- [Configuring SSH Options, page 9](#)
- [Configuring the Management Interface with a Second IP Address, page 19](#)
- [VM Hardware Verification, page 20](#)

Initial StarOS Configuration

Following successful installation of VPC-DI across all VMs, you must configure a set of StarOS parameters via the active Control Function (CF) VM. You then save these settings in a configuration file on the active CF that is accessed whenever a VM in the VPC-DI instance is rebooted. The standby CF and all Service Function (SF) VMs read this configuration file from the active CF.

This chapter provides instructions for connecting to the active CF console port and creating the initial local context management configuration.

Using the StarOS Quick Setup Wizard

The Quick Setup Wizard consists of three parts:

- Configuring a context-level security administrator and hostname
- Configuring the Ethernet interface for out-of-band (OOB) management
- Configuring the system for remote CLI access via Telnet, Secure Shell (SSH), or File Transfer Protocol (FTP)

The following figure and table provides a flow diagram that shows the run logic of the wizard along with additional information and notes.

Figure 1: StarOS Quick Setup Wizard Logic Diagram

Table 1: Quick Setup Wizard Logic Diagram Callout Descriptions

Item	Task	Description/Notes
1	Enter or exit the wizard.	Enter no at the prompt to automatically be directed to the command line interface (CLI). Proceed to Using the StarOS CLI for Initial Configuration, on page 5 for instructions on performing an initial system configuration with the CLI.
		Enter setup at the command prompt to re-invoke the wizard.
2	<i>For release 19.2 and higher, configure a tech-support password.</i>	The tech-support password is used to access cli test-commands.
	Configure an administrative username/password and the a hostname for the system.	The name of the default administrative user configured through the wizard is <i>admin</i> .
		Administrative user name is an alphanumeric string of 1 through 32 characters that is case sensitive.
		Administrative user password is an alphanumeric string of 1 through 63 characters that is case sensitive. For release 21.0 and later, you can enter 127 characters for the password.
Configure a valid, non-null hostname. The hostname is an alphanumeric string of 1 through 63 characters that is case sensitive.		
3	Configure a single out-of-band management interface for the system.	Traffic on the management LAN is not transferred over the same media as user data and control signaling.
		For security reasons, it is recommended that management functions be maintained on a separate network from user data and control signaling.
		Configure an IP address, subnet mask, and gateway for the interface.
4	Enable the remote access protocol for accessing the system.	Secure Shell (SSH) uses TCP port number 22 by default, if enabled. SSH V1 and/or V2 are supported. For maximum security, use only SSH v2.

Item	Task	Description/Notes
5	Enable file transfer protocols for copying files to/from the system.	If SSH is enabled, you can also enable SSH File Transfer Protocol (SFTP) server functionality. Telnet uses TCP port number 23 by default, if enabled. The File Transfer Protocol (FTP) uses TCP port number 21 by default, if enabled.
6	Review and/or modify the configuration of previous prompts.	<ol style="list-style-type: none"> 1 Enter the number of the prompt to be modified. 2 Configure the parameter. 3 <i>Optional.</i> Repeat <i>step 1</i> and <i>step 2</i> to modify additional settings. 4 Enter "done" when you have completed all changes.
7	Review the configure script created by the wizard based on your inputs.	A sample of a created script is displayed in the example below. Variables are displayed in italics (<i>variable</i>).
8	Apply the configuration file to the system.	Once applied, the parameter configuration is automatically saved to the system.cfg file stored in /flash memory.

Sample Quick Setup Script

This is how the setup script appears if you run the EXEC mode **setup** command:

```
[local]host_name# setup
1. Do you wish to continue with the Quick Setup Wizard[yes/no]: yes
2. Enable basic configuration[yes/no]: yes
3. Change chassis key value[yes/no]: yes
4. New chassis key value: chassis_key
5. Create new tech-support password[yes/no]: yes
6. New tech-support password: new_password
7. local context administrator username[admin]: context_admin_username
8. local context administrator password: context_admin_password
9. confirm local context administrator password: context_admin_password
10. hostname[asr5500]: hostname
```

The chassis key can be configured using the Quick Setup Script only if Cisco Elastic Services Controller (ESC) is not used to deploy the system. To configure a custom chassis key where ESC is used for deployment, you must specify the desired chassis key in ESC. For more information, refer to [Onboarding the VPC-DI with ESC on OpenStack](#).

Using the StarOS CLI for Initial Configuration

The initial configuration consists of the following:

- Configuring a context-level security administrator and hostname
- Configuring the Ethernet interface on the vNIC
- Configuring the VPC-DI instance for remote CLI access via SSH

This section provides instructions for performing these tasks using the CLI.

