CHAPTER 1

SaMOG Gateway Overview 1
  Product Description 1
    Qualified Platforms 2
      DPC2 on ASR 5500 3
      MIO Demux Card on ASR 5500 3
    Licenses 3
  SaMOG Services 3
    CGW Service 4
      CGW Features and Functions 4
        DSCP Marking—CGW 4
        GTPUv1 Support toward the P-GW—CGW 5
        GTP based Interface Support—CGW 5
        GRE Tunnel Support—CGW 5
        P-GW Selection for LTE-to-WiFi Mobility—CGW 6
        Proxy MIP Support—CGW 6
        EoGRE Support—CGW 6
        S2a Interface using PMIPv6—CGW 6
    MRME Service 7
      MRME Features and Functions 8
EAP Authentication over RADIUS—MRME 8
EAP Identity of Decorated NAI Formats—MRME 8
EAP Identity of Emergency NAI Formats—MRME 8
EAP Identity of Fast Reauthentication NAI Formats—MRME 9
EAP Identity of Pseudonym NAI Formats—MRME 10
EAP Identity of Root NAI Formats—MRME 10
EAP Agnostic Authentication—MRME 11
User Equipment (UE) Identity—MRME 11
Access Point (AP) Location—MRME 11
Access Point Group Name—MRME 12
Diameter STa Interface Support—MRME 13
Operator Policy Support (IMSI-based Server Selection)—MRME 13
P-GW Selection—MRME 13
  Static Selection 13
  Dynamic Selection 14
  Topology/Weight-based Selection 16
  Local P-GW Selection 16
  P-GW Selection Fall-back 16
GGSN Selection—MRME 18
RADIUS Accounting Proxy—MRME 19
RADIUS Authentication Server—MRME 19
RADIUS Disconnection—MRME 19
Reauthorization Support—MRME 19
RADIUS Client Authentication—MRME 19
NAS-Identifier Support—MRME 19
TWAP Triggered PDN—MRME 20

Network Deployment and Interfaces 20
  Network Elements 21
    eNodeB 21
    MME 21
    S-GW 22
    P-GW 22

About This Guide

This preface describes the *SaMOG Administration Guide*, how it is organized, and its document conventions. The guide provides information on the SaMOG (S2a-based Mobility over GTP) Gateway and includes network deployments and interfaces, feature descriptions, session establishment and disconnection flows, configuration instructions, and CLI commands for monitoring the system.

- **Conventions Used**, page xvii
- **Supported Documents and Resources**, page xix
- **Contacting Customer Support**, page xx

## Conventions Used

The following tables describe the conventions used throughout this documentation.

<table>
<thead>
<tr>
<th>Notice Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Information Note</td>
<td>Provides information about important features or instructions.</td>
</tr>
<tr>
<td>Caution</td>
<td>Alerts you of potential damage to a program, device, or system.</td>
</tr>
<tr>
<td>Warning</td>
<td>Alerts you of potential personal injury or fatality. May also alert you of potential electrical hazards.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Typeface Conventions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Text represented as a <em>screen display</em></td>
<td>This typeface represents displays that appear on your terminal screen, for example: Login:</td>
</tr>
</tbody>
</table>
## Typeface Conventions

<table>
<thead>
<tr>
<th>Typeface Conventions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Text represented as commands</td>
<td>This typeface represents commands that you enter, for example: <code>show ip access-list</code> This document always gives the full form of a command in lowercase letters. Commands are not case sensitive.</td>
</tr>
<tr>
<td>Text represented as a command variable</td>
<td>This typeface represents a variable that is part of a command, for example: <code>show card slot_number</code> <code>slot_number</code> is a variable representing the desired chassis slot number.</td>
</tr>
<tr>
<td>Text represented as menu or sub-menu names</td>
<td>This typeface represents menus and sub-menues that you access within a software application, for example: Click the <code>File</code> menu, then click <code>New</code></td>
</tr>
</tbody>
</table>

## Command Syntax Conventions

<table>
<thead>
<tr>
<th>Command Syntax Conventions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>{ keyword or variable }</code></td>
<td>Required keyword options and variables are those components that are required to be entered as part of the command syntax. Required keyword options and variables are surrounded by grouped braces <code>{ }</code>. For example: `sctp-max-data-chunks { limit max_chunks</td>
</tr>
<tr>
<td><code>[ keyword or variable ]</code></td>
<td>Optional keywords or variables, or those that a user may or may not choose to use, are surrounded by brackets.</td>
</tr>
<tr>
<td>`</td>
<td>`</td>
</tr>
</tbody>
</table>
Supported Documents and Resources

Related Common Documentation

The most up-to-date information for this product is available in the product Release Notes provided with each product release.

The following common documents are available:

• AAA Interface Administration and Reference
• Command Line Interface Reference
• GTPP Interface Administration and Reference
• Installation Guide (platform dependent)
• Release Change Reference
• SNMP MIB Reference,
• Statistics and Counters Reference
• System Administration Guide (platform dependent)
• Thresholding Configuration Guide

Related Product Documentation

The following product documents are also available and work in conjunction with SaMOG:

• ECS Administration Guide
• GGSN Administration Guide
• SGSN Administration Guide
• S-GW Administration Guide
• P-GW Administration Guide
• MME Administration Guide
• NAT Administration Guide

Obtaining Documentation

The most current Cisco documentation is available on the following website:
Use the following path selections to access the SaMOG documentation:
Products > Wireless > Mobile Internet> Network Functions > Cisco SaMOG S2a Mobility over GTP
Contacting Customer Support

Use the information in this section to contact customer support.

Refer to the support area of http://www.cisco.com for up-to-date product documentation or to submit a service request. A valid username and password are required to access this site. Please contact your Cisco sales or service representative for additional information.
SaMOG Gateway Overview

This chapter contains an overview of the SaMOG (S2a Mobility Over GTP) Gateway. This chapter covers the following topics:

- Product Description, page 1
- SaMOG Services, page 3
- Network Deployment and Interfaces, page 20
- How the SaMOG Gateway Works, page 28
- SaMOG Features and Functionality - Base Software, page 47
- SaMOG Features and Functionality - License Enhanced Feature Software, page 71
- SaMOG Features and Functionality - Inline Service Support, page 76
- Supported Standards, page 77

Product Description

Until recently, Wireless LAN (WLAN) security was considered poor in strength and ease-of-use compared with that of LTE networks and devices, and operators used their core networks to add security layers such as IKEv2 for UE authentication and authorization and IPSec for network security between the UEs and the core network gateways. With the deployment of 802.1x, 802.11u, 802.11i, and Hotspot 2.0, operators now consider WLAN security strength and ease-of-use to be as acceptable as LTE security.

The Cisco® S2a Mobility Over GTP (SaMOG) Gateway addresses this next step in network evolution by enabling mobile operators to provide IP access from trusted non-3GPP access networks to the 3GPP EPC (Evolved Packet Core) network via the S2a interface, including traffic from trusted WiFi, femtocell, metrocell, and small cell access networks. The SaMOG Gateway allows operators to provide services to 3G subscribers using GGSN (GTPv1) and 4G subscribers using P-GW (GTPv2, PMIPv6) via PMIPv6, EoGRE or L3IP access-types.

The SaMOG Gateway has the following key features:

- Provides seamless mobility between the 3GPP EPC network and WLANs for EPS (Evolved Packet System) services via the GTPv1 based Gn interface, or GTPv2/PMIPv6-based S2a interface.
• Functions as a 3GPP Trusted WLAN Access Gateway (TWAG) as the Convergence Gateway (CGW) service. The CGW service terminates the S2a interface to the GGSN/P-GW and acts as the default router for the WLAN UEs on its access link.

• Functions as a 3GPP Trusted WLAN AAA Proxy (TWAP) as the Multi Radio Management Entity (MRME) service. The MRME service terminates the S1a interface to the 3GPP AAA server and relays the AAA information between the WLAN IP access network and the AAA server, or AAA proxy in the case of roaming.

The following figure provides the network architecture of the SaMOG Gateway:

Figure 1: SaMOG Gateway Network Architecture

Qualified Platforms

The SaMOG Gateway is a StarOS™ application that runs on Cisco ASR 5x00 and virtualized platforms. For additional platform information, refer to the appropriate System Administration Guide and/or contact your Cisco account representative.
**DPC2 on ASR 5500**

The SaMOG Gateway is fully qualified to run on the second generation Data Processing Card (DPC2) on the ASR 5500.

The DPC2 offers increased performance versus the first generation DPC, while maintaining backwards compatibility with other ASR 5500 cards. The raw input/output has been increased from 80Gbps (DPC/UDPC) to 150Gbps (DPC2).

The DPC2 has three CPU subsystems. Each subsystem consists of two CPUs with 24 cores each (maximum 144 cores) that are paired with a Platform Controller Hub (PCH). Each CPU is associated with 32 GB of DDR4 memory (total of 192 GB per DPC2) and a latest generation crypto offload engine.

For more information on the DPC2 card, refer the System Administration Guide.

**MIO Demux Card on ASR 5500**

The SaMOG Gateway is fully qualified to run on the Management Input/Output (MIO) card for demux functions. SaMOG can leverage on the additional card for user plane processing to increase the capacity of the chassis.

For more information on the MIO Demux card, refer the System Administration Guide.

**Licenses**

The SaMOG Gateway is a licensed Cisco product. Two mutually exclusive SaMOG base licenses are available for operators with different network deployment models:

- **SaMOG General License**: This base license is available for operators with a pure 4G deployment model or a Mixed Mode (running both 3G and 4G) deployment model. Operators can configure subscribers to setup 3G or 4G sessions based on the serving PLMN and the subscription of the subscriber.

- **SaMOG 3G License**: This base license is available for operators with a pure 3G deployment model. Operators can setup 3G (GTPv1) sessions through the SaMOG Gateway. This license does not permit configuration of a Diameter-based authentication.

In addition to the base license for running SaMOG services, separate session and feature licenses may also be required. Contact your Cisco account representative for detailed information on specific licensing requirements. For information on installing and verifying licenses, see "Managing License Keys" in the System Administration Guide.

**SaMOG Services**

The SaMOG Gateway acts as the termination point of the WLAN access network. The SaMOG service enables the WLAN UEs in the trusted non-3GPP IP access network to connect to the EPC network via Wireless LAN Controllers (WLCs). During configuration, the SaMOG service gets associated with two services: the Convergence Gateway (CGW) service and the Multi Radio Mobility Entity (MRME) service. These collocated services combine to enable the SaMOG Gateway functionality.
CGW Service

The Convergence Gateway (CGW) service functions as a 3GPP Trusted WLAN Access Gateway (TWAG), terminating the S2a interface to the GGSN/P-GW and acts as the default router for the WLAN UEs on its access link.

The CGW service has the following key features and functions:

- Functions as a Local Mobility Anchor (LMA) towards the WLCs, which functions as a Mobile Access Gateway (MAG) with Proxy MIP capabilities per RFC 5213 and 3GPP TS 29.275 V11.5.
- Enables the S2a GTPv2 interface towards the P-GW for session establishment per 3GPP TS 29.274 V11.5.0.
- Enables the S2a PMIPv6 interface towards the P-GW for session establishment per 3GPP TS 29.275 V11.5.0.
- Enables the Gn interface towards the GGSN for session establishment per 3GPP TS 29.060 V11.5.0.
- Support for Layer 3 IP (L3IP) with out-of-band DHCP, and IP address assigned by the WLC (IP@W).
- Routing of packets between the P-GW and the WLAN UEs via the Wireless LAN Controllers (WLCs).
- Support for PDN type IPv4 and IPv6.
- Interacts with the MRME service to provide user profile information to establish the GTP-variant S2a interface towards the GGSN/P-GW per 3GPP TS 29.274.
- Provides a Generic Routing Encapsulation (GRE) data path towards the WLCs per RFCs 1701 and 1702 for tunneling of data towards the WLCs. Also follows RFC 5845 for exchanging GRE keys with WLC-based PMIP signaling.
- Receives and sends GTPU data packets towards the GGSN/P-GW per 3GPP TS 29.281 V11.5.

CGW Features and Functions

The CGW service includes the following features and functions:

DSCP Marking—CGW

Differentiated Services Code Point (DSCP) levels can be assigned to specific traffic patterns in order to ensure that data packets are delivered according to the precedence with which they are tagged. The DiffServ markings are applied to the IP header for every subscriber data packet transmitted in the downlink direction to the WLAN access network. The four traffic patterns have the following order of precedence:

1. Background (lowest)
2. Interactive
3. Streaming
4. Conversational (highest)

In addition, for class type Interactive, further categorization is done in combination with traffic handling priority and allocation-retention priority. Data packets falling under the category of each of the traffic patterns are tagged with a DSCP marking. Each traffic class is mapped to a QCI value according to mapping defined in TS 23.203. Therefore, DSCP values must be configured for different QCI values.
DSCP markings can be configured to control the DSCP markings for downlink packets. The IP header of the packet is updated with the value in TOS field. Note that there is no tunnel at the access side in SaMOG Gateway, hence the TOS field in the subscriber IP packet is marked with the DSCP value directly. For more information on DSCP Marking on the SaMOG Gateway, refer DSCP Marking, on page 143.

GTPv1 Support toward the P-GW—CGW

The SaMOG Gateway's CGW service supports GTPv1 towards the P-GW as defined in 3GPP TS 29.281, V11, including the following functions:

- The SaMOG Gateway's CGW service supports fragmentation and reassembly of the outer IP packets that flow over the S2a interface via GRE tunnels, and supports reassembly of the incoming packets, including stripping the GRE encapsulation and tunneling the resultant packets to the GGSN/P-GW via GTP encapsulation. The CGW service supports GRE payloads over IPv4, IPv6, and IPv4v6 transports.
- Routing of packets between the GGSN/P-GW and the WLAN UE via the WLC.
- Tunnel management procedures for session creation and deletion.
- Path management procedures for path existence checks.
- Handling of the Recovery IE for detecting path failures.

GTP based Interface Support—CGW

The SaMOG Gateway's CGW service supports the GTPv2/GTPv1-based S2a/Gn interface towards the GGSN/P-GW for session establishment per 3GPP TS 29.274 and 29.060 Release 11.5, including the following functions:

- Routing of packets between the GGSN/P-GW and the WLAN UE via the WLC.
- Establishment of flows towards the WLC and the GGSN/P-GW.
- Tunnel management procedures for session creation and deletion.
- Path management procedures for path existence checks.
- Handling of the Recovery IE for detecting path failures.

Important

SaMOG does not initiate any MODIFY_BEARER_COMMAND (to P-GW) or UPDATE_PDP_CONTEXT (to GGSN) message when a QoS update notification is received from the AAA server during reauthentication. SaMOG expects the AAA server to initiate an RAR for notification of any QoS updates (QoS changes are notified in the AA-Answer).

GRE Tunnel Support—CGW

The SaMOG Gateway's CGW service supports dynamic per-session Generic Routing Encapsulation (GRE) tunnels from the trusted 3GPP WLAN per RFC 5845.
P-GW Selection for LTE-to-WiFi Mobility—CGW

During LTE-to-WiFi mobility, the SaMOG Gateway's CGW service selects the same P-GW that anchored the session over LTE. The CGW service selects the GGSN/P-GW via an internal trigger from the SaMOG Gateway's MRME service.

Proxy MIP Support—CGW

The SaMOG Gateway's CGW service provides the underlying mechanism to terminate per-session Proxy Mobile IP (PMIPv6) tunnels from the WLAN infrastructure. To accomplish this, the CGW service acts as an Local Mobility Anchor (LMA) towards the Wireless LAN Controllers (WLCs), which acts as a Mobile Access Gateway (MAG) with PMIPv6 functionality as defined in RFC 5213. The LMA and MAG functions use Proxy Mobile IPv6 signaling to provide network-based mobility management on behalf of the UEs attached to the network. With this approach, the attached UEs are no longer involved in the exchange of signaling messages for mobility.

The LMA function on the SaMOG Gateway's CGW service and the MAG function on the WLCs maintain a single shared tunnel. To distinguish between individual subscriber sessions, separate GRE keys are allocated in the Proxy-MIP Binding Update (PBU) and Proxy-MIP Binding Acknowledgement (PBA) messages between the CGW service and the WLCs. To handle AAA server initiated disconnections, the CGW service supports RFC 5846 for Binding Revocation Indication (BRI) and Binding Revocation Acknowledgement (BRA) messaging with the WLCs.

EoGRE Support—CGW

CGW connects 3G/4G subscribers to EPC/Internet through the Trusted Wifi SSIDs served by EoGRE enabled Residential Gateways. CGW acts as the tunnel endpoint for the EoGRE tunnel initiated from the Residential Gateway. With the use of SSID-based WLAN access, the subscribers are authenticated based on the SSID they use in order to connect to the WLAN. The Residential-GW/WLC maintains a separate SSID for providing the 3G/4G access to help the UE in selecting the correct SSID for obtaining 3G/4G access through Wifi network. SaMOG (MRME) act as the AAA server and DHCP server for the UE attaching to the WLAN network. This helps in processing all the control packets from the UE and maintaining the subscriber session to provide 3G/4G access. While acting as DHCP-Server, CGW creates the PDP-Context with GGSN/P-GW to obtain the IP Address to be allocated to UE through DHCP-Response in the access side. The DHCP and data packets generated by UE will be tunneled over EoGRE by Residential-GW/WLC node to SaMOG.

S2a Interface using PMIPv6—CGW

In StarOS Release 18 and later, the SaMOG Gateway can connect to the P-GW service over the S2a interface based on the PMIPv6 protocol as specified by 3GPP TS 29.275, Release 11 standards. The SaMOG Gateway performs a SNAPTR-based DNS query towards the DNS server to get the P-GW IP address, and initiates a PMIPv6-based registration procedure (acting as a Mobile Access Gateway (MAG)) by sending a Proxy Binding Update message to the P-GW. The IP address of the User Equipment (UE) allocated by P-GW (acting as the Local Mobility Anchor (LMA)) is then received in the Proxy Binding Acknowledge message.

