **class** system-cpp-police-protocol-snooping CPU queue is disabled.

```
Device> enable
Device# configure terminal
Device(config) # policy-map system-cpp-policy
Device(config-pmap)# class system-cpp-police-protocol-snooping
Device (config-pmap-c) # no police rate 100 pps
Device(config-pmap-c) # end
Device# show running-config | begin system-cpp-policy
policy-map system-cpp-policy
 class system-cpp-police-data
 police rate 200 pps
class system-cpp-police-sys-data
 police rate 100 pps
class system-cpp-police-sw-forward
 police rate 1000 pps
 class system-cpp-police-multicast
 police rate 500 pps
class system-cpp-police-multicast-end-station
 police rate 2000 pps
 class system-cpp-police-punt-webauth
 class system-cpp-police-12-control
class system-cpp-police-routing-control
 police rate 500 pps
 class system-cpp-police-control-low-priority
 class system-cpp-police-wireless-priority1
 class system-cpp-police-wireless-priority2
 class system-cpp-police-wireless-priority3-4-5
class system-cpp-police-topology-control
class system-cpp-police-dot1x-auth
class system-cpp-police-protocol-snooping
class system-cpp-police-forus
 class system-cpp-default
```

```
<output truncated>
```

Example: Setting the Default Policer Rates for All CPU Queues

This example shows how to set the policer rates for all CPU queues to their default and then verify the setting.

Device> enable
Device# configure terminal
Device(config)# cpp system-default
Defaulting CPP : Policer rate for all classes will be set to their defaults
Device(config)# end

Device# show platform hardware fed switch 1 gos queue stats internal cpu policer

Monitoring CoPP

Use these commands to display policer settings, such as, traffic types and policer rates (user-configured and default rates) for CPU queues:

Command	Purpose
show policy-map control-plane	Displays the rates configured for the various traffic types
show policy-map system-cpp-policy	Displays all the classes configured under system-cpp policy, and policer rates

Feature History for CoPP

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.10.1	Control Plane Policing (CoPP) or CPP	The CoPP feature improves security on your device by protecting the CPU from unnecessary traffic, or DoS traffic, and by prioritizing control plane and management traffic.
		The feature provides CLI configuration options to enable and disable CPU queues, to change the policer rate, and set policer rates to default.
Cisco IOS XE Cupertino 17.7.1	Control Plane Policing (CoPP) or CPP	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to https://cfnng.cisco.com.

Configuring Lawful Intercept

- Prerequisites for Lawful Intercept, on page 685
- Restrictions for Lawful Intercept, on page 685
- Information About Lawful Intercept, on page 686
- How to Configure Lawful Intercept, on page 693
- Configuration Examples for Lawful Intercept, on page 696
- Feature History for Lawful Intercept, on page 697

Prerequisites for Lawful Intercept

- You must be running images that support secure shell (SSH). Lawful intercept is not supported on images that do not support SSH.
- The switch you are logged into must have the highest access level (L15). To log in with L15 access, enter the **enable** command and specify the highest-level password defined for the switch.
- The time of day on the switch and the mediation device (supplied by a third-party vendor) connected to the network must be must be synchronized; also, configure Network Time Protocol (NTP) on both the switch and the mediation device.
- (Optional) It might be helpful to use a loopback interface for the switch to communicate with the mediation device. If you do not use a loopback interface, you must configure the mediation device with multiple physical interfaces on the switch to handle network failures.

Restrictions for Lawful Intercept

- Intercept or tap can be configured using only SNMP. Also, configuring interface-specific intercept is not allowed.
- The CISCO-IP-TAP-MIB does not support the virtual routing and forwarding (VRF) OID citapStreamVRF.
- IPv4 multicast, IPv6 unicast, and IPv6 multicast flows are not supported. Only IPv4 unicast traffic is supported.
- Lawful Intercept is not supported on Layer 2 interfaces. However, lawful intercept can intercept traffic on VLANs that run over a Layer 2 interface.

- Lawful Intercept is not supported in packets that are encapsulated within other packets, for example, tunneled packets or Q-in-Q packets.
- Lawful Intercept is not supported for Layer 2 taps.
- Lawful Intercept is not supported in packets that are subject to Layer 3 or Layer 4 rewrite, for example, Network Address Translation (NAT) or TCP reflexive.

Information About Lawful Intercept

Overview of Lawful Intercept

Lawful intercept is a process that enables a law enforcement agency to perform electronic surveillance on an individual (a target) as authorized by a judicial (court) or administrative order. To facilitate the lawful intercept process, certain legislation and regulations require service providers and Internet Service Providers (ISPs) to implement their networks to explicitly support authorized electronic surveillance.

Surveillance is performed through the use of wiretaps on traditional telecommunications and internet services in voice, data, and multiservice networks. The law enforcement agencies deliver a request for a wiretap to the target's service provider who is responsible for intercepting data communication to and from the individual. The service provider uses the target's IP address to determine which of its edge devices handles the target's traffic (data communication). The service provider then intercepts the target's traffic as it passes through the device, and sends a copy of the intercepted traffic to the LEA without the target's knowledge.

The Lawful Intercept feature supports the Communications Assistance for Law Enforcement Act (CALEA), which describes how service providers in the United States must support lawful intercept. Currently, lawful intercept is defined by the following standards:

- Telephone Industry Association (TIA) specification J-STD-025
- Packet Cable Electronic Surveillance Specification (PKT-SP-ESP-101-991229)

For information about the Cisco lawful intercept solution, contact your Cisco account representative.

Note The Lawful Intercept feature supports the interception of IPv4 protocol as defined by the citapStreamprotocol object in the CISCO-IP-TAB-MIB that includes voice and date interception.

Benefits of Lawful Intercept

- Allows multiple LEAs to run a lawful intercept on the same target without each other's knowledge.
- Does not affect subscriber services on the device.
- Supports wiretaps in both the input and output direction.
- Supports wiretaps of Layer 1 and Layer 3 traffic. Layer 2 traffic is supported as IP traffic over VLANs.
- Supports Layer 3 physical interfaces or Switch Virtual Interfaces (SVI).
- Supports wiretaps of individual subscribers that share a single physical interface.

- Cannot be detected by the target. Neither the network administrator nor the calling party is aware that packets are being copied or that the call is being tapped.
- Uses Simple Network Management Protocol Version 3 (SNMPv3) and security features such as the View-based Access Control Model (SNMP-VACM-MIB) and the User-based Security Model (SNMP-USM-MIB) to restrict access to lawful intercept information and components.
- Hides information about lawful intercepts from all but the most privileged users. An administrator must set up access rights to enable privileged users to access lawful intercept information.
- Provides two secure interfaces for performing an intercept; one for setting up the wiretap and one for sending the intercepted traffic to the LEA.

CALEA for Voice

The Communications Assistance for Law Enforcement Act (CALEA) for Voice feature allows the lawful interception of voice conversations that are running on VoIP. Although the devices are not voice gateway devices, VoIP packets traverse the devices at the edge of the service provider network.

When an approved government agency determines that a telephone conversation is interesting, CALEA for Voice copies the IP packets comprising the conversation and sends the duplicate packets to the appropriate monitoring device for further analysis.

Configuration Guidelines

- To deploy Lawful Intercept at a node, do not configure optimized ACL logging, VLAN access control list (VACL) capture, or Intrusion Detection System (IDS) at the node. Deploying lawful intercept at the node causes unpredictable behavior in optimized ACL logging, VACL capture, and IDS.
- When provisioning the mediation device, if the interface index passed is zero, the switch selects the best possible interface to reach the mediation device. If the interface index is set to another value, the switch uses that interface index to reach the mediation device.
- (Optional) The domain name for both the device and the mediation device can be registered in the Domain Name System (DNS).
- · The mediation device must have an access function.
- You must add the mediation device to the SNMP user group that has access to the CISCO-TAP2-MIB view. Specify the username of the mediation device as the user to add to the group.
- When you add the mediation device as a CISCO-TAP2-MIB user, you must also include the mediation device's authorization password.
- The device intercepts and replicates packets even if the packets are later dropped, for example, due to rate limiting or an access control list (ACL) deny statement.
- Lawful intercept ACLs are applied internally to both the ingress and the egress directions of an interface.
- Packets that are subject to hardware rate limiting are processed by lawful intercept as follows:
 - Packets that are dropped by the rate limiter are not intercepted or processed.
 - Packets that are passed by the rate limiter are intercepted and processed.

- If multiple law enforcement agencies use a single mediation device and each of these agencies is executing a wiretap on the same target, the device sends a single packet to the mediation device. It is up to the mediation device to duplicate the packet for each law enforcement agency.
- Lawful intercept can intercept IPv4 packets with values that match a combination of one or more of the following fields:
 - · Destination IP address and mask
 - Destination port range
 - · Source IP address and mask
 - · Source port range
 - · Protocol ID

Network Components Used for Lawful Intercept

This section describes the network components used for lawful intercept.

Mediation Device

A mediation device (supplied by a third-party vendor) handles most of the processing for lawful intercept. The mediation device:

- Provides the interface used to set up and provision the lawful intercept.
- · Generates requests to other network devices to set up and run the lawful intercept.
- Converts the intercepted traffic into the format required by the LEA (which can vary from country to country) and sends a copy of the intercepted traffic to the LEA without the target's knowledge.

Note

If multiple LEAs are performing intercepts on the same target, the mediation device must make a copy of the intercepted traffic for each LEA. The mediation device is also responsible for restarting the lawful intercepts that are disrupted due to a failure.

Lawful Intercept Administration

Lawful intercept administration (LIA) provides the authentication interface for lawful intercept or wiretap requests and administration.

Intercept Access Point

An intercept access point (IAP) is a device that provides information to lawful intercept. There are two types of IAPs:

• Identification (ID) IAP—A device, such as an authentication, authorization, and accounting (AAA) server that provides intercept-related information (IRI) for the intercept (for example, the target's username and system IP address) or call agents for VoIP. The IRI helps a service provider determine which content IAP (switch) the target's traffic passes through.

- Content IAP—A device that the target's traffic passes through. The content IAP:
 - Intercepts traffic to and from the target for the length of time specified in the court order. The device continues to forward traffic to its destination to ensure that the wiretap is undetected.
 - Creates a copy of the intercepted traffic, encapsulates it in User Datagram Protocol (UDP) packets, and forwards the packets to the mediation device without the target's knowledge. Note that the IP option header is not supported.

```
Note
```

If multiple LEAs are performing intercepts on the same target, the mediation device must make a copy of the intercepted traffic for each LEA.

Content Intercept Access Point

Content IAP intercepts the interested data stream, duplicates the content, and sends the duplicated content to the mediation device. The mediation device receives the data from the ID IAP and content IAP, converts the information to the required format depending on country-specific requirements and forwards it to the law enforcement agency.

Lawful Intercept Processing

After acquiring a court order or warrant to perform surveillance, the LEA delivers a surveillance request to the target's service provider. Service provider personnel use an administration function that runs on the mediation device to configure a lawful intercept to monitor the target's electronic traffic for a specific period of time (as defined in the court order).

After the intercept is configured, user intervention is no longer required. The administration function communicates with other network devices to set up and execute the lawful intercept. The following sequence of events occurs during a lawful intercept:

- 1. The administration function contacts the ID IAP for intercept-related information (IRI), such as the target's username and the IP address of the system, to determine which content IAP (switch) the target's traffic passes through.
- 2. After identifying the device that handles the target's traffic, the administration function sends SNMPv3 get and set requests to the device's Management Information Base (MIB) to set up and activate the lawful intercept. The CISCO-TAP2-MIB is the supported lawful intercept MIB to provide per-subscriber intercepts.
- 3. During lawful intercept, the device:
 - **a.** Examines incoming and outgoing traffic and intercepts any traffic that matches the specifications of the lawful intercept request.
 - **b.** Creates a copy of the intercepted traffic and forwards the original traffic to its destination so that the target does not suspect anything.
 - c. Encapsulates the intercepted traffic in UDP packets, and forwards the packets to the mediation device without the target's knowledge.

Lawful Intercept MIBs

- CISCO-TAP2-MIB: Used for lawful intercept processing.
- CISCO-IP-TAP-MIB: Used for intercepting Layer 3 (IPv4) traffic.

Due to its sensitive nature, the Cisco lawful intercept MIBs are only available in software images that support the Lawful Intercept feature. To access the Cisco IOS MIB Locator page, go to:

http://mibs.cloudapps.cisco.com/ITDIT/MIBS/servlet/index.

CISCO-TAP2-MIB

The CISCO-TAP2-MIB contains SNMP management objects that control lawful intercepts. The mediation device uses the MIB to configure and run lawful intercepts on targets whose traffic passes through the device.

The CISCO-TAP2-MIB contains several tables that provide information for lawful intercepts that are running on the device:

- cTap2MediationTable: Contains information about each mediation device that is currently running lawful
 intercept on the device. Each table entry provides information that the device uses to communicate with
 the mediation device, for example, the device's address, the interfaces to send intercepted traffic over,
 and the protocol to use to transmit the intercepted traffic.
- cTap2StreamTable: Contains information used to identify the traffic to intercept. Each table entry contains a pointer to a filter that is used to identify the traffic stream associated with the target of a lawful intercept. Traffic that matches the filter is intercepted, copied, and sent to the corresponding mediation device application (cTap2MediationContentId).

The cTap2StreamTable table also contains counts of the number of packets that were intercepted, and counts of dropped packets that should have been intercepted, but were not.

• cTap2DebugTable: Contains debug information for troubleshooting lawful intercept errors.

The CISCO-TAP2-MIB also contains several SNMP notifications for lawful intercept events. For detailed descriptions of MIB objects, see corresponding MIBs.

CISCO-TAP2-MIB Processing

The administration function (running on the mediation device) issues SNMPv3 set and get requests to the device's CISCO-TAP2-MIB to set up and initiate a lawful intercept. To do this, the administration function performs the following actions:

1. Creates a cTap2MediationTable entry to define how the device is to communicate with the mediation device executing the intercept.

Note The cTap2MediationNewIndex object provides a unique index for the mediation table entry.

- **2.** Creates an entry in the cTap2StreamTable to identify the traffic stream to intercept.
- 3. Sets cTap2StreamInterceptEnable to true(1) to start the intercept. The device intercepts traffic in the stream until the intercept expires (cTap2MediationTimeout).