Step 1 Log into the Console port of the active CF VM via the hypervisor.

Step 2 At the CLI prompt, enter:

```
[local]cf_host_name configure [local]cf_host_name (config)
```

Step 3 Enter the context configuration mode by entering the following command:

```
[local]cf_host_name (config) context local [local]cf_host_name (config-ctx)
```

The *local* context is the VPC-DI instance's management context. Contexts allow you to logically group services or interfaces. A single context can consist of multiple services and can be bound to multiple interfaces.

Step 4 Enter the following command to configure a context-level security administrator for the VPC-DI instance:

```
administrator user_name [ encrypted ] password password
| [ ecs ] [ expiry-date date_time ] [ ftp ] [ li-administration ] [ nocli ] [ noecs ]
|
```

Note You must configure a context-level security administrator during the initial configuration. After you complete the initial configuration process and end the CLI session, if you have not configured a security administrator, CLI access will be locked. See the *Context Configuration Mode Commands* chapter in the *Command Line Interface Reference* for complete information about this command.

Step 5 Enter the following command at the prompt to exit the context configuration mode:

```
[local]cf_host_name (config-ctx) exit
[local]cf_host_name (config)
```

Step 6 Enter the following command to configure a hostname by which the VPC-DI instance will be recognized on the network:

```
[local]cf_host_name (config) system hostname cf_host_name
```

cf_host_name is the name by which the VPC-DI instance will be recognized on the network. The hostname is an alphanumeric string of 1 through 63 characters that is case sensitive. The default hostname is "qvp-di".

Step 7 Configure the network interfaces on the vNIC as follows:

a) Enter the context configuration mode by entering the following commands:

```
[local]cf_host_name (config) context local
[local]cf_host_name (config-ctx)
```

b) Enter the following command to specify a name for the interface:

```
[local]cf_host_name (config-ctx) interface interface_name
```

interface_name is the name of the interface expressed as an alphanumeric string of 1 through 79 characters that is case sensitive. The following prompt appears as StarOS enters the Ethernet Interface Configuration mode:

```
[local]cf_host_name (config-if-eth)
```

- c) Configure an IP address for the interface configured in the previous step by entering the following command:

```
{ ip address | ipv6 address } ipaddress subnetmask
```

Note If you are executing this command to correct an address or subnet that was mis-configured with the Quick Setup Wizard, you must verify the default route and port binding configuration. Use *step 11* and *step 6* of this procedure. If there are issues, perform steps *7e* through *7k* to reconfigure the information.

- d) Enter the following command to exit the Ethernet interface configuration mode:

```
[local]cf_host_name(config-if-eth) exit
```

```
[local]cf_host_name(config-ctx)
```

- e) Configure a static route, if required, to point the VPC-DI instance to a default gateway. Entering the following command:

```
{ ip | ipv6 } route gw_address interface_name
```

- f) Enter the following to exit from the context configuration mode:

```
[local]cf_host_name(config-ctx) exit
```

```
[local]cf_host_name(config)
```

- g) Enter the Ethernet Port Configuration mode:

```
[local]cf_host_name(config) port ethernet slot/port
```

For VPC-DI, the *slot* corresponds to a CF or SF VM within the virtual chassis. The hypervisor assigns a unique slot number to each VM during initial configuration of the VPC-DI instance. Slots 1 and 2 are assigned to the CF VMs; slot numbers 3 through 32 are assigned to SF VMs. The CF only supports port 1. Each SF supports four vNICs numbered 1 through 4 with corresponding virtual ethernet ports numbered 10 through 14. SF port number 10 must be configured.

- h) Bind the port to the interface that you created in step 7b. Binding associates the port and all of its settings to the interface. Enter the following command:

```
[local]cf_host_name(config-port-slot/port) bind interface interface_name local
```

```
[local]cf_host_name(config-port-slot/port) no shutdown
```

interface_name is the name of the interface that you configured in *step 7b*.

- i) Exit the Ethernet Interface Configuration mode by entering the command:

```
[local]cf_host_name(config-port-slot/port) exit
```

```
[local]cf_host_name(config)
```

Note The management port also supports VLANs. For additional information, refer to the *VLANs* section of the *Interfaces and Ports* chapter.

Configuring System Administrative Users

This section describes some of the security features that allow security administrators to control user accounts.

Limiting the Number of Concurrent CLI Sessions

Security administrators can limit the number of concurrent interactive CLI sessions. Limiting the number of concurrent interactive sessions reduces the consumption of system-wide resources. It also prevents a user from potentially accessing sensitive user information which is already in use.

Most privileged accounts do not require multiple concurrent logins.

Important Configuring the maximum number of sessions is recommended for all privileged accounts.