How S2a Interface using PMIPv6 Works

The UE performs an 802.11 initial attach procedures and connect to Access Points (AP) and Wireless LAN Controllers (WLC), which in turn triggers a RADIUS-based authentication with the SaMOG Gateway. The SaMOG Gateway selects a RADIUS/Diameter-based AAA server or AAA proxy based on the local profile configuration and performs a RADIUS/Diameter-based authentication with the AAA server. After multiple
rounds of authentication, the AAA server confirms the authentication status for the UE and shares the subscriber profile with the SaMOG Gateway. The SaMOG Gateway selects the P-GW based on the subscriber's authorization information and setup a PMIPv6-based session with the P-GW. The data between the SaMOG Gateway and P-GW are exchanged through GRE tunnels using GRE keys for uplink and downlink data.

Limitations
The following are the current limitations for the SaMOG S2a interface using PMIPv6:

- As a PMIPv6-based S2a interface on the SaMOG Gateway cannot be used with a GGSN service, the SaMOG 3G license is not supported.
- The SaMOG Local Breakout - Enhanced model, and the SaMOG Web Authorization features are currently not supported.
- QoS negotiation and updates are not applicable for PMIPv6-based S2a interface, as there is no provision in the S2a interface PMIPv6 control messages to carry the requested QoS.

MRME Service
The Multi Radio Mobility Entity (MRME) service functions as a 3GPP Trusted WLAN AAA Proxy (TWAP), terminating the STa interface to the 3GPP AAA server and relays the AAA information between the WLAN IP access network and the AAA server, or AAA proxy in the case of roaming.

The MRME service has the following key features and functions:

- Relays the AAA information between the Wireless LAN Controllers (WLCs) and the 3GPP AAA server.
- Supports EAP-over-RADIUS between the SaMOG Gateway and the WLCs to authenticate the WLAN UEs per RFC 3579.
- Supports the Diameter-based STa interface between the 3GPP AAA server/proxy and the SaMOG Gateway per 3GPP TS 29.273 V11.4.0.
- Supports the exchange of EAP messages over the STa interface per RFC 4072.
- Functions as a RADIUS accounting proxy for WLC-initiated accounting messages as per RFC 2866.
- Supports RADIUS Dynamic Authorization Extensions per RFC 3576 to handle HSS/AAA-initiated detach and Diameter re-authorization procedures.
- Supports authentication between the WLAN UEs and the 3GPP AAA server using EAP-AKA, EAP-AKA', and EAP-SIM.
- Supports static and dynamic P-GW selection after the authentication procedures as per 3GPP TS 29.303 v 11.2.0.
- Support for PDN type IPv4 and IPv6.
- Maintains a username database to re-use existing resources when the CGW service receives PMIPv6 and EoGRE procedures initiated by the WLCs.
- Interacts with the CGW service to provide user profile information to establish the GTP-variant S2a/Gn interface towards the P-GW/GGSN per 3GPP TS 29.274 and 3GPP TS 29.060.
MRME Features and Functions

The MRME service includes the following features and functions.

EAP Authentication over RADIUS—MRME

The SaMOG Gateway’s MRME service supports Extensible Authentication Protocol (EAP) over RADIUS to interact with the WLCs for authenticating the WLAN UEs based on RFC 3579. Two attributes, EAP-Message and Message-Authenticator, are used to transport EAP messages as defined in RFC 3579. The MRME service validates and processes these messages as follows:

• Validates the EAP header fields (Code, Identifier, and Length attributes) prior to forwarding an EAP packet.
• Discards Access-Request packets that include an EAP-Message attribute without a Message-Authenticator attribute.
• If multiple EAP-Message attributes are contained within an Access-Request or Access-Challenge packet, concatenates them to form a single EAP packet.
• For Access-Challenge, Access-Accept, and Access-Reject packets, calculates the Message-Authenticator attribute as follows: Message-Authenticator = HMAC-MD5 (Type, Identifier, Length, and Request Authenticator attributes).

EAP Identity of Decorated NAI Formats—MRME

The SaMOG Gateway supports the use of the EAP identity of the Decorated NAI in the following format: homerealm!username@otherrealm

The username part of the Decorated NAI complies with RFCs 4187, 4816, and 5448 for EAP AKA, EAP SIM, and EAP AKA’, respectively.

The following are examples of a typical NAI:

• For EAP AKA authentication:
  wlan.mnc<homeMNC>.mcc<homeMCC>.3gppnetwork.org!0<IMSI>@wlan.mnc<visitedMNC> .mcc<visitedMCC>.3gppnetwork.org

• For EAP SIM authentication:
  wlan.mnc<homeMNC>.mcc<homeMCC>.3gppnetwork.org!1<IMSI>@wlan.mnc<visitedMNC> .mcc<visitedMCC>.3gppnetwork.org

• For EAP AKA' authentication:
  wlan.mnc<homeMNC>.mcc<homeMCC>.3gppnetwork.org!6<IMSI>@wlan.mnc<visitedMNC> .mcc<visitedMCC>.3gppnetwork.org

EAP Identity of Emergency NAI Formats—MRME

The SaMOG Gateway’s MRME service supports the use of the EAP identity of the Emergency NAI in the following format:

0<IMSI>@sos.wlan.mnc015.mcc234.3gppnetwork.org/1<IMSI>@sos.wlan.mnc015.mcc234.3gppnetwork.org
If the IMSI is not available, the Emergency NAI can include the IMEI/MAC address, as follows:

- `imei:<IMEI>@sos.wlan.mnc<visitedMNC>.mcc<visitedMCC>.3gppnetwork.org`
- `mac:<MAC>@sos.wlan.mnc<visitedMNC>.mcc<visitedMCC>.3gppnetwork.org`

As per RFC 29.273, UEs without an IMSI are not authorized via the STA Interface. If the Emergency NAI includes an IMEI or MAC username format, the authentication request will be rejected.

**EAP Identity of Fast Reauthentication NAI Formats—MRME**

Where the AAA server supports fast reauthentication, the AAA server assigns an identity to the subscriber which is used by the subscriber’s UE to initiate a reattach or reauthentication. This authentication method is faster than the full reauthentication method as the AAA server and UE use the authentication key from a previous full authentication. The UE sends the assigned fast reauthentication NAI for subsequent authentication attempts, and the AAA server looks up the mapping between the fast reauthentication NAI and the identity of the subscriber.

The SaMOG gateway supports the use of the EAP identity of the Fast Reauthentication NAI in the following normal and decorated formats:

- **Normal:** `<prefix+fast-reauth-id>@nai.epc.mnc<homeMNC>.mcc<homeMCC>.3gppnetwork.org`
- **Decorated:** `nai.epc.mnc<homeMNC>.mcc<homeMCC>.3gppnetwork.org!<prefix+fast-reauth-id>@nai.epc.mnc<visitedMNC>.mcc<visitedMCC>.3gppnetwork.org`

Currently, SaMOG does not support multi-PLMN. If the PLMN ID of a UE changes during a re-attach procedure, the User-Name changes from root to decorated NAI format or vice versa. The SaMOG service simply logs the event and continues with the session setup. The IPSG manager is updated with the permanent NAI (root format) and sent to the WLC to be included in the PBU for the PMIPv6 session. If the WLC does not use the NAI format in the PBU, call setup fails as the PBU is rejected. To avoid the change from root to decorated NAI or vice versa, specify a serving PLMN ID with an IMSI range. When a serving PLMN ID changes, the existing call is taken down and a re-attach procedure occurs.

The fast-reauth-id part of the Fast Reauthentication NAI complies with 3GPP 23.003 standards.

The following are examples of a typical NAI:

- **For EAP AKA authentication:**
  
  `4<fast-reauth-id>@nai.epc.mnc<homeMNC>.mnc<homeMCC>.3gppnetwork.org`
  `nai.epc.mnc<homeMNC>.mcc<homeMCC>.3gppnetwork.org!4<fast-reauth-id>@nai.epc.mnc<visitedMNC>.mcc<visitedMCC>.3gppnetwork.org`

- **For SIM authentication:**
  
  `5<fast-reauth-id>@nai.epc.mnc<homeMNC>.mnc<homeMCC>.3gppnetwork.org`
  `nai.epc.mnc<homeMNC>.mcc<homeMCC>.3gppnetwork.org!5<fast-reauth-id>@nai.epc.mnc<visitedMNC>.mcc<visitedMCC>.3gppnetwork.org`

- **For EAP AKA’ authentication:**
  
  `8<fast-reauth-id>@nai.epc.mnc<homeMNC>.mnc<homeMCC>.3gppnetwork.org`
  `nai.epc.mnc<homeMNC>.mcc<homeMCC>.3gppnetwork.org!8<fast-reauth-id>@nai.epc.mnc<visitedMNC>.mcc<visitedMCC>.3gppnetwork.org`
EAP Identity of Pseudonym NAI Formats—MRME

The pseudonym NAI is a temporary identity provided to a user by the AAA server that the subscriber uses while connecting to the network. This enables the subscriber to connect and authenticate without revealing their IMSI information on the network. The AAA server maintains a mapping between the real identity and the pseudonym NAI of the subscriber, and uses the mapping to identify the subscriber.

The SaMOG gateway supports the use of the EAP identity of the Pseudonym NAI in the following normal and decorated formats:

**Normal:** `<prefix+pseudonym-id>@nai.epc.mnc<homeMNC>.mcc<homeMCC>.3gppnetwork.org`

**Decorated:**
nai.epc.mnc<homeMNC>.mcc<homeMCC>.3gppnetwork.org!<prefix+pseudonym-id>@nai.epc.mnc<visitedMNC>.mcc<visitedMCC>.3gppnetwork.org

Currently, SaMOG does not support multi-PLMN. If the PLMN ID of a UE changes during a re-attach procedure, the User-Name changes from root to decorated NAI format or vice versa. The SaMOG service simply logs the event and continues with the session setup. The IPSG manager is updated with the permanent NAI (root format) and sent to the WLC to be included in the PBU for the PMIPv6 session. If the WLC does not use the NAI format in the PBU, call setup fails as the PBU is rejected. To avoid the change from root to decorated NAI or vice versa, specify a serving PLMN ID with an IMSI range. When a serving PLMN ID changes, the existing call is taken down and a re-attach procedure is initiated.

The pseudonym-id part of the Pseudonym NAI complies with 3GPP 23.003 standards.

The following are examples of a typical NAI:

- **For EAP AKA authentication:**
  2<pseudonym-id>@nai.epc.mnc<homeMNC>.mcc<homeMCC>.3gppnetwork.org
  nai.epc.mnc<homeMNC>.mcc<homeMCC>.3gppnetwork.org!2<pseudonym-id>@nai.epc.mnc<visitedMNC>.mcc<visitedMCC>.3gppnetwork.org

- **For SIM authentication:**
  3<pseudonym-id>@nai.epc.mnc<homeMNC>.mcc<homeMCC>.3gppnetwork.org
  nai.epc.mnc<homeMNC>.mcc<homeMCC>.3gppnetwork.org!3<pseudonym-id>@nai.epc.mnc<visitedMNC>.mcc<visitedMCC>.3gppnetwork.org

- **For EAP AKA' authentication:**
  7<pseudonym-id>@nai.epc.mnc<homeMNC>.mcc<homeMCC>.3gppnetwork.org
  nai.epc.mnc<homeMNC>.mcc<homeMCC>.3gppnetwork.org!7<pseudonym-id>@nai.epc.mnc<visitedMNC>.mcc<visitedMCC>.3gppnetwork.org

EAP Identity of Root NAI Formats—MRME

The SaMOG Gateway supports the use of the EAP identity of the Root NAI in the following format:

username@otherrealm

The username part of the Root NAI complies with RFCs 4187, 4816, and 5448 for EAP AKA, EAP SIM, and EAP AKA’, respectively.

The following are examples of a typical NAI:

- **For EAP AKA authentication:** 0<IMSI>@wlan.mnc<MNC>.mcc<MCC>.3gppnetwork.org
For EAP SIM authentication: 1<IMSI>@wlan.mnc<MNC>.mcc<MCC>.3gppnetwork.org

For EAP AKA' authentication: 6<IMSI>@wlan.mnc<MNC>.mcc<MCC>.3gppnetwork.org

EAP Agnostic Authentication—MRME

The SaMOG Gateway additionally supports EAP-based authentication where the inner layer of EAP protocols is agnostic. This enables SaMOG to support authentication mechanisms such as EAP-TLS and EAP-TTLS/MSCHAPv2, to connect non-UICC devices to the EPC core.

EAP-TLS

This authentication mechanism enables SaMOG to provide a certificate-based mutual authentication mechanism between the UE and the EAP Server for non-UICC devices.

EAP-TTLS/MSCHAPv2

SaMOG performs this authentication mechanism in two phases. During the first phase, SaMOG authenticates the server using a certificate that is used to create a secure tunnel. In the second phase, the subscriber is authenticated using MSCHAPv2 authentication mechanism within the secure tunnel.

Authentication

SaMOG considers the EAP-response/identity messages between the WLC and the AAA server as an uncategorized EAP authentication mechanism. SaMOG allows messages to be exchanged until a success/failure message is received from the AAA server, or the session setup timer expires.

NAI Usage

As with SIM-based authentications, in compliance to 3GPP 23.003 standard, SaMOG expects the NAI forwarded by the UE to be in the same format for P-GW selection, with the flexibility to support non-IMSI-based user-name in the AVP.

If the prefix for the user-name is uncategorized (not between 0 and 9), SaMOG considers the username portion of the NAI as non-IMSI based.

User Equipment (UE) Identity—MRME

In StarOS Release 18 and later, the SaMOG Gateway can receive the User Equipment's (UE) MAC address as the UE's identity in the Calling-Station-ID AVP in the Radius message (Access-Request). The UE's identity can then be forwarded over the GTPv1 or GTPv2 interface in the IMEI Software Version (SV) IE to GGSN, or Mobile Equipment Identity (MEI) IE to P-GW.

As the UE identity (MAC address) is 12 Bytes long (6 Bytes in the TBCD format), and the total length of the IMEIsv is 8 bytes, the additional 2 Bytes can be padded with an user configurable filler value.

Access Point (AP) Location—MRME

In StarOS Release 18 and later, the SaMOG Gateway can share the location information of the AP in the User Location Information (ULI) IE during the PDP context setup, and update the locations as Update Context Requests on the GTPv1 interface. When SaMOG detects a change in the AP's location during handovers, an Update PDP Context message is triggered.
SaMOG supports a new format to facilitate AP location in the Called-Station-ID AVP forwarded in the Radius messages. APs are assigned AP-Names which contain the location details and its MAC address (identity). The AP location (CGI) consists of the Location Area Code (LAC) and the Cell Identity (CI). SaMOG supports the following formats in the Called-Station-ID AVP:

- `<MAC>`
- `mac<MAC>`
- `<MAC>;<SSID>`
- `mac<MAC>;<SSID>`
- `cgi<CGI>;<SSID>`
- `mac<MAC>:cgi<CGI>`
- `cgi<CGI>:mac<MAC>`
- `mac<MAC>:cgi<CGI>:<SSID>`
- `cgi<CGI>:mac<MAC>:<SSID>`

For example, if an AP is assigned LAC = 1235, CI = 6789, AP-MAC = 11-22-33-44-55-66, and SSID = test, the Called-Station-ID AVP will contain `cgi<12356789>:mac<112233445566>:test`.

**Access Point Group Name—MRME**

The SaMOG Gateway supports access point (AP) group name format in the Called-Station-ID AVP to enable a way to apply policies based on WiFi AP groups. The AP/WLC forwards the AP group name to the SaMOG Gateway in the Access-Request message during initial attach, re-authentication, or handover. The SaMOG Gateway parses the AP group name and forwards it to:

- STa Diameter AAA server in the ANID AVP over DER/AAR messages
- RADIUS AAA server in the Called-Station-Id AVP over the Access-Request message
- External, co-located, or Local P-GW (LBO) in the TWAN-Identifier IE in the SSID sub-field over the Create Session Request message.

**Important** If the maximum length of the AP group name exceeds 32 octets, the SaMOG Gateway will not include the AP group name in the SSID field of the TWAN-Identifier IE.

The AAA server and P-GW can use the AP group name information to select Gx policies for the P-GW session. Different Gx policies can be chosen for different AP groups based on the AAA/PCRF configuration.

The AP group name information can be included with or without the "grp" prefix. When the AP Group name is included with the "grp" prefix, it can be present anywhere in the Called-Station-Id AVP. When the AP Group name is included without the "grp" prefix, it must be the last token preceded by the SSID token in the "Called-Station-Id" attribute.

The SaMOG Gateway currently supports the following AP group name formats in the Called-Station-ID AVP:

- `mac<MAC>:grp<AP-Group-Name>`
- `grp<AP-Group-Name>;<SSID>`
Diameter STa Interface Support—MRME

The SaMOG Gateway complies with 3GPP Release 11 SaMOG specifications for the STa interface as defined in TS 29.273 V11.4. The STa interface is defined between a non-3GPP access network and a 3GPP AAA server/proxy. The SaMOG Gateway uses the STa interface to authenticate and authorize the WLAN UEs. The SaMOG Gateway can communicate with the AAA Server/proxy over the IPv4 or IPv6 interface.

Operator Policy Support (IMSI-based Server Selection)—MRME

The SaMOG Gateway's MRME service supports the selection of a 3GPP AAA proxy based on the IMSI via the operator policy feature.

The operator policy provides mechanisms to fine tune the behavior of subsets of subscribers above and beyond the behaviors described in the user profile. It also can be used to control the behavior of visiting subscribers in roaming scenarios, enforcing roaming agreements and providing a measure of local protection against foreign subscribers.

An operator policy associates APNs, APN profiles, an APN remap table, and a call-control profile to ranges of IMSIs. These profiles and tables are created and defined within their own configuration modes to generate sets of rules and instructions that can be reused and assigned to multiple policies. In this manner, an operator policy manages the application of rules governing the services, facilities, and privileges available to subscribers. These policies can override standard behaviors and provide mechanisms for an operator to get around the limitations of other infrastructure elements, such as DNS servers and HSSs.

The operator policy configuration to be applied to a subscriber is selected on the basis of the selection criteria in the subscriber mapping at attach time. A maximum of 1,024 operator policies can be configured. If a UE was associated with a specific operator policy and that policy is deleted, the next time the UE attempts to access the policy, it will attempt to find another policy with which to be associated.

A default operator policy can be configured and applied to all subscribers that do not match any of the per-PLMN or IMSI range policies.

