

CHAPTER 24

Configuring FlexLinks and the MAC Address-Table Move Update

Finding Feature Information

Your software release may not support all the features documented in this chapter. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Restrictions for the FlexLinks and the MAC Address-Table Move Update

- To use this feature, the switch must be running the LAN Base image.

Information About Configuring the FlexLinks and the MAC Address-Table Move Update

FlexLinks

FlexLinks are a pair of a Layer 2 interfaces (switch ports or port channels) where one interface is configured to act as a backup to the other. The feature provides an alternative solution to the Spanning Tree Protocol (STP). Users can disable STP and still retain basic link redundancy. FlexLinks are typically configured in service provider or enterprise networks where customers do not want to run STP on the switch. If the switch is running STP, FlexLinks is not necessary because STP already provides link-level redundancy or backup.

You configure FlexLinks on one Layer 2 interface (the active link) by assigning another Layer 2 interface as the FlexLinks or backup link. When one of the links is up and forwarding traffic, the other link is in standby mode, ready to begin forwarding traffic if the other link shuts down. At any given time, only one

of the interfaces is in the linkup state and forwarding traffic. If the primary link shuts down, the standby link starts forwarding traffic. When the active link comes back up, it goes into standby mode and does not forward traffic. STP is disabled on FlexLinks interfaces.

In [Figure 24-1](#), ports 1 and 2 on switch A are connected to uplink switches B and C. Because they are configured as FlexLinks, only one of the interfaces is forwarding traffic; the other is in standby mode. If port 1 is the active link, it begins forwarding traffic between port 1 and switch B; the link between port 2 (the backup link) and switch C is not forwarding traffic. If port 1 goes down, port 2 comes up and starts forwarding traffic to switch C. When port 1 comes back up, it goes into standby mode and does not forward traffic; port 2 continues forwarding traffic.

You can also choose to configure a preemption mechanism, specifying the preferred port for forwarding traffic. For example, in the example in [Figure 24-1](#), you can configure the FlexLinks pair with preemption mode. In the scenario shown, when port 1 comes back up and has more bandwidth than port 2, port 1 begins forwarding traffic after 60 seconds. Port 2 becomes the standby port. You do this by entering the interface configuration **switchport backup interface preemption mode bandwidth** and **switchport backup interface preemption delay** commands.

Figure 24-1 FlexLinks Configuration Example

If a primary (forwarding) link goes down, a trap notifies the network management stations. If the standby link goes down, a trap notifies the users.

FlexLinks are supported only on Layer 2 ports and port channels, not on VLANs or on Layer 3 ports.

VLAN FlexLinks Load Balancing and Support

VLAN FlexLinks load-balancing allows you to configure a FlexLinks pair so that both ports simultaneously forward the traffic for some mutually exclusive VLANs. For example, if FlexLinks ports are configured for 1 to 100 VLANs, the traffic of the first 50 VLANs can be forwarded on one port and the rest on the other port. If one of the ports fail, the other active port forwards all the traffic. When the failed port comes back up, it resumes forwarding traffic in the preferred VLANs. This way, apart from providing the redundancy, this FlexLinks pair can be used for load balancing. FlexLinks VLAN load balancing does not impose any restrictions on uplink switches.

Figure 24-2 VLAN FlexLinks Load Balancing Configuration Example

201398

FlexLinks Multicast Fast Convergence

FlexLinks Multicast Fast Convergence reduces the multicast traffic convergence time after a FlexLinks failure.

Learning the Other FlexLinks Port as the mrouter Port

In a typical multicast network, there is a querier for each VLAN. A switch deployed at the edge of a network has one of its FlexLinks ports receiving queries. FlexLinks ports are also always forwarding at any given time.

A port that receives queries is added as an *mrouter* port on the switch. An mrouter port is part of all the multicast groups learned by the switch. After a changeover, queries are received by the other FlexLinks port. The other FlexLinks port is then learned as the mrouter port. After the changeover, multicast traffic flows through the other FlexLinks port. To achieve faster convergence of traffic, both FlexLinks ports are learned as mrouter ports whenever either FlexLinks port is learned as the mrouter port. Both FlexLinks ports are always part of multicast groups.