Security administrators can limit the number of concurrent interactive CLI sessions with three different ways depending on the authentication method which is used for that particular user account.

StarOS supports three login authentication methods:

- TACACS+ Server users
- Local-User users
- AAA Context users

For additional information on configuring the maximum number of sessions for TACACS+ Server users, see [Operation](#). For additional information on configuring the maximum number of sessions for Local-User users and AAA context users, see [Configuring Context-Level Administrative Users](#).

Each authentication method must be configured separately because each of the three authentication methods can use the same user name.

Automatic Logout of CLI Sessions

Security administrators can configure an automatic logout of certain user accounts. Limiting the number of minutes that an interactive CLI session can be in use reduces the consumption of system-wide resources. It also prevents a user from potentially accessing a user account in a terminal window which is left idle. All authentication methods described in this section support both the idle session timeout technique and the absolute session timeout technique.

Most privileged accounts do not require an indefinite login timeout limit.

Important Configuring the session timeout is strongly recommended for all privileged accounts.

The idle timeout and session timeout fields in the **show tacacs summary** and **show tacacs session id** commands allow administrators to configure an automatic logout of certain accounts.

Session Timeout: allows a security administrator to specify the maximum amount of minutes that a user can be logged in to a session before the session is automatically disconnected.

Idle Timeout: allows a security administrator to specify the maximum amount of minutes that a session can remain in an idle state before the session is automatically disconnected.

Important The session timeout and idle timeout fields are not exclusive. If both are specified, then the idle timeout should always be lower than the session timeout since a lower session timeout will always be reached first.

For additional information on configuring the maximum number of minutes that an interactive CLI session can be in use, see the **idle-sessions threshold** command and the **clear tacacs sessions** CLI command in the *CLI Reference* and the **show tacacs summary** and **show tacacs session id** in the *Statistics and Counter Reference*.

Configuring the System for Remote Access

Configure the system for remote access. An administrative user may access the instance from a remote location over the management network:

- Telnet
- Secure Shell (SSH)
- File Transfer Protocol (FTP) (secured or unsecured)
- Trivial File Transfer Protocol (TFTP)

Note If there are two simultaneous telnet sessions, and one administrator deletes the context into which the other administrator is logged, the administrator in the deleted context will not be automatically kicked into the *local* context. Although the deleted context will still appear in the CLI prompt, context specific commands will generate errors.

Note For maximum security, use SSH v2.

Step 1 Enter the context configuration mode by entering the following command:

```
[local]cf_host_name(config) context local
[local]cf_host_name(config-ctx)
```

Step 2 Configure the system to allow Telnet access, if desired:

```
[local]cf_host_name(config-ctx) server telnetd
```

Step 3 Configure the system to allow SSH access, if desired:

```
[local]cf_host_name(config-ctx) ssh generate key [ type v2-rsa ]
```

Note **v2-rsa** is the recommended key type.

Note In Release 4.0 and higher, the **v1-rsa** keyword has been removed and the **v2-dsa** keyword has been concealed within the Context Configuration mode **ssh generate** CLI command. A keyword that was supported in a previous release may be concealed in subsequent releases. The system continues to parse concealed keywords in existing scripts and configuration files created in a previous release. But the concealed keyword no longer appears in the command syntax for use in new scripts or configuration files. Entering a question mark (?) will not display a concealed keyword as part of the Help text. A removed keyword generates an error message when parsed.

```
[local]cf_host_name(config-ctx) server sshd
[local]cf_host_name(config-sshd) subsystem sftp
[local]cf_host_name(config-sshd) exit
```

Step 4 Configure the system to allow FTP access, if desired, by entering the following command:

```
[local]cf_host_name(config-ctx) server ftpd
```

Step 5 Exit the configuration mode by entering the following command:

```
[local]cf_host_name(config-ctx) end
[local]cf_host_name
```

Step 6 Verify the configuration by entering the following command:

```
[local]cf_host_name show configuration
```

The CLI output should be similar to the sample output:

```
context local
  interface interface_name
    ip address ipaddress subnetmask
    exit
  subscriber default
    exit
  administrator admin_name password admin_password
  server telnetd
  server ftpd
  ssh generate key
  server sshd
  subsystem sftp
  exit
port ethernet 1/1
  bind interface interface_name local
  exit
port ethernet 1/1
  no shutdown
  exit
snmp engine-id local 800007e580ed826c191ded2d3d
end
```

Step 7 Verify the configuration of the IP routes by entering the following command:
[local]*cf_host_name* **show ip route**

The CLI output should be similar to the sample output:

"*" indicates the Best or Used route.