Changes to the operator policy take effect when the subscriber re-attaches and subsequent EPS Bearer activations.

P-GW Selection—MRME

The P-GW selection function enables the SaMOG Gateway's MRME service to allocate a P-GW to provide PDN connectivity to the WLAN UEs in the trusted non-3GPP IP access network. The P-GW selection function can employ either static or dynamic selection.

Static Selection

The PDN-GW-Allocation-Type AVP indicates whether the P-GW address is statically allocated or dynamically selected by other nodes, and is considered only if MIP6-Agent-Info is present.
The figure below shows the message exchange for static selection. The table that follows the figure describes each step in the flow.

**Figure 2: P-GW Static Selection**

![Diagram of P-GW Static Selection]

**Table 1: P-GW Static Selection**

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>The SaMOG Gateway's MRME service receives the P-GW FQDN or P-GW IP address from the AAA server as part of the MIP-Home-Agent-Host AVP in the Diameter EAP Answer message.</td>
</tr>
<tr>
<td>2.</td>
<td>If it receives a P-GW FQDN, and if the FQDN starts with &quot;topon&quot;, the MRME service removes the first two labels of the received FQDN to obtain the Canonical Node Name (ID) of the P-GW. The MRME service uses this P-GW ID to send an S-NAPTR query to the DNS.</td>
</tr>
<tr>
<td>3.</td>
<td>The MRME service receives the results of the query and selects the replacement string (P-GW FQDN) matching the Service Parameters of &quot;x-3gpp-pgw:x-s2a-gtp&quot;.</td>
</tr>
<tr>
<td>4.</td>
<td>The MRME service then performs a DNS A/AAAA query with selected replacement string (P-GW FQDN). The DNS returns the IP address of the P-GW.</td>
</tr>
</tbody>
</table>

**Dynamic Selection**

For a given APN, when the HSS returns Dynamic Allocation Allowed for the P-GW ID and the selection is not for a 3GPP-to-non-3GPP handover, the MRME service ignores the P-GW ID and instead performs dynamic selection.

SaMOG Administration Guide, StarOS Release 21.8
The figure below shows the message exchange for dynamic selection. The table that follows the figure describes each step in the flow.

**Figure 3: P-GW Dynamic Selection**

![Diagram of P-GW Dynamic Selection](image)

**Table 2: P-GW Dynamic Selection**

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>The MRME service receives an APN name from the 3GPP AAA server.</td>
</tr>
<tr>
<td>2.</td>
<td>The MRME service constructs the APN FQDN from the received APN name and uses this as the query string to send to the DNS.</td>
</tr>
<tr>
<td>3.</td>
<td>The APN FQDN query returns NAPTR Resource Records (RRs) with an &quot;s&quot; flag.</td>
</tr>
<tr>
<td>4.</td>
<td>Result(s) from this operation are fed to a filter where only RRs with service-parameter &quot;x-3gpp-pgw:x-s2a-gtp&quot; are considered by the MRME service.</td>
</tr>
<tr>
<td>5.</td>
<td>Each of the resulting NAPTR RRs for that record set will be resolved further by performing DNS SRV queries using the replacement string pointed to by the NAPTR RRs.</td>
</tr>
<tr>
<td>6.</td>
<td>The MRME service receives a list of P-GW FQDNs from the DNS. After all the SRV queries are completed, the MRME service builds a candidate list of P-GW host names.</td>
</tr>
<tr>
<td>7.</td>
<td>The resulting P-GW entries are compared against the configured MRME service FQDN and the longest suffix-matching entry is chosen. If there are more than one pair of MRME service/P-GW combinations with the same degree of label match, attributes from the RR may be used to break the tie. The attributes include priority, weight, and order. Load-balancing of P-GWs occur based on weight, as per the procedure defined in RFC 2782.</td>
</tr>
<tr>
<td>8.</td>
<td>The selected P-GW FQDN is further resolved using a DNS A/AAAA query to resolve to the IPv4/IPv6 address of the S2a interface on the P-GW.</td>
</tr>
<tr>
<td>9.</td>
<td>The DNS returns the IP address of the P-GW.</td>
</tr>
</tbody>
</table>
Topology/Weight-based Selection

Topology/weight-based selection uses DNS requests to enable P-GW load balancing based on topology and/or weight.

For topology-based selection, once the DNS procedure outputs a list of P-GW hostnames for the APN FQDN, the SaMOG Gateway performs a longest-suffix match and selects the P-GW that is topologically closest to the SaMOG Gateway and subscriber. If there are multiple matches with the same suffix length, the Weight and Priority fields in the NAPTR resource records are used to sort the list. The record with the lowest number in the Priority field is chosen first, and the Weight field is used for those records with the same priority.

For weight-based selection, once the DNS procedure outputs a list of P-GW hostnames for the APN FQDN, if there are multiple entries with same priority, calls are distributed to these P-GWs according to the Weight field in the resource records. The Weight field specifies a relative weight for entries with the same priority. Larger weights are given a proportionately higher probability of being selected. The SaMOG Gateway uses the value of (65535 minus NAPTR preference) as the statistical weight for NAPTR resource records in the same way as the SRV weight is used for SRV records, as defined in RFC 2782.

When both topology-based and weight-based selection are enabled on the SaMOG Gateway, topology-based selection is performed first, followed by weight-based selection. A candidate list of P-GWs is constructed based on these, and the SaMOG Gateway selects a P-GW from this list for call establishment. If the selected P-GW does not respond, the MRME service selects the alternate P-GW(s) from the candidate list.

Local P-GW Selection

The SaMOG Gateway can configure and use local P-GW addresses either as a fall-back selection method to static and dynamic P-GW selection, or as the preferred selection method.

For more information, refer SaMOG Local P-GW Selection, on page 245

P-GW Selection Fall-back

The SaMOG Gateway currently supports the following P-GW selection mechanisms:

- AAA server provided P-GW address (static selection)
- DNS provided P-GW address for P-GW FQDN resolution (static selection)
- DNS provided P-GW addresses for APN FQDN resolution (dynamic selection)
- Locally configured P-GW addresses

When the AAA server provided P-GW address or DNS provided P-GW address for P-GW FQDN (static selection) fails, the SaMOG Gateway will perform P-GW selection using the following mechanisms over an S2a GTPv2 interface:

- Locally configured P-GW address
- DNS resolution using APN FQDN (dynamic selection)

The order of the P-GW fall-back selection mechanism can be configured using the pgw-selection local-configuration-preferred command under the MRME Service Configuration Mode. When this command is enabled, SaMOG first uses the locally configured P-GW addresses to fall-back to. When the locally configured P-GW addresses are not reachable, SaMOG then uses APN FQDN based P-GW address resolution. When this command is not enabled, SaMOG first uses APN FQDN based P-GW address resolution to fall-back to. When the P-GW address resolved using APN FQDN is not reachable, SaMOG then uses the locally configured P-GW addresses.

The SaMOG Gateway can also be configured with the maximum alternate P-GW attempts using the gateway-selection max-alternate-pgw maximum_pgw_addresses command under the APN Profile.
Configuration Mode. When the maximum alternate P-GW attempts is reached, P-GW addresses will not be resolved even if the next resolved address is reachable.

When a P-GW address or addresses are configured under the respective APN Profile Configuration Mode, the following table provides the various P-GW selection fall-back scenarios over a GTPv2 interface:

<table>

**GGSN Selection—MRME**

The SaMOG Gateway uses the Gn’ reference point between the SaMOG and GGSN. The SaMOG (acting like an SGSN) initiates the creation of PDP context a GTP tunnel with the GGSN for each UE. The SGTP is compliant to Release 7 for GTPv1 specification 29.060. The GGSN selection is based on the DNS query.

The GGSN node is selected as per the 3GPP standard for resolving the IP address using DNS query. The DNS query contains the dns-apn string in the form of `<apn-name>.mncXXX.mccYYY.gprs`, and the apn-name is obtained from AAA-Server during Access-Accept message. The MCC and MNC values are derived in the following priority:

- From the NAI sent by UE in Access-Request message in the form of `IMSI@wlan.mncXXX.mccYYY.3gppnetwork.org`.
- Local configuration

When SaMOG interacts with pre-release 7 network elements (RADIUS based interfaces) it uses A/AAA queries. When SaMOG interacts with post-release 7 network elements (Diameter based interfaces) it uses the NAPTR queries.
RADIUS Accounting Proxy—MRME

The SaMOG Gateway's MRME service proxies RADIUS accounting messages to a RADIUS accounting server and selects the server based on an IMSI range. Upon receiving an Accounting Stop message, the MRME service clears the subscriber session.

RADIUS Authentication Server—MRME

The SaMOG Gateway's MRME service terminates RADIUS authentication requests. IEEE 802.1X authenticators will function as RADIUS clients and generate Access Request messages to authenticate and authorize the WLAN UEs.

RADIUS Disconnection—MRME

The SaMOG Gateway's MRME service generates RADIUS disconnect messages that are sent to the WLCs over IPv4 or IPv6 transport for network or AAA initiated detach and admin disconnections. For a network initiated detach, the SaMOG Gateway's MRME service sends a RADIUS disconnect message to the WLC as per RFC 3576, which is the RADIUS client. Disconnect Message transactions between the WLC and SaMOG are authenticated using a shared secret mechanism. Statistics for these RADIUS disconnect messages can be retrieved via bulk statistics or the output of CLI show commands.

Reauthorization Support—MRME

The SaMOG Gateway's MRME service uses an STainterface re-authorization procedure between the 3GPP AAA server and the trusted non-3GPP access network to enable the 3GPP AAA server to modify previously-provided authorization parameters, which may occur due to a modification of a subscriber profile in the HSS.

RADIUS Client Authentication—MRME

Transactions between the RADIUS client and the RADIUS server are authenticated through the use of a shared secret. To authenticate Access Request messages containing the EAP-Message attribute, the SaMOG Gateway's MRME service uses the Message-Authenticator as defined in RFC 3579. The Message-Authenticator is an HMAC-MD5 hash of the entire Access-Request packet, including Type, ID, Length and Authenticator attributes, using the shared secret as the key, as follows: Message-Authenticator = HMAC-MD5 (Type, Identifier, Length, and Request Authenticator attributes).

NAS-Identifier Support—MRME

SaMOG supports the RADIUS attribute "NAS-Identifier" in the RADIUS Authentication and Accounting messages, as defined by RFC 2865. The Access point/WLC can include the NAS-Identifier AVP either in the Authentication or Accounting messages (Start/Interim). SaMOG supports NAS-Identifier value as a 64-byte string value and validates string formats only. SaMOG includes the "NAS-Identifier" attribute in the Disconnect Message towards the WLC/Access point (if received from WLC) during UE (DHCP-release) initiated detach and network initiated disconnect procedures or admin clear.
TWAP Triggered PDN—MRME

With StarOS Release 18 and later, the Trusted WLAN AAA Proxy (TWAP) sends the Layer 2 attach trigger to the Trusted WLAN Access Gateway (TWAG) (with the MAC address and subscription data of the UE) after a successful EAP authentication. The SaMOG Gateway waits until a tunnel is established for S2a/Gn procedures before forwarding the EAP Success message to the UE.

For an EoGRE access-type, the IP address of the UE is communicated using tunneled DHCP procedure.

For L3IP access-type, the IP address of the UE is communicated using out-of-band DHCP.

For call flow information, refer SaMOG Gateway Session Establishment (StarOS Release 18 and later), on page 32 for PMIPv6 access-type, and SaMOG Gateway EoGRE Session Establishment (StarOS Release 18 and later), on page 52 for EoGRE access-type.

Network Deployment and Interfaces

The SaMOG Gateway provides IP access from the WLAN UEs to the P-GW and the Packet Data Network (PDN) in the Evolved Packet Core (EPC) network. From Release 16.0 and above, the SaMOG Gateway provides IP access from the WLAN UEs to GGSN/P-GW and the Packet Data Network (PDN) over PMIPv6 or EoGRE tunnel.

Deployment Scenarios

Operators deploying SaMOG in their WLAN offload scheme typically fall under one of the three categories described below:

• **4G Deployments**: The operator has already upgraded their core network elements to EPC specifications and wants to use SaMOG to provide services to PLMNs which have the network devices capable of setting up 4G calls. In addition, the deployed DNS server supports the post release 7 DNS procedures (S-NAPTR queries) to resolve the P-GW address from APN/P-GW FQDN.

A 3G subscriber can connect to an SaMOG Gateway in 4G deployment as long as the STa based AAA server is capable of fetching the 3G policy from HLR/HSS and convert the 3G profile parameters to 4G parameters as per 3GPP specification 23.401 and provide the same to the SaMOG during authentication.

• **3G Deployments**: For operators with a 3G infrastructure, and wants to use SaMOG to provide services only to 3G subscribers using RADIUS authentication with a AAA server assuming that the AAA server is capable of fetching the 3G profile from HLR/HSS and provide the same to SaMOG. The network elements of all the PLMNs served by this SaMOG are pre-release 8. The DNS server in such a network is capable of doing pre-release 8 DNS procedures only to resolve GGSN address from APN FQDN.

A 4G subscriber can connect to an SaMOG Gateway in 3G deployment as long as the RADIUS based AAA server can fetch 4G profiles from HSS, convert the 4G profile parameters to 3G values, and provide the same to SaMOG during authentication.

• **Mixed Mode Deployment**: For operators with infrastructure to deploy both 3G and 4G sessions, and wants to use SaMOG to provide services to both 3G and 4G subscribers.

When a 3G/4G subscriber connects to a PLMN supporting 3G network elements, a GTPv1 session is established with GGSN for the subscriber.

When a 3G subscriber connects to a PLMN supporting 4G network elements, if the DNS procedures result in a GGSN IP address, GTPv1 call is set for the subscriber. If the DNS query provides a P-GW, or both GGSN and P-GW interface IP address, a GTPv2 session is established with the P-GW. The AAA server will forward a 3G QoS profile or map it to a 4G QoS profile, and forward the same to SaMOG.
The SaMOG Gateway converts the QoS back to 3G/4G parameters depending on whether GTPv1 or GTPv2 call is set.

The figure below shows the SaMOG Gateway terminating the WLAN interface from the trusted non-3GPP IP access network and providing access to the P-GW and the operator’s IP services via GTPv2 over the S2a interface. It also shows the network interfaces used by the MME, S-GW, and P-GW in the EPC network.

*Figure 4: SaMOG Gateway in the EPC Network*

---

**Network Elements**

This section provides a description of the network elements that work with the SaMOG Gateway in the E-UTRAN/EPC network.

**eNodeB**

The evolved Node B (eNodeB) is the termination point for all radio-related protocols. As a network, E-UTRAN is simply a mesh of eNodeBs connected to neighboring eNodeBs via the X2 interface.

**MME**

The Mobility Management Entity (MME) is the key control node for the LTE access network. It works in conjunction with the eNodeB and the S-GW to control bearer activation and deactivation. The MME is typically responsible for selecting the P-GW for the UEs to access the PDN, but for access from trusted non-3GPP IP access networks, the SaMOG Gateway's MRME service is responsible for selecting the P-GW.
S-GW
The Serving Gateway (S-GW) routes and forwards data packets from the 3GPP UEs and acts as the mobility anchor during inter-eNodeB handovers. The S-GW receives signals from the MME that control the data traffic. All 3GPP UEs accessing the EPC network are associated with a single S-GW.

P-GW
The Packet Data Network Gateway (P-GW) is the network node that terminates the SGi interface towards the PDN. The P-GW provides connectivity to external PDNs for the subscriber UEs by being the point of entry and exit for all subscriber UE traffic. A subscriber UE may have simultaneous connectivity with more than one P-GW for accessing multiple PDNs. The P-GW performs policy enforcement, packet filtering, charging support, lawful interception, and packet screening. The P-GW is the mobility anchor for both trusted and untrusted non-3GPP IP access networks. For trusted non-3GPP IP access networks, the P-GW hosts the LMA (Local Mobility Anchor) function for the PMIP-based S2b interface, and the SaMOG Gateway's CGW service hosts the LMA function for the PMIP/EoGRE-based S2a interface.

GGSN
The GGSN works in conjunction with Serving GPRS Support Nodes (SGSNs) within the network and routes data traffic between the subscriber's Mobile Station (MS) and a Packet Data Networks (PDNs) such as the Internet or an intranet. GGSN can be configured to support Mobile IP and/or Proxy Mobile IP data applications to provide mobility for subscriber IP PDP contexts. When supporting these services, the system can be configured to either function as a GGSN and Foreign Agent (FA), a standalone Home Agent (HA), or a GGSN, FA, and HA simultaneously within the carrier's network.

3GPP AAA Server
The 3GPP Authentication, Authorization, and Accounting (AAA) server provides UE authentication via the Extensible Authentication Protocol - Authentication and Key Agreement (EAP-AKA) authentication method.

HSS
The Home Subscriber Server (HSS), is the master user database that supports the IP Multimedia Subsystem (IMS) network entities. It contains subscriber profiles, performs subscriber authentication and authorization, and provides information about the subscriber's location and IP information.

PCRF
The PCRF (Policy and Charging Rules Function) determines policy rules in the IMS network. The PCRF operates in the network core, accesses subscriber databases and charging systems, and makes intelligent policy decisions for subscribers.

Trusted Non-3GPP IP Access
The trusted non-3GPP IP access contains one or more WLAN access points. An access point terminates the UE's WLAN IEEE 802.11 link defined in IEEE standard 802.11-2007.
Logical Network Interfaces

The following table provides descriptions of the logical network interfaces supported by the SaMOG Gateway in the EPC network.