Though both FlexLinks ports are part of the groups in normal operation mode, all traffic on the backup port is blocked. So the normal multicast data flow is not affected by the addition of the backup port as an mrouter port. When the changeover happens, the backup port is unblocked, allowing the traffic to flow. In this case, the upstream multicast data flows as soon as the backup port is unblocked.

Generating IGMP Reports

When the backup link comes up after the changeover, the upstream new distribution switch does not start forwarding multicast data, because the port on the upstream router, which is connected to the blocked FlexLinks port, is not part of any multicast group. The reports for the multicast groups were not forwarded by the downstream switch because the backup link is blocked. The data does not flow on this port, until it learns the multicast groups, which occurs only after it receives reports.

The reports are sent by hosts when a general query is received, and a general query is sent within 60 seconds in normal scenarios. When the backup link starts forwarding, to achieve faster convergence of multicast data, the downstream switch immediately sends proxy reports for all the learned groups on this port without waiting for a general query.

Leaking IGMP Reports

To achieve multicast traffic convergence with minimal loss, a redundant data path must be set up before the FlexLinks active link goes down. This can be achieved by leaking only IGMP report packets on the FlexLinks backup link. These leaked IGMP report messages are processed by upstream distribution routers, so multicast data traffic gets forwarded to the backup interface. Because all incoming traffic on the backup interface is dropped at the ingress of the access switch, no duplicate multicast traffic is received by the host. When the FlexLinks active link fails, the access switch starts accepting traffic from the backup link immediately. The only disadvantage of this scheme is that it consumes bandwidth on the link between the distribution switches and on the backup link between the distribution and access switches. This feature is disabled by default and can be configured by using the **switchport backup interface *interface-id* multicast fast-convergence** command.

When this feature has been enabled at changeover, the switch does not generate the proxy reports on the backup port, which became the forwarding port.

MAC Address-Table Move Update

The MAC address-table move update feature allows the switch to provide rapid bidirectional convergence when a primary (forwarding) link goes down and the standby link begins forwarding traffic.

In [Figure 24-3](#), switch A is an access switch, and ports 1 and 2 on switch A are connected to uplink switches B and D through a FlexLinks pair. Port 1 is forwarding traffic, and port 2 is in the backup state. Traffic from the PC to the server is forwarded from port 1 to port 3. The MAC address of the PC has been learned on port 3 of switch C. Traffic from the server to the PC is forwarded from port 3 to port 1.

If the MAC address-table move update feature is not configured and port 1 goes down, port 2 starts forwarding traffic. However, for a short time, switch C keeps forwarding traffic from the server to the PC through port 3, and the PC does not get the traffic because port 1 is down. If switch C removes the MAC address of the PC on port 3 and relearns it on port 4, traffic can then be forwarded from the server to the PC through port 2.

If the MAC address-table move update feature is configured and enabled on the switches in [Figure 24-3](#) and port 1 goes down, port 2 starts forwarding traffic from the PC to the server. The switch sends a MAC address-table move update packet from port 2. Switch C gets this packet on port 4 and immediately learns the MAC address of the PC on port 4, which reduces the reconvergence time.

You can configure the access switch, switch A, to *send* MAC address-table move update messages. You can also configure the uplink switches B, C, and D to *get* and process the MAC address-table move update messages. When switch C gets a MAC address-table move update message from switch A, switch C learns the MAC address of the PC on port 4. Switch C updates the MAC address table, including the forwarding table entry for the PC.

Switch A does not need to wait for the MAC address-table update. The switch detects a failure on port 1 and immediately starts forwarding server traffic from port 2, the new forwarding port. This change occurs in 100 milliseconds (ms). The PC is directly connected to switch A, and the connection status does not change. Switch A does not need to update the PC entry in the MAC address table.

Figure 24-3 MAC Address-Table Move Update Example

Default Settings for FlexLinks and MAC Address-Table Move Update

Default Settings

FlexLinks is not configured, and there are no backup interfaces defined.

The preemption mode is off.