Destination	Nexthop	Protocol	Prec	Cost	Interface
*0.0.0.0/0	<i>ipaddress</i>	static	1	0	vnic1
* <i>network</i>	0.0.0.0	connected	0	0	vnic1

Step 8 Verify the interface binding by entering the following command:
[local]*cf_host_name* **show ip interface name** *interface_name*
interface_name is the name of the interface that was configured in *step 7b*. The CLI output should be similar to the sample output:

```
Intf Name:      vnic1

Description:
IP State:      UP (Bound to 1/1 untagged, ifIndex 83951617)
IP Address:    ipaddress          Subnet Mask:    subnetmask
Bcast Address: bcastaddress        MTU:            1500
Resoln Type:   ARP                ARP timeout:    3600 secsL3 monitor LC-port
switchover:   DiasabledNumber of Secondary Addresses: 0
```

Step 9 Save your configuration as described in the *Verifying and Saving Your Configuration* chapter.

Configuring SSH Options

SSHv2 RSA is the only version of SSH supported under StarOS. Keywords previously supported for SSHv1 RSA and SSHv2 DSA have been removed from or concealed within the StarOS CLI.

**Important**

A keyword that was supported in a previous release may be concealed in subsequent releases. StarOS continues to parse concealed keywords in existing scripts and configuration files created in a previous release. But the concealed keyword no longer appears in the command syntax for use in new scripts or configuration files. Entering a question mark (?) will not display a concealed keyword as part of the Help text. Removed keywords generate an error message when parsed.

Version 1 of the SSH protocol is now obsolete due to security vulnerabilities. The **v1-rsa** keyword has been removed for the Context Configuration mode **ssh** command. Running a script or configuration that uses the SSHv1-RSA key returns an error message and generates an event log. The output of the error message is shown below:

```
CLI print failure Failure: SSH V1 contains multiple structural vulnerabilities and is no longer considered secure. Therefore we don't support v1-rsa SSH key any longer, please generate a new v2-rsa key to replace this old one.
```

If the system boots from a configuration that contains the **v1-rsa** key, you can expect a boot failure when logging in through SSH. The workaround is to log in via the Console port, re-generate a new ssh v2-rsa key, and configure server sshd. It will then be possible to log in via ssh.

The **v2-dsa** keyword is now concealed for the Context Configuration mode **ssh** command

The **v1-rsa** keyword has been removed from the Exec mode **show ssh key** CLI command.

SSH Host Keys

SSH key-based authentication uses two keys, one "public" key that anyone is allowed to see, and another "private" key that only the owner is allowed to see. You create a key pair, securely store the private key on the device you want to log in from, and store the public key on the system (VPC-DI) that you wish to log into.

SSH host keys are generated within a specified StarOS context. The context is associated with a user interface.

You set or remove an administrative user name having authorized keys for access to the sshd server associated with context.

Setting SSH Key Size

The Global Configuration mode **ssh key-size** CLI command configures the key size for SSH key generation for all contexts (RSA host key only).

Step 1 Enter the Global Configuration mode.

```
[local]host_name# configure
[local]host_name(config)#
```

Step 2 Specify the bit size for SSH keys.

```
[local]host_name(config)# ssh key-size { 2048 | 3072 | 4096 | 5120 | 6144 | 7168 | 9216 }
```

The default bit size for SSH keys is 2048 bits.

Configuring SSH Key Generation Wait Time

SSH keys can only be generated after a configurable time interval has expired since the last key generation. The **ssh key-gen wait-time** command specifies this wait time in seconds. The default interval is 300 seconds (5 minutes).

Step 1

Enter the context configuration mode.

```
[local]host_name(config)# context context_name
[local]host_name(config-ctx)#
```

Step 2

Specify the wait time interval.

```
[local]host_name(config-ctx)# ssh key-gen wait-time seconds
[local]host_name(config-ctx)#
```

Notes:

- *seconds* is specified as an integer from 0 through 86400. Default = 300

Specifying SSH Encryption Ciphers

The SSH Configuration mode **ciphers** CLI command configures the cipher priority list in sshd for SSH symmetric encryption. It changes the cipher options for that context.