*Table 3: Logical Network Interfaces on the SaMOG Gateway*

<table>
<thead>
<tr>
<th>Interface</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WLAN Interface</td>
<td>The interface to the WLCs and WLAN UEs in the trusted non-3GPP IP access network has not yet been defined in the 3GPP standards. The SaMOG Gateway uses Remote Access Dial In User Service (RADIUS) messages generated by the IP access network to provide session information such as the IP addresses of the WLAN UEs to the EPC network via the WLCs and to set up the access side associations.</td>
</tr>
<tr>
<td>STa Interface</td>
<td>The interface from the SaMOG Gateway's MRME service to the 3GPP AAA server, the STa interface is used for WLAN UE authentication. It supports the transport of mobility parameters, tunnel authentication, and authorization data. The EAP-AKA, EAP-SIM, and EAP-AKA’ methods are used for authenticating the WLAN UEs over this interface.</td>
</tr>
<tr>
<td>S2a Interface</td>
<td>The interface from the SaMOG Gateway's CGW service to the GGSN/P-GW, the S2a interface runs the GTPv1/GTPv2 protocol to establish WLAN UE sessions with the GGSN/P-GW.</td>
</tr>
</tbody>
</table>

IPv6 and Dual-Stack (IPv4v6) Support

The SaMOG Gateway supports IPv6 and dual-stack (IPv4v6) address allocation for trusted Wi-Fi subscribers on the EPC core. This enables SaMOG Gateway to support a rapidly increasing number of subscribers accessing the internet via mobile devices, and technologically advanced (example, Internet of Things) internet-enabled devices (sensors, machine-readable identifiers) that demand high network address assignment.

*S2a GTPv2 Interface Towards the P-GW*

SaMOG provides seamless mobility between the 3GPP EPC network and WLANs for EPS (Evolved Packet System) services via. GTPv2-based S2a interface using IPv4 and IPv6 addresses over the EoGRE and PMIPv6 access types. SaMOG can bind IPv4 and IPv6 addresses in the EGTP and GTPU services associated with the CGW service. SaMOG DNS can query P-GW IPv6 addresses and support static IPv6 address allocation from the AAA server.

**Important**

Dual-stack (IPv4v6) bind address is currently not supported.
**Supported Transport Combinations**

The following table lists the supported IP transport combinations between P-GW and the EGTP service over the S2a GTPv2 interface.

<table>
<thead>
<tr>
<th>P-GW Address (from DNS/AAA)</th>

</table>
### Access Types

**Important**

In Release19, IPv6 transport using the PMIPv6 access type is supported as lab quality only.

The SaMOG gateway supports IPv6 transport for trusted Wi-Fi subscribers on the EPC core using the PMIPv6 and EoGRE access types. The access side peers (WLC/AP) and SaMOG communicate over an IPv6 transport, and data travels over the GRE tunnel between the IPv6 endpoints.

### Limitations

- Though dual-stack binding is supported by the CGW service, only IPv6 transport is used for a PMIPv6 access type when a dual-stack configuration exists. To use both IPv4 and IPv6 transports for the PMIPv6 access type, configure two different SaMOG contexts, one context for IPv4 CGW service binding, and the other context for an IPv6 CGW service binding.

### Subscriber User Equipment (UE)

SaMOG can support IPv6 or dual-stack (IPv4v6) address allocation for both SIM and non-SIM (non-UICC) based subscriber's user equipment (UE) on the trusted Wi-Fi network. This is achieved using an external P-GW for SIM-based devices, and internal P-GW (Local Breakout - Heavy) for non-SIM-based devices to provide access to the EPC core. In this release, SaMOG supports IPv6/IPv4v6 address allocation over PMIPv6 and EoGRE access types along with GTPv2-based S2a interface.

### Accepted PDN-Type for IPv4, IPv6, and IPv4v6 Subscribers on PMIPv6 and EoGRE Access Types

<table>

</tr>
</tbody>
</table>
### Unsolicited Router Advertisement and Deprecation of IPv6 Prefix

SaMOG supports sending unsolicited router advertisements (RA) for the EoGRE access type.

**IPv6 Prefix Advertisement**

SaMOG can send unsolicited RA with a newly allocated IPv6 prefix when a session is established, and the AAA server has authorized the IPv6 or IPv4v6 PDN type for the session without waiting for an RS message from the UE.

The total number of retries and retry interval for RA to advertise an IPv6 prefix can be configured using the `ipv6 unsolicited-router-advt advertise` command under the APN Profile Configuration mode.

**IPv6 Prefix Deprecation**

SaMOG sends an RA with the preferred and valid lifetime as 0 to deprecate the IPv6 prefix in the following scenarios:

<table>
<thead>
<tr>
<th>UE Req WLC1</th>
<th>SaMOG v4</th>
<th>SaMOG v6</th>

<td></td>
<td>PBA (v6), BRI to old</td>
</tr>
</tbody>
</table>
• When the network, SaMOG or the AAA server triggers a disconnect for an IPv6 or IPv4v6 PDN-type session.

• When a session receives an IPv6 packet with an old prefix (prefix that does not match the currently allocated prefix for the session), and the AAA server has authorized an IPv6 or IPv4v6 PDN-type for the session.

The total number of retries and retry interval for RA to deprecate an IPv6 prefix can be configured using the `ipv6 unsolicited-router-advt deprecate` command under the APN Profile Configuration mode.

**DNS Support Over the IPv4 and IPv6 Transport**

The SaMOG Gateway can perform SNAPTR, SRV, A/AAAA-based DNS queries towards the DNS server over the IPv4 or IPv6 transport to get the P-GW IP address.

The following are some use cases to resolve the P-GW IP address between the SaMOG Gateway and the DNS server:

• On an IPv4, IPv6 or IPv4v6 PDN, when the AAA server forwards the PGW-Allocation-Type value as Dynamic and Destination-Host, the DNS server responds with the P-GW IPv4 address.

  The SaMOG Gateway performs SNAPTR DNS queries over the IP transport with the P-GW FQDN based on the Destination-Host received from the AAA Server to successfully resolve the P-GW IPv4 address.

• On an IPv4, IPv6 or IPv4v6 PDN, when the AAA server forwards the PGW-Allocation-Type value as Dynamic with no Destination-Host, the DNS server responds with the P-GW IPv6 address.

  The SaMOG Gateway performs SNAPTR DNS queries over the IP transport with the APN FQDN to successfully resolve the P-GW IPv6 address.

• On an IPv4, IPv6 or IPv4v6 PDN, when the AAA server forwards the PGW-Allocation-Type value as Dynamic and Destination-Host, the DNS server responds with more than one P-GW IPv4 addresses with different weights and priorities.

  The SaMOG Gateway performs SNAPTR DNS queries over the IP transport with the P-GW FQDN based on the Destination-Host received from the AAA Server, and selects the P-GW IPv4 address with the highest priority.

• On an IPv4, IPv6 or IPv4v6 PDN, when the AAA server forwards the PGW-Allocation-Type value as Dynamic and Destination-Host, the DNS server responds with more than one P-GW IPv6 addresses with different weights and priorities.

  The SaMOG Gateway performs SNAPTR DNS queries over the IP transport with the P-GW FQDN based on the Destination-Host received from the AAA Server, and selects the P-GW IPv6 address with the highest priority.

• On an IPv4, IPv6 or IPv4v6 PDN, when the AAA server forwards the PGW-Allocation-Type value as Dynamic and Destination-Host, the DNS server responds with P-GW IPv6 and IPv4 addresses with different weights and priorities.

  The SaMOG Gateway performs SNAPTR DNS queries over the IP transport with the P-GW FQDN based on the Destination-Host received from the AAA Server, and selects the P-GW IP address with the highest priority.
Transport Combinations

The table below lists the IPv4, IPv6 and IPv4v6 transport combinations for the SaMOG Gateway, and whether each combination is supported for deployment in this release.

**Table 4: Transport Combinations for the SaMOG Gateway**

<table>

In this release, SaMOG does not support IPv6 transport for PMIPv6 and L3IP access types.

**How the SaMOG Gateway Works**

This section describes the SaMOG Gateway during session establishment and disconnection.
SaMOG Gateway Session Establishment (StarOS Release 17 and earlier)

The figure below shows an SaMOG Gateway session establishment flow in Release 17 and earlier. The table that follows the figure describes each step in the flow.

**Figure 5: SaMOG Gateway Session Establishment**

**Table 5: SaMOG Gateway Session Establishment**

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>An association between the UE and WLC is established.</td>
</tr>
<tr>
<td>2.</td>
<td>The initial attach procedure starts with the authenticator sending an EAP Request/Identity message toward the supplicant.</td>
</tr>
<tr>
<td>3.</td>
<td>The UE responds to the EAP Request/Identity message with an EAP Response/Identity message, which contains the permanent identity (IMSI) on the SIM.</td>
</tr>
<tr>
<td>Step</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td>4.</td>
<td>The WLC requests MRME for authentication using EAP over RADIUS by sending an &quot;Access-Request&quot; message. The WLC includes the User-Name, EAP-Identity as part of the EAP-Message, Acct-Session-Id in the &quot;Access-Request&quot; message.</td>
</tr>
<tr>
<td>5.</td>
<td>The MRME initiates Authentication and Authorization procedures by sending &quot;Diameter EAP Request&quot; message to the 3GPP AAA Server, containing the user identity and EAP-Payload.</td>
</tr>
<tr>
<td>6.</td>
<td>The 3GPP AAA Server fetches the user profile and authentication vectors from the HSS/HLR (if these parameters are not available in the 3GPP AAA Server). The 3GPP AAA Server looks for the IMSI of the authenticated user based on the received user identity (root NAI or Decorated NAI), and includes the EAP-AKA as the requested authentication method in the request sent to the HSS. The HSS then generates authentication vectors and sends them back to the 3GPP AAA server. The 3GPP AAA Server checks if the user's subscription is authorized for a trusted non-3GPP access. The 3GPP AAA Server initiates the authentication challenge. The user identity is not requested again.</td>
</tr>
<tr>
<td>7.</td>
<td>The MRME responds to WLC with a &quot;Radius Access-Challenge&quot; message by including EAP-AKA AKA-Challenge in the EAP-Messages.</td>
</tr>
<tr>
<td>8.</td>
<td>WLC sends an authentication challenge towards the UE.</td>
</tr>
<tr>
<td>9.</td>
<td>The UE responds with a challenge response.</td>
</tr>
<tr>
<td>10.</td>
<td>The WLC forwards the &quot;Radius Access-Request&quot; by including EAP-Response/AKA-Challenge in the EAP-Message to MRME.</td>
</tr>
<tr>
<td>11.</td>
<td>The MRME forwards the EAP-Response/AKA-Challenge message to the 3GPP AAA Server by sending a &quot;Diameter EAP Request&quot; message. The AAA Server checks if the authentication response is correct.</td>
</tr>
<tr>
<td>12.</td>
<td>The 3GPP AAA Server forwards the final Authentication and Authorization answer by initiating &quot;Diameter EAP Answer&quot; (with a result code indicating success) including the relevant service authorization information, an EAP success and the key material to the MRME. The MRME performs P-GW Resolution (Steps 13-16) for dynamic P-GW selection by delaying the EAP-Response (Access-Accept) message to the WLC.</td>
</tr>
<tr>
<td>13.</td>
<td>The MRME sends a &quot;DNS Request&quot; with S-NAPTR Query by constructing an APN FQDN to the DNS Server.</td>
</tr>
<tr>
<td>14.</td>
<td>The MRME receives a &quot;DNS Answer&quot; with a list of A-Records from the DNS Server.</td>
</tr>
<tr>
<td>15.</td>
<td>The MRME sends a &quot;DNS Request&quot; by including the selected A-Record to get the P-GW IPv4 address.</td>
</tr>
<tr>
<td>Step</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td>16.</td>
<td>The MRME receives the resolved P-GW IPv4 address in the &quot;DNS Response&quot; from the DNS Server.</td>
</tr>
<tr>
<td>17.</td>
<td>The MRME sends the &quot;Radius Access-Accept&quot; message to the WLC by including the Shared Secret generated in the EAP exchange, and the User-Name.</td>
</tr>
<tr>
<td>18.</td>
<td>The WLC originates the &quot;PMIPv6 Proxy-Binding-Update&quot; message to the CGW. The information for the subscriber to form the PBU message is included. In addition, WLC also allocates a GRE tunnel ID for downlink data transfer, and includes it in the PBU message.</td>
</tr>
<tr>
<td>19.</td>
<td>The CGW originates a &quot;GTPv2 Create Session Request&quot; message on the S2a interface towards PDN-GW, by including S2a GTP-U TEID to be used for downlink data transfer, MSISDN, IMSI, APN, PAA, PDNType, Bearer-Context-List, APN-AMBR and Charging characteristic.</td>
</tr>
<tr>
<td>20.</td>
<td>The PDN-GW allocates the requested IP address for the subscriber and responds to the CGW with a &quot;GTPv2 Create Session Response&quot; message by including the Cause, PAA, Bearer-Context-List, APN-AMBR and GTP-U PGW TEID for uplink data transfer.</td>
</tr>
<tr>
<td>21.</td>
<td>The CGW responds with a &quot;PMIPv6 PBA&quot; to the WLC, by including the UE's IP address.</td>
</tr>
<tr>
<td>22.</td>
<td>A GTPv2 tunnel is established between the CGW and P-GW.</td>
</tr>
<tr>
<td>23.</td>
<td>A PMIPv6 tunnel is established between the WLC and CGW.</td>
</tr>
<tr>
<td>24.</td>
<td>The WLC initiates a &quot;Radius Accounting-Request&quot; with &quot;Acct-Status-Type&quot; as &quot;Start&quot; and by including the assigned UE's address.</td>
</tr>
<tr>
<td>25.</td>
<td>The MRME proxies the received &quot;Radius Accounting-Request&quot; towards the RADIUS accounting server.</td>
</tr>
<tr>
<td>26.</td>
<td>The MRME receives the &quot;Radius Accounting-Response&quot; from the Radius accounting server.</td>
</tr>
<tr>
<td>27.</td>
<td>The MRME proxies the received &quot;Radius Accounting-Response&quot; towards the WLC.</td>
</tr>
</tbody>
</table>
SaMOG Gateway Session Establishment (StarOS Release 18 and later)

The figure below shows an SaMOG Gateway session establishment flow in StarOS Release 18 and later. The table that follows the figure describes each step in the flow.

### Table 6: SaMOG Gateway Session Establishment

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>The UE initiates an initial attach procedure towards the WLC.</td>
</tr>
<tr>
<td>2.</td>
<td>The WLC forms an Access-Request message with the EAP-Identity payload, User-Name and Acct-Session-Id, and sends the same to SaMOG.</td>
</tr>
<tr>
<td>3.</td>
<td>SaMOG forms a Radius Access-Request or Diameter DEA message towards the AAA server using the attributes received from the WLC.</td>
</tr>
<tr>
<td>4.</td>
<td>The AAA server performs an EAP authentication and sends the Access-Challenge/DEA to SaMOG with the EAP payload.</td>
</tr>
<tr>
<td>5.</td>
<td>SaMOG copies the EAP payload to the Access-Challenge towards WLC.</td>
</tr>
<tr>
<td>6.</td>
<td>The WLC sends an EAP Request towards UE.</td>
</tr>
<tr>
<td>7.</td>
<td>The UE sends an EAP response.</td>
</tr>
<tr>
<td>8.</td>
<td>The WLC sends the Access-Request to SaMOG with the EAP payload received from the UE.</td>
</tr>
<tr>
<td>9.</td>
<td>SaMOG sends the Access-Request/DER to the AAA server with the EAP payload.</td>
</tr>
<tr>
<td>10.</td>
<td>The AAA server fetches the subscriber profile from HLR/HSS and validates the EAP Challenge response sent from the UE. The Access-Accept/DEA is sent to SaMOG with the user profile and EAP Success payload. SaMOG saves the user profile information.</td>
</tr>
<tr>
<td>11.</td>
<td>SaMOG performs DNS procedures towards the DNS server to get the P-GW/GGSN IP address.</td>
</tr>
<tr>
<td>12.</td>
<td>SaMOG delays sending the Access-Accept to the WLC and initiates S2a/Gn procedures towards P-GW/GGSN, by including the IMEI V IE with the UE MAC value received as &quot;Calling-Station-ID&quot; AVP in the Access-Request if sending of IE is enabled (via. configuration).</td>
</tr>
<tr>
<td>13.</td>
<td>SaMOG sends Access-Accept to the WLC with EAP-Success payload after completion of S2a/Gn procedures.</td>
</tr>
<tr>
<td>14.</td>
<td>The WLC sends EAP-Success to the UE.</td>
</tr>
<tr>
<td>15.</td>
<td>The UE sends DHCP discover (broadcast) request to the WLC.</td>
</tr>
<tr>
<td>16.</td>
<td>The WLC acts as a DHCP server and initiates PMIPv6 PBU towards SaMOG for L3 Attachment by including the NAI and Service-Selection parameters.</td>
</tr>
<tr>
<td>Step</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td>17.</td>
<td>SaMOG will process the received PMIPv6 PBU and responds back with a PMIPv6 PBA by including the allocated home-address by P-GW/GGSN and the default gateway IP address.</td>
</tr>
<tr>
<td>18.</td>
<td>The WLC sends a DHCP offer towards the UE with the allocated UEs IP address and the default gateway.</td>
</tr>
<tr>
<td>19.</td>
<td>The UE sends DHCP request to the WLC for DHCP, by including router options and the allocated UE's IP address for further confirmation.</td>
</tr>
<tr>
<td>20.</td>
<td>The WLC sends DHCP Ack message to the UE.</td>
</tr>
<tr>
<td>21.</td>
<td>If proxy accounting is enabled, SaMOG will proxy accounting messages between the WLC and AAA server.</td>
</tr>
<tr>
<td>22.</td>
<td>The UE performs ARP request for the default gateway received from SaMOG. The WLC includes the virtual MAC address in the ARP response for the received Default gateway IP address in the ARP.</td>
</tr>
</tbody>
</table>
SaMOG Gateway IPv6 prefix Over PMIPv6 Using Stateless Address Auto-configuration (SLAAC)

The figure below shows the message flow to delegate an IPv6 prefix to the user equipment (UE) using SLAAC for PMIPv6 access type. The table that follows the figure describes each step in the message flow.