The preemption delay is 35 seconds.

MAC address-table move update is not configured on the switch.

Configuration Guidelines for FlexLinks and MAC Address-Table Move Update

Follow these guidelines to configure FlexLinks:

- You can configure up to 16 backup links.
- You can configure only one FlexLinks backup link for any active link, and it must be a different interface from the active interface.
- An interface can belong to only one FlexLinks pair. An interface can be a backup link for only one active link. An active link cannot belong to another FlexLinks pair.
- Neither of the links can be a port that belongs to an EtherChannel. However, you can configure two port channels (EtherChannel logical interfaces) as FlexLinks, and you can configure a port channel and a physical interface as FlexLinks, with either the port channel or the physical interface as the active link.
- A backup link does not have to be the same type (Fast Ethernet, Gigabit Ethernet, or port channel) as the active link. However, you should configure both FlexLinks with similar characteristics so that there are no loops or changes in behavior if the standby link begins to forward traffic.
- STP is disabled on FlexLinks ports. A FlexLinks port does not participate in STP, even if the VLANs present on the port are configured for STP. When STP is not enabled, be sure that there are no loops in the configured topology. Once the FlexLinks configurations are removed, STP is reenabled on the ports.

Follow these guidelines to configure VLAN load balancing on the FlexLinks feature:

- For FlexLinks VLAN load balancing, you must choose the preferred VLANs on the backup interface.
- You cannot configure a preemption mechanism and VLAN load balancing for the same FlexLinks pair.

Follow these guidelines to configure the MAC address-table move update feature:

- You can enable and configure this feature on the access switch to *send* the MAC address-table move updates.
- You can enable and configure this feature on the uplink switches to *receive* the MAC address-table move updates.

How to Configure the FlexLinks and MAC Address-Table Move Update

Configuring FlexLinks

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>interface interface-id</code>	Specifies the interface, and enters interface configuration mode. The interface can be a physical Layer 2 interface or a port channel (logical interface). The port-channel range is 1 to 6.

	Command	Purpose
Step 3	switchport backup interface <i>interface-id</i>	Configures a physical Layer 2 interface (or port channel) as part of a FlexLinks pair with the interface. When one link is forwarding traffic, the other interface is in standby mode.
Step 4	end	Returns to privileged EXEC mode.

Configuring a Preemption Scheme for FlexLinks

	Command	Purpose
Step 1	configure terminal	Enters global configuration mode.
Step 2	interface <i>interface-id</i>	Specifies the interface, and enter interface configuration mode. The interface can be a physical Layer 2 interface or a port channel (logical interface). The port-channel range is 1 to 6.
Step 3	switchport backup interface <i>interface-id</i>	Configures a physical Layer 2 interface (or port channel) as part of a FlexLinks pair with the interface. When one link is forwarding traffic, the other interface is in standby mode.
Step 4	switchport backup interface <i>interface-id</i> preemption mode [forced bandwidth off]	Configures a preemption mechanism and delay for a FlexLinks interface pair. You can configure the preemption as: <ul style="list-style-type: none"> • forced—The active interface always preempts the backup. • bandwidth—The interface with the higher bandwidth always acts as the active interface. • off—No preemption happens from active to backup.
Step 5	switchport backup interface <i>interface-id</i> preemption delay <i>delay-time</i>	Configures the time delay until a port preempts another port. Note Setting a delay time only works with forced and bandwidth modes.
Step 6	end	Returns to privileged EXEC mode.

Configuring VLAN Load Balancing on FlexLinks

	Command	Purpose
Step 1	configure terminal	Enters global configuration mode.
Step 2	interface <i>interface-id</i>	Specifies the interface, and enters interface configuration mode. The interface can be a physical Layer 2 interface or a port channel (logical interface). The port-channel range is 1 to 6.

	Command	Purpose
Step 3	switchport backup interface <i>interface-id</i> prefer vlan <i>vlan-range</i>	Configures a physical Layer 2 interface (or port channel) as part of a FlexLinks pair with the interface, and specifies the VLANs carried on the interface. The VLAN ID range is 1 to 4096.
Step 4	end	Returns to privileged EXEC mode.