Step 1

Enter the SSH Configuration mode.

```
[local]host_name(config-ctx)# server sshd
```

Step 2

Specify the desired encryption algorithms.

```
[local]host_name(config-sshd)# ciphers algorithms
```

Notes:

- *algorithms* is a string of 1 through 511 alphanumeric characters that specifies the algorithm(s) to be used as a single string of comma-separated variables (no spaces) in priority order (left to right) from those shown below:
 - **blowfish-cbc** – symmetric-key block cipher, Cipher Block Chaining, (CBC)
 - **3des-cbc** – Triple Data Encryption Standard, CBC
 - **aes128-cbc** – Advanced Encryption Standard (AES), 128-bit key size, CBC
 - **aes128-ctr** – AES, 128-bit key size, Counter-mode encryption (CTR)
 - **aes192-ctr** – AES, 192-bit key size, CTR
 - **aes256-ctr** – AES, 256-bit key size, CTR
 - **aes128-gcm@openssh.com** – AES, 128-bit key size, Galois Counter Mode [GCM], OpenSSH
 - **aes256-gcm@openssh.com** – AES, 256-bit key size, GCM, OpenSSH

- **chacha20-poly1305@openssh.com** – ChaCha20 symmetric cipher, Poly1305 cryptographic Message Authentication Code [MAC], OpenSSH

The default string for *algorithms* in a Normal build is:

```
blowfish-cbc,3des-cbc,aes128-cbc,aes128-ctr,aes192-ctr,aes256-ctr,aes128-gcm@openssh.com,aes256-gcm@openssh.com,
chacha20-poly1305@openssh.com
```

The default string for *algorithms* in a Trusted build is:

```
aes256-ctr,aes192-ctr,aes128-ctr
```

Step 3 Exit the SSH Configuration mode.

```
[local]host_name(config-sshd)# end
[local]host_name#
```

Generating SSH Keys

The **ssh generate** command generates a public/private key pair which is to be used by the SSH server. The **v1-rsa** keyword has been removed from and the **v2-dsa** keyword concealed within the **ssh generate** CLI command. The only keyword available for generating SSH keys is **v2-rsa**.

Important

The generated key pair remains in use until the command is issued again.

Step 1 Enter the context configuration mode:

```
[local]host_name(config)# context context_name
[local]host_name(config-ctx)#
```

Step 2 Generate an SSH key pair.

```
[local]host_name(config-ctx)# ssh generate key type v2-rsa
[local]host_name(config-ctx)#
```

Setting SSH Key Pair

The **ssh key** command sets the public/private key pair to be used by the system. The **v2-dsa** keyword is concealed in the **ssh key** command.

Specify the SSH key pair parameters.

```
[local]host_name(config-ctx)# ssh key data length octets type v2-rsa
```

Notes:

- *data* is the encrypted key expressed as an alphanumeric string of 1 through 1023 characters
- **length** *octets* is the length of the encrypted key in octets expressed as an integer from 0 through 65535
- **type** specifies the key type; **v2-rsa** is the only supported type.

Important For releases prior to 20.0, StarOS supports a maximum of 64 configurable authorized SSH keys. For release 20.0 and higher, StarOS supports a maximum of 200 configurable authorized SSH keys.

Authorized SSH User Access

You must authorize users to access a StarOS context from a specific host with an SSH authentication-key pair.

Authorizing SSH User Access

The SSH Configuration mode **authorized-key** command grants user access to a context from a specified host.

Step 1

Go to the SSH Configuration mode.

```
[local]host_name(config-ctx)# server sshd
[local]host_name(config-sshd)#
```

Step 2

Specify administrative user access via the **authorized-key** command.

```
[local]host_name(config-sshd)# authorized-key username user_name host host_ip [ type { v2-dsa | v2-rsa } ]
```

Notes:

- **username** *user_name* specifies an existing StarOS administrator user name as having authorized keys for access to the sshd server. The *user_name* is expressed as an alphanumeric string of 1 through 255 characters. User names should have been previously created via the Context Configuration mode **administrator** command using the **nopassword** option to prevent bypassing of the sshd keys. Refer to the *System Settings* chapter for additional information on creating administrators.
- **host** *host_ip* specifies the IP address of an SSH host having the authorization keys for this username. The IP address must be in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.
- **type** specifies the key type; **v2-rsa** is the only supported type.

SSH User Login Restrictions

An administrator can restrict SSH access to the StarOS CLI to a "white list" of allowed users. Access to a service may be restricted to only those users having a legitimate need. Only explicitly allowed users will be able connect to a host via SSH. The user name may optionally include a specific source IP address.

The AllowUsers list consists of user name patterns, separated by space. If the pattern takes the form 'USER' then login is restricted for that user. If pattern is in the format 'USER@IP_ADDRESS' then USER and IP address are separately checked, restricting logins to those users from the specified IP address.

The default is to allow unrestricted access by any user.

Creating an Allowed Users List

The **allowusers add** command allows an administrator to create a list of users who may log into the StarOS CLI.