**Figure 7: SaMOG Gateway IPv6 prefix Over PMIPv6 Using SLAAC**

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>SaMOG authenticates between the UE and the AAA/Radius server via. WLC. During Authentication, SaMOG receives the PDN-Type IPv6 value as part of the APN-Profile AVP in the Diameter EAP Answer or Access-Accept message from the AAA/Radius server.</td>
</tr>
<tr>
<td>2.</td>
<td>After P-GW selection, SaMOG performs S2a procedures towards P-GW by including the PDN-Type, and receives the IPv6 Prefix for the subscriber's UE using S2a procedures as per APN subscription profile at P-GW</td>
</tr>
</tbody>
</table>
### SaMOG Gateway Overview

**SaMOG Gateway IPv6 prefix Over PMIPv6 Using Stateless Address Auto-configuration (SLAAC)**

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>3.</td>
<td>SaMOG sends the Radius Access-Accept message towards WLC. SaMOG includes the PDN-Type (IPv6) in the Cisco-AVPair attribute.</td>
</tr>
<tr>
<td>4.</td>
<td>The UE sends the IPv6 ICMPv6 Router Solicitation (ICMPv6 Type 133) message to the destination as &quot;Link-Local Scope multicast All Routers Address (ff02:2)&quot; with the source address as UEs Link-Local address. The UE also includes the ICMPv6 option &quot;source link-layer address&quot;, which is the MAC address of the UE.</td>
</tr>
</tbody>
</table>
| 5.   | The WLC starts PMIPv6 procedures when any of the following triggers occur:  
  - When an Access-Accept message is received from SaMOG and authentication is completed with the UE (Step 3).  
  - When an IPv6 Router Solicitation message is received from the UE.  
For IPv6 Support, the WLC sends the PMIPv6 PBU towards SaMOG by including the Home Network Prefix: "::" and Link Local Address: "::". |
| 6.   | SaMOG processes the received PMIPv6 PBU and responds with a PMIPv6 PBA, by including the valid Home Network Prefix and Link Local Address provided by the P-GW during S2a procedures. SaMOG also includes the IPv6 DNS Primary/Secondary addresses in the PMIPv6 PBA message.  
SaMOG provides the DNS parameters in the PBA only when the WLC requests for it in the PBU.  
**Important**  
6.1 | The WLC processes the received ICMPv6 Router Solicitation message over the CAP-WAP Tunnel and responds with an ICMPv6 Router Advertisement (ICMPv6 Type 134) message over CAP-WAP Tunnel towards the UE.  
The WLC also includes the RDNSS, DNSSSL options as per RFC 6106. |
| 7.   | The WLC may optionally send the Unsolicited IPv6 Router Advertisement (RA) over CAP-WAP Tunnel based on the local configuration. The IPv6 options included would be same as in Step 7.  
**Important** For PMIPv6 access type, SaMOG silently drops unsolicited RA packets received from the WLC. |
| 8.   | The WLC receives the DHCPv6 Information-Request message over the CAP-WAP tunnel to fetch the configuration parameters based on the UE's behavior by including the Client-identifier and Option Request option with "DNS Recursive Name Server" and "Domain Search List". |
| 9.   | The WLC responds with a DHCPv6 Reply over the CAP-WAP Tunnel by including the "DNS Recursive Name Server" and "Domain Search List". |
| 10.  | SaMOG acts as an Accounting proxy between WLC and Radius Accounting Server where all Accounting messages will have "Framed-IPv6-Prefix" AVP. |

---

**Important**
SaMOG Gateway IPv6 prefix Over PMIPv6 using Stateful DHCPv6

The figure below shows the message flow to delegate an IPv6 prefix to the user equipment (UE) using stateful DHCPv6 for a PMIPv6 access type. The table that follows the figure describes each step in the message flow.

Figure 8: SaMOG Gateway IPv6 prefix Over PMIPv6 Using Stateful DHCPv6

Table 8: SaMOG Gateway IPv6 prefix Over PMIPv6 Using Stateful DHCPv6

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>SaMOG authenticates between the UE and the AAA/Radius server via WLC. During Authentication, SaMOG receives the PDN-Type IPv6 value as part of the APN-Profile AVP in the Diameter EAP Answer or Access-Accept message from the AAA/Radius server.</td>
</tr>
<tr>
<td>2.</td>
<td>After P-GW selection, SaMOG performs S2a procedures towards GGSN/PGW by including the PDN-Type value received from the AAA/Radius server during authentication. SaMOG receives the IPv6 Prefix for the subscriber’s UE using S2a procedures as per APN subscription profile at P-GW.</td>
</tr>
<tr>
<td>3.</td>
<td>SaMOG sends the Radius Access-Accept message towards WLC. SaMOG includes the PDN-Type (IPv6) in the Cisco-AVPair attribute.</td>
</tr>
<tr>
<td>4.</td>
<td>The UE sends the DHCPv6 Solicit message over the CAP-WAP tunnel by including the Client Identifier (DUID), FQDN, Option Req:(DNSRNS Req, DNSSL Req), Elapsed Time, and IA_PD Option.</td>
</tr>
</tbody>
</table>
The WLC starts PMIPv6 procedures when any of the following triggers occur:

- When an Access-Accept message is received from SaMOG and authentication is completed with the UE (Step 3).
- When a DHCPv6 Solicit message is received from the UE (Step 4).

For IPv6 Support, the WLC sends the PMIPv6 PBU towards SaMOG by including the Home Network Prefix: "::" and Link Local Address: "::".

SaMOG processes the received PMIPv6 PBU and responds with a PMIPv6 PBA, by including the valid Home Network Prefix and Link Local Address provided by the P-GW during S2a procedures. SaMOG also includes the IPv6 DNS Primary/Secondary addresses in the PMIPv6 PBA message.

The WLC responds with a DHCPv6 Advertise message over the CAP-WAP tunnel by including the IA_PD (IA_PD prefix) Options, FQDN, Client Identifier, Server Identifier, Domain Search List, DNS Recursive Name Server options.

The UE sends the DHCPv6 Request message over the CAP-WAP tunnel by including the Client Identifier (DUID), Server Identifier (DUID), Option Req(DNSRNS Req, DNSSL Req), Elapsed Time, FQDN, IA_PD (IA_PD Prefix) Options.

The WLC responds with a DHCPv6 Reply message over the CAP-WAP Tunnel by including the Client Identifier (DUID), Server Identifier (DUID), Elapsed Time, FQDN, IA_PD (IA_PD Prefix) Options.

SaMOG acts as an Accounting proxy between WLC and Radius Accounting Server where all Accounting messages will have "Framed-Ipv6-Address" AVP.

Important

For PMIPv6 access type, the SLAAC and stateful DHCPv6 process remains the same as the Radius server/DHCPv6-Inf-Req is exchanged between the UE and the WLC.

### SaMOG Gateway Dual-stack Support Over PMIPv6

The table below describes the steps in the message flow for dual-stack support over PMIPv6.

#### Table 9: SaMOG Gateway Dual-stack Support Over PMIPv6 Using SLAAC

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>Refer SaMOG Gateway IPv6 prefix Over PMIPv6 Using Stateless Address Auto-configuration (SLAAC), on page 36 and SaMOG Gateway IPv6 prefix Over PMIPv6 using Stateful DHCPv6, on page 38 for the sequence of messages between the WLC to SaMOG, and SaMOG to P-GW.</td>
</tr>
<tr>
<td>Step</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td>2.</td>
<td>SaMOG receives the PDN-Type as IPv4, IPv6, or IPv4v6 in the APN-Profile during authentication with the Radius/AAA Server.</td>
</tr>
<tr>
<td>3.</td>
<td>SaMOG starts S2a procedures based on the PDN-Type, towards P-GW/GGSN</td>
</tr>
<tr>
<td>4.</td>
<td>The WLC initiates PMIPv6 PBU by including the IPv4 Home Address and/or Home Network Prefix as per the received PDN-Type in the Cisco-AVPair from SaMOG.</td>
</tr>
<tr>
<td>5.</td>
<td>SaMOG provides the configuration parameters (DNS IPv4/IPv6 Addresses) in the PCO Mobility option of the PMIPv6 PBA.</td>
</tr>
<tr>
<td>6.</td>
<td>UE triggers the sequence of messages using SLAAC or Stateful DHCPv6 to get the IPv6 prefix and DHCPv4 to get the IPv4 address.</td>
</tr>
</tbody>
</table>
P-GW Initiated Session Disconnection

The figure below shows the message flow during a P-GW initiated session disconnection. The table that follows the figure describes each step in the message flow.

Figure 9: P-GW Initiated Session Disconnection

Table 10: P-GW Initiated Session Disconnection

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>The P-GW initiates a &quot;GTPv2 Delete Bearer Request&quot; to remove the session resources from CGW.</td>
</tr>
<tr>
<td>2.</td>
<td>The CGW responds back with a &quot;GTPv2 Delete Bearer Response&quot; to P-GW.</td>
</tr>
<tr>
<td>3.</td>
<td>The CGW sends a &quot;PMIPv6 Binding Revocation Indication&quot; message to WLC to detach PMIPv6 GRE Tunnel between WLC and CGW.</td>
</tr>
<tr>
<td>4.</td>
<td>The MRME initiates a &quot;Diameter Session-Termination-Request&quot; message towards 3GPP AAA Server without waiting for GTPv2 Response procedures.</td>
</tr>
<tr>
<td>Step</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td>5.</td>
<td>The MRME also initiates a &quot;Radius Disconnect Request&quot; Message towards WLC to release the resources on WLC and towards UE.</td>
</tr>
<tr>
<td>6.</td>
<td>If the MRME had received Accounting Records for the session, then MRME initiates &quot;Disconnect Wait Timer&quot; to wait for &quot;Accounting Request with Acct-Status-Type as Stop&quot; message from WLC.</td>
</tr>
<tr>
<td>7.</td>
<td>The WLC responds with a &quot;PMIPv6 Binding Revocation Ack&quot; message to the CGW.</td>
</tr>
<tr>
<td>8.</td>
<td>The 3GPP AAA server responds with a &quot;Diameter Session-Termination-Answer&quot; message.</td>
</tr>
</tbody>
</table>
| 9.   | The WLC respond back with a "Radius Disconnect Response ACK/NAK" message to the MRME.  
  • If the MRME receives a "Radius Disconnect NAK" message, then MRME will stop the "Disconnect Wait Timer" and proceed to cleanup the call immediately.  
  • If the MRME receives a "Radius Disconnect ACK" message, then MRME will wait for the "Accounting Stop" message based on the "Disconnect Wait Timer" value. |
| 10.  | The WLC triggers a "Radius Accounting-Request" message with "Acct-Status-Type" as "STOP" and an appropriate "Terminate-Cause". |
| 11.  | The MRME proxies the received "Radius Accounting-Request" message towards the RADIUS accounting server. |
| 12.  | The MRME receives the "Radius Accounting-Response" message from the RADIUS accounting server. |
| 13.  | The MRME proxies the received "Radius Accounting-Response" to the WLC. |
WLC Initiated Session Disconnection

The figure below shows the message flow during a WLC initiated session disconnection. The table that follows the figure describes each step in the message flow.

**Table 11: WLC Initiated Session Disconnection**

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>

</tbody>
</table>
| 10.  | WLC sends a "Radius Disconnect Response ACK/NAK" message to the MRME.  
  
  • If the MRME receives a "Radius Disconnect NAK" message, then MRME stops the "Disconnect Wait Timer" and proceed to cleanup the call immediately.  
  
  • If the MRME receives a "Radius Disconnect ACK" message, then MRME waits for the "Accounting Stop" message based on the "Disconnect Wait Timer" value. |
| 11.  | The P-GW responds with a "GTPv2 Delete Session Response" message. |
| 12.  | The WLC triggers a "Radius Accounting-Request" message with the "Acct-Status-Type" as "STOP", and an appropriate "Terminate-Cause". |
| 13.  | The MRME proxies the received "Radius Accounting-Request" message towards the RADIUS accounting server. |
| 14.  | The MRME receives the "Radius Accounting-Response" message from the RADIUS accounting server. |
| 15.  | The MRME proxies the received "Radius Accounting-Response" message to the WLC. |
SaMOG Gateway Data Flow

The figure below shows the user data flow on the SaMOG Gateway. The table that follows the figure describes each step in the flow.

Figure 12: SaMOG Gateway Data Flow

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>The UE sends the uplink (UL) data to the WLC.</td>
</tr>
<tr>
<td>2.</td>
<td>The WLC sends the user data to the SaMOG Gateway's CGW service over the established bi-directional GRE tunnel.</td>
</tr>
<tr>
<td>3.</td>
<td>The CGW service sends the user data over a GTPU tunnel to the P-GW.</td>
</tr>
<tr>
<td>4.</td>
<td>The P-GW maps the downlink (DL) data on the GTPU tunnel to a GRE tunnel to the WLC.</td>
</tr>
<tr>
<td>5.</td>
<td>The CGW service sends the user data to the WLC over the GRE tunnel.</td>
</tr>

SaMOG Features and Functionality - Base Software

This section describes the SaMOG Gateway features and functions. The following features and functions are supported:

- Bulk Statistics, on page 48
- Congestion Control Support, on page 49
Bulk Statistics

The system's support for CGW and MRME service bulk statistics allows operators to choose to view not only statistics that are of importance to them, but also to configure the format in which it is presented. This simplifies the post-processing of statistical data since it can be formatted to be parsed by external, back-end processors.

The system can be configured to collect bulk statistics and send them to a collection server called a receiver. Bulk statistics are collected in a group. The individual statistics are grouped by schema. The following is a partial list of supported schemas:

- **SaMOG**: Provides statistics to support the SaMOG Gateway.
- **System**: Provides system-level statistics.
- **Card**: Provides card-level statistics.
- **Port**: Provides port-level statistics.

The system supports the configuration of up to four sets of receivers. Each set can have primary and secondary receivers. Each set can be configured to collect specific sets of statistics from the various schemas. Bulk statistics can be periodically transferred, based on the transfer interval, using ftp/tftp/sftp mechanisms.

Bulk statistics are stored on the receivers in files. The format of the bulk statistic data files can be configured by the user. Users can specify the format of the file name, file headers, and/or footers to include information such as the date, system host name, system uptime, the IP address of the system generating the statistics (available for headers and footers only), and/or the time that the file was generated.

When the Web Element Manager is used as the receiver, it is capable of further processing the statistics data through XML parsing, archiving, and graphing.

The Bulk Statistics Server component of the Web Element Manager parses collected statistics and stores the information in the PostgreSQL database. If XML file generation and transfer is required, this element generates the XML output and can send it to a northbound NMS or an alternate bulk statistics server for further processing.

Additionally, if archiving of the collected statistics is desired, the Bulk Statistics Server writes the files to an alternative directory on the server. A specific directory can be configured by the administrative user or the
For more information on bulk statistics, see the System Administration Guide.

Important

**Congestion Control Support**

SaMOG enhances on the StarOS framework to provide congestion control policies and threshold crossing alerts to ensure smooth performance of the SaMOG service and prevent congestion. The Congestion Control feature enables policies and thresholds to be configured to specify how the system should react in the event of a heavy load condition.

Congestion control monitors the system for conditions that could potentially degrade performance when the system is under heavy load. Typically, these conditions are temporary (for example, high CPU or memory utilization) and are quickly resolved. However, continuous or large numbers of these conditions within a specific time interval may have an impact the system's ability to service subscriber sessions. Congestion control helps identify such conditions and invokes policies for addressing the situation.

Congestion control operation is based on configuring the following:

- **Congestion Condition Thresholds:** Thresholds dictate the conditions for which congestion control is enabled and establish limits for defining the state of the system (congested or clear). These thresholds function in a way similar to operational thresholds that are configured for the system as described in the Thresholding Configuration Guide. The primary difference is that when congestion thresholds are reached, a service congestion policy and an SNMP trap, starCongestion, are generated. A threshold tolerance dictates the percentage under the configured threshold that must be reached in order for the condition to be cleared. An SNMP trap, starCongestionClear, is then triggered.

  - **Port Utilization Thresholds:** If you set a port utilization threshold, when the average utilization of all ports in the system reaches the specified threshold, congestion control is enabled.

  - **Port-specific Thresholds:** If you set port-specific thresholds, when any individual port-specific threshold is reached, congestion control is enabled system-wide.

- **Service Congestion Policies:** Congestion policies are configurable for each service. These policies dictate how services respond when the system detects that a congestion condition threshold has been crossed.

For the SaMOG Gateway, congestion control monitors the following resources:

- Licensing utilization
- Maximum sessions per service utilization
- Demux message queue utilization
- Demux message queue wait time
- Port Rx specific utilization
- Port Tx specific utilization
- Average transmit port Tx utilization
• Process CPU utilization
• System CPU utilization
• System memory utilization

For more information on congestion control, refer to the Congestion Control chapter in the System Administration Guide. For configuration on congestion control specific to the SaMOG Gateway, refer to Configuring the SaMOG Gateway in this guide.

DHCP Trigger-based Session Creation

This feature enables the SaMOG Gateway to create sessions on receiving DHCP Discover or DHCP Request messages for a subscriber over the EoGRE tunnel.

For more information, refer DHCP Trigger-based Session Creation, on page 133.

Ethernet over GRE (EoGRE)

In addition to the PMIPv6 access type, SaMOG can use both Ethernet over GRE based access type from a trusted WLAN network to connect subscribers to 3G/4G networks.

4G/3G subscribers can connect to EPC/Internet using the trusted WiFi SSIDs served by EoGRE-enabled Residential Gateways in SaMOG. SaMOG acts as the tunnel endpoint for the EoGRE tunnel initiated from the Residential Gateway. Using the SSID-based WLAN access, users are authenticated based on the SSID they select to connect to WLAN. The Residential Gateway/WLC maintains separate SSIDs to provide 3G/4G access, and users can select the appropriate SSID based on their subscription to obtain 3G or 4G access through the WiFi network. EoGRE access type supports IPv4, IPv6 and IPv4v6 addressing.

With this feature, SaMOG acts as the AAA server and DHCP server to the user equipment (UE) that connects to the WLAN network. SaMOG processes all the control packets from the UE and maintains the subscriber session to provide 3G/4G access. Acting as the DHCP-server, SaMOG creates the PDP context with GGSN/P-GW and obtains the IP address to allocate to the UE through DHCP-Response in the access-side. The interface with GGSN is similar to the TTG's Gn' interface with GGSN for 3G, and the existing SaMOG's S2a interface with P-GW for 4G. The DHCP and data packets originating from the UE are forwarded by the Residential Gateway/WLC node through the EoGRE tunnel to SaMOG.

The MRME service maintains all the access network parameters (Radius client and access client details) locally. The MRME service determines the session's access-type and if a request should be accepted or rejected, based on the NAS IP (AVP in the Access-Request/ Accounting-Request) or Source IP of the request (if NAS IP AVP is not available), by looking up the local configuration and conveys the same to CGW for session setup.