CISCO-IP-TAP-MIB

The CISCO-IP-TAP-MIB contains the SNMP management objects to configure and execute lawful intercepts on IPv4 traffic streams that flow through the device. This MIB is an extension of the CISCO-TAP2-MIB.

You can use the CISCO-IP-TAP-MIB to configure lawful intercept on a device to intercept IPv4 packets with values that match a combination of one or more of the following fields:

- Destination IP address and mask
- Destination port range
- Source IP address and mask
- Source port range
- Protocol ID

CISCO-IP-TAP-MIB Processing

When data is intercepted, two streams are created. One stream is for packets that originate from the target IP address to any other IP address using any port. The second stream is created for packets that are routed to the target IP address from any other address using any port. For VoIP, two streams are created, one for RTP packets from the target and the second stream for the RTP packets to target using the specific source and destination IP addresses and ports specified in the SDP information used to set up the RTP stream.

MIB Guidelines

The following Cisco MIBs are used for lawful intercept processing. Include these MIBs in the SNMP view of lawful intercept MIBs to enable the mediation device to configure and execute wiretaps on traffic that flows through the device.

- CISCO-TAP2-MIB: Required for both types of lawful intercepts: regular and broadband.
- CISCO-IP-TAP-MIB: Required for wiretaps on Layer 3 (IPv4) streams. Supported for regular and broadband lawful intercept.

- The CISCO-IP-TAB-MIB imposes limitations on the following features:
 - If one or all of the following features are configured and functioning and lawful intercept is enabled, lawful intercept takes precedence, and the feature behaves as follows:
 - Optimized ACL logging (OAL): Does not function.
 - VLAN access control list (VACL) capturing: Does not function properly.
 - Intrusion detection system (IDS): Does not function properly.

These features start to function after you disable or unconfigure lawful intercept.

• IDS cannot capture traffic on its own, but captures traffic that has been intercepted by lawful intercept.

Security Considerations

- SNMP notifications for lawful intercept must be sent to UDP port 161 on the mediation device, not port 162 (which is the SNMP default).
- The only users who should be allowed to access the lawful intercept MIBs are the mediation device and system administrators who need to know about lawful intercepts on the device. In addition, these users must have authPriv or authNoPriv access rights to access the lawful intercept MIBs. Users with NoAuthNoPriv access cannot access the lawful intercept MIBs.
- You cannot use the SNMP-VACM-MIB to create a view that includes the lawful intercept MIBs.
- The default SNMP view excludes the following MIBs:
 - CISCO-TAP2-MIB
 - CISCO-IP-TAP-MIB
 - SNMP-COMMUNITY-MIB
 - SNMP-USM-MIB
 - SNMP-VACM-MIB

We recommend that you also see the information provided in #unique_949 and Prerequisites for Lawful Intercept, on page 685.

Restricting Access to the Lawful Intercept MIBs

Only the mediation device and users who need to know about lawful intercepts should be allowed to access the lawful intercept MIBs. To restrict access to these MIBs, you must:

- 1. Create a view that includes the Cisco lawful intercept MIBs.
- Create an SNMP user group that has read-and-write access to the view. Only users assigned to this user group can access information in the MIBs.
- **3.** Add users to the Cisco lawful intercept user groups to define who can access the MIBs along with information, if any, related to lawful intercepts. Be sure to add the mediation device as a user in this group; otherwise, the device cannot perform lawful intercepts.

Note

Access to the Cisco lawful intercept MIB view should be restricted to the mediation device and to system administrators who need to be aware of lawful intercepts on the device. To access the MIB, users must have level-15 access rights on the device.

How to Configure Lawful Intercept

Creating a Restricted SNMP View of Lawful Intercept MIBs

To create and assign users to an SNMP view that includes the Cisco lawful intercept MIBs, perform the steps provided in this section.

Before you begin

• SNMPv3 must be configured on the device.

Note

Issue the commands in global configuration mode with level-15 access rights.

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode. Enter your
	Example:	password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	snmp-server view view-name MIB-name	Creates an SNMP view that includes the
		CISCO-TAP2-MIB, where <i>exampleView</i> is the name of the view to create for the MIB.
	Example:	This MIB is required for both regular and
	Device(config)# snmp-server view exampleView ciscoTap2MIB included	broadband lawful intercept.
Step 4	snmp-server view view-name MIB-name included	Adds the CISCO-IP-TAP-MIB to the SNMP view.
	Example:	

	Command or Action	Purpose
	Device(config)# snmp-server view exampleView ciscoIpTapMIB included	
Step 5	snmp-server view view-name MIB-name included	Adds the CISCO-802-TAP-MIB to the SNMP view.
	Example:	
	Device(config)# snmp-server view exampleView cisco802TapMIB included	
Step 6	snmp-server view view-name MIB-name included	Adds the CISCO-USER-CONNECTION-TAP-MIB to
	Example:	the SNMP view.
	Device(config)# snmp-server view exampleView ciscoUserConnectionTapMIB included	
Step 7	snmp-server view view-name MIB-name included	Adds the CISCO-MOBILITY-TAP-MIB to the SNMP view.
	Example:	
	Device(config)# snmp-server view exampleView ciscoMobilityTapMIB included	
Step 8	snmp-server group group-name v3 auth read view-name write view-name	Creates an SNMP user group that has access to the LI MIB view and defines the group's
	Example:	access rights to the view.
	Device(config)# snmp-server group exampleGroup v3 auth read exampleView write exampleView	
Step 9	snmp-server user user-name group-name v3 auth md5 auth-password	Adds users to the specified user group.
	Example:	
	Device(config)# snmp-server user exampleUser exampleGroup v3 auth md5 examplePassword	
Step 10	end	Exits global configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config)# end	

Enabling SNMP Notifications for Lawful Intercept

SNMP automatically generates notifications for lawful intercept events. To configure the device to send lawful intercept notifications to the mediation device, perform the steps in this section.

Before you begin

• SNMPv3 must be configured on the device..

Note

e Issue the commands in global configuration mode with level-15 access rights.

Procedure

	Command or Action	Purpose	
Step 1	enable	Enables privileged EXEC mode.	
	Example:	• Enter your password if prompted.	
	Device> enable		
Step 2	configure terminal	Enters global configuration mode.	
	Example:		
	Device# configure terminal		
Step 3	snmp-server host ip-address community-string udp-port port notification-type	Specifies the IP address of the mediation device and the password-like community-string that is sent with a notification request.	
	Example:	• For lawful intercept, the udp-port must be 161 and not 162 (the SNMP default).	
	Device(config)# snmp-server host 10.2.2.1 community-string udp-port 161 udp		
Step 4	snmp-server enable traps snmp authentication linkup linkdown coldstart	Configures the device to send RFC 1157 notifications to the mediation device.	
	warmstart	• These notifications indicate authentication	
	Example:	failures, link status (up or down), and device restarts.	
	Device(config) # snmp-server enable traps snmp authentication linkup linkdown coldstart warmstart		
Step 5	end	Exits global configuration mode and returns to	
	Example:	privileged EXEC mode.	
	Device(config)# end		

Disabling SNMP Notifications

To disable SNMP notifications on the device, perform the steps provided in this section.

To disable lawful intercept notifications, use SNMPv3 to set the CISCO-TAP2-MIB object cTap2MediationNotificationEnable to false(2). To re-enable lawful intercept notifications through SNMPv3, reset the object to true(1).

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode. Enter your password if prompted.
	Example:	password if prohipted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	no snmp-server enable traps	Disables all SNMP notification types that are
	Example:	available on your system.
	Device(config)# no snmp-server enable traps	
Step 4	end	Exits global configuration mode and returns to
	Example:	privileged EXEC mode.
	Device(config)# end	

Configuration Examples for Lawful Intercept

Example: Enabling Mediation Device Access Lawful Intercept MIBs

The following example shows how to enable the mediation device to access the lawful intercept MIBs. It creates an SNMP view (tapV) that includes three LI MIBs (CISCO-TAP2-MIB, CISCO-IP-TAP-MIB, CISCO-802-TAP-MIB). It also creates a user group that has read, write, and notify access to MIBs in the tapV view.

```
Device> enable
Device# configure terminal
Device(config)# snmp-server view tapV ciscoTap2MIB included
Device(config)# snmp-server view tapV ciscoIpTapMIB included
```

L

```
Device(config)# snmp-server view tapV cisco802TapMIB included
Device(config)# snmp-server group tapGrp v3 auth read tapV write tapV notify tapV
Device(config)# snmp-server user MDuser tapGrp v3 auth md5 MDpasswd
Device(config)# snmp-server engineID local 1234
Device(config)# end
```

Feature History for Lawful Intercept

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.11.1	Lawful Intercept	The Lawful Intercept feature supports service providers in meeting the requirements of law enforcement agencies to provide electronic surveillance as authorized by a judicial or administrative order.

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

Configuring Authorization and Revocation of Certificates in a PKI

• Configuring Authorization and Revocation of Certificates in a PKI, on page 699

Configuring Authorization and Revocation of Certificates in a PKI

This module describes the authorization and revocation of certificates in a public key infrastructure (PKI).

Prerequisites for Authorization and Revocation of Certificates

Plan Your PKI Strategy

Tip It is strongly recommended that you plan your entire PKI strategy before you begin to deploy actual certificates.

Authorization and revocation can occur only after you or a network administrator have completed the following tasks:

- Configured the certificate authority (CA).
- Enrolled peer devices with the CA.
- Identified and configured the protocol (such as IPsec or secure socket layer [SSL]) that is to be used for peer-to-peer communication.

You should decide which authorization and revocation strategy you are going to configure before enrolling peer devices because the peer device certificates might have to contain authorization and revocation-specific information.

High Availability

For high availability, IPsec-secured Stream Control Transmission Protocol (SCTP) must be configured on both the active and the standby devices. For synchronization to work, the redundancy mode on the certificate servers must be set to ACTIVE/STANDBY after you configure SCTP.

Restrictions for Authorization and Revocation of Certificates

• Depending on your Cisco IOS XE release, Lightweight Directory Access Protocol (LDAP) is supported.

Information About Authorization and Revocation of Certificates

PKI Authorization

PKI authentication does not provide authorization. Current solutions for authorization are specific to the router that is being configured, although a centrally managed solution is often required.

There is not a standard mechanism by which certificates are defined as authorized for some tasks and not for others. This authorization information can be captured in the certificate itself if the application is aware of the certificate-based authorization information. But this solution does not provide a simple mechanism for real-time updates to the authorization information and forces each application to be aware of the specific authorization information embedded in the certificate.

When the certificate-based access control list (ACL) mechanism is configured as part of the trustpoint authentication, the application is no longer responsible for determining this authorization information, and it is no longer possible to specify for which application the certificate is authorized. In some cases, the certificate-based ACL on the router gets so large that it cannot be managed. Additionally, it is beneficial to retrieve certificate-based ACL indications from an external server.

Current solutions to the real-time authorization problem involve specifying a new protocol and building a new server (with associated tasks, such as management and data distribution).

PKI and AAA Server Integration for Certificate Status

Integrating your PKI with an authentication, authorization, and accounting (AAA) server provides an alternative online certificate status solution that leverages the existing AAA infrastructure. Certificates can be listed in the AAA database with appropriate levels of authorization. For components that do not explicitly support PKI-AAA, a default label of "all" from the AAA server provides authorization. Likewise, a label of "none" from the AAA database indicates that the specified certificate is not valid. (The absence of any application label is equivalent, but "none" is included for completeness and clarity). If the application component does support PKI-AAA, the component may be specified directly; for example, the application component could be "ipsec," "ssl," or "osp." (ipsec=IP Security, ssl=Secure Sockets Layer, and osp=Open Settlement Protocol.)

Note Currently, no application component supports specification of the application label.

• There may be a time delay when accessing the AAA server. If the AAA server is not available, the authorization fails.

RADIUS or TACACS+ Choosing a AAA Server Protocol

The AAA server can be configured to work with either the RADIUS or TACACS+ protocol. When you are configuring the AAA server for the PKI integration, you must set the RADIUS or TACACS attributes that are required for authorization.

If the RADIUS protocol is used, the password that is configured for the username in the AAA server should be set to "cisco," which is acceptable because the certificate validation provides authentication and the AAA database is only being used for authorization. When the TACACS protocol is used, the password that is configured for the username in the AAA server is irrelevant because TACACS supports authorization without requiring authentication (the password is used for authentication).

In addition, if you are using TACACS, you must add a PKI service to the AAA server. The custom attribute "cert-application=all" is added under the PKI service for the particular user or usergroup to authorize the specific username.

Attribute-Value Pairs for PKI and AAA Server Integration

The table below lists the attribute-value (AV) pairs that are to be used when setting up PKI integration with a AAA server. (Note the values shown in the table are possible values.) The AV pairs must match the client configuration. If they do not match, the peer certificate is not authorized.

Note

Users can sometimes have AV pairs that are different from those of every other user. As a result, a unique username is required for each user. The **all** parameter (within the **authorization username** command) specifies that the entire subject name of the certificate will be used as the authorization username.

AV Pair	Value	
cisco-avpair=pki:cert-application=all	Valid value	es are "all" and "none."
cisco-avpair=pki:cert-trustpoint=msca	The value is a Cisco IOS XE command-line interfac (CLI) configuration trustpoint label.	
	Note	The cert-trustpoint AV pair is normally optional. If it is specified, the device query must be coming from a certificate trustpoint that has a matching label, and the certificate that is authenticated must have the specified certificate serial number.
cisco-avpair=pki:cert-serial=16318DB7000100001671	The value i	s a certificate serial number.
	Note	The cert-serial AV pair is normally optional. If it is specified, the Cisco device query must be coming from a certificate trustpoint that has a matching label, and the certificate that is authenticated must have the specified certificate serial number.

Table 43: AV Pairs That Must Match

AV Pair	Value
cisco-avpair=pki:cert-lifetime-end=1:00 jan 1, 2003	 The cert-lifetime-end AV pair is available to artificially extend a certificate lifetime beyond the time period that is indicated in the certificate itself. If the cert-lifetime-end AV pair is used, the cert-trustpoint and cert-serial AV pairs must also be specified. The value must match the following form: hours:minutes month day, year. Note Only the first three characters of a month are used: Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, Dec. If more than three characters are entered for the month, the remaining characters are ignored (for example Janxxxx).