-
- Step 1** Enter the context configuration mode.
- ```
[local]host_name(config)# context context_name
[local]host_name(config-ctx)#
```
- Step 2** Go to the SSH Configuration mode.
- ```
[local]host_name(config-ctx)# server sshd
```
- Step 3** Configure the SSH user list.
- ```
[local]host_name(config-sshd)# allowusers add user_list
```
- user\_list* specifies a list of user name patterns, separated by spaces, as an alphanumeric string of 1 through 999 characters. If the pattern takes the form 'USER' then login is restricted for that user.
- If the pattern is in the format 'USER@IP\_ADDRESS' then user name and IP address are separately checked, restricting logins to those users from that particular IP address.
- If the pattern is in the format 'USER@<context>@IP\_ADDRESS' then user name, StarOS context and IP address are separately checked, restricting logins to those users associated with the specific context from that particular IP address.
- The following limits apply to the *user\_list*:
- The maximum length of this string is 3000 bytes including spaces.
  - The maximum number of AllowUsers, which is counted by spaces, is 256, which is consistent with the limit from OpenSSH.
- Important** If you exceed either of the above limits, an error message is displayed. The message prompts you to use a regular expression pattern to shorten the string, or remove all the allowusers with **no allowusers add** or **default allowusers add** and re-configure.
- For additional information, see the *SSH Configuration Mode Commands* chapter in the *Command Line Interface Reference*.
- Step 4** Exit the SSH Configuration mode.
- ```
[local]host_name(config-sshd)# end
[local]host_name#
```
-

SSH User Login Authentication

StarOS authenticates SSH user login attempts via authorized-key/user-account pairings for the following scenarios:

- User tries to login with local context username through local context (VPN) interface with authorized-key configured on local context.
- User tries to login with non-local context username through non-local context interface with authorized-key configured on non-local context.
- User tries to login with local context username through non-local context interface with authorized-key configured on local context.
- User tries to login with non-local context username through local context interface with authorized-key configured on non-local context.

A failure to authenticate based on the current system configuration prevents the login and generates an error message.

StarOS does not permit users with different user IDs but having the same public SSH key to login to an unauthorized context. Authentication of the user takes into account the authorized-key/user-account pairing.

**Important**

For StarOS release 21.0 onwards, a user cannot access the /flash directory if the user logs in from a non-local context.

Secure Session Logout

When StarOS is disconnected from an SSH client, the default behavior has sshd terminate the CLI or SFTP session in about 45 seconds (using default parameters). Two SSH Configuration mode CLI commands allow you to disable or modify this default sshd disconnect behavior.

**Important**

For higher security, Cisco recommends at least a `client-alive-countmax` of 2 and `client-alive-interval` of 5. Smaller session logout values may lead to occasional ssh session logouts. Adjust values to balance security and user friendliness.

The **client-active-countmax** command sets the number of client-alive messages which may be sent without sshd receiving any messages back from the SSH client (default =3). If this threshold is reached while the client-alive messages are being sent, sshd disconnects the SSH client thus terminating the session.

The **client-alive-interval** command sets a timeout interval in seconds (default = 15) after which if no data has been received from the SSH client, sshd sends a message through the encrypted channel to request a response from the client. The number of times that the message is sent is determined by the `client-alive-countmax` parameter. The approximate amount of time before sshd disconnects an SSH client $\text{disconnect} = \text{client-alive-countmax} \times \text{client-alive-interval}$.

The client-alive mechanism is valuable when the client or server depend on knowing when a connection has become inactive.

**Important**

The client-alive messages are sent through the encrypted channel and, therefore, are not spoofable.

Important These parameter apply to SSH protocol version 2 only.

Changing Default sshd Secure Session Logout Parameters

The following command sequence modifies the default settings for the ClientAliveCountmax (default = 3) and ClientAliveInterval (default = 15 seconds) parameters.

-
- Step 1** Enter the context configuration mode.
`[local]host_name# configure`
- Step 2** Go to the SSH Configuration mode.
`[local]host_name(config)# context context_name`
- Step 3** Set the ClientAliveCountmax parameter to 2.
`[local]host_name(config-sshd)# client-alive-countmax 2`
- Step 4** Set the ClientAliveInterval parameter to 5 seconds.
`[local]host_name(config-sshd)# client-alive-interval 5`
- Step 5** Exit the SSH Configuration mode.
`[local]host_name(config-sshd)# end`
`[local]host_name#`
-

SSH Client Login to External Servers

StarOS supports public key authentication for SSH/SFTP access from the StarOS gateway to external servers. You configure this feature by generating SSH client key pairs and pushing the client public key to external servers

Note By default StarOS only supports username-password authentication to external servers.

Setting SSH Client Ciphers

The SSH Client Configuration mode **ciphers** CLI command configures the cipher priority list when logging into an external server.