SaMOG as a Default Gateway

The SaMOG Gateway can act as the first-hop L3 router (default gateway) for the UE, and the UEs can forward data traffic directly to SaMOG using the EoGRE tunnel from the Residential Gateway/WLC. For 3G access, the default gateway IP address is obtained from the local configuration and supplied by P-GW for 4G access over the S2a interface.
UEs wanting to send data traffic will resolve the MAC address of the default gateway using an ARP request which is forwarded by the residential gateway/WLC over EoGRE using the mapped VLAN. The SaMOG Gateway responds with the virtual MAC address in the ARP response to enable data packets to reach SaMOG from the UE.

The SaMOG default gateway does not handle ICMP packets. The ICMP packets are considered as data and forwarded to GGSN/P-GW.

**EoGRE Call Flows**

This section describes the call flows for the EoGRE access-type.
SaMOG Gateway EoGRE Session Establishment (StarOS Release 18 and later)

The figure below shows an SaMOG Gateway session establishment flow using the EoGRE access type in StarOS Release 18 and later. The table that follows the figure describes each step in the flow.

</tr>
</tbody>
</table>
SaMOG Gateway IPv6 prefix Over EoGRE Using SLAAC

The figure below shows the message flow to delegate an IPv6 prefix to the user equipment (UE) using SLAAC for EoGRE access type. The table that follows the figure describes each step in the message flow.

**Figure 14: SaMOG Gateway IPv6 prefix Over EoGRE Using SLAAC**

![Diagram showing the message flow](image)

**Table 15: SaMOG Gateway IPv6 prefix Over EoGRE Using SLAAC**

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>SaMOG authenticates between the UE and the AAA/Radius server via WLC. During Authentication, SaMOG receives the PDN-Type IPv6 value as part of the APN-Profile AVP in the Diameter EAP Answer or Access-Accept message from the AAA/Radius server.</td>
</tr>
<tr>
<td>2.</td>
<td>After P-GW selection, SaMOG performs S2a procedures towards GGSN/PGW by including the PDN-Type, and receives the IPv6 Prefix for the subscriber's UE using S2a procedures as per APN subscription profile at P-GW</td>
</tr>
<tr>
<td>3.</td>
<td>SaMOG sends the Radius Access-Accept message towards WLC.</td>
</tr>
<tr>
<td>4.</td>
<td>The UE sends the IPv6 ICMPv6 Router Solicitation (ICMPv6 Type 133) message to the destination as &quot;Link-Local Scope multicast All Routers Address (ff02:2)&quot; with the source address as UEs Link-Local address. The UE also includes the ICMPv6 option &quot;source link-layer address&quot;, which is the MAC address of the UE.</td>
</tr>
</tbody>
</table>
### Step 5
For **EoGRE** access type sessions, the WLC is transparent between the UE and SaMOG for Neighbor Discovery and **DHCPv6** messages.

The WLC forwards the above messages to SaMOG by adding an EoGRE Tunnel Header received from the UE over CAP-WAP tunnel.

Vice versa, the WLC discards the EoGRE tunnel header received from SaMOG and forwards the same to the UE over the CAP-WAP tunnel.

The WLC sends the **ICMPv6** Router Solicitation Message towards SaMOG by adding the EoGRE tunnel header.

### Step 6
SaMOG processes the received **ICMPv6** Router Solicitation message over the EoGRE tunnel and responds with an **ICMPv6** Router Advertisement (**ICMPv6** Type 134) message over the EoGRE tunnel towards WLC.

The WLC also includes the RDNSS, DNSSSL options as per **RFC 6106**.

### Step 7
The WLC forwards the IPv6 Router Advertisement (**RA**) over the CAP-WAP tunnel based on the mapping maintained between the UE's MAC address and the CAP-WAP tunnel information.

### Step 8
SaMOG sends unsolicited IPv6 Router Advertisement (**RA**) over the EoGRE tunnel by including the IPv6 options mentioned in Step 6.

### Step 9
The WLC forwards the Unsolicited IPv6 Router Advertisement (**RA**) over CAP-WAP Tunnel based on the mapping maintained between the UE's MAC Address and CAP-WAP tunnel information.

### Step 10
The WLC receives the **DHCPv6** Information-Request message over the CAP-WAP tunnel to fetch the configuration parameters based on the UE's behavior by including the Client-identifier and Option Request option with "DNS Recursive Name Server" and "Domain Search List".

### Step 11
The WLC forwards the **DHCPv6** Information-Request towards SaMOG by adding the EoGRE tunnel header.

### Step 12
SaMOG responds with a **DHCPv6** Reply message over the EoGRE tunnel by including the "DNS Recursive Name Server" and "Domain Search List".

### Step 13
The WLC forwards the **DHCPv6** Reply message over the CAP-WAP tunnel based on the mapping maintained between the UE's MAC address and the CAP-WAP tunnel information.

### Step 13
SaMOG acts as an Accounting proxy between the WLC and Radius Accounting Server where all Accounting messages will have "Framed-IP-Address" and "Framed-IPv6-Address" based on the PDN-Type.
**SaMOG Gateway Dual-stack Support Using SLAAC Over EoGRE**

The table below describes the steps in the message flow for dual-stack support using SLAAC over EoGRE.

**Table 16: SaMOG Gateway Dual-stack Support Using SLAAC Over EoGRE**

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>Refer for the sequence of messages between the WLC to SaMOG, and SaMOG to P-GW.</td>
</tr>
<tr>
<td>2.</td>
<td>The UE triggers the sequence of messages using SLAAC to get the IPv6 prefix and DHCPv4 to get the IPv4 address.</td>
</tr>
<tr>
<td>3.</td>
<td>The WLC is transparent for the received SLAAC and DHCPv6 Info-req to get IPv6 Prefix and configuration parameters by encapsulating and decapsulating the EoGRE Tunnel header to and from SaMOG.</td>
</tr>
<tr>
<td>4.</td>
<td>WLC transparently receives DHCPv4 to get IPv4 address and configuration parameters by encapsulating and decapsulating the EoGRE Tunnel header to and from SaMOG.</td>
</tr>
</tbody>
</table>

---

**MAC Address in Decimal Format for P-GW**

This feature enables the SaMOG Gateway to encode the User Equipment's MAC address in the IMEISV IE value in decimal format, in order to support inter-operability with P-GW from third party vendors.

For more information, refer [MAC Address in Decimal Format for P-GW](#), on page 153.

**Newcall Policy Reject for SaMOG Service**

During planned maintenance or congestion scenarios, this feature can either be used to restrict new calls on specified SaMOG service(s), or drop new calls on all SaMOG services. As this feature restricts new calls only, the existing established user sessions are not affected. This manner of restricting new calls, and clearing existing established sessions locally at SaMOG can ensure a graceful maintenance mode where no stale sessions on peer nodes (WLC/P-GW) exist.

This feature can be enabled using the `newcall policy samog-service { all | name service_name } drop` command under the Exec Mode, and disabled using the `no newcall policy samog-service { all | name service_name }` command. This configuration is disabled by default, and does not persist after a system reboot.

The output of the `show samog-service { all | name service_name }` command will indicate if newcall policy is enabled or disabled. Additionally, the output of the `show samog-service statistics` will indicate the total number of new calls dropped when the `newcall policy samog-service` command is enabled.

**Offline Charging**

The SaMOG Gateway supports generation of CDR files for offline charging. Offline charging works by collecting charging information concurrently with resource usage and passes the information through a chain
of logical charging functions. At the end of the process, CDR files are generated by the network and transferred to the network operator's Billing Domain.

For more information on offline charging for the SaMOG Gateway, refer to the SaMOG Gateway Offline Charging chapter of this guide.

**RADIUS Accounting-based Session Creation**

This feature enables the SaMOG Gateway to create sessions on receiving a RADIUS Accounting-Start messages for subscribers.

For more information, refer RADIUS Accounting-based Session Creation, on page 177.

**Rate Limiting Function (RLF) on STa Interface**

The SaMOG Gateway supports the Rate Limiting Function (RLF) feature on the STa interface. The SaMOG Gateway rate limits the messages sent towards the AAA server when the RLF feature is enabled.

The RLF feature implements a generic framework that can be used by multiple interfaces and products for rate limiting/throttling outgoing messages like Diameter messages on Gx, Gy interface towards PCRF.

For more information on Rate Limiting Function (RLF), refer the AAA Interface Administration and Reference guide.

**Sample Configuration**

The following is a sample configuration to enable the use of RLF templates from the Global Configuration Mode:

```config
cfg rlf  
    rlf-template rlf1
    msg-rate 1000 burst-size 100
    threshold upper 80 lower 60
    delay-tolerance 4
    exit
  
  rlf-template rlf2
  msg-rate 20
  threshold upper 80 lower 60
  exit
  
  rlf-template rlf3
  msg-rate 3000
  delay-tolerance 4
  exit
  
  rlf-template rlf4
  msg-rate 4000
  threshold lower 60
  delay-tolerance 0
  exit
end
```

**SaMOG GTPP Using Same Source Address but Different Port**

In multi-product deployment environments where CDRs are received from ePDG, SaMOG (pseudo) and P-GW (Local Breakout), the mediation server cannot differentiate between the products that provide the CDRs. With this feature, CDRs can easily be identified by mapping CDRs corresponding to each Gateway service to different ports of the same CGF server. This is achieved using CLI configurations for multiple GTPP groups with the same CGF server IP address and different port numbers. This configuration provides the flexibility to send ePDG, SaMOG and P-GW LBO CDRs to the same CGF server on different ports.
Whenever AAA proxy logs are displayed, it includes both CGF IP address and port, and can be filtered using the port keyword in the gtp test accounting, show gtp counters, show gtp statistics and clear gtp statistics CLI commands. If the port is not specified, then all GTPP servers with the specified IP address will be considered irrespective of the configured port.

SaMOG Wireless Access Gateway (WAG) Integration

Overview

The SaMOG Gateway supports additional deployment models and access-side connectivity by integrating various Wireless Access Gateway (WAG) functions. The WAG functions include:

- Deployment in environments where the WLC/RGs do not use bridge mode to forward packets between the User Equipment (UE) and the SaMOG Gateway.
- Receive IP packets in 'plain L3' or within GRE, MPLS or VLL tunnels.
- Route packets based on the IP address and the Layer 2 tunnel on the access-side to the GTP tunnel for the uplink, and vice versa for the downlink.
- Allow IP address allocation by either WLAN or SaMOG.

Layer 3 IP (L3IP)

The SaMOG Gateway supports out of band DHCP Layer 3 packet processing, and call setup with L3IP access type.

IP address assigned by the WLC (IP@W)

The User Equipment's (UE) IP address is assigned by WLC, and DHCP is not required in the call flow. WLC forwards the assigned IP address in the Accounting-Start message inside the Framed IPAddress field. SaMOG NATs the IP@W with the IP address assigned by P-GW (IP@G).

IP over GRE (IPoGRE)

The SaMOG Gateway supports GRE encapsulation on the L3IP access-type to ensure a scalable deployment model. The SaMOG Gateway adds an extra IP and GRE header on top of the plain L3 IP. All control and data packets from one or more WLCs use the same IPoGRE tunnel. The SaMOG Gateway performs encapsulation and decapsulation before processing any control or data packets. After the packets are encapsulated or decapsulated, the session is handled in the same way as that of L3IP or IP@W deployment models. The IPoGRE functionality is achieved using the StarOS GRE tunnel feature, and one-to-one mapping between the GRE tunnel interfaces (or same TWAN profile multiple GRE tunnel interfaces) and VRFs.

Important: The IP over GRE model requires a GRE Interface Tunneling license to create GRE tunnels. For more information on licenses, contact your Cisco account representative.

IP over VLAN (IPoVLAN)

The SaMOG Gateway supports VLAN encapsulation on the L3IP access-type to ensure a scalable deployment model. The SaMOG Gateway adds an extra VLAN header next to the Ethernet header and the session is
handled in the same way as that of the L3IP or IP@W deployment models. The IPoVLAN functionality is achieved using the StarOS VLAN feature, and one-to-one mapping between the VLANs (or same TWAN profiles) and VRFs.

**Authentication**

SaMOG supports proxy-based authentication, and session creation based on the MAC address received in the Access-Request messages. SaMOG acts as both authentication and accounting proxy. In accordance to 3GPP 23.402 standards, a PDN connection establishment is completed before the Radius Access-Accept is sent to the WLC.

**Accounting**

The SaMOG Gateway functions in a server mode acting as a AAA accounting server in the uplink direction to receive the accounting requests. The accounting start message is used between the WLC and the SaMOG Gateway to communicate the IP@WLAN assigned by the WLC to the SaMOG Gateway. The server mode for the SaMOG Gateway is enabled when there is no accounting server configuration present in the Operator Policy Configuration Mode.

**User Equipment’s (UE) Address**

The SaMOG Gateway provides support for different models for the UE Home Address (UE-HA) and UE Network Address (UE-NA) as follows:

- The WLAN assigns an address directly to the UE and communicates it to the SaMOG Gateway through an accounting start-request message with the Framed-IP-address set to IP@W.
- The WLC relays the DHCP requests to the SaMOG Gateway, and the SaMOG Gateway provides the address it receives from the P-GW.
- The WLC relays DHCP requests to the SaMOG Gateway, and the SaMOG Gateway assigns the address from its local pool and shares the same to the UE (For Local Breakout (Basic)).
- The SaMOG Gateway assigns the address from the P-GW to the UE.

**Static NAT**

The SaMOG gateway can perform static NAT when the UE-HA and the UE-Na are not the same. Static NAT is achieved through the Enhanced Charging Service's (ECSv2) Firewall and NAT functionality.

**DHCP Server**

SaMOG supports DHCP server at system level for L3IP models where the UE session is identified by parsing the DHCP options inside the DHCP packets (using DeMUX). SaMOG supports DHCP packets in-band where the VLAN or GRE tunnel from which the DHCP packets are received is considered to be the same tunnel to receive the data path traffic.

**Access Type**

The SaMOG Gateway supports the following access-types:
- Ethernet over GRE (EoGRE)
- PMIPv6
- Layer3 IP (L3IP)
- IP over VLAN (IPoVLAN)
- IP over GRE (IPoGRE)

The SaMOG Gateway determines the NPU flow for a session using the configured access-type CLI command under the TWAN Profile Configuration Mode. Although the SaMOG Gateway does not support a change in the access-type mid-session, the SaMOG Gateway drops the previous session and the access request message when a change in the access-type is detected, and the NPU flows are switched to the changed access-type.

**Call Flows for WAG Models**

This section describes the call flows for the different WAG models.
Session Establishment for Layer 3 IP with DHCP Server

The figure below shows an SaMOG Gateway session establishment flow for Layer 3 IP with a DHCP server in StarOS Release 18 and later. The table that follows the figure describes each step in the flow.

Session Establishment for Layer 3 IP, with IP Assigned by WLAN (IP@W)

The figure below shows an SaMOG Gateway session establishment flow for Layer 3 IP with the IP address assigned by WLAN (IP@W) using NAT in StarOS Release 18 and later. The table that follows the figure describes each step in the flow.

*Figure 16: Session Establishment for Layer 3 IP, with IP@W*

</tr>
<tr>
<td>15.</td>
<td>The UE performs DHCP with the WLC and obtains the IP address (IP@W).</td>
</tr>
<tr>
<td>16.</td>
<td>The WLC sends an Accounting Start Req with the Framed-IP-Address value (IP@W). If the Accounting Server is configured at SaMOG (SaMOG acting as an Accounting Proxy), the Accounting Start Req is forwarded to the Accounting server.</td>
</tr>
<tr>
<td>17.</td>
<td>SaMOG creates a NAT entry between the IP@W and IP@G.</td>
</tr>
</tbody>
</table>
Step | Description
--- | ---
18. | The UE sends/receives data packets with the IP address (IP@W) over the 802.11 interface towards/from the Access Point (AP), and the AP sends/receives data packets over CAP/WAP to/from WLC or intermediate routers. The WLC or the intermediate routers will forward/receive data packets as plain IP towards/from SaMOG.

19. | SaMOG performs NAT, changing the IP from IP@W to IP@G, and forwards the IP packets over GTP-u tunnel towards the P-GW/GGSN (Local P-GW/GGSN in case of LBO). Also, reverse NATing (IP@G to IP@W) occurs when the data is received from the P-GW/GGSN in the GTP-u tunnel and forwarded to the UE.

Limitations, Restrictions, and Dependencies

This section identifies limitations, restrictions, and dependencies for the SaMOG WAG integration:

- The AP location is sent from the WLC in the Called-Station-Id attribute. The WLC may include either the AP MAC, AP Name, AP MAC and SSID, or AP Name and SSID. If the WLC is configured to send the AP Name (for sending ULI on Gn interface), SaMOG will not be able to send the AP MAC in TWAN Identifier AVP over the S2a interface.

- The SaMOG Gateway does not support overlapping WLC-IP-Address for IPoVLAN and IPoGRE for Radius/DHCP packets.

Secondary P-GW or GGSN Fallback

The SaMOG Gateway supports session establishment between the GTP interface and an alternate P-GW or GGSN when connection establishment fails towards the primary P-GW or GGSN (response timeout or localized issues). Where SaMOG selects the P-GW or GGSN using DNS queries, the secondary P-GW or GGSN IP address is determined using the A/AAAA (Pre-release 8) or SNAPTR (Post-release 7) DNS procedure with the DNS server.

A/AAAA DNS Query-based Selection

The SaMOG Gateway performs the pre-release 8 DNS procedure when the local policy has A/AAAA configured as the DNS query type. As the DNS server returns a list of GGSN IP addresses that serve the APN, the SaMOG Gateway selects the GGSN IP address from the list and tries to establish a GTPv1 session. The SaMOG Gateway will keep trying to establish a connection with the GGSN IP addresses from the list provided by the DNS server until a session is established. When the list is exhausted, or the session setup timer expires, the session setup attempt is aborted and the session is cleared.