CRLs or OCSP Server Choosing a Certificate Revocation Mechanism

After a certificate is validated as a properly signed certificate, a certificate revocation method is performed to ensure that the certificate has not been revoked by the issuing CA. Cisco IOS XE software supports two revocation mechanisms--certificate revocation lists (CRLs) and Online Certificate Status Protocol (OCSP). Cisco IOS XE software also supports AAA integration for certificate checking; however, additional authorization functionality is included. For more information on PKI and AAA certificate authorization and status check, see the PKI and AAA Server Integration for Certificate Status section.

The following sections explain how each revocation mechanism works:

What Is a CRL

A certificate revocation list (CRL) is a list of revoked certificates. The CRL is created and digitally signed by the CA that originally issued the certificates. The CRL contains dates for when each certificate was issued and when it expires.

CAs publish new CRLs periodically or when a certificate for which the CA is responsible has been revoked. By default, a new CRL is downloaded after the currently cached CRL expires. An administrator may also configure the duration for which CRLs are cached in router memory or disable CRL caching completely. The CRL caching configuration applies to all CRLs associated with a trustpoint.

When the CRL expires, the router deletes it from its cache. A new CRL is downloaded when a certificate is presented for verification; however, if a newer version of the CRL that lists the certificate under examination is on the server but the router is still using the CRL in its cache, the router does not know that the certificate has been revoked. The certificate passes the revocation check even though it should have been denied.

When a CA issues a certificate, the CA can include in the certificate the CRL distribution point (CDP) for that certificate. Cisco IOS client devices use CDPs to locate and load the correct CRL. The Cisco IOS client supports multiple CDPs, but the Cisco IOS CA currently supports only one CDP; however, third-party vendor CAs may support multiple CDPs or different CDPs per certificate. If a CDP is not specified in the certificate, the client device uses the default Simple Certificate Enrollment Protocol (SCEP) method to retrieve the CRL. (The CDP location can be specified through the **cdp-url**command.)

When implementing CRLs, you should consider the following design considerations:

- CRL lifetimes and the security association (SA) and Internet Key Exchange (IKE) lifetimes.
- The CRL lifetime determines the length of time between CA-issued updates to the CRL. The default CRL lifetime value, which is 168 hours [1 week], can be changed through the **lifetime crl** command.
- The method of the CDP determines how the CRL is retrieved; some possible choices include HTTP, Lightweight Directory Access Protocol (LDAP), SCEP, or TFTP. HTTP, TFTP, and LDAP are the most commonly used methods. Although Cisco IOS software defaults to SCEP, an HTTP CDP is recommended for large installations using CRLs because HTTP can be made highly scalable.
- The location of the CDP determines from where the CRL is retrieved; for example, you can specify the server and file path from which to retrieve the CRL.

Querying All CDPs During Revocation Check

When a CDP server does not respond to a request, the Cisco IOS XE software reports an error, which may result in the peer's certificate being rejected. To prevent a possible certificate rejection and if there are multiple CDPs in a certificate, the Cisco IOS XE software will attempt to use the CDPs in the order in which they appear in the certificate. The device will attempt to retrieve a CRL using each CDP URL or directory specification. If an error occurs using a CDP, an attempt will be made using the next CDP.

ρ

Tip Although the Cisco IOS XE software will make every attempt to obtain the CRL from one of the indicated CDPs, it is recommended that you use an HTTP CDP server with high-speed redundant HTTP servers to avoid application timeouts because of slow CDP responses.

What Is OCSP

OCSP is an online mechanism that is used to determine certificate validity and provides the following flexibility as a revocation mechanism:

- OCSP can provide real-time certificate status checking.
- OCSP allows the network administrator to specify a central OCSP server, which can service all devices within a network.
- OCSP also allows the network administrator the flexibility to specify multiple OCSP servers, either per client certificate or per group of client certificates.
- OCSP server validation is usually based on the root CA certificate or a valid subordinate CA certificate, but may also be configured so that external CA certificates or self-signed certificates may be used. Using external CA certificates or self-signed certificates allows the OCSP servers certificate to be issued and validated from an alternative PKI hierarchy.

A network administrator can configure an OCSP server to collect and update CRLs from different CA servers. The devices within the network can rely on the OCSP server to check the certificate status without retrieving and caching each CRL for every peer. When peers have to check the revocation status of a certificate, they send a query to the OCSP server that includes the serial number of the certificate in question and an optional unique identifier for the OCSP request, or a nonce. The OCSP server holds a copy of the CRL to determine if the CA has listed the certificate as being revoked; the server then responds to the peer including the nonce. If the nonce in the response from the OCSP server does not match the original nonce sent by the peer, the response is considered invalid and certificate verification fails. The dialog between the OCSP server and the peer consumes less bandwidth than most CRL downloads.

If the OCSP server is using a CRL, CRL time limitations will be applicable; that is, a CRL that is still valid might be used by the OCSP server although a new CRL has been issued by the CRL containing additional certificate revocation information. Because fewer devices are downloading the CRL information on a regular basis, you can decrease the CRL lifetime value or configure the OCSP server not to cache the CRL. For more information, check your OCSP server documentation.

N.

Note OCSP multiple response handling: Support has been enabled for handling of multiple OCSP single

responses from an OCSP responder in a response packet. In addition to the debug log messages the following debug log message will be displayed:

CRYPTO_PKI: Number of single Responses in OCSP response:1(this value can change depending upon the number of responses).

When to Use an OCSP Server

OCSP may be more appropriate than CRLs if your PKI has any of the following characteristics:

- Real-time certificate revocation status is necessary. CRLs are updated only periodically and the latest CRL may not always be cached by the client device. For example, if a client does not yet have the latest CRL cached and a newly revoked certificate is being checked, that revoked certificate will successfully pass the revocation check.
- There are a large number of revoked certificates or multiple CRLs. Caching a large CRL consumes large portions of Cisco IOS memory and may reduce resources available to other processes.
- CRLs expire frequently, causing the CDP to handle a larger load of CRLs.

When to Use Certificate-Based ACLs for Authorization or Revocation

Certificates contain several fields that are used to determine whether a device or user is authorized to perform a specified action.

Because certificate-based ACLs are configured on the device, they do not scale well for large numbers of ACLs; however, certificate-based ACLs do provide very granular control of specific device behavior. Certificate-based ACLs are also leveraged by additional features to help determine when PKI components such as revocation, authorization, or a trustpoint should be used. They provide a general mechanism allowing users to select a specific certificate or a group of certificates that are being validated for either authorization or additional processing.

Certificate-based ACLs specify one or more fields within the certificate and an acceptable value for each specified field. You can specify which fields within a certificate should be checked and which values those fields may or may not have.

There are six logical tests for comparing the field with the value--equal, not equal, contains, does not contain, less than, and greater than or equal. If more than one field is specified within a single certificate-based ACL, the tests of all of the fields within the ACL must succeed to match the ACL. The same field may be specified multiple times within the same ACL. More than one ACL may be specified, and ACL will be processed in turn until a match is found or all of the ACLs have been processed.

Ignore Revocation Checks Using a Certificate-Based ACL

Certificate-based ACLs can be configured to instruct your router to ignore the revocation check and expired certificates of a valid peer. Thus, a certificate that meets the specified criteria can be accepted regardless of the validity period of the certificate, or if the certificate meets the specified criteria, revocation checking does not have to be performed. You can also use a certificate-based ACL to ignore the revocation check when the communication with a AAA server is protected with a certificate.

Ignoring Revocation Lists

To allow a trustpoint to enforce CRLs except for specific certificates, enter the **match certificate**command with the **skip revocation-check** keyword. This type of enforcement is most useful in a hub-and-spoke configuration in which you also want to allow direct spoke-to-spoke connections. In pure hub-and-spoke configurations, all spokes connect only to the hub, so CRL checking is necessary only on the hub. For one spoke to communicate directly with another spoke, the **match certificate**command with the **skip revocation-check** keyword can be used for neighboring peer certificates instead of requiring a CRL on each spoke.

Ignoring Expired Certificates

To configure your router to ignore expired certificates, enter the **match certificate** command with the **allow expired-certificate** keyword. This command has the following purposes:

- If the certificate of a peer has expired, this command may be used to "allow" the expired certificate until the peer can obtain a new certificate.
- If your router clock has not yet been set to the correct time, the certificate of a peer will appear to be not yet valid until the clock is set. This command may be used to allow the certificate of the peer even though your router clock is not set.

- Note
- If Network Time Protocol (NTP) is available only via the IPSec connection (usually via the hub in a hub-and-spoke configuration), the router clock can never be set. The tunnel to the hub cannot be "brought up" because the certificate of the hub is not yet valid.
 - "Expired" is a generic term for a certificate that is expired or that is not yet valid. The certificate has a start and end time. An expired certificate, for purposes of the ACL, is one for which the current time of the router is outside the start and end times specified in the certificate.

Skipping the AAA Check of the Certificate

If the communication with an AAA server is protected with a certificate, and you want to skip the AAA check of the certificate, use the **match certificate** command with the **skip authorization-check** keyword. For example, if a virtual private network (VPN) tunnel is configured so that all AAA traffic goes over that tunnel, and the tunnel is protected with a certificate, you can use the **match certificate** command with the **skip authorization-check** keyword to skip the certificate check so that the tunnel can be established.

The **match certificate**command and the **skip authorization-check** keyword should be configured after PKI integration with an AAA server is configured.

Note

If the AAA server is available only via an IPSec connection, the AAA server cannot be contacted until after the IPSec connection is established. The IPSec connection cannot be "brought up" because the certificate of the AAA server is not yet valid.

PKI Certificate Chain Validation

A certificate chain establishes a sequence of trusted certificates --from a peer certificate to the root CA certificate. Within a PKI hierarchy, all enrolled peers can validate the certificate of one another if the peers share a trusted root CA certificate or a common subordinate CA. Each CA corresponds to a trustpoint.

When a certificate chain is received from a peer, the default processing of a certificate chain path continues until the first trusted certificate, or trustpoint, is reached. An administrator may configure the level to which a certificate chain is processed on all certificates including subordinate CA certificates.

Configuring the level to which a certificate chain is processed allows for the reauthentication of trusted certificates, the extension of a trusted certificate chain, and the completion of a certificate chain that contains a gap.

Reauthentication of Trusted Certificates

The default behavior is for the device to remove any trusted certificates from the certificate chain sent by the peer before the chain is validated. An administrator may configure certificate chain path processing so that the device does not remove CA certificates that are already trusted before chain validation, so that all certificates in the chain are re-authenticated for the current session.

Extending the Trusted Certificate Chain

The default behavior is for the device to use its trusted certificates to extend the certificate chain if there are any missing certificates in the certificate chain sent by the peer. The device will validate only certificates in the chain sent by the peer. An administrator may configure certificate chain path processing so that the certificates in the peer's certificate chain and the device's trusted certificates are validated to a specified point.

Completing Gaps in a Certificate Chain

An administrator may configure certificate chain processing so that if there is a gap in the configured trustpoint hierarchy, certificates sent by the peer can be used to complete the set of certificates to be validated.

Note If the trustpoint is configured to require parent validation and the peer does not provide the full certificate chain, the gap cannot be completed and the certificate chain is rejected and invalid.

Note

It is a configuration error if the trustpoint is configured to require parent validation and there is no parent trustpoint configured. The resulting certificate chain gap cannot be completed and the subordinate CA certificate cannot be validated. The certificate chain is invalid.

How to Configure Authorization and Revocation of Certificates in a PKI

Configuring PKI Integration with a AAA Server

Perform this task to generate a AAA username from the certificate presented by the peer and specify which fields within a certificate should be used to build the AAA database username.

- **Note** The following restrictions should be considered when using the **all** keyword as the subject name for the **authorization username** command:
 - Some AAA servers limit the length of the username (for example, to 64 characters). As a result, the entire certificate subject name cannot be longer than the limitation of the server.
 - Some AAA servers limit the available character set that may be used for the username (for example, a space [] and an equal sign [=] may not be acceptable). You cannot use the **all** keyword for a AAA server having such a character-set limitation.
 - The **subject-name** command in the trustpoint configuration may not always be the final AAA subject name. If the fully qualified domain name (FQDN), serial number, or IP address of the router are included in a certificate request, the subject name field of the issued certificate will also have these components. To turn off the components, use the **fqdn**, **serial-number**, and **ip-address** commands with the **none** keyword.
 - CA servers sometimes change the requested subject name field when they issue a certificate. For example, CA servers of some vendors switch the relative distinguished names (RDNs) in the requested subject names to the following order: CN, OU, O, L, ST, and C. However, another CA server might append the configured LDAP directory root (for example, O=cisco.com) to the end of the requested subject name.
 - Depending on the tools you choose for displaying a certificate, the printed order of the RDNs in the subject name could be different. Cisco IOS software always displays the least significant RDN first, but other software, such as Open Source Secure Socket Layer (OpenSSL), does the opposite. Therefore, if you are configuring a AAA server with a full distinguished name (DN) (subject name) as the corresponding username, ensure that the Cisco IOS software style (that is, with the least significant RDN first) is used.

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password, if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	aaa new-model	Enables the AAA access control model.
	Example:	
	Device(config)# aaa new-model	

	Command or Action	Purpose
Step 4	aaa authorization network listname [method]	Sets the parameters that restrict user access to a network.
	Example: Device(config)# aaa authorization network maxaaa group tacacs+	• <i>method</i> : Can be group radius, group tacacs+, or group group-name.
Step 5	crypto pki trustpoint name Example: Device (config) # crypto pki trustpoint msca	Declares the trustpoint and a given name and enters ca-trustpoint configuration mode.
Step 6	enrollment [mode] [retry period minutes] [retry count number] url url [pem]	Specifies the following enrollment parameters of the CA:
	<pre>Example: Device(ca-trustpoint)# enrollment url http://caserver.myexample.com - OF-</pre>	• (Optional) The mode keyword specifies the registration authority (RA) mode, if your CA system provides an RA. By default, RA mode is disabled.
	Device(ca-trustpoint)# enrollment url http://[2001:DB8:1:1::1]:80	• (Optional) The retry period keyword and <i>minutes</i> argument specifies the period, in minutes, in which the router waits before sending the CA another certificate request. Valid values are from 1 to 60. The default is 1.
		• (Optional) The retry count keyword and <i>number</i> argument specifies the number of times a router will resend a certificate request when it does not receive a response from the previous request. Valid values are from 1 to 100. The default is 10.
		• The <i>url</i> argument is the URL of the CA to which your router should send certificate requests.
		Note An IPv6 address can be added to the http: enrollment method. For example: http://[ipv6-address]:80. The IPv6 address must be enclosed in brackets in the URL.
		• (Optional) The pem keyword adds privacy-enhanced mail (PEM) boundaries to the certificate request.