-
- Step 1** Enter the SSH Client Configuration mode.
`[local]host_name(config)# client ssh`

Step 2 Specify the desired encryption algorithms.

```
[local]host_name(config-ssh)# ciphers algorithms
```

Notes:

- *algorithms* is a string of 1 through 511 alphanumeric characters that specifies the algorithm(s) to be used as a single string of comma-separated variables (no spaces) in priority order (left to right) from those shown below:
 - **blowfish-cbc** – symmetric-key block cipher, Cipher Block Chaining, (CBC)
 - **3des-cbc** – Triple Data Encryption Standard, CBC
 - **aes128-cbc** – Advanced Encryption Standard (AES), 128-bit key size, CBC
 - **aes128-ctr** – AES, 128-bit key size, Counter-mode encryption (CTR)
 - **aes192-ctr** – AES, 192-bit key size, CTR
 - **aes256-ctr** – AES, 256-bit key size, CTR
 - **aes128-gcm@openssh.com** – AES, 128-bit key size, Galois Counter Mode [GCM], OpenSSH
 - **aes256-gcm@openssh.com** – AES, 256-bit key size, GCM, OpenSSH
 - **chacha20-poly1305@openssh.com** – ChaCha20 symmetric cipher, Poly1305 cryptographic Message Authentication Code [MAC], OpenSSH

The default string for *algorithms* in a Normal build is:

```
aes256-ctr,aes192-ctr,aes128-ctr,aes256-gcm@openssh.com,aes128-gcm@openssh.com,chacha20-poly1305@openssh.com,blowfish-cbc,3des-cbc,aes128-cbc
```

The default string for *algorithms* in a Trusted build is:

```
aes256-ctr,aes192-ctr,aes128-ctr
```

Step 3 Exit the SSH Client Configuration mode.

```
[local]host_name(config-ssh)# end  
[local]host_name#
```

Setting Preferred Authentication Methods

The SSH Client Configuration mode **preferredauthentications** CLI command configures the preferred methods of authentication.

Step 1 Enter the SSH Client Configuration mode.

```
[local]host_name(config)# client ssh
```

Step 2 Specify the preferred authentication methods.

```
[local]host_name(config-ssh)# preferredauthentications methods
```

Notes:

- *methods* – specifies the preferred methods of authentication to be used as a single string of comma-separated variables (no spaces) in priority order (left to right) from those shown below:
 - **publickey** – authentication via SSH v2-RSA protocol.
 - **keyboard-interactive** – request for an arbitrary number of pieces of information. For each piece of information the server sends the label of the prompt.
 - **password** – simple request for a single password
- **default** – resets the value of methods to: publickey,password

Step 3 Exit the SSH Client Configuration mode.

```
[local]host_name(config-ssh)# exit
[local]host_name(config)#
```

Generating SSH Client Key Pair

You use commands in the SSH Client Configuration mode to specify a private key and generate the SSH client key pair.

Step 1 Enter the SSH client configuration mode.

```
[local]host_name(config)# client ssh
[local]host_name(config-ssh)#
```

Step 2 Enter SSH private key information and key type.

```
[local]host_name(config-ssh)# ssh key private_key_string length key_length [ type v2-rsa ]
[local]host_name(config-ssh)#
```

key private_key_string specifies a private key value as an alphanumeric string of 1 through 4499 characters.

length key_length specifies the length of the key in bytes as an integer from 0 through 65535.

type v2-rsa specifies the SSH client key type. The only supported SSH client key type is **v2-rsa**.

Step 3 Generate SSH client key pair.

```
[local]host_name(config-ssh)# ssh generate key [ type v2-rsa ]
[local]host_name(config-ssh)#
```

type v2-rsa specifies the SSH client key type. The only supported SSH client key type is **v2-rsa**.

Step 4 Verify that the SSH client key has been generated.

```
[local]host_name(config-ssh)# do show ssh client key
```

Step 5 Exit the SSH Client Configuration mode.

```
[local]host_name(config-ssh)# exit
[local]host_name(config)#
```

Pushing an SSH Client Public Key to an External Server

You must push the SSH client public key to an external server to support SSH/SFTP access to that server.

Step 1

From the Exec mode run the **push ssh-key** command.

```
[local]host_name# push ssh-key { host_name | host_ip_address } user username [ context context_name ]  
[local]host_name#
```

host_name specifies the remote server using its logical host name which must be resolved via DNS lookup. It is expressed as an alphanumeric string of 1 to 127 characters.

host_ip_address is expressed in IPv4 dotted-decimal or IPv6 colon-separated-hexadecimal notation.

user username specifies a valid username on the external server as an alphanumeric string of 1 to 79 characters.

context context_name specifies a valid context name. The context name is optional. If it is not provided the current context is used for processing.

Step 2

Repeat Step 1 to support SSH/SFTP access on other external servers.