SNAPTR DNS Query-based Selection

The SaMOG Gateway performs the post-release 7 DNS procedure when the local policy has SNAPTR configured as the DNS query type. The SNAPTR query is performed on an APN FQDN or P-GW FQDN with a service string mapped to the S2a-Gn, P-GW-Gn, and GGSN-Gn in the same order of preference. This results in a list of IP addresses of the P-GW or GGSN whose interfaces corresponds to the service string that currently serves the specified APN.
The SaMOG Gateway performs a topology or weight-based match (as configured) from the list and tries to establish a GTPv2 or GTPv1 connection with the matched P-GW or GGSN. On failure, SaMOG performs a topology or weight-based match with the rest of the IP addresses from the list until the list is exhausted. The SaMOG Gateway then builds a list from the next service parameter in preference. When the list is exhausted, or the session setup timer expires, the session setup attempt is aborted and the session is cleared.

**Trigger for Secondary P-GW or GGSN Fallback**

The SaMOG Gateway triggers fallback to the secondary P-GW or GGSN selection when the following GTP cause values are received in the Create Session Response (CSR) and Create PDP Context Response (CPCR) messages:

<table>
<thead>
<tr>
<th>CSR/CPC Request Rejection Cause</th>
<th>GTPv2 Cause Code</th>
<th>GTPv1 Cause Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service not supported</td>
<td>68</td>
<td>200</td>
</tr>
<tr>
<td>No resources available</td>
<td>73</td>
<td>199</td>
</tr>
<tr>
<td>All dynamic addresses are occupied</td>
<td>84</td>
<td>211</td>
</tr>
<tr>
<td>Service denied</td>
<td>89</td>
<td>—</td>
</tr>
<tr>
<td>No memory available</td>
<td>91</td>
<td>212</td>
</tr>
<tr>
<td>APN congestion</td>
<td>113</td>
<td>229</td>
</tr>
</tbody>
</table>

The call setup attempt is terminated for all other cause values.

In addition to the above rejection causes, the P-GW or GGSN selection fallback is triggered when the primary P-GW or GGSN fails to respond to the CSR/CPCR Request message.

The fallback to secondary P-GW or GGSN is not applicable for SaMOG Local Break Out or Web Authorization features.

**SNMP Traps**

The SaMOG Gateway generates SNMP traps for the SaMOG service startup and shutdown events. For detailed descriptions of the traps, refer to the SNMP MIB Reference guide.

**Threshold Crossing Alerts (TCA) Support**

Thresholding on the system is used to monitor the system for conditions that could potentially cause errors or outage. Typically, these conditions are temporary (i.e. high CPU utilization, or packet collisions on a network) and are quickly resolved. However, continuous or large numbers of these error conditions within a specific time interval may be indicative of larger, more severe issues. The purpose of thresholding is to help identify potentially severe conditions so that immediate action can be taken to minimize and/or avoid system downtime.
The system supports Threshold Crossing Alerts for certain key resources such as CPU, memory, IP pool addresses, etc. With this capability, the operator can configure threshold on these resources whereby, should the resource depletion cross the configured threshold, a SNMP Trap would be sent.

The following thresholding models are supported by the system:

- **Alert**: A value is monitored and an alert condition occurs when the value reaches or exceeds the configured high threshold within the specified polling interval. The alert is generated then generated and/or sent at the end of the polling interval.

- **Alarm**: Both high and low threshold are defined for a value. An alarm condition occurs when the value reaches or exceeds the configured high threshold within the specified polling interval. The alarm is generated then generated and/or sent at the end of the polling interval.

In addition to the existing generic StarOS system level TCA thresholds, an SaMOG service session count threshold is available to check if the total number of subscribers have exceeded the high threshold.

Thresholding reports conditions using one of the following mechanisms:

- **SNMP traps**: SNMP traps have been created that indicate the condition (high threshold crossing and clear) of each of the monitored values.
  Generation of specific traps can be enabled or disabled on the chassis. Ensuring that only important faults get displayed. SNMP traps are supported in both Alert and Alarm modes.

- **Logs**: The system provides a facility called threshold for which active and event logs can be generated. As with other system facilities, logs are generated Log messages pertaining to the condition of a monitored value are generated with a severity level of WARNING.
  Logs are supported in both the Alert and the Alarm models.

- **Alarm System**: High threshold alarms generated within the specified polling interval are considered outstanding until a condition no longer exists or a condition clear alarm is generated. Outstanding alarms are reported to the system’s alarm subsystem and are viewable through the Alarm Management menu in the Web Element Manager.

---

**Important**
For more information on threshold crossing alert configuration, refer to the *Thresholding Configuration Guide*.

---

**Virtual MAC Validation**

SaMOG can validate if the destination MAC address in the packet received over the EoGRE tunnel matches with its virtual MAC, broadcast, or multicast address. Packets whose address does not match are dropped. This validation can be enabled using the `violation drop` keywords in the `virtual-mac` command under the APN Profile Configuration Mode.

**SaMOG Features and Functionality - License Enhanced Feature Software**

This section describes the optional enhanced features and functions for SaMOG service.
The following features require the purchase of an additional feature license to implement the functionality with the SaMOG service. For more information on the feature licenses, contact your Cisco account representative.

This section describes the following enhanced features:

- Lawful Intercept, on page 72
- SaMOG Local Break Out, on page 72
- Session Recovery, on page 72
- Web Authorization, on page 73
- Optimized Web Authorization, on page 76

### Inter-Chassis Session Recovery

SaMOG is capable of providing chassis-level and geographic-level redundancy and can recover fully created sessions in the event of a chassis failure.

The Cisco ASR 5x00 and virtualized platforms provide industry leading carrier class redundancy. The systems protects against all single points of failure (hardware and software) and attempts to recover to an operational state when multiple simultaneous failures occur.

For more information, refer the Inter-Chassis Session Recovery chapter of this guide.

### Lawful Intercept

The Cisco Lawful Intercept feature is supported on the SaMOG (CGW, MRME) Gateway. Lawful Intercept is a license-enabled, standards-based feature that provides telecommunications service providers with a mechanism to assist law enforcement agencies in monitoring suspicious individuals for potential illegal activity. For additional information and documentation on the Lawful Intercept feature, contact your Cisco account representative.

### SaMOG Local Break Out

The SaMOG Local Break Out (LBO) feature enables subscribers to access the Internet directly without connecting to the EPC or 3G core.

For more information on the Local Breakout feature for the SaMOG Gateway, refer to the SaMOG Local Breakout chapter of this guide.

### Session Recovery

SaMOG has the ability to recover fully created sessions in the event of process level or card level failures.

This feature supports the following types of session recovery:
• **Task level recovery:** SaMOG sessions are recovered when a Session Manager task serving the session is terminated due to a software error.

• **Card level recovery:** SaMOG sessions are recovered when the entire PSC/DPC card hosting the Session Manager fails, and all the tasks running on that card have to be recovered. The SaMOG sessions can be recovered in the event of a PSC/DPC card failures in the following scenarios:

  - **Unplanned card failure:** SaMOG can recover tasks running on the failed card to the standby card by fetching the CRR information from the peer Session Managers and AAA Managers in the other card.

  - **Planned card migration:** The system administrator can migrate the sessions from one PSC/DPC card to a standby card using the CLI. Planned migration can be performed by transferring the entire memory contents from the source card to the destination card, re-opening the sockets, and updating the NPU flows.

*Important* In this release, card level recovery and npusim recovery are not supported on the virtualized platform (VPC).

When the Session Recovery feature is enabled for the SaMOG Gateway using the CLI, the Session Manager maintains a backup of the session critical information with the AAA Manager that has the same instance number. A paired AAA Manager with the same instance number as the Session Manager is started on a different PSC/DPC card. When a failure is detected, the Call Recovery Record (CRR) that contains the backed up information is fetched from the AAA Manager, and the sessions are re-created on the recovered Session Manager.

As the SaMOG session recovery feature makes use of the existing StarOS IPSG framework, new fields are added to the IPSG session recovery record to recover attributes specific to the SaMOG session (For example: GRE end point address, SaMOG EGTPC information, etc).

The Session Recovery feature requires a minimum of four PSC/DPC cards (3 active and 1 standby). One PSC/DPC card will be used the DEMUX managers and VPN manager, two PSC/DPC cards will be used by the Session manager and AAA manager, and one PSC/DPC card will be used for standby.

*Important* For more information on session recovery, refer to the *Session Recovery* chapter in the *System Administration Guide*.

---

### Web Authorization

The Web Authorization feature enables the SaMOG Gateway to authenticate a subscriber's user equipment (UE) over a web portal, based on a user ID and password combination, a one-time password, or a voucher. On successful authentication, the AAA server stores the subscriber profile (APN, IMSI, QoS) from the HLR/HSS for the subscriber's device, and SaMOG establishes the network connection for the UE.

Web-based authorization can be performed in the following scenarios:

- The UE with the Universal Integrated Circuit Card (UICC) does not support EAP-AKA, EAP-SIM, or EAP-AKA' based authentication.

- The UE with the UICC uses a prepaid voucher.
Phases

The SaMOG web-based authorization and session establishment for a non-EAP or non-UICC device occurs in two phases:

- **Pre-Authentication Phase**, on page 74
- **Transparent Auto-logon (TAL) Phase**, on page 74

**Pre-Authentication Phase**

During the pre-authentication phase, SaMOG supports local IP address assignment and redirects the UE traffic to a web portal where the subscriber authenticates with a username and password combination, a one-time password, or a voucher. On successful authentication, the subscriber's IMSI profile is associated with the MAC address of the UE and forwarded to the AAA server. SaMOG can allocate IPv4, IPv6, or IPv4v6 addresses to the UE during this phase.

The IP address to the UE is allocated from a locally configured IP address pool in order to communicate with the web portal. The pool name can either be locally configured or received from the AAA server. SaMOG then processes the HTTP(S) and DNS packets from the UE by using ACL filters on the traffic. All other packets are dropped. The ACL filter is locally configured, and the filter ID can either be locally configured or received from the AAA server. The received HTTP(S) packets are then redirected to the web portal using a locally configured ECS rulebase that provides the URL for redirection. The rulebase name can either be locally configured or received from the AAA server. SaMOG shares the primary and secondary DNS server address with the UE. The DNS server addresses can either be locally configured or received from the AAA server.

For assigning an IPv6 address, SaMOG uses the following AVPs in the Diameter AA-Answer message in the MRME STa dictionary:

- **Framed-IPv6-Pool**: The AAA server uses this attribute to send the IPv6 pool-name configured in the Gi context. SaMOG uses this IPv6 pool-name to allocate the IPv6 prefix during the pre-authentication phase.
- **SN1-IPv6-Primary-DNS**: The AAA server uses this attribute to send the IPv6 address of the primary DNS server in the ADDRESS format.
- **SN1-IPv6-Secondary-DNS**: The AAA server uses this attribute to send the IPv6 address of the secondary DNS server in the ADDRESS format.

**Transparent Auto-logon (TAL) Phase**

During the TAL phase, the subscriber profile is cached on the AAA server for a designated duration to enable subscribers to reconnect without further portal authentication, thus enabling a seamless user experience. During this phase, SaMOG can allocate IPv4, IPv6, or IPv4v6 addresses to the UE.
**Multiple PDN Connections**

Using web authorization, a subscriber can connect multiple non-EAP devices and one EAP based device using the same IMSI-based subscription at the same time. All PDN connections of a subscriber have different bearer IDs. The connections are routed to the same P-GW or GGSN in order to apply the APN level QoS on all the PDN connections. The SaMOG Gateway performs P-GW, GGSN, or L-GW selection for the first PDN connection for the subscriber, and all subsequent connections are routed to the same P-GW, GGSN, or L-GW.

**DHCP Lease Time**

When pre-authentication completes and on successful authentication of the UE through the external web portal, SaMOG disconnects the UE from the WiFi. The UE then automatically reconnects to WiFi, and SaMOG obtains a new IP address for the UE using a GTP tunnel towards P-GW (TAL phase). The UE is then expected to send a DHCP Request/Discover message to learn the new IP address (as WiFi was disconnected and reconnected).

The DHCP lease time for the IP address assigned during the pre-authentication and TAL phases can be configured using the `dhclease` command under the APN Profile Configuration Mode.

**Session Recovery**

The SaMOG gateway can recover AAA manager and Session manager failures for both pre-authentication phase and TAL phase as long as the sessions are fully connected. SaMOG maintains the MAC to IMSI mapping and MAC to Session manager mapping with the IPSG manager to ensure that the PDN connections of the subscriber is connected to the same Session manager.

**Limitations, Restrictions, and Dependencies**

This section identifies limitations, restrictions, and dependencies for the SaMOG Web Authorization feature:

- After a successful portal-based authentication, the UE will be disconnected and a new connection attempt is required to setup the TAL phase session.

- The Web Authorization feature cannot be configured with the pseudonym and fast reauthorization NAIs. If configured, the session for the same IMSI number might get established in a different GGSN, P-GW, or L-GW.

- The MAC to IMSI mapping table cannot be retrieved during an IPSG manager recovery.

- When two devices with the same IMSI number try to connect simultaneously, the sessions are sent to two different session managers. The device connecting later is locally dropped and its Access-Request message is ignored. However, a subsequent re-transmission of the Access-Request message succeeds as the IMSI session manager entry is found and the message is sent to the session manager.

- Only one IP context must be configured and all portal traffic routed from that VPN context.

- All IP pools must be under the same context.

- The timeout value for the pre-authentication phase (when the DM/ASR is not received) is 5 minutes and cannot be configured.

- For a MAC-based authentication, the AAA server is selected based on the SSID as no IMSI information is available in the Access-Request message. To avoid a different operation policy being selected when
the IMSI is present, configure the SSID-based policy with a higher priority than the IMSI-based policy. Alternatively, configure both SSID and IMSI in the policy configuration.

**Optimized Web Authorization**

Optimized Web Authorization feature provides a seamless experience to the subscriber by continuing the SaMOG session with no session disconnection after the Pre-Authentication phase. The SaMOG Gateway uses the SaMOG Local Breakout – Enhanced feature where a P-GW (GTPv2) or GGSN (GTPv1) is collocated with SaMOG in the same chassis.

The address assigned to the subscriber’s UE is retained by maintaining the same IP address range pools within a single Gi context, and shared across the P-GW or GGSN service and SaMOG service. The SaMOG service uses the VPNMgr address transfer feature to transfer the IP address or IPv6 prefix to the P-GW or GGSN service.

This feature is supported on both EoGRE and PMIPv6 access types, with IPv4 and IPv6 transports to the WLC.

**SaMOG Features and Functionality - Inline Service Support**

This section describes the features and functions of inline services supported on the SaMOG Gateway.

---

**Important**

The following features require the purchase of an additional feature license to implement the functionality with the SaMOG service. For more information on the feature licenses, contact your Cisco account representative.

This section describes the following features:

- Network Address Translation (NAT), on page 76

**Network Address Translation (NAT)**

NAT translates non-routable private IP address(es) to routable public IP address(es) from a pool of public IP addresses that have been designated for NAT. This enables to conserve on the number of public IP addresses required to communicate with external networks, and ensures security as the IP address scheme for the internal network is masked from external hosts, and each outgoing and incoming packet goes through the translation process.

NAT works by inspecting both incoming and outgoing IP datagrams and, as needed, modifying the source IP address and port number in the IP header to reflect the configured NAT address mapping for outgoing datagrams. The reverse NAT translation is applied to incoming datagrams.

NAT can be used to perform address translation for simple IP and mobile IP. NAT can be selectively applied/denied to different flows (5-tuple connections) originating from subscribers based on the flows' L3/L4 characteristics—Source-IP, Source-Port, Destination-IP, Destination-Port, and Protocol.

NAT supports the following mappings:

- One-to-One
Many-to-One

For more information on NAT, refer to the *Network Address Translation Administration Guide*.

## Supported Standards

The SaMOG Gateway complies with the following standards:

- **3GPP References**, on page 77
- **IETF References**, on page 78

CHAPTER 2

Configuring the SaMOG Gateway

This chapter provides configuration instructions for the SaMOG (S2a Mobility Over GTP) Gateway. Information about the commands in this chapter can be found in the Command Line Interface Reference.

• Configuring the System to Perform as a SaMOG Gateway, page 79

Configuring the System to Perform as a SaMOG Gateway

This section provides a high-level series of steps and the associated configuration file examples for configuring the system to perform as a SaMOG Gateway in a test environment.

Required Information

The following sections describe the minimum amount of information required to configure and make the SaMOG Gateway operational in the network. To make the process more efficient, it is recommended that this information be available prior to configuring the system.

The following table lists the information that is required to configure the SaMOG Gateway context and service.