	Command or Action	Purpose
Step 7	revocation-check method Example: Device(ca-trustpoint)# revocation-check crl	(Optional) Checks the revocation status of a certificate.
Step 8	exit Example: Device(ca-trustpoint)# exit	Exits ca-trustpoint configuration mode and returns to global configuration mode.
Step 9	authorization username subjectname subjectname	Sets parameters for the different certificate fields that are used to build the AAA usernam
	Example:	The <i>subjectname</i> argument can be any of th following:
		• all: Entire distinguished name (subject name) of the certificate.
		• commonname: Certification common name.
		• country: Certificate country.
		• email: Certificate e-mail.
		• ipaddress: Certificate IP address.
		• locality: Certificate locality.
		organization: Certificate organization
		 organizationalunit: Certificate organizational unit.
		• postalcode: Certificate postal code.
		• serialnumber: Certificate serial number
		• state: Certificate state field.
		• streetaddress: Certificate street address
		• title: Certificate title.
		• unstructuredname : Certificate unstructured name.
Step 10	authorization list listname Example:	Specifies the AAA authorization list.
	Device(config)# authorization list maxaaa	

	Command or Action	Purpose
Step 11	tacacs server server-name	Specifies a TACACS+ server.
	Example:	
	Device(config)# tacacs server yourserve	r
Step 12	address {ipv4 ipv6} ip-address	Configures the IP address for the TACACS
	Example:	server.
	Device(config-server-tacacs)# address ipv4 192.0.2.2	
Step 13	key string	Configures the authorization and encryption
	Example:	key used between the switch and the TACACS
	Device(config-server-tacacs)# key a_secret_key	server.
Step 14	end	Returns to privileged EXEC mode.
	Example:	
	Device(config-server-tacacs)# end	
	Example:	

Troubleshooting Tips

To display debug messages for the trace of interaction (message type) between the CA and the router, use the **debug crypto pki transactions**command. (See the sample output, which shows a successful PKI integration with AAA server exchange and a failed PKI integration with AAA server exchange.)

Successful Exchange

Device# debug crypto pki transactions

Apr 22 23:15:03.695: CRYPTO_PKI: Found a issuer match Apr 22 23:15:03.955: CRYPTO_PKI: cert revocation status unknown. Apr 22 23:15:03.955: CRYPTO PKI: Certificate validated without revocation check

Each line that shows "CRYPTO_PKI_AAA" indicates the state of the AAA authorization checks. Each of the AAA AV pairs is indicated, and then the results of the authorization check are shown.

```
Apr 22 23:15:04.019: CRYPTO_PKI_AAA: checking AAA authorization (ipsecca_script_aaalist,
PKIAAA-L, <all>)
Apr 22 23:15:04.503: CRYPTO_PKI_AAA: reply attribute ("cert-application" = "all")
Apr 22 23:15:04.503: CRYPTO_PKI_AAA: reply attribute ("cert-trustpoint" = "CA1")
Apr 22 23:15:04.503: CRYPTO_PKI_AAA: reply attribute ("cert-serial" = "15DE")
Apr 22 23:15:04.503: CRYPTO_PKI_AAA: authorization passed
Apr 22 23:12:30.327: CRYPTO_PKI: Found a issuer match
```

Failed Exchange

Device# debug crypto pki transactions

Apr 22 23:11:13.703: CRYPTO PKI AAA: checking AAA authorization =

Apr 22 23:11:14.203: CRYPTO_PKI_AAA: reply attribute ("cert-application" = "all") Apr 22 23:11:14.203: CRYPTO_PKI_AAA: reply attribute ("cert-trustpoint"= "CA1") Apr 22 23:11:14.203: CRYPTO_PKI_AAA: reply attribute ("cert-serial" = "233D") Apr 22 23:11:14.203: CRYPTO_PKI_AAA: parsed cert-lifetime-end as: 21:30:00 Apr 22 23:11:14.203: CRYPTO_PKI_AAA: timezone specific extended Apr 22 23:11:14.203: CRYPTO_PKI_AAA: cert-lifetime-end is expired Apr 22 23:11:14.203: CRYPTO_PKI_AAA: cert-lifetime-end is expired Apr 22 23:11:14.203: CRYPTO_PKI_AAA: cert-lifetime-end check failed. Apr 22 23:11:14.203: CRYPTO_PKI_AAA: authorization failed

In the above failed exchange, the certificate has expired.

Configuring a Revocation Mechanism for PKI Certificate Status Checking

Perform this task to set up a CRL as the certificate revocation mechanism--CRLs or OCSP--that is used to check the status of certificates in a PKI.

The revocation-check Command

Use the **revocation-check** command to specify at least one method (OCSP, CRL, or skip the revocation check) that is to be used to ensure that the certificate of a peer has not been revoked. For multiple methods, the order in which the methods are applied is determined by the order specified via this command.

If your device does not have the applicable CRL and is unable to obtain one or if the OCSP server returns an error, your device will reject the peer's certificate--unless you include the **none** keyword in your configuration. If the **none** keyword is configured, a revocation check will not be performed and the certificate will always be accepted.

Nonces and Peer Communications with OCSP Servers

When using OCSP, nonces, unique identifiers for OCSP requests, are sent by default during peer communications with your OCSP server. The use of nonces offers a more secure and reliable communication channel between the peer and OCSP server.

If your OCSP server does not support nonces, you may disable the sending of nonces. For more information, see your OCSP server documentation.

Before you begin

- Before issuing any client certificates, the appropriate settings on the server (such as setting the CDP) should be configured.
- When configuring an OCSP server to return the revocation status for a CA server, the OCSP server must be configured with an OCSP response signing certificate that is issued by that CA server. Ensure that the signing certificate is in the correct format, or the router will not accept the OCSP response. See your OCSP manual for additional information.

Note

- OCSP transports messages over HTTP, so there may be a time delay when you access the OCSP server.
- If the OCSP server depends on normal CRL processing to check revocation status, the same time delay
 that affects CRLs will also apply to OCSP.

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	crypto pki trustpoint name	Declares the trustpoint and a given name and
	Example:	enters ca-trustpoint configuration mode.
	Device(config)# crypto pki trustpoint hazel	
Step 4	ocsp url url	The url argument specifies the URL of an OCSP
	Example:	server so that the trustpoint can check the certificate status. This URL overrides the URL
	Device(ca-trustpoint)# ocsp url http://ocsp-server	of the OCSP server (if one exists) in the Authority Info Access (AIA) extension of the
	- or -	certificate. All certificates associated with a configured trustpoint are checked by the OCSP server. The URL can be a hostname, IPv4
	Device(ca-trustpoint)# ocsp url http://10.10.10.1:80	address, or an IPv6 address.
	- or -	
	<pre>Device(ca-trustpoint)# ocsp url http://[2001DB8:1:1::2]:80</pre>	
Step 5	revocation-check <i>method1</i> [<i>method2 method3</i>]]	Checks the revocation status of a certificate.
	Example:	• crl —Certificate checking is performed by a CRL. This is the default option.
	Device(ca-trustpoint)# revocation-check ocsp none	• none —Certificate checking is ignored.
		• ocsp —Certificate checking is performed by an OCSP server.
		If a second and third method are specified, each method will be used only if the previous method returns an error, such as a server being down.
Step 6	ocsp disable-nonce	(Optional) Specifies that a nonce, or an OCSP
	Example:	request unique identifier, will not be sent during peer communications with the OCSP server.
	Device(ca-trustpoint)# ocsp disable-nonce	

	Command or Action	Purpose
Step 7	end Example:	Exits ca-trustpoint configuration mode and returns to privileged EXEC mode.
	Device(ca-trustpoint)# end	
Step 8	show crypto pki certificates Example:	(Optional) Displays information about your certificates.
	Device# show crypto pki certificates	
Step 9	show crypto pki trustpoints [status label [status]]	Displays information about the trustpoint configured in router.
	Example:	
	Device# show crypto pki trustpoints	

Configuring Certificate Authorization and Revocation Settings

Perform this task to specify a certificate-based ACL, to ignore revocation checks or expired certificates, to manually override the default CDP location, to manually override the OCSP server setting, to configure CRL caching, or to set session acceptance or rejection based on a certificate serial number, as appropriate.

Configuring Certificate-Based ACLs to Ignore Revocation Checks

To configure your router to use certificate-based ACLs to ignore revocation checks and expired certificates, perform the following steps:

- Identify an existing trustpoint or create a new trustpoint to be used when verifying the certificate of the peer. Authenticate the trustpoint if it has not already been authenticated. The router may enroll with this trustpoint if you want. Do not set optional CRLs for the trustpoint if you plan to use the **match certificate** command and **skip revocation-check** keyword.
- Determine the unique characteristics of the certificates that should not have their CRL checked and of the expired certificates that should be allowed.
- Define a certificate map to match the characteristics identified in the prior step.
- You can add the **match certificate** command and **skip revocation-check** keyword and the **match certificate command** and **allow expired-certificate** keyword to the trustpoint that was created or identified in the first step.

Note

Certificate maps are checked even if the peer's public key is cached. For example, when the public key is cached by the peer, and a certificate map is added to the trustpoint to ban a certificate, the certificate map is effective. This prevents a client with the banned certificate, which was once connected in the past, from reconnecting.

Manually Overriding CDPs in a Certificate

Users can override the CDPs in a certificate with a manually configured CDP. Manually overriding the CDPs in a certificate can be advantageous when a particular server is unavailable for an extended period of time. The certificate's CDPs can be replaced with a URL or directory specification without reissuing all of the certificates that contain the original CDP.

Manually Overriding the OCSP Server Setting in a Certificate

Administrators can override the OCSP server setting specified in the Authority Information Access (AIA) field of the client certificate or set by the issuing the **ocsp url** command. One or more OCSP servers may be manually specified, either per client certificate or per group of client certificates by the **match certificate override ocsp** command. The **match certificate override ocsp** command overrides the client certificate AIA field or the **ocsp url** command setting if a client certificate is successfully matched to a certificate map during the revocation check.

Note

Only one OCSP server can be specified per client certificate.

Configuring CRL Cache Control

By default, a new CRL will be downloaded after the currently cached CRL expires. Administrators can either configure the maximum amount of time in minutes a CRL remains in the cache by issuing the **crl cache delete-after** command or disable CRL caching by issuing the **crl cache none** command. Only the **crl-cache delete-after** command or the **crl-cache none** command may be specified. If both commands are entered for a trustpoint, the last command executed will take effect and a message will be displayed.

Neither the **crl-cache none** command nor the **crl-cache delete-after** command affects the currently cached CRL. If you configure the **crl-cache none** command, all CRLs downloaded after this command is issued will not be cached. If you configure the **crl-cache delete-after** command, the configured lifetime will only affect CRLs downloaded after this command is issued.

This functionality is useful is when a CA issues CRLs with no expiration date or with expiration dates days or weeks ahead.

Configuring Certificate Serial Number Session Control

A certificate serial number can be specified to allow a certificate validation request to be accepted or rejected by the trustpoint for a session. A session may be rejected, depending on certificate serial number session control, even if a certificate is still valid. Certificate serial number session control may be configured by using either a certificate map with the **serial-number** field or an AAA attribute, with the **cert-serial-not** command.

Using certificate maps for session control allows an administrator to specify a single certificate serial number. Using the AAA attribute allows an administrator to specify one or more certificate serial numbers for session control.

Before you begin

- The trustpoint should be defined and authenticated before attaching certificate maps to the trustpoint.
- The certificate map must be configured before the CDP override feature can be enabled or the **serial-number** command is issued.

• The PKI and AAA server integration must be successfully completed to use AAA attributes as described in "PKI and AAA Server Integration for Certificate Status."

Procedure

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	crypto pki certificate map label sequence-number	Defines values in a certificate that should be matched or not matched and enters
	Example:	ca-certificate-map configuration mode.
	Device(config)# crypto pki certificate map Group 10	
Step 4	field-name match-criteria match-value Example:	Specifies one or more certificate fields together with their matching criteria and the value to match.
	Device(ca-certificate-map)# subject-name co MyExample	The <i>field-name</i> is one of the following case-insensitive name strings or a date:
		• alt-subject-name
		• expires-on
		• issuer-name
		• name
		• serial-number
		• subject-name
		 unstructured-subject-name
		• valid-start
		Note Date field format is dd mm yyyy hh:mm:ss or mmm dd yyyy hh:mm:ss.
		The <i>match-criteria</i> is one of the following logical operators:

	Command or Action	Purpose
		• co —contains (valid only for name fields and serial number field)
		• eq —equal (valid for name, serial number, and date fields)
		• ge —greater than or equal (valid only for date fields)
		• It —less than (valid only for date fields)
		• nc —does not contain (valid only for name fields and serial number field)
		• ne —not equal (valid for name, serial number, and date fields)
		The <i>match-value</i> is the name or date to test with the logical operator assigned by match-criteria.
		Note Use this command only when setting up a certificate-based ACL—not when setting up a certificate-based ACL to ignore revocation checks or expired certificates.
Step 5	exit Example:	Exits ca-certificate-map configuration mode and returns to global configuration mode.
	Device(ca-certificate-map)# exit	
Step 6	crypto pki trustpoint name	Declares the trustpoint, given name and en
	Example:	ca-trustpoint configuration mode.
	Device(config)# crypto pki trustpoint Access2	
Step 7	Do one of the following:	(Optional) Disables CRL caching completely
	• crl-cache none	for all CRLs associated with the trustpoint.
	• crl-cache delete-after time	The crl-cache none command does not affect any currently cached CRLs. All CRLs
	Example:	downloaded after this command is configured will not be cached.
	Device(ca-trustpoint)# crl-cache none Example:	(Optional) Specifies the maximum time CRLs will remain in the cache for all CRLs associated with the trustpoint.
	Device(ca-trustpoint)# crl-cache delete-after 20	• <i>time</i> —The amount of time in minutes before the CRL is deleted.