Configuring the MAC Address-Table Move Update Feature

	Command	Purpose
Step 1	configure terminal	Enters global configuration mode.
Step 2	interface <i>interface-id</i>	Specifies the interface, and enters interface configuration mode. The interface can be a physical Layer 2 interface or a port channel (logical interface). The port-channel range is 1 to 6.
Step 3	switchport backup interface <i>interface-id</i> or switchport backup interface <i>interface-id</i> mmu primary vlan <i>vlan-id</i>	Configures a physical Layer 2 interface (or port channel), as part of a FlexLinks pair with the interface. The MAC address-table move update VLAN is the lowest VLAN ID on the interface. Configures a physical Layer 2 interface (or port channel) and specifies the VLAN ID on the interface, which is used for sending the MAC address-table move update. When one link is forwarding traffic, the other interface is in standby mode.
Step 4	end	Returns to global configuration mode.
Step 5	mac address-table move update transmit	Enables the access switch to send MAC address-table move updates to other switches in the network if the primary link goes down and the switch starts forwarding traffic through the standby link.
Step 6	end	Returns to privileged EXEC mode.

Configuring the MAC Address-Table Move Update Messages

	Command	Purpose
Step 1	configure terminal	Enters global configuration mode.
Step 2	mac address-table move update receive	Enables the switch to get and process the MAC address-table move updates.
Step 3	end	Returns to privileged EXEC mode.
Step 4	show mac address-table move update	Verifies the configuration.
Step 5	copy running-config startup config	(Optional) Saves your entries in the switch startup configuration file.

Maintaining and Monitoring the FlexLinks and MAC Address-Table Move Update

Command	Purpose
<code>show interfaces [interface-id] switchport backup</code>	Displays the FlexLinks backup interface configured for an interface or all the configured FlexLinks and the state of each active and backup interface (up or standby mode). When VLAN load balancing is enabled, the output displays the preferred VLANs on active and backup interfaces.
<code>show mac address-table move update</code>	Verifies the configuration.

Configuration Examples for the FlexLinks and MAC Address-Table Move Update

Configuring FlexLinks Port: Examples

These are configuration examples for learning the other FlexLinks port as the mrouter port when FlexLinks is configured, with output for the `show interfaces switchport backup` command:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface GigabitEthernet1/1
Switch(config-if)# switchport trunk encapsulation dot1q
Switch(config-if)# switchport mode trunk
Switch(config-if)# switchport backup interface GigabitEthernet1/2
Switch(config-if)# exit
Switch(config)# interface GigabitEthernet1/2
Switch(config-if)# switchport mode trunk
Switch(config-if)# end
Switch# show interfaces switchport backup detail
Switch Backup Interface Pairs:
Active Interface Backup Interface State
Preemption Mode : off
Multicast Fast Convergence : Off
Mac Address Move Update Vlan : auto
```

This output shows a querier for VLANs 1 and 401, with their queries reaching the switch through the specified port:

```
Switch# show ip igmp snooping querier
Vlan    IP Address    IGMP Version    Port
-----
1       1.1.1.1       v2               Gi0/1
401     41.41.41.1   v2               Gi0/1
```

Here is output for the `show ip igmp snooping mrouter` command for VLANs 1 and 401:

```
Switch# show ip igmp snooping mrouter
Vlan    ports
```

```

-----
1      Gi1/1(dynamic), Gi1/2(dynamic)
401    Gi1/1(dynamic), Gi1/2(dynamic)

```

Similarly, both FlexLinks ports are part of learned groups. In this example, GigabitEthernet1/1 is a receiver/host in VLAN 1, which is interested in two multicast groups:

```

Switch# show ip igmp snooping groups
Vlan   Group      Type   Version  Port List
-----
1      228.1.5.1  igmp   v2       Gi1/1, Gi1/2, Fa2/1
1      228.1.5.2  igmp   v2       Gi1/1, Gi1/2, Fa2/1

```

When a host responds to the general query, the switch forwards this report on all the mrouter ports. In this example, when a host sends a report for the group 228.1.5.1, it is forwarded only on GigabitEthernet1/1, because the backup port GigabitEthernet1/2 is blocked. When the active link, GigabitEthernet1/1, goes down, the backup port, GigabitEthernet1/2, begins forwarding.

As soon as this port starts forwarding, the switch sends proxy reports for the groups 228.1.5.1 and 228.1.5.2 on behalf of the host. The upstream router learns the groups and starts forwarding multicast data. This is the default behavior of FlexLinks. This behavior changes when the user configures fast convergence using the **switchport backup interface GigabitEthernet1/2 multicast fast-convergence** command. This example shows how this feature is configured:

```

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface GigabitEthernet1/1
Switch(config-if)# switchport backup interface GigabitEthernet1/2 multicast
fast-convergence
Switch(config-if)# exit
Switch# show interfaces switchport backup detail

```

```

Switch Backup Interface Pairs:
Active          Interface          Backup Interface State
-----
GigabitEthernet1/1 GigabitEthernet1/2 Active Up/Backup Standby
Preemption Mode : off
Multicast Fast Convergence : On
Mac Address Move Update Vlan : auto

```

This output shows a querier for VLAN 1 and 401 with their queries reaching the switch through the configured port:

```

Switch# show ip igmp snooping querier
Vlan   IP Address   IGMP Version  Port
-----
1      1.1.1.1     v2            Gi1/1
401    41.41.41.1  v2            Gi1/1

```

This is output for the **show ip igmp snooping mrouter** command for VLAN 1 and 401:

```

Switch# show ip igmp snooping mrouter
Vlan   ports
-----
1      Gi1/1(dynamic), Gi1/2(dynamic)
401    Gi1/1(dynamic), Gi1/2(dynamic)

```

Similarly, both the FlexLinks ports are a part of the learned groups. In this example, the port is a receiver/host in VLAN 1, which is interested in two multicast groups:

```

Switch# show ip igmp snooping groups
Vlan   Group      Type   Version  Port List
-----

```

```

1      228.1.5.1  igmp   v2      Gi1/1, Gi1/2, Gi1/1
1      228.1.5.2  igmp   v2      Gi1/1, Gi1/2, Gi1/1

```

Whenever a host responds to the general query, the switch forwards this report on all the mrouter ports. When you turn on this feature through the command-line port, and when a report is forwarded by the switch on the configured GigabitEthernet1/1, it is also leaked to the backup port GigabitEthernet1/2. The upstream router learns the groups and starts forwarding multicast data, which is dropped at the ingress because the GigabitEthernet1/2 is blocked. When the active link, GigabitEthernet1/1 goes down, the backup port, GigabitEthernet1/2, begins forwarding. You do not need to send any proxy reports because the multicast data is already being forwarded by the upstream router. By leaking reports to the backup port, a redundant multicast path has been set up, and the time taken for the multicast traffic convergence is minimal.

Configuring a Backup Interface: Example

This example shows how to configure an interface with a backup interface and to verify the configuration:

```

Switch# configure terminal
Switch(conf)# interface gigabitethernet1/1
Switch(conf-if)# switchport backup interface gigabitethernet1/2
Switch(conf-if)# end

```

```

Switch# show interfaces switchport backup
Switch Backup Interface Pairs:

```

Active Interface	Backup Interface	State

Vlans Preferred on Active Interface: 1-3,5-4096		
Vlans Preferred on Backup Interface: 4		

Configuring a Preemption Scheme: Example

This example shows how to configure the preemption mode as *forced* for a backup interface pair and to verify the configuration:

```

Switch# configure terminal
Switch(conf)# interface gigabitethernet1/1
Switch(conf-if)# switchport backup interface gigabitethernet1/2 preemption mode forced
Switch(conf-if)# switchport backup interface gigabitethernet1/2 preemption delay 50
Switch(conf-if)# end

```

```

Switch# show interfaces switchport backup detail
Active Interface Backup Interface State
-----

```