Step 3

Test SSH client login to an external server.

```
local]host_name# ssh { hostname | ip_address } user username port port_number
```

Enabling NETCONF

An SSH key is a requirement before NETCONF protocol and the ConfD engine can be enabled in support of Cisco Network Service Orchestrator (NSO).

Refer to the *NETCONF and ConfD* appendix in this guide for detailed information on how to enable NETCONF.

Configuring the Management Interface with a Second IP Address

If necessary, you can configure a second IP address on the vNIC management interface.

DETAILED STEPS

	Command or Action	Purpose
Step 1	Enter the configuration mode by entering the following command at the prompt:	<code>[local]host_name configure</code> <code>[local]host_name (config)</code>
Step 2	Enter the following to enter the context configuration mode:	<code>[local]host_name (config) context local</code> <code>[local]host_name (config-ctx)</code>
Step 3	Enter the interface slot number and port number via the following command:	<code>[local]host_name (config-ctx) 1/1</code> <code>[local]host_name (config-if-eth)</code>
Step 4	Enter the secondary IP address and subnet mask by entering the following command:	<code>[local]host_name (config-if-eth) { ip ipv } address ipaddress subnet_mask secondary</code>
Step 5	Exit the configuration mode by entering the following command:	<code>[local]host_name (config-if-eth) end</code>
Step 6	Confirm the interface ip addresses by entering the following command:	<code>[local]host_name show config context local</code> The CLI output should look similar to this example: config context local interface interface_name ip address ipaddress subnetmask ip address ipaddress subnetmask secondary exit
Step 7	Continue with Verifying and Saving Your Interface and Port Configuration .	

VM Hardware Verification

To prevent resource allocation issues, it is important that all VMs used for in the system have the same size CPU and the same size memory. To balance performance across all interfaces, make sure that the service ports and DI ports have the same throughput capabilities.

To verify the hardware configuration for all cards or a specific card, use the **show cloud hardware** [*card_number*] command. Sample output from this command on card 1 (CF) is shown here:

```
[local]s1# show cloud hardware 1

Card 1:
  CPU Nodes           : 1
  CPU Cores/Threads   : 8
  Memory              : 16384M (qvmc-di-medium)
  Hugepage size       : 2048kB
  cpeth0              :
  Driver              : virtio_net
  loeth0              :
  Driver              : virtio_net
```

Sample output from this command on card 3 (SF) is shown here:

```
[local]s1# show cloud hardware 1

Card 3:
```

```

CPU Nodes           : 1
CPU Cores/Threads  : 8
Memory              : 16384M (qvpc-di-medium)
Hugepage size      : 2048kB
cpeth0              :
  Driver            : vmxnet3
port3_10            :
  Driver            : vmxnet3
port3_11            :
  Driver            : vmxnet3

```

To display the optimum configuration of the underlying VM hardware, use the **show hardware optimum**. To compare your current VM configuration to the optimum configuration, use the **show cloud hardware test** command. Any parameters not set to the optimum are flagged with an asterisk, as shown in this sample output. In this example, the CPU cores/threads and memory are not configured optimally.

```
[local]s1# show cloud hardware test 1
```

```

Card 1:
  CPU Nodes           : 1
* CPU Cores/Threads  : 8                      Optimum value is 4
* Memory              : 8192M (qvpc-di-medium) Optimum value is 16384
  Hugepage size      : 2048kB
  cpeth0              :
    Driver            : virtio_net
  loeth0              :
    Driver            : virtio_net

```

To display the configuration file on the config disk or local flash, use the **show cloud configuration card_number** command. The location parameter file on flash memory is defined during the installation. And the config disk is usually created by the orchestrator and then attached to the card. Sample output from this command is shown here for card 1:

```
[local]s1# show cloud configuration 1
```

```

Card 1:
  Config Disk Params:
  -----
  No config disk available

  Local Params:
  -----
CARD SLOT=1
CARDTYPE=0x40010100
CPUID=0

```

To display the IFTASK configuration for all cards or a specific card, use the **show cloud hardware iftask** command. By default, the cores are configured to be used for both PMD and VNPU. Sample output from this command on card 4 is shown here:

```

[local]mySystem# show cloud hardware iftask 4
Card 4:
  Total number of cores on VM:      24
  Number of cores for PMD only:     0
  Number of cores for VNPU only:    0
  Number of cores for PMD and VNPU: 3
  Number of cores for MCDMA:        4
  Hugepage size:                    2048 kB
  Total hugepages:                   16480256 kB
  NPUSHM hugepages:                  0 kB
  CPU flags: avx sse sse2 ssse3 sse4_1 sse4_2
  Poll CPU's: 1 2 3 4 5 6 7
  KNI reschedule interval: 5 us

```