	Command or Action	Purpose
		The crl-cache delete-after command does not affect any currently cached CRLs. The configured lifetime will only affect CRLs downloaded after this command is configured.
Step 8	<pre>match certificate certificate-map-label [allow expired-certificate skip revocation-check skip authorization-check Example: Device(ca-trustpoint)# match certificate Group skip revocation-check</pre>	 (Optional) Associates the certificate-based ACL (that was defined via the crypto pki certificate map command) to a trustpoint. <i>certificate-map-label</i> —Must match the <i>label</i> argument specified via the crypto pki certificate map command. allowexpired-certificate —Ignores expired certificates. skip revocation-check —Allows a trustpoint to enforce CRLs except for specific certificates. skip authorization-check —Skips the AAA check of a certificate when PKI integration with an AAA server is configured.
Step 9	<pre>match certificate certificate-map-label override cdp {url directory} string Example: Device(ca-trustpoint) # match certificate Groupl override cdp url http://server.cisco.com</pre>	 (Optional) Manually overrides the existing CDP entries for a certificate with a URL or directory specification. <i>certificate-map-label</i> —A user-specified label that must match the <i>label</i> argument specified in a previously defined crypto pki certificate map command. url —Specifies that the certificate's CDPs will be overridden with an HTTP or LDAP URL. directory —Specifies that the certificate's CDPs will be overridden with an LDAP directory specification. <i>string</i> —The URL or directory specification. string and will report an error message. The error message will not affect the router, and the Cisco IOS software will continue attempting to retrieve a CRL until all CDPs have been tried.

I

	Command or Action	Purpose
Step 10	<pre>Command or Action match certificate certificate-map-label override ocsp [trustpoint trustpoint-label] sequence-number url ocsp-url Example: Device(ca-trustpoint) # match certificate mycertmapname override ocsp trustpoint mytp 15 url http://192.0.2.2</pre>	(Optional) Specifies an OCSP server, either per client certificate or per group of client certificates, and may be issued more than once to specify additional OCSP servers and client certificate settings including alternative PKI hierarchies.
		continue to apply to the client certificates.
Step 11	exit	Exits Returns to global configuration mode.
	Example:	
	Device(ca-trustpoint)# exit	
Step 12	aaa new-model	(Optional) Enables the AAA access control
	Example:	model.

	Command or Action	Purpose
	Device(config)# aaa new-model	
Step 13	<pre>aaa attribute list list-name Example: Device(config)# aaa attribute list crl</pre>	(Optional) Defines an AAA attribute list locally on a router and enters config-attr-list configuration mode.
Step 14	attribute type {name} {value} Example:	(Optional) Defines an AAA attribute type that is to be added to an AAA attribute list locally on a router.
	Device(config-attr-list)# attribute type cert-serial-not 6C4A	To configure certificate serial number session control, an administrator may specify a specific certificate in the <i>value</i> field to be accepted or rejected based on its serial number where <i>name</i> is set to cert-serial-not . If the serial number of the certificate matches the serial number specified by the attribute type setting, the certificate will be rejected.
		For a full list of available AAA attribute types, execute the show aaa attributes command.
Step 15	exit	Returns to privileged EXEC mode.
	Example:	
	Device(ca-trustpoint)# end	
	Example:	
	Device(config-attr-list)# end	
Step 16	show crypto pki certificates	(Optional) Displays the components of the
	Example:	certificates installed on the router if the CA certificate has been authenticated.
	Device# show crypto pki certificates	

Example

The following is a sample certificate. The OCSP-related extensions are shown using exclamation points.

```
Certificate:

Data:

Version: v3

Serial Number:0x14

Signature Algorithm:SHAwithRSA - 1.2.840.113549.1.1.4

Issuer:CN=CA server,OU=PKI,O=Cisco Systems

Validity:

Not Before:Thursday, August 8, 2002 4:38:05 PM PST

Not After:Tuesday, August 7, 2003 4:38:05 PM PST
```

!

ļ

```
Subject:CN=OCSP server,OU=PKI,O=Cisco Systems
           Subject Public Key Info:
               Algorithm:RSA - 1.2.840.113549.1.1.1
                Public Key:
                   Exponent:65537
                   Public Key Modulus: (2048 bits) :

           Extensions:
               Identifier:Subject Key Identifier - 2.5.29.14
                   Critical:no
                   Key Identifier:
                        <snip>
                Identifier: Authority Key Identifier - 2.5.29.35
                   Critical:no
                   Key Identifier:
                       <snip>
                Identifier:OCSP NoCheck: - 1.3.6.1.5.5.7.48.1.5
                    Critical:no
                Identifier:Extended Key Usage:- 2.5.29.37
                    Critical:no
                    Extended Key Usage:
                    OCSPSigning
                Identifier:CRL Distribution Points - 2.5.29.31
                   Critical:no
                   Number of Points:1
                   Point 0
                       Distribution Point:
[URIName:ldap://CA-server/CN=CA server,OU=PKI,O=Cisco Systems]
       Signature:
           Algorithm:SHAwithRSA - 1.2.840.113549.1.1.4
           Signature:
           <snip>
```

The following example shows an excerpt of the running configuration output when adding a **match** certificate override ocsp command to the beginning of an existing sequence:

```
match certificate map3 override ocsp 5 url http://192.0.2.3/
show running-configuration
        match certificate map3 override ocsp 5 url http://192.0.2.3/
        match certificate map1 override ocsp 10 url http://192.0.2.1/
        match certificate map2 override ocsp 15 url http://192.0.2.2/
```

The following example shows an excerpt of the running configuration output when an existing **match** certificate override ocsp command is replaced and a trustpoint is specified to use an alternative PKI hierarchy:

```
match certificate map4 override ocsp trustpoint tp4 10 url http://192.0.2.4/newvalue
show running-configuration
.
        match certificate map3 override ocsp trustpoint tp3 5 url http://192.0.2.3/
        match certificate map1 override ocsp trustpoint tp1 10 url http://192.0.2.1/
       match certificate map4 override ocsp trustpoint tp4 10 url
http://192.0.2.4/newvalue
       match certificate map2 override ocsp trustpoint tp2 15 url http://192.0.2.2/
```

Troubleshooting Tips

If you ignored revocation check or expired certificates, you should carefully check your configuration. Verify that the certificate map properly matches either the certificate or certificates that should be allowed or the AAA checks that should be skipped. In a controlled environment, try modifying the certificate map and determine what is not working as expected.

Configuring Certificate Chain Validation

Perform this task to configure the processing level for the certificate chain path of your peer certificates.

Before you begin

- The device must be enrolled in your PKI hierarchy.
- The appropriate key pair must be associated with the certificate.

```
Note
```

• A trustpoint associated with the root CA cannot be configured to be validated to the next level.

The **chain-validation** command is configured with the **continue** keyword for the trustpoint associated with the root CA, an error message will be displayed and the chain validation will revert to the default **chain-validation** command setting.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	crypto pki trustpointname	Declares the trustpoint and a given name and
	Example:	enters ca-trustpoint configuration mode.
	Device(config)# crypto pki trustpoint ca-subl	
Step 4	chain-validation [{stop continue}	Configures the level to which a certificate chain
	[parent-trustpoint]]	is processed on all certificates including
	Example:	subordinate CA certificates.
	Device(ca-trustpoint)# chain-validation continue ca-subl	• Use the stop keyword to specify that the certificate is already trusted. This is the default setting.

Procedure

	Command or Action	Purpose
		• Use the continue keyword to specify that the that the subordinate CA certificate associated with the trustpoint must be validated.
		• The <i>parent-trustpoint</i> argument specifies the name of the parent trustpoint the certificate must be validated against.
Step 5	exit	Exits ca-trustpoint configuration mode and
	Example:	returns to global configuration mode
	Device(ca-trustpoint)# exit	

Configuration Examples for Authorization and Revocation of Certificates in a PKI

Configuration and Verification Examples fo PKI AAA Authorization

This section provides configuration examples of PKI AAA authorizations:

Example: Device Configuration

The following **show running-config** command output shows the working configuration of a device that is set up to authorize VPN connections using the PKI Integration with AAA Server feature:

```
Device#show running-config

Example: Debug of a Failed PKI AAA Authorization

The following **show debugging** command output shows that the device is not authorized to connect using VPN. The messages are typical of those that you might see in such a situation.

In this example, the peer username was configured as not authorized, by moving the username to a Cisco Secure ACS group called VPN_Disabled in Cisco Secure ACS. The device, device9.example.com, has been configured to check with a Cisco Secure ACS AAA server prior to establishing a VPN connection to any peer.

Examples: Configuring a Revocation Mechanism

This section contains the following configuration examples that can be used when specifying a revocation mechanism for your PKI:

Example:Configuring an OCSP Server

The following example shows how to configure the router to use the OCSP server that is specified in the AIA extension of the certificate:

```
Device> enable
Device# configure terminal
Device(config)#crypto pki trustpoint mytp
Device(ca-trustpoint)# revocation-check ocsp
Device(ca-trustpoint)# end
```

Example:Specifying a CRL and Then an OCSP Server

The following example shows how to configure the router to download the CRL from the CDP. If the CRL is unavailable, the OCSP server that is specified in the AIA extension of the certificate will be used. If both options fail, certificate verification will also fail.

```
Device> enable
Device# configure terminal
Device(config)#crypto pki trustpoint mytp
Device(ca-trustpoint)#revocation-check crl ocsp
Device(ca-trustpoint)# end
```

Example: Specifying an OCSP Server

The following example shows how to configure your router to use the OCSP server at the HTTP URL "http://myocspserver:81." If the server is down, the revocation check will be ignored.

```
Device> enable
Device# configure terminal
Device(config)# crypto pki trustpoint mytp
Device(ca-trustpoint)# ocsp url http://myocspserver:81
Device(ca-trustpoint)# revocation-check ocsp none
Device(ca-trustpoint)# end
```

Example: Disabling Nonces in Communications with the OCSP Server

The following example shows communications when a nonce, or a unique identifier for the OCSP request, is disabled for communications with the OCSP server:

```
Device> enable
Device# configure terminal
Device(config)# crypto pki trustpoint mytp
Device(ca-trustpoint)# ocsp url http://myocspserver:81
Device(ca-trustpoint)# revocation-check ocsp none
Device(ca-trustpoint)# ocsp disable-nonce
Device(ca-trustpoint)# end
```

Example:Configuring a Hub Device at a Central Site for Certificate Revocation Checks

The following example shows a hub device at a central site that is providing connectivity for several branch offices to the central site.

The branch offices are also able to communicate directly with each other using additional IPSec tunnels between the branch offices.

The CA publishes CRLs on an HTTP server at the central site. The central site checks CRLs for each peer when setting up an IPSec tunnel with that peer.

The example does not show the IPSec configuration--only the PKI-related configuration is shown.

Home Office Hub Configuration

```
Device> enable
Device# configure terminal
Device(config)# crypto pki trustpoint VPN-GW
Device(ca-trustpoint)# enrollment url http://ca.home-office.com:80/certsrv/mscep/mscep.dll
Device(ca-trustpoint)# serial-number none
Device(ca-trustpoint)# fqdn none
Device(ca-trustpoint)# ip-address none
Device(ca-trustpoint)# ip-address none
Device(ca-trustpoint)# subject-name o=Home Office Inc,cn=Central VPN Gateway
Device(ca-trustpoint)# revocation-check crl
Device(ca-trustpoint)# end
```

Central Site Hub Device

Device# show crypto ca certificate

```
Certificate
Status: Available
```

```
Certificate Serial Number: 2F62BE1400000000CA0
  Certificate Usage: General Purpose

  Associated Trustpoints: VPN-GW
```

Trustpoint on the Branch Office Device

```
Device> enable
Device# configure terminal
Device(ca-trustpoint)# crypto pki trustpoint home-office
Device(ca-trustpoint)# enrollment url http://ca.home-office.com:80/certsrv/mscep/mscep.dll
Device(ca-trustpoint)# serial-number none
Device(ca-trustpoint)# fqdn none
Device(ca-trustpoint)# ip-address none
Device(ca-trustpoint)# subject-name o=Home Office Inc,cn=Branch 1
Device(ca-trustpoint)# revocation-check crl
Device(ca-trustpoint)# end
```

A certificate map is entered on the branch office device.

```
branch1# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
branch1(config)# crypto pki certificate map central-site 10
branch1(ca-certificate-map)# end
```

The output from the **show certificate** command on the central site hub device shows that the certificate was issued by the following:

```
cn=Central Certificate Authority
o=Home Office Inc
```

These two lines are combined into one line using a comma (,) to separate them, and the original lines are added as the first criteria for a match.

Device(ca-certificate-map)# issuer-name co cn=Central Certificate Authority, ou=Home Office Inc

!The above line wrapped but should be shown on one line with the line above it.

The same combination is done for the subject name from the certificate on the central site device (note that the line that begins with "Name:" is not part of the subject name and must be ignored when creating the certificate map criteria). This is the subject name to be used in the certificate map.

cn=Central VPN Gateway

o=Home Office Inc

Device (ca-certificate-map) # subject-name eq cn=central vpn gateway, o=home office inc

Now the certificate map is added to the trustpoint that was configured earlier.