```

GigabitEthernet1/1 GigabitEthernet1/2 Active Up/Backup Standby
Interface Pair : Gi1/1, Gi1/2
Preemption Mode : forced
Preemption Delay : 50 seconds
Bandwidth : 100000 Kbit (Gi1/1), 100000 Kbit (Gi1/2)
Mac Address Move Update Vlan : auto

```

Configuring VLAN Load Balancing on FlexLinks: Examples

In the following example, VLANs 1 to 50, 60, and 100 to 120 are configured on the switch:

```
Switch(config)# interface gigabitEthernet 1/2
Switch(config-if)# switchport backup interface gigabitEthernet 1/2 prefer vlan 60,100-120
```

When both interfaces are up, GigabitEthernet1/1 forwards traffic for VLANs 60 and 100 to 120, and GigabitEthernet1/2 forwards traffic for VLANs 1 to 50.

```
Switch# show interfaces switchport backup
Switch Backup Interface Pairs:
```

Active Interface	Backup Interface	State
GigabitEthernet1/1	GigabitEthernet1/2	Active Up/Backup Standby
Vlans Preferred on Active Interface: 1-50		
Vlans Preferred on Backup Interface: 60, 100-120		

When a FlexLinks interface goes down (LINK_DOWN), VLANs preferred on this interface are moved to the peer interface of the FlexLinks pair. In this example, if interface Gigabit Ethernet1/1 goes down, Gigabit Ethernet1/2 carries all VLANs of the FlexLinks pair.

```
Switch# show interfaces switchport backup
Switch Backup Interface Pairs:
```

Active Interface	Backup Interface	State
GigabitEthernet1/1	GigabitEthernet1/2	Active Down/Backup Up
Vlans Preferred on Active Interface: 1-50		
Vlans Preferred on Backup Interface: 60, 100-120		

When a FlexLinks interface comes up, VLANs preferred on this interface are blocked on the peer interface and moved to the forwarding state on the interface that has just come up. In this example, if interface Gigabit Ethernet1/1 comes up, VLANs preferred on this interface are blocked on the peer interface Gigabit Ethernet1/2 and forwarded on Gigabit Ethernet1/1.

```
Switch# show interfaces switchport backup
Switch Backup Interface Pairs:
```

Active Interface	Backup Interface	State
GigabitEthernet1/1	GigabitEthernet1/2	Active Down/Backup Up
Vlans Preferred on Active Interface: 1-50		
Vlans Preferred on Backup Interface: 60, 100-120		

```
Switch# show interfaces switchport backup detail
Switch Backup Interface Pairs:
```

Active Interface	Backup Interface	State
FastEthernet1/3	FastEthernet1/4	Active Down/Backup Up
Vlans Preferred on Active Interface: 1-2,5-4096		
Vlans Preferred on Backup Interface: 3-4		
Preemption Mode : off		
Bandwidth : 10000 Kbit (Fa1/3), 100000 Kbit (Fa1/4)		
Mac Address Move Update Vlan : auto		

Configuring MAC Address-Table Move Update: Example

This example shows how to configure an access switch to send MAC address-table move update messages:

```
Switch(conf)# interface gigabitethernet1/1
Switch(conf-if)# switchport backup interface gigabitethernet1/2 mmu primary vlan 2
Switch(conf-if)# exit
Switch(conf)# mac address-table move update transmit
Switch(conf)# end
```

This example shows how to verify the configuration:

```
Switch# show mac-address-table move update
Switch-ID : 010b.4630.1780
Dst mac-address : 0180.c200.0010
Vlans/Macs supported : 1023/8320
Default/Current settings: Rcv Off/On, Xmt Off/On
Max packets per min : Rcv 40, Xmt 60
Rcv packet count : 5
Rcv conforming packet count : 5
Rcv invalid packet count : 0
Rcv packet count this min : 0
Rcv threshold exceed count : 0
Rcv last sequence# this min : 0
Rcv last interface : Po2
Rcv last src-mac-address : 000b.462d.c502
Rcv last switch-ID : 0403.fd6a.8700
Xmt packet count : 0
Xmt packet count this min : 0
Xmt threshold exceed count : 0
Xmt pak buf unavail cnt : 0
Xmt last interface : None
```