```
Device> enable
Device# configure terminal
Device(ca-certificate-map)# crypto pki trustpoint home-office
Device(ca-trustpoint)# match certificate central-site skip revocation-check
Device(ca-trustpoint)# end
```

The configuration is checked (most of configuration is not shown).

Device# write term

```
!Many lines left out
.
.
.
crypto pki trustpoint home-office
enrollment url http://ca.home-office.com:80/certsrv/mscep/mscep.dll
serial-number none
fqdn none
ip-address none
subject-name o=Home Office Inc,cn=Branch 1
revocation-check crl
match certificate central-site skip revocation-check
!
!
crypto pki certificate map central-site 10
issuer-name co cn = Central Certificate Authority, ou = Home Office Inc
subject-name eq cn = central vpn gateway, o = home office inc
!many lines left out
```

Note that the issuer-name and subject-name lines have been reformatted to make them consistent for later matching with the certificate of the peer.

If the branch office is checking the AAA, the trustpoint will have lines similar to the following:

```
Device> enable
Device# configure terminal
Device(config)# crypto pki trustpoint home-office
Device(ca-trustpoint)# authorization list allow_list
Device(ca-trustpoint)# authorization username subjectname commonname
Device(ca-trustpoint)# end
```

After the certificate map has been defined as was done above, the following command is added to the trustpoint to skip AAA checking for the central site hub.

Device (ca-trustpoint) # match certificate central-site skip authorization-check

In both cases, the branch site device has to establish an IPSec tunnel to the central site to check CRLs or to contact the AAA server. However, without the **match certificate**command and **central-site skip authorization-check (argument and keyword)**, the branch office cannot establish the tunnel until it has checked the CRL or the AAA server. (The tunnel will not be established unless the **match certificate**command and **central-site skip authorization-check** argument and keyword are used.)

The **match certificate** command and **allow expired-certificate** keyword would be used at the central site if the device at a branch site had an expired certificate and it had to establish a tunnel to the central site to renew its certificate.

Trustpoint on the Central Site Device

```
Device> enable
Device# configure terminal
Device(config)# crypto pki trustpoint VPN-GW
Device(ca-trustpoint)# enrollment url http://ca.home-office.com:80/certsrv/mscep/mscep.dll
Device(ca-trustpoint)# serial-number none
Device(ca-trustpoint)# fqdn none
Device(ca-trustpoint)# ip-address none
Device(ca-trustpoint)# ip-address none
Device(ca-trustpoint)# subject-name o=Home Office Inc,cn=Central VPN Gateway
Device(ca-trustpoint)# revocation-check crl
Device(ca-trustpoint)# end
```

Trustpoint on the Branch 1 Site Device

```
Device# show crypto ca certificate
Certificate
 Status: Available
  Certificate Serial Number: 2F62BE1400000000CA0
  Certificate Usage: General Purpose
  Issuer:
   cn=Central Certificate Authority
   o=Home Office Inc
  Subject:
   Name: Branch 1 Site
   cn=Branch 1 Site
   o=Home Office Inc
  CRL Distribution Points:
   http://ca.home-office.com/CertEnroll/home-office.crl
  Validity Date:
   start date: 00:43:26 GMT Sep 26 2003
   end date: 00:53:26 GMT Oct 3 2003
   renew date: 00:00:00 GMT Jan 1 1970
 Associated Trustpoints: home-office
CA Certificate
  Status: Available
  Certificate Serial Number: 1244325DE0369880465F977A18F61CA8
 Certificate Usage: Signature
  Issuer:
   cn=Central Certificate Authority
   o=Home Office Inc
  Subject:
    cn=Central Certificate Authority
```

```
o=Home Office Inc
CRL Distribution Points:
  http://ca.home-office.com/CertEnroll/home-office.crl
Validity Date:
  start date: 22:19:29 GMT Oct 31 2002
  end date: 22:27:27 GMT Oct 31 2017
Associated Trustpoints: home-office
```

A certificate map is entered on the central site device.

```
Device> enable
Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# crypto pki certificate map branch1 10
Device(ca-certificate-map)# issuer-name co cn=Central Certificate Authority, ou=Home Office
Inc
!The above line wrapped but should be part of the line above it.
Device(ca-certificate-map)# subject-name eq cn=Brahcn 1 Site,o=home office inc
Device(ca-certificate-map)# end
```

The certificate map is added to the trustpoint.

```
Device> enable
Device# configure terminal
Device(ca-certificate-map)# crypto pki trustpoint VPN-GW
Device(ca-trustpoint)# match certificate branch1 allow expired-certificate
Device(ca-trustpoint)# exit
Device (config) #exit
```

The configuration should be checked (most of the configuration is not shown).

Device# write term

```
!many lines left out
crypto pki trustpoint VPN-GW
enrollment url http://ca.home-office.com:80/certsrv/mscep/mscep.dll
serial-number none
fqdn none
ip-address none
subject-name o=Home Office Inc,cn=Central VPN Gateway
revocation-check crl
match certificate branch1 allow expired-certificate
!
!
crypto pki certificate map central-site 10
issuer-name co cn = Central Certificate Authority, ou = Home Office Inc
subject-name eq cn = central vpn gateway, o = home office inc
! many lines left out
```

The **match certificate**command and **branch1 allow expired-certificate** (argument and keyword) and the certificate map should be removed as soon as the branch device has a new certificate.

Examples:Configuring Certificate Authorization and Revocation Settings

This section contains the following configuration examples that can be used when specifying a CRL cache control setting or certificate serial number session control:

Example: Configuring CRL Cache Control

The following example shows how to disable CRL caching for all CRLs associated with the CA1 trustpoint:

Device> enable Device# configure terminal

```
Device(config)# crypto pki trustpoint CA1
Device(ca-trustpoint)# enrollment url http://CA1:80
Device(ca-trustpoint)# ip-address FastEthernet0/0
Device(ca-trustpoint)# crl query ldap://ldap_CA1
Device(ca-trustpoint)# revocation-check crl
Device(ca-trustpoint)# crl cache none
Device(ca-trustpoint)# end
```

The current CRL is still cached immediately after executing the example configuration shown above:

Device# show crypto pki crls

```
CRL Issuer Name:

cn=name Cert Manager,ou=pki,o=example.com,c=US

LastUpdate: 18:57:42 GMT Nov 26 2005

NextUpdate: 22:57:42 GMT Nov 26 2005

Retrieved from CRL Distribution Point:

ldap://ldap.example.com/CN=name Cert Manager,O=example.com
```

When the current CRL expires, a new CRL is then downloaded to the router at the next update. The **crl-cache none**command takes effect and all CRLs for the trustpoint are no longer cached; caching is disabled. You can verify that no CRL is cached by executing the **show crypto pki crls** command. No output will be shown because there are no CRLs cached.

The following example shows how to configure the maximum lifetime of 2 minutes for all CRLs associated with the CA1 trustpoint:

```
Device> enable
Device# configure terminal
Device(config)# crypto pki trustpoint CA1
Device(ca-trustpoint)# enrollment url http://CA1:80
Device(ca-trustpoint)# ip-address FastEthernet 0/0
Device(ca-trustpoint)# crl query ldap://ldap_CA1
Device(ca-trustpoint)# revocation-check crl
Device(ca-trustpoint)# crl cache delete-after 2
Device(ca-trustpoint)# end
```

The current CRL is still cached immediately after executing the example configuration above for setting the maximum lifetime of a CRL:

Device# show crypto pki crls

```
CRL Issuer Name:
    cn=name Cert Manager,ou=pki,o=example.com,c=US
    LastUpdate: 18:57:42 GMT Nov 26 2005
    NextUpdate: 22:57:42 GMT Nov 26 2005
    Retrieved from CRL Distribution Point:
        ldap://ldap.example.com/CN=name Cert Manager,O=example.com
When the current CRL expires, a new CRL is downloaded to the router at the next update and
    the crl-cache delete-after
    command takes effect. This newly cached CRL and all subsequent CRLs will be deleted after
    a maximum lifetime of 2 minutes.
You can verify that the CRL will be cached for 2 minutes by executing the show crypto pki
    crls
    command. Note that the NextUpdate time is 2 minutes after the LastUpdate time.
```

Device# show crypto pki crls

```
CRL Issuer Name:
cn=name Cert Manager,ou=pki,o=example.com,c=US
LastUpdate: 22:57:42 GMT Nov 26 2005
```

NextUpdate: 22:59:42 GMT Nov 26 2005 Retrieved from CRL Distribution Point:

ldap://ldap.example.com/CN=name Cert Manager,O=example.com

Example: Configuring Certificate Serial Number Session Control

The following example shows the configuration of certificate serial number session control using a certificate map for the CA1 trustpoint:

```
Device> enable

Device# configure terminal

Device(config)# crypto pki trustpoint CA1

Device(ca-trustpoint)# enrollment url http://CA1

Device(ca-trustpoint)# chain-validation stop

Device(ca-trustpoint)# crl query ldap://ldap_server

Device(ca-trustpoint)# revocation-check crl

Device(ca-trustpoint)# match certificate crl

Device(ca-trustpoint)# exit

Device(ca-trustpoint)# exit

Device(config)# crypto pki certificate map crl 10

Device(ca-certificate-map)# serial-number co 279d

Device(ca-certificate-map)# end
```

Note

If the *match-criteria* value is set to **eq** (equal) instead of **co** (contains), the serial number must match the certificate map serial number exactly, including any spaces.

The following example shows the configuration of certificate serial number session control using AAA attributes. In this case, all valid certificates will be accepted if the certificate does not have the serial number "4ACA."

```
Device> enable
Device# configure terminal
Device(config)# crypto pki trustpoint CA1
Device(ca-trustpoint)# enrollment url http://CA1
Device(ca-trustpoint)# ip-address FastEthernet0/0
Device(ca-trustpoint)# crl query ldap://ldap_CA1
Device(ca-trustpoint)# revocation-check crl
Device(ca-trustpoint)# exit
Device(config)# aaa new-model
Device(config)# aaa attribute list crl
Device(config-attr-list)# attribute-type aaa-cert-serial-not 4ACA
Device(config-attr-list)# end
```

The server log shows that the certificate with the serial number "4ACA" was rejected. The certificate rejection is shown using exclamation points.

Dec 3 04:24:39.135: CRYPTO PKI: Selected AAA username: 'PKIAAA' Dec 3 04:24:39.135: CRYPTO PKI: Anticipate checking AAA list:'CRL' Dec 3 04:24:39.135: CRYPTO PKI AAA: checking AAA authorization (CRL, PKIAAA-L1, <all>) Dec 3 04:24:39.135: CRYPTO PKI AAA: pre-authorization chain validation status (0x4) Dec 3 04:24:39.135: AAA/BIND(00000021): Bind i/f Dec 3 04:24:39.135: AAA/AUTHOR (0x21): Pick method list 'CRL' Dec 3 04:24:39.175: CRYPTO PKI AAA: reply attribute ("cert-application" = "all") Dec 3 04:24:39.175: CRYPTO PKI AAA: reply attribute ("cert-trustpoint" = "CA1") Dec 3 04:24:39.175: CRYPTO PKI AAA: reply attribute ("cert-serial-not" = "4ACA") Dec 3 04:24:39.175: CRYPTO PKI AAA: cert-serial doesn't match ("4ACA" != "4ACA") 1 Dec 3 04:24:39.175: CRYPTO PKI AAA: post-authorization chain validation status (0x7) Dec 3 04:24:39.175: CRYPTO PKI: AAA authorization for list 'CRL', and user 'PKIAAA' failed. Examples: Configuring Certificate Chain Validation

This section contains the following configuration examples that can be used to specify the level of certificate chain processing for your device certificates:

Configuring Certificate Chain Validation from Peer to Root CA

In the following configuration example, all of the certificates will be validated--the peer, SubCA11, SubCA1, and RootCA certificates.

```
Device> enable
Device# configure terminal
Device(config) # crypto pki trustpoint RootCA
Device(ca-trustpoint) # enrollment terminal
Device (ca-trustpoint) # chain-validation stop
Device (ca-trustpoint) # revocation-check none
Device (ca-trustpoint) # rsakeypair RootCA
Device(ca-trustpoint) # exit
Device (config) # crypto pki trustpoint SubCA1
Device (ca-trustpoint) # enrollment terminal
Device (ca-trustpoint) # chain-validation continue RootCA
Device(ca-trustpoint) # revocation-check none
Device (ca-trustpoint) # rsakeypair SubCA1
Device(ca-trustpoint)# exit
Device (config) # crypto pki trustpoint SubCA11
Device (ca-trustpoint) # enrollment terminal
Device (ca-trustpoint) # chain-validation continue SubCA1
Device(ca-trustpoint) # revocation-check none
Device (ca-trustpoint) # rsakeypair SubCA11
Device (ca-trustpoint) # end
```

Configuring Authorization and Revocation of Certificates in a PKI

Configuring Certificate Chain Validation from Peer to Subordinate CA

In the following configuration example, the following certificates will be validated--the peer and SubCA1 certificates.

```
Device> enable
Device# configure terminal
Device(config) # crypto pki trustpoint RootCA
Device (ca-trustpoint) # enrollment terminal
Device(ca-trustpoint) # chain-validation stop
Device(ca-trustpoint) # revocation-check none
Device(ca-trustpoint) # rsakeypair RootCA
Device(ca-trustpoint)# exit
Device (config) # crypto pki trustpoint SubCA1
Device(ca-trustpoint) # enrollment terminal
Device (ca-trustpoint) # chain-validation continue RootCA
Device(ca-trustpoint) # revocation-check none
Device (ca-trustpoint) # rsakeypair SubCA1
Device(ca-trustpoint)# exit
Device(config) # crypto pki trustpoint SubCA11
Device (ca-trustpoint) # enrollment terminal
Device(ca-trustpoint) # chain-validation continue SubCA1
Device (ca-trustpoint) # revocation-check none
Device(ca-trustpoint) # rsakeypair SubCA11
Device(ca-trustpoint) # end
```

Configuring Certificate Chain Validation Through a Gap

In the following configuration example, SubCA1 is not in the configured Cisco IOS hierarchy but is expected to have been supplied in the certificate chain presented by the peer.

If the peer supplies the SubCA1 certificate in the presented certificate chain, the following certificates will be validated--the peer, SubCA11, and SubCA1 certificates.

If the peer does not supply the SubCA1 certificate in the presented certificate chain, the chain validation will fail.

```
Device> enable
Device# configure terminal
Device(config)# crypto pki trustpoint RootCA
Device(ca-trustpoint)# enrollment terminal
Device(ca-trustpoint)# chain-validation stop
Device(ca-trustpoint)# revocation-check none
Device(ca-trustpoint)# rsakeypair RootCA
Device(ca-trustpoint)# exit
Device(ca-trustpoint)# exit
Device(ca-trustpoint)# enrollment terminal
Device(ca-trustpoint)# chain-validation continue RootCA
Device(ca-trustpoint)# revocation-check none
Device(ca-trustpoint)# chain-validation continue RootCA
Device(ca-trustpoint)# revocation-check none
Device(ca-trustpoint)# revocation-check none
Device(ca-trustpoint)# reakeypair SubCA11
Device(ca-trustpoint)# reakeypair SubCA11
```

Feature History for Authorization and Revocation of Certificates in a PKI

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.11.1	Authorization and Revocation of Certificates in a PKI	Certificates contain several fields that are used to determine whether a device or user is authorized to perform a specified action. Certificate-based ACLs also help determine when PKI components such as revocation, authorization, or a trustpoint should be used.
Cisco IOS XE Cupertino 17.7.1	Authorization and Revocation of Certificates in a PKI	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

Source Interface Selection for Outgoing Traffic with Certificate Authority

The Source Interface Selection for Outgoing Traffic with Certificate Authority feature allows the IP address of an interface to be specified and used as the source address for all outgoing TCP connections associated with that trustpoint when a designated trustpoint has been configured.

- Information About Source Interface Selection for Outgoing Traffic with Certificate Authority, on page 737
- How to Configure Source Interface Selection for Outgoing Traffic with Certificate Authority, on page 738
- Configuration Examples for Source Interface Selection for Outgoing Traffic with Certificate Authority, on page 740
- Feature History for Source Interface Selection for Outgoing Traffic with Certificate Authority, on page 741

Information About Source Interface Selection for Outgoing Traffic with Certificate Authority

Certificates That Identify an Entity

Certificates can be used to identify an entity. A trusted server, known as the certification authority (CA), issues the certificate to the entity after determining the identity of the entity. A device that is running Cisco IOS XE software obtains its certificate by making a network connection to the CA. Using the Simple Certificate Enrollment Protocol (SCEP), the device transmits its certificate request to the CA and receives the granted certificate. The device obtains the certificate of the CA in the same manner using SCEP. When validating a certificate from a remote device, the device may again contact the CA or a Lightweight Directory Access Protocol (LDAP) or HTTP server to determine whether the certificate of the remote device has been revoked. (This process is known as checking the certificate revocation list [CRL].)

In some configurations, the device may make the outgoing TCP connection using an interface that does not have a valid or IP address that can be routed. The user must specify that the address of a different interface be used as the source IP address for the outgoing connection. Cable modems are a specific example of this requirement because the outgoing cable interface (the RF interface) usually does not have an IP address that can be routed. However, the user interface (usually Ethernet) does have a valid IP address.

Source Interface for Outgoing TCP Connections Associated with a Trustpoint

The **crypto ca trustpoint** command is used to specify a trustpoint. The **source interface**command is used along with the **crypto ca trustpoint**command to specify the address of the interface that is to be used as the source address for all outgoing TCP connections associated with that trustpoint.

Ŵ

Note

If the interface address is not specified using the **source interface**command, the address of the outgoing interface is used.

How to Configure Source Interface Selection for Outgoing Traffic with Certificate Authority

Configuring the Interface for All Outgoing TCP Connections Associated with a Trustpoint

Perform this task to configure the interface that you want to use as the source address for all outgoing TCP connections associated with a trustpoint.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	crypto ca trustpoint name	Declares the Certificate Authority (CA) that
	Example:	your device should use and enters ca-trustpoint configuration mode.
	Device(config)# crypto ca trustpoint ms-ca	
Step 4	enrollment [mode] [retry period minutes] [retry count number] url url [pem]	Specifies the following enrollment parameters of the CA:
	Example:	• (Optional) The mode keyword specifies
· · ·	Device(ca-trustpoint)# enrollment url http://caserver.myexample.com	the registration authority (RA) mode, if your CA system provides an RA. By default, RA mode is disabled.

	Command or Action	Purpose
	- OF- Device(ca-trustpoint)# enrollment url http://[2001:DB8:1:1::1]:80	• (Optional) The retry period keyword and <i>minutes</i> argument specifies the period, in minutes, in which the device waits before sending the CA another certificate request. Valid values are from 1 to 60. The default is 1.
		• (Optional) The retry count keyword and <i>number</i> argument specifies the number of times a device will resend a certificate request when it does not receive a response from the previous request. Valid values are from 1 to 100. The default is 10.
		• The <i>url</i> argument is the URL of the CA to which your device should send certificate requests.
		• (Optional) The pem keyword adds privacy-enhanced mail (PEM) boundaries to the certificate request.
Step 5	source interface interface-address Example:	Interface to be used as the source address for all outgoing TCP connections associated with that trustpoint.
	Device(ca-trustpoint)# source interface gigabitethernet 0/1/0	
Step 6	exit	Exits ca-trustpoint configuration mode and
	Example:	returns to global configuration mode.
	Device(ca-trustpoint)# exit	
Step 7	interface type slot / port	Configures an interface type and enters
-	Example:	interface configuration mode.
	Device(config)# interface gigabitethernet 1/0/1	
Step 8	description string	Adds a description to an interface
	Example:	configuration.
	<pre>Device(config-if)# description inside interface</pre>	
Step 9	ip address ip-address mask	Sets a primary or secondary IP address for an
		interface.

	Command or Action	Purpose
	Device(config-if)# ip address 10.1.1.1 255.255.255.0	
Step 10	exit Example:	Exits interface configuration mode and returns to global configuration mode.
Step 11	Device(config-if)# exit interface type slot/port Example:	Configures an interface and enters interface configuration mode.
Step 12	Device(config-if)# interface gigabitethernet 1/0/2 description string	Adds a description to an interface
	Example: Device(config-if)# description outside interface 10.1.1.205 255.255.255.0	configuration.
Step 13	<pre>ip address ip-address mask Example: Device(config-if)# ip address 10.2.2.205 255.255.255.0</pre>	Sets a primary or secondary IP address for an interface.
Step 14	crypto map map-name Example:	Applies a previously defined crypto map set to an interface and enters crypto map configuration mode.
Step 15	Device(config-if)# crypto map mymap end Example:	Exits crypto map configuration mode and returns to privileged EXEC mode.
	Device(config-crypto-map)# end	

Configuration Examples for Source Interface Selection for Outgoing Traffic with Certificate Authority

Example:Source Interface Selection for Outgoing Traffic with Certificate Authority

In the following example, the device is located in a branch office. The device uses IPSec to communicate with the main office. GigabitEthernet 1/0/1 is the "outside" interface that connects to the ISP. GigabitEthernet

0/1/0 is the interface connected to the LAN of the branch office. To access the CA server located in the main office, the device must send its IP datagrams out interface Ethernet 1 (address 10.2.2.205) using the IPSec tunnel. Address 10.2.2.205 is assigned by the ISP. Address 10.2.2.205 is not a part of the branch office or main office.

The CA cannot access any address outside the company because of a firewall. The CA sees a message coming from 10.2.2.205 and cannot respond (that is, the CA does not know that the device is located in a branch office at address 10.1.1.1, which it is able to reach).

Adding the **source interface** command tells the device to use address 10.1.1.1 as the source address of the IP datagram that it sends to the CA. The CA is able to respond to 10.1.1.1.

This scenario is configured using the **source interface** command and the interface addresses as described above.

```
Device> enable
Device# configure terminal
Device(config)# crypto ca trustpoint ms-ca
Device(ca-trustpoint)# enrollment url http://ms-ca:80/certsrv/mscep/mscep.dll
Device(ca-trustpoint)# source interface gigabitethernet 0/1/0
Device(ca-trustpoint)# exit
Device(config)# interface gigabitethernet 0/1/0
Device(config-if)# description inside interface
Device(config-if)# ip address 10.1.1.1 255.255.255.0
Device(config)# interface gigabitethernet 1/0/1
Device(config-if)# description outside interface
Device(config-if)# ip address 10.2.2.205 255.255.0
Device(config-if)# ip address 10.2.2.05 255.255.0
Device(config-if)# exit
```

Feature History for Source Interface Selection for Outgoing Traffic with Certificate Authority

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.11.1	Source Interface Selection for Outgoing Traffic with Certificate Authority	The Source Interface Selection for Outgoing Traffic with Certificate Authority feature allows you to specify that the address of an interface be used as the source address for all outgoing TCP connections associated with that trustpoint when a designated trustpoint has been configured.
Cisco IOS XE Cupertino 17.7.1	Source Interface Selection for Outgoing Traffic with Certificate Authority	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

Feature History for Source Interface Selection for Outgoing Traffic with Certificate Authority

Source Interface and VRF Support in LDAP

The Source Interface and VRF Support in LDAP feature allows you to configure a dedicated LDAP source interface IP address and virtual routing and forwarding (VRF) details on Cisco Integrated Services Routers (ISR) Generation 2. The source interface address (the address can be an IPv4 or IPv6 address) and VRF details are populated while creating a TCP connection between the Cisco ISR Generation 2 and the LDAP server. This module describes how to configure this feature.

- Information About Source Interface and VRF Support in LDAP, on page 743
- How to Configure Source Interface and VRF Support in LDAP, on page 744
- Configuration Examples for Source Interface and VRF Support in LDAP, on page 745
- Feature History for Source Interface and VRF Support in LDAP, on page 745

Information About Source Interface and VRF Support in LDAP

Source Interface and VRF Support in LDAP Overview

Prior to the introduction of the Source Interface and VRF Support in LDAP feature, the source interface address cannot be specified in the source IP field of the Lightweight Directory Access Protocol (LDAP) query; instead the tunnel interface IP address was used in the source IP field.

The Source Interface and VRF Support in LDAP feature helps you configure a dedicated LDAP source interface address on a Cisco device. The source interface address is configured on the Cisco device, and the device uses this interface address to originate all LDAP packets it sends to the LDAP server. The source interface address is also used for polling the end-server to ensure the reachability of the end-server.

The source interface IP (either an IPv4 or IPv6 address) address and virtual routing and forwarding (VRF) details are populated in the LDAP query while creating a TCP connection between the Cisco device (client) and the LDAP server.

The VRF instance is configured on the Cisco device and VRF table ID details are set in the socket option before creating a TCP connection to allow multiple instances of a routing table to coexist on the same device at the same time. Because routing instances are independent of each other, the same or overlapping IP address can be used without conflict.

How to Configure Source Interface and VRF Support in LDAP

Configuring LDAP Source Interface and VRF

If you have configured the source interface address and virtual routing and forwarding (VRF) instance under the **aaa group server ldap** command and in global configuration mode, the configuration under the **aaa group server ldap** command has the highest priority.

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device(config) # configure terminal	
Step 3	aaa new-model	Enables the authentication, authorization, and
	Example:	accounting (AAA) access control model.
	Device(config)# aaa new-model	
Step 4	aaa group server ldap group-name	Groups different Lightweight Directory Access
	Example:	Protocol (LDAP) servers into distinct lists and methods and enters LDAP server-group
	Device(config)# aaa group server ldap ldap-server-group	configuration mode.
Step 5	{ ip ipv6 } Idap source-interface <i>interface-type interface-number</i>	Specifies the source interface IP address in the LDAP packets.
	Example:	I
	Device(config-ldap-sg)# ip ldap source-interface gigabitethernet 0/0/0	
Step 6	{ip ipv6} vrf forwarding vrf-name	Configures a VRF reference of a AAA LDAP
	Example:	server group.
	Device(config-ldap-sg)# ip vrf forwarding cws-vrf	
Step 7	server name	Specifies the LDAP server.
	Example:	
	Device(config-ldap-sg)# server ldap-server	

	Command or Action	Purpose
Step 8	exit	Exits LDAP server-group configuration mode and returns to global configuration mode.
	Example:	
	<pre>Device(config-ldap-sg)# exit</pre>	
Step 9	{ ip ipv6 } Idap source-interface <i>interface-type interface-number</i> [vrf <i>vrf-name</i>]	Specifies the source interface IP address in the LDAP packets.
	Example:	
	<pre>Device(config)# ip ldap source-interface gigabitethernet 0/1/0 vrf cws-vrf-1</pre>	
Step 10	end	Exits global configuration mode and returns
	Example:	to privileged EXEC mode.
	Device(config)# end	

Configuration Examples for Source Interface and VRF Support in LDAP

Example: Configuring LDAP Source Interface and VRF

```
Device> enable
Device(config)# configure terminal
Device(config)# aaa new-model
Device(config)# aaa group server ldap ldap-server-group
Device(config-ldap-sg)# ip ldap source-interface gigabitethernet 0/0/0
Device(config-ldap-sg)# ip vrf forwarding cws-vrf
Device(config-ldap-sg)# server ldap-server
Device(config-ldap-sg)# exit
Device(config)# ip ldap source-interface gigabitethernet 0/1/0 vrf cws-vrf-1
Device(config)# end
```

Feature History for Source Interface and VRF Support in LDAP

This table provides release and related information for the features explained in this module.

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.11.1	Source Interface and VRF Support in LDAP	The source interface, which can be an IPv4 or IPv6 interface, and virtual routing and forwarding (VRF) details are populated while creating a TCP connection between a Cisco device and the LDAP server.

Release	Feature	Feature Information
Cisco IOS XE Cupertino 17.7.1	Source Interface and VRF Support in LDAP	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

Configuring IPv6 Support for LDAP

- Restrictions for Configuring IPv6 Support for LDAP, on page 747
- Information About Configuring IPv6 Support for LDAP, on page 747
- LDAP Operations, on page 748
- How to Configure IPv6 Support for LDAP, on page 749

Restrictions for Configuring IPv6 Support for LDAP

- Only bind, search, and compare operations are supported.
- The Lightweight Directory Access Protocol (LDAP) referrals are not supported.
- Unsolicited messages or notifications from LDAP server are not handled.

Information About Configuring IPv6 Support for LDAP

IPv6 Support for LDAP

To support Lightweight Directory Access Protocol (LDAP) over IPv6, changes are made to authentication, authorization and accounting (AAA) transactions in terms of authentication and authorization while communicating over an IPv6 network. In order to support LDAP over an IPv6 network, transport calls have been modified to support both IPv4 and IPv6 based on the server configuration.

Transport Layer Security

Transport Layer Security (TLS) is an application-level protocol that enables secure transactions of data through privacy, authentication, and data integrity. It relies upon certificates, public keys, and private keys for clients to prove the identity. Certificates are issued by Certificate Authorities (CAs). Each certificate includes the name of the authority that issued it, the name of the entity to which the certificate was issued, the entity's public key, and time stamps that indicate the certificate's expiration date. TLS support for LDAP is mentioned in RFC 2830 as an extension to the LDAP protocol.

LDAP Operations

Bind

The bind operation is used to authenticate a user to the server. It is used to start a connection with the LDAP server. LDAP is a connection-oriented protocol. The client specifies the protocol version and the client authentication information. LDAP supports the following binds:

- Authenticated bind
- · Anonymous bind

An authenticated bind is performed when a root distinguished name (DN) and password are available. In the absence of a root DN and password, an anonymous bind is performed. In LDAP deployments, the search operation is performed first and the bind operation later. This is because, if a password attribute is returned as part of the search operation, the password verification can be done locally on an LDAP client. Thus, there is no need to perform an extra bind operation. If a password attribute is not returned, the bind operation can be performed later. Another advantage of performing a search operation first and a bind operation later is that the DN received in the search result can be used as the user DN instead of forming a DN by prefixing the username (cn attribute) with the base DN. All entries stored in an LDAP server have a unique DN. The DN consists of two parts: the Relative Distinguished Name (RDN) and the location within the LDAP server where the record resides.

Most of the entries that you store in an LDAP server will have a name, and the name is frequently stored in the Common Name (cn) attribute. Because every object has a name, most objects you store in an LDAP will use their cn value as the basis for their RDN.

Compare

The compare operation is used to replace a bind request with a compare request for an authentication. The compare operation helps to maintain the initial bind parameters for the connection.

Search

A search operation is used to search the LDAP server. The client specifies the starting point (base DN) of the search, the search scope (either the object, its children, or the subtree rooted at the object), and a search filter.

For authorization requests, the search operation is directly performed without a bind operation. The LDAP server can be configured with certain privileges for the search operation to succeed. This privilege level is established with the bind operation.

An LDAP search operation can return multiple user entries for a specific user. In such cases, the LDAP client returns an appropriate error code to AAA. To avoid these errors, appropriate search filters that help to match a single entry must be configured.

How to Configure IPv6 Support for LDAP

Configuring Device-to-LDAP Server Communication

The Lightweight Directory Access Protocol (LDAP) host is a multiuser system running LDAP server software, such as Active Directory (Microsoft) and OpenLDAP. Configuring device-to-LDAP server communication can have several components:

- Hostname or IP address
- Port number
- Timeout period
- Base distinguished name (DN)

To configuring Device-to-LDAP server communication, perform this procedure:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	aaa new-model	Enables AAA.
	Example:	
	Device(config)# aaa new-model	
Step 4	ldap server name	Configures a device as an LDAP protocol and
	Example:	enters LDAP server configuration mode.
	Device(config)# ldap server server1	
Step 5	ipv6 ipv6-address	Specifies an IPv6 address to the LDAP server.
	Example:	
	Device(config-ldap-server)# ipv6 2001:DB8:0:0:8:800	

	Command or Action	Purpose
Step 6	transport port port-number Example:	Configures the transport protocol for connecting to the LDAP server.
	Device(config-ldap-server)# transport port 200	
Step 7	<pre>timeout retransmit seconds Example: Device(config-ldap-server)# timeout retransmit 20</pre>	Specifies the number of seconds a device waits for a reply to an LDAP request before retransmitting the request.
Step 8	exit Example:	Exits the LDAP server configuration mode and enters global configuration mode.
	Device(config-ldap-server)# exit	

Configuring LDAP Protocol Parameters

To configure LDAP protocol parameters, perform this procedure:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	aaa	Enables AAA.
	Example:	
	Device(config)# aaa new-model	
Step 4	Idap server name	Defines a Lightweight Directory Access
	Example:	Protocol (LDAP) server and enters LDAP server configuration mode.
	Device(config) # ldap server server1	
Step 5	bind authenticate root-dn password [0 string 7 string] string	Specifies a shared secret text string used between the device and an LDAP server. Use

	Command or Action	Purpose
	Example: Device(config-ldap-server) # bind authenticate root-dn "Gradministrator,Grugers,dormac-blr2,dorexample,dorom password"	the 0 line option to configure an unencrypted shared secret. Use the 7 line option to configure an encrypted shared secret.
Step 6	search-filter user-object-type string Example:	Specifies the search filter to be used in the search requests.
	<pre>Device(config-ldap-server)# search-filter user-object-type string1</pre>	
Step 7	base-dn <i>string</i> Example:	Specifies the base distinguished name (DN) of the search.
	Device(config-ldap-server)# base-dn " dc=sns,dc=example,dc=com "	
Step 8	mode secure [no-negotiation] Example:	Configures LDAP to initiate the transport layer security (TLS) connection and specifies the secure mode.
	Device(config-ldap-server)# mode secure no-negotiation	
Step 9	secure cipher 3des-ede-cbc-sha Example:	Specifies the ciphersuite in the case of a secure connection.
	Device(config-ldap-server)# secure cipher 3des-ede-cbc-sha	
Step 10	exit Example:	Exits LDAP server configuration mode and enters global configuration mode.
	Device(config-ldap-server)# exit	

Configuring Search and Bind Operations for an Authentication Request

To configure search and bind operations for an authentication request, perform this procedure:

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	Enter your password if prompted.
	Device> enable	

I

	Command or Action	Purpose
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	aaa new-model	Enables AAA.
	Example:	
	Device(config)# aaa new-model	
Step 4	ldap server name	Defines a Lightweight Directory Access
	Example:	Protocol (LDAP) server and enter LDAP server configuration mode.
	Device(config)# ldap server server1	
Step 5	authentication bind-first	Configures the sequence of search and bind
	Example:	operations for an authentication request.
	Device(config-ldap-server)# authentication bind-first	
Step 6	authentication compare	Replaces the bind request with the compare
	Example:	request for authentication.
	Device(config-ldap-server)# authentication compare	
Step 7	exit	Exits LDAP server configuration mode.
	Example:	
	Device(config-ldap-server)# exit	

Monitoring and Maintaining LDAP Scalability Enhancements

The following show and debug commands can be entered in any order.

Step 1	Procedure		
	enable		
	Example:		
	> enable		
	Enables privileged EXEC mode.		

	Enter your password if prompted.		
Step 2	configure terminal		
	Example:		
	<pre># configure terminal</pre>		
	Enters global configuration mode.		
Step 3	clear ldap server		
	Clears the Lightweight Directory Ac	cess Protocol	(LDAP) server of the TCP connection.
	Example:		
	# clear ldap server		
Step 4	debug ldap		
	Displays information associated with	n LDAP.	
	Example:		
	# debug ldap		
Step 5	show ldap server		
	Displays the LDAP server state info	rmation and v	arious other counters for the server.
	Example:		
	<pre># show ldap server</pre>		
Step 6	show ldap attributes		
	Displays information about default I	DAP attribut	e mapping.
	Example:		
	Device# show ldap attributes		
	LDAP Attribute	Format	AAA Attribute
	airespaceBwDataBurstContract userPassword airespaceBwRealBurstContract	Ulong String Ulong	bsn-data-bandwidth-burst-contr password bsn-realtime-bandwidth-burst-c

userPassword	String	password
airespaceBwRealBurstContract	Ulong	bsn-realtime-bandwidth-burst-c
employeeType	String	employee-type
airespaceServiceType	Ulong	service-type
airespaceACLName	String	bsn-acl-name
priv-lvl	Ulong	priv-lvl
memberOf	String DN	supplicant-group
cn	String	username
airespaceDSCP	Ulong	bsn-dscp
policyTag	String	tag-name
airespaceQOSLevel	Ulong	bsn-qos-level
airespace8021PType	Ulong	bsn-8021p-type
airespaceBwRealAveContract	Ulong	bsn-realtime-bandwidth-average
airespaceVlanInterfaceName	String	bsn-vlan-interface-name
airespaceVapId	Ulong	bsn-wlan-id
airespaceBwDataAveContract	Ulong	bsn-data-bandwidth-average-con
sAMAccountName	String	sam-account-name
meetingContactInfo	String	contact-info

telephoneN
Map: att_m
department

Jumber	String	telephone-number
nap_1	String DN	element-req-qos

Configuration Examples of IPv6 Support for LDAP

Example: Device-to-LDAP Server Communication

The following example shows how to create server group server1 and specify the IP address, transport port 200, and retransmit values:

```
Device> enable
Device# configure terminal
Device(config)# aaa new-model
Device(config)# ldap server server1
Device(config-ldap-server)# ipv6 2001:DB8:0:0:8:800
Device(config-ldap-server)# transport port 200
Device(config-ldap-server)# timeout retransmit 20
Device(config-ldap-server)# exit
```

Example: LDAP Protocol Parameters

The following example shows how to configure Lightweight Directory Access Protocol (LDAP) parameters:

```
Device> enable
Device# configure terminal
Device(config)# aaa new-model
Device(config)# ldap server server1
Device(config-ldap-server)# bind authenticate root-dn
"cn=administrator,cn=users,dc=nac-blr2,dc=example,dc=com password"
Device(config-ldap-server)# base-dn "dc=sns,dc=example,dc=com"
Device(config-ldap-server)# mode secure no-negotiation
Device(config-ldap-server)# secure cipher 3des-ede-cbc-sha
Device(config-ldap-server)# exit
```

Example: Search and Bind Operations for an Authentication Request

The following example shows how to configure the sequence of search and bind operations for an authentication request:

```
Device> enable
Device# configure terminal
Device(config)# aaa new-model
Device(config)# ldap server server1
Device(config-ldap-server)# authentication bind-first
Device(config-ldap-server)# authentication compare
Device(config-ldap-server)# exit
```

Example: Server Information from an LDAP Server

The following is sample output from an LDAP server:

Device# show ldap server all		
Server Information for se	rver1	
Server listening Port Connection status Root Bind status Server mode Cipher Suite Authentication Seq Authentication Procedure Request timeout	:2001:DB8:0:0:8:800 :389 :DOWN :No Bind :Non-Secure :0x00 :Search first. Then Bind/Compare :Bind with user password :30	password next
* LDAP STATISTICS * Total messages [Sent:0, Response delay(ms) [Aver Total search [Request Total bind [Request Total extended [Request Total compare [Request Search [Success:0, Failu Bind [Success:0, Failu Missing attrs in Entry [<pre>Received:0] age:0, Maximum:0] :0, ResultEntry:0, ResultDone:0] :0, Response:0] :0, Response:0] :0, Response:0] res:0] res:0] 0]</pre>

Feature History for IPv6 Support for LDAP

This table provides release and related information for the features explained in this module.

Release	Feature	Feature Information
Cisco IOS XE Gibraltar 16.11.1	IPv6 Support for LDAP	The IPv6 Support for LDAP feature describes IPv6 transport support for the LDAP protocol by introducing changes in authentication, authorization, and accounting (AAA) transactions.
Cisco IOS XE Cupertino 17.7.1	IPv6 Support for LDAP	Support for this feature was introduced on the Cisco Catalyst 9600 Series Supervisor 2 Module (C9600X-SUP-2).

These features are available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Use the Cisco Feature Navigator to find information about platform and software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn.

Secure Operation in FIPS Mode

- FIPS 140-2 Overview, on page 757
- Configure FIPS 140-2, on page 758
- Key Zeroization, on page 758
- Disable FIPS Mode, on page 759
- Verify FIPS Configuration, on page 759
- Additional References for Secure Operation in FIPS Mode , on page 760

FIPS 140-2 Overview

The Federal Information Processing Standards (FIPS) Publication 140-2 (Security Requirements for Cryptographic Modules) details the U.S and Canadian governments' requirements for cryptographic modules. FIPS 140-2 specifies certain cryptographic algorithms as secure, and it also identifies which algorithms should be used if a cryptographic module is to be called FIPS compliant. For more information on the FIPS 140-2 standard and validation program, refer National Institute of Standards and Technology (NIST) website.

The FIPS 140-2 Compliance Review (CR) documents for Cisco Catalyst series switches are posted on the following website:

https://www.cisco.com/c/en/us/solutions/industries/government/global-government-certifications/fips-140.html

Click the link in the "Certification Date" column to view the CR Certificate.

Security Policy document describes the FIPS implementation, hardware installation, firmware initialization, and software configuration procedures for FIPS operation. You can access the FIPS 140-2 Consolidated Validation Certificate and Security Policy document on NIST Computer Security Resource Center. This website opens a Search window. In the **Vendor** field, enter "Cisco" and click **Search**. The resulting window provides a list of Cisco platforms that are FIPS Compliant. From the list, click the desired platform to obtain its Security Policy and Consolidated Certificate.

Important

This document describes FIPS mode behavior for Cisco Catalyst Switches in general. For more information on platform-specific FIPS 140-2 implementation, refer the FIPS 14-2 Security Policy document for the platform.

Configure FIPS 140-2

Following is a generic procedure to enable FIPS mode of operation for Cisco Catalyst Switches. For a detailed configuration procedure, refer FIPS 140-2 Security Policy document for the required device.

Procedure

```
      Step 1
      (Optional) Enable FIPS 140-2 logging.

      Example:
```

Device(config) # logging console errors

Step 2 Configure Authorization key.

Example:

Device(config) # fips authorization-key key

Note that key is 128 bits, which is, 16 HEX byte key.

What to do next

After you enable FIPS, reboot the system to start operating in FIPS mode.

Key Zeroization

A critical FIPS requirement is the capability to zeroize keys and passwords in the event of unsafe state triggers during FIPS mode of operation.

You can delete the FIPS authorization keys using the **no fips authorization-key** command in global configuration mode. This command deletes the key from flash. A reboot takes the system out of FIPS mode of operation.

If there is a security breach, use the **fips zeroize** command to delete all data including the running configuration, Trust Anchor Module, FIPS authorization keys, all ISE Server certificates, and IOS image in flash.

The system reboots after this command is executed.

Caution

tion FIPS zeroization is a critical step where all data is lost. Use it with caution.

Session keys are zeroized by the protocols programmatically.

Device (config) #fips zeroize

```
**Critical Warning** - This command is irreversible
and will zeroize the FVPK by Deleting the IOS
image and config files, please use extreme
caution and confirm with Yes on each of three
iterations to complete. The system will reboot
```

```
after the command executes successfully Proceed ?? (yes/[no]):
```

Disable FIPS Mode

You can disable FIPS mode using the no fips authorization-key command.

The **no fips authorization-key** command deletes the authorization key from flash. Note that the authorization key is operational until you reload the switch.

To completely remove the authorization key and disable FIPS mode, reload the switch.

```
Device> enable
Device# config terminal
Device(config)# no fips authorization-key
Device(config)# end
```

Verify FIPS Configuration

Use the show fips status command to display the FIPS configuration information.

Use the **show fips authorization-key** command to display the hashed FIPS key.

Note

FIPS configuration information does not appear when you list the active configuration using the show running-config command or when you list the startup configuration using the show startup-config command.

The following are sample outputs of the **show** commands:

```
Device# show fips authorization-key
Device#show romvar