Table 19: Required Information for SaMOG Configuration

<table>
<thead>
<tr>
<th>Required Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SaMOG Context and MRME, CGW and SaMOG Service Configuration</td>
<td></td>
</tr>
<tr>
<td>SaMOG context name</td>
<td>The name of the SaMOG context, which can be from 1 to 79 alpha and/or numeric characters.</td>
</tr>
<tr>
<td>MRME service name</td>
<td>The name of the MRME service, which can be from 1 to 63 alpha and/or numeric characters.</td>
</tr>
<tr>
<td>IPv4 address</td>
<td>The IP address to which you want to bind the MRME service.</td>

**LTE Policy Configuration**

| Subscriber map name                     | The name of the subscriber map to associate with the LTE policy, which can be from which can be from 1 to 64 alpha and/or numeric characters. |
| Precedence priority                     | Specifies the precedence for the subscriber map. Must be an integer from 1 to 1024. |
### Required Information

<table>
<thead>
<tr>
<th>Description</th>
<th>Required Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the service criteria that must be matched for the subscriber map. Must be one of <strong>imsi</strong>, <strong>service-plmnid</strong> or <strong>all</strong>.</td>
<td>Service criteria type</td>
</tr>
<tr>
<td>The Mobile Country Code for use in this LTE policy.</td>
<td>MCC number</td>
</tr>
<tr>
<td>The Mobile Network code for use in this LTE policy.</td>
<td>MNC</td>
</tr>
<tr>
<td>The name of the operator policy use with the subscriber map, which can be from 1 to 64 alpha and/or numeric characters.</td>
<td>Operator policy name</td>
</tr>
<tr>
<td>The name of the Tracking Area Identifier database for use with the LTE policy, which can be from 1 to 64 alpha and/or numeric characters.</td>
<td>TAI mgmt db name</td>
</tr>
</tbody>
</table>

### GTPU and EGTP Service Configuration

<table>
<thead>
<tr>
<th>Description</th>
<th>Required Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>The name of the SaMOG context configured previously.</td>
<td>SaMOG context name</td>
</tr>
<tr>
<td>The name for this EGTP service, which can be from 1 to 63 alpha and/or numeric characters.</td>
<td>EGTP service name</td>
</tr>
<tr>
<td>The name of the EGTP service name that you want to associate with the GTPU service. This is the EGTP service name configured previously.</td>
<td>EGTP service name</td>
</tr>
<tr>
<td>The IPv4 address to which you want to use to bind the EGTP service to the GTPU service.</td>
<td>IPv4 address</td>
</tr>
<tr>
<td>The name of the GTPU service, which can be from 1 to 63 alpha and/or numeric characters.</td>
<td>GTPU service name</td>
</tr>
<tr>
<td>The IP address to which the GTPU service will bind.</td>
<td>IPv4 address</td>
</tr>
</tbody>
</table>

### AAA and Diameter Endpoint Configuration

<table>
<thead>
<tr>
<th>Description</th>
<th>Required Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>The name assigned to the AAA context, which can be from 1 to 79 alpha and/or numeric characters.</td>
<td>AAA context name</td>
</tr>
<tr>
<td>The name assigned to the AAA interface, which can be from 1 to 79 alpha and/or numeric characters.</td>
<td>AAA interface name</td>
</tr>
<tr>
<td>The primary IPv4 address and subnetmask for use by the AAA interface.</td>
<td>IPv4 address/subnetmask</td>
</tr>
<tr>
<td>The secondary IPv4 address and subnetmask for use by the AAA interface.</td>
<td>IPv4 address subnetmask</td>
</tr>
<tr>
<td>The name of the SaMOG context configured earlier.</td>
<td>SaMOG context name</td>
</tr>
</tbody>
</table>
### Required Information

<table>
<thead>
<tr>
<th>Required Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AAA DIAMETER STa1 group name</td>
<td>The primary AAA group name for use over the STa interface, which can be from 1 to 63 alpha and/or numeric characters.</td>
</tr>
<tr>
<td>DIAMETER endpoint name</td>
<td>The DIAMETER authentication endpoint name for use with this AAA group.</td>
</tr>
<tr>
<td>AAA DIAMETER STa2 group name</td>
<td>The secondary AAA group name for use over the STa interface, which can be from 1 to 63 alpha and/or numeric characters.</td>
</tr>
<tr>
<td>DIAMETER endpoint name</td>
<td>The DIAMETER authentication endpoint name for use with the secondary AAA group.</td>
</tr>
<tr>
<td>AAA Accounting Group Name</td>
<td>The name of the AAA Accounting group, which can be from 1 to 63 alpha and/or numeric characters.</td>
</tr>
<tr>
<td>Diameter authentication dictionary</td>
<td>The name of the Diameter dictionary used for authentication. This must be configured as the aaa-custom13 dictionary.</td>
</tr>
<tr>
<td>DIAMETER endpoint name</td>
<td>The name of the DIAMETER endpoint, which can be from 1 to 63 alpha and/or numeric characters. This is the name of the external 3GPP AAA server.</td>
</tr>
<tr>
<td>STa endpoint name</td>
<td>The name of the DIAMETER endpoint, which can be from 1 to 63 alpha and/or numeric characters. This is the name of the external 3GPP AAA server.</td>
</tr>
<tr>
<td>Origin real name</td>
<td>Name of the local Diameter realm, which can be a string from 1 to 127 alpha and/or numeric characters.</td>
</tr>
<tr>
<td>Origin host STa endpoint IPv4 address</td>
<td>The IPv4 address of the origin host STa endpoint.</td>
</tr>
<tr>
<td>IPv4 address</td>
<td>The IPv4 address used for the origin host STa endpoint.</td>
</tr>
<tr>
<td>Port</td>
<td>The port used for the origin host STa endpoint.</td>
</tr>
<tr>
<td>Peer name</td>
<td>The name of the Diameter peer, which can be from 1 to 63 alpha and/or numeric characters.</td>
</tr>
<tr>
<td>SaMOG realm name</td>
<td>The name of the peer Diameter realm, which can be from 1 to 63 alpha and/or numeric characters.</td>
</tr>
<tr>
<td>IPv4 address</td>
<td>The IPv4 address for the peer STa endpoint.</td>
</tr>
<tr>
<td>Port</td>
<td>The port used for the peer STa endpoint.</td>
</tr>
</tbody>
</table>

### DNS Configuration
<table>
<thead>
<tr>
<th>Required Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DNS context name</td>
<td>The name of the context in which DNS will be configured, which can be from 1 to 79 alpha and/or numeric characters.</td>
</tr>
<tr>
<td>DNS interface name</td>
<td>The name of the DNS interface, which can be from 1 to 79 alpha and/or numeric characters.</td>
</tr>
<tr>
<td>IPv4 address</td>
<td>The IPv4 address of the DNS server.</td>
</tr>
<tr>
<td>IP name server IP address</td>
<td>The IP name server IPv4 address.</td>
</tr>
<tr>
<td>DNS client</td>
<td>The name of the DNS client, which can be from 1 to 63 alpha and/or numeric characters.</td>
</tr>
<tr>
<td>IPv4 address</td>
<td>The IPv4 address to which you want to bind the DNS client service.</td>
</tr>
<tr>
<td><strong>Configuring and Binding the Interfaces</strong></td>
<td></td>
</tr>
<tr>
<td>SaMOG service Interface port/slot</td>
<td>The slot and port number to which you want to bind the SaMOG service.</td>
</tr>
<tr>
<td>GTP SaMOG interface name and context</td>
<td>The SaMOG interface and context name that will be bound to the SaMOG interface port/slot.</td>
</tr>
<tr>
<td>STa Accounting service interface port/slot</td>
<td>The slot and port number to which you want to bind the STa accounting interface.</td>
</tr>
<tr>
<td>STa Accounting service name and context</td>
<td>The name and context name of the STa accounting interface that you want to bind to the STa accounting port/slot.</td>
</tr>
<tr>
<td>DNS service Interface slot/port</td>
<td>The slot and port number that to which you want to bind the DNS service.</td>
</tr>
<tr>
<td>DNS service interface name and context</td>
<td>The name and context name that you want to bind to the DNS interface slot/port.</td>
</tr>
<tr>
<td>Radius PMIP-side service interface port/slot</td>
<td>The slot and port number to which you want to bind the PMIP-side RADIUS interface.</td>
</tr>
<tr>
<td>Radius PMIP-side service interface name and context</td>
<td>The name and context name of the PMIP side RADIUS interface you want to bind to the RADIUS interface port/slot.</td>
</tr>
<tr>
<td>Radius SaMOG-side service interface port/slot</td>
<td>The slot and port number to which you want to bind the SaMOG-side RADIUS interface.</td>
</tr>
<tr>
<td>GTPU interface port/slot</td>
<td>The slot and port number to which you want to bind the GTPU-interface.</td>
</tr>
</tbody>
</table>
SaMOG Gateway Configuration

The high-level steps below summarize the SaMOG gateway configuration tasks. Steps 1 through 8 are mandatory. Steps 8 through 11 are optional. Note that the SaMOG Gateway is a licensed Cisco product. Separate session and feature licenses may be required. Contact your Cisco account representative for detailed information on specific licensing requirements. For information on installing and verifying licenses, see "Managing License Keys" in the System Administration Guide.

---

**Step 1**
Set system configuration parameters such as activating PSC2s, ports, and enabling session recovery by following the configuration examples in the System Administration Guide.

**Step 2**
Create the SaMOG context by applying the example configuration in Creating the SaMOG Gateway Context, on page 85.

**Step 3**
Configure the MRME, CGW, and SaMOG services by applying the example configuration in Configuring the MRME, CGW and SaMOG Services, on page 85.

**Step 4**
Configure the LTE policy by applying the example configuration in Configuring the LTE Policy, on page 86.

**Step 5**
Create the GTPU and EGTP services by applying the example configuration in Configuring the GTPU and EGTP Services, on page 87.

**Step 6**
Create MAG services for a PMIPv6-based S2a interface by applying the example configuration in Configuring MAG Services, on page 87.

**Step 7**
Optional. Configure the IP over GRE (IPoGRE) encapsulation for processing DHCP Layer 3 IP packets by applying the example configuration in Configuring IPoGRE, on page 87.

**Step 8**
Optional. Configure the IP over VLAN (IPoVLAN) encapsulation for processing DHCP Layer 3 IP packets by applying the example configuration in Configuring IPoVLAN, on page 88.

**Step 9**
Create and configure the AAA group for Diameter and AAA authentication and accounting by applying the example configuration in Configuring AAA, on page 89.

**Step 10**
Configure the GTPP group consisting of the GTPP dictionary and CDR attributes, to be used for SGW and SGSN CDRs, and associate the GTPP group to the SaMOG Call Control Profile by applying the example configuration in Configuring GTPP Dictionary and CDR Attributes, on page 90.

**Step 11**
Configure the DNS service by applying the example configuration in Configuring DNS, on page 90.

**Step 12**
Optional. Enable Local breakout for an APN by applying the example configuration in Configuring Local Breakout, on page 90.

**Step 13**
Optional. Enable web-based authorization by applying the example configuration in Configuring Web-based Authorization, on page 93.

**Step 14**
Configure and bind interfaces to the relevant interfaces by applying the example configuration in Configuring and Binding the Interfaces, on page 95.

**Step 15**
Optional. Enable event logging by applying the example configuration in Enabling Logging, on page 96.

**Step 16**
Optional. Enable the sending of CGW and SaMOG SNMP traps by applying the example configuration in Enabling SNMP Traps, on page 96.

**Step 17**
Optional. Configure the system to gather and transfer bulk statistics by applying the example configuration in Configuring Bulk Statistics, on page 97.

**Step 18**
Save the completed configuration by following the instructions in Saving the Configuration, on page 97.

---
Creating the SaMOG Gateway Context

Create the context in which the SaMOG service will reside. The MRME, CGW, SaMOG and other related services will be configured in this context. Create the SaMOG context by applying the configuration example below.

```config
context samog_context_name
end
```

Configuring the MRME, CGW and SaMOG Services

The MRME and CGW services provide the SaMOG functionality. They must be configured in the SaMOG context and then associated with a SaMOG service name. Configure the MRME, CGW, and SaMOG services by applying the example configuration below.

```config
context context_name
twan-profile twan_profile_name
  radius client { ipv4/ipv6_address [mask] } [encrypted] key value [disconnect-message [dest-port destination_port_number] ] [[dictionary { custom70 | custom71 } ]]
  ue-address [ dhcp | twan ]
exit
mrme-service mrme_service_name
  bind address ip4_address
  bind { ipv4-address ipv4_address [ipv6-address ipv6_address] | ipv6-address [ipv4-address ipv4_address] }
  associate twan-profile twan_profile_name
dns-pgw context dns
  radius client ip4_address/subnetmask encrypted key disconnect-message dest-port port_no
exit
cgw-service cgw_service_name
  bind { ipv4-address ipv4_address [ipv6-address ipv6_address] | ipv6-address [ipv4-address ipv4_address] }
  associate egress-egtp_service egress-egtp_service_name
  revocation enable
  session-delete-delay timeout timeout_msecs
exit
samog-service samog_service_name
associate mrme-service mrme_service_name
  associate cgw-service cgw_service_name
associate subscriber-map subscriber_map_name
associate dhcp-service dhcp_service_name [level {system | user}]
  # Associate a DHCPv6 service
associate dhcpv6-service dhcpv6_service_name
exit
```
Configure the custom71 dictionary when Cisco WLC is used with PMIPv6 as the access-type. Configuring the custom71 dictionary enables attributes like the UE’s permanent identity (NAI), subscribed APN, network protocol (PMIPv6), and LMA address (CGW service's bind address) to be sent in the Cisco Vendor-specific attributes to WLC. The WLC uses this information to build the PMIPv6 PBU to the SaMOG gateway when the **aaa-override** option is enabled on the Cisco WLC. These attributes are not sent when the custom70 dictionary is configured.

**Important**

Configure the LTE policy by applying the example configuration below.

```
config
operator-policy policy-name
    apn network-identifier apn_net_id apn-profile apn_profile_name
    associate call-control-profile profile_id
exit
call-control-profile profile_name
    accounting mode gtp
    authenticate context context_name aaa-group aaa_group_name
    accounting context context_name aaa-group aaa_group_name
    accounting context context_name gtp-group gtp_group_name
    associate accounting-policy policy_name
exit
apn-profile profile_name
    accounting mode none
    local-offload
    address-resolution-mode local
    pgw-address IP_address
    qos default-bearer qci qci_id
    qos default-bearer arp arp_value preemption-capability may vulnerability not-preemptable
    qos apn-ambr max-ul mbr-up max-dl mbr-dwn
    pdp-type-ipv4v6-override ipv4
    virtual-mac { mac_address | violation drop }
    twan default-gateway ipv4/ipv6_address/mask
exit
lte-policy
    subscriber-map subscriber_map_name
        precedence precedence_priority match-criteria service_criteria_type mcc mcc_number mnc
    mnc_number operator-policy-name operator_policy_name
        precedence precedence_priority match-criteria service_criteria_type operator-policy-name
    operator_policy_name
    exit
    tai-mgmt-db tai_mgmt_db_name
exit
```
Configuring the GTPU and EGTP Services

Configure the GTPU and EGTP services by applying the example configuration below.

```
config
c    context samog_context_name
c        egtp-service egtp_service_name
        associate gtpu-service egtp_service_name
        gtpc bind ipv4-address ipv4_address
        exit
    gtpu-service gtpu_service_name
        bind ipv4-address ipv4_address
        exit
```

Configuring MAG Services

Create MAG services to configure a PMIPv6-based S2a interface by applying the example configuration below.

```
config
c    context context_name
    cgw-service cgw_service_name
        bind ipv4-address ipv4_address
        associate mag-service mag_service_name
        exit
    mag-service mag_service_name
        bind ipv4-address ipv4_address
        reg-lifetime max_reg_duration
        mobility-option-type-value standard
        end
```

Configuring IPoGRE

**Important**
The IP over GRE functionality requires an additional GRE Interface Tunneling license to create IP-GRE tunnels. For more information, contact your Cisco account representative.

Configure IP over GRE (IPoGRE) encapsulation for processing DHCP Layer 3 IP packets by applying the example configuration below.

```
config
c    context context_name
    ip vrf vrf_name
    exit
    interface interface_name
        ip address ip_address[/mask ]ipv4/v6_address
        exit
    interface interface_name1
        ip address ip_address[/mask ]ipv4/v6_address
        exit
    interface interface_tunnel_name tunnel
```
ip vrf forwarding gre_vrf_name
ip address ip_address[ipv4/v6_address
  tunnel-mode gre
  source interface interface_name
  destination address ipv4_address
  exit
exit
ip route ipv4_address ipv4_address tunnel interface_tunnel_name
port ethernet port_number
  no shutdown
  bind interface interface_name context_name
vlan vlan_number
  no shutdown
  ingress-mode
  bind interface interface_name context_name
end

Notes:

• Use the interface interface_name1 configuration only if a VRF-GRE tunnel is required.
• Use the ip vrf forwarding command to associate a GRE tunnel with the VRF.

Configuring IPoVLAN

Configure IP over VLAN (IPoVLAN) encapsulation for processing DHCP Layer 3 IP packets by applying the example configuration below.

config
context context_name
  ip vrf vrf_name
exit
interface interface_name
  ip address ip_address ip_address
  exit
interface interface_name1
  ip vrf forwarding vrf_name
  ip address ip_address ip_address
  exit
ip route ip_address[mask | next-hop ip_address interface_name1 vrf vrf_name
ip route ip_address[ipv4_address | mask | next-hop ip_address interface_name1 vrf vrf_name
port ethernet port_number
  no shutdown
  ingress-mode
  bind interface interface_name context_name
vlan vlan_number
  ingress-mode
  bind interface interface_name1 context_name
  no shutdown
end
c
context context_name
twan-profile twan_profile_name
  ue-address dhcp
  access-type client ipv4_address[ipv4_address[mask | ip
  access-type ip vrf vrf_name
Configuring AAA

Create the AAA group for DIAMETER authentication and then configure AAA accounting and authentication by applying the example configuration below.

```
config
context aaa_context_name
    interface aaa_interface_name
        ip address ipv4_address/subnetmask
        ip address ipv4_address/subnetmask secondary
    end
config
context samog_context_name
    aaa group aaa_diameter_STa1_group_name
diameter authentication dictionary aaa-custom13
diameter authentication endpoint endpoint_name
    exit
    aaa group aaa_group_diameter_STa2_name
diameter authentication dictionary aaa-custom13
diameter authentication endpoint endpoint_name
    exit
    aaa group aaa_acct_group_name
    radius attribute nas-ip-address address ipv4-address
    radius accounting server ipv4_address encrypted key key port port_no
    exit
    aaa group default
exit
gtpgp group default
exit
diameter endpoint STa_endpoint_name
    origin realm realm_name
    use-proxy
    origin host STa_endpoint_ipv4_address address ipv4_address port port_no
    no watchdog-timeout
    peer peer_name realm samog_realm_name address ipv4_address port port_no
exit
```
Configuring GTPP Dictionary and CDR Attributes

Configure the GTPP dictionary to be used for SGW and SGSN CDRs and the CDR attributes for the SaMOG gateway by applying the example configuration below.

```
config
    context samog_context_name
        gtpp group gtpp_group_name
            gtpp charging-agent IPv4/IPv6_Address
            gtpp server Server_IPv4/IPv6_Address max Maximum_GTPP_Messages
            gtpp trigger volume-limit
            gtpp trigger time-limit
            gtpp dictionary custom24
            gtpp attribute local-record-sequence-number
            gtpp attribute diagnostics
            gtpp attribute dynamic-flag
            gtpp attribute record-type sgsnpdprecord
            gtpp attribute record-type sgwrecord
            gtpp attribute qos max-length qos_max_length
        end
    config
        call-control-profile call_control_profile_name
            accounting context samog_context_name gtpp group gtpp_group_name
```

Configuring DNS

Configure DNS for the SaMOG gateway by applying the example configuration below.

```
config
    context dns_context_name
        interface dns_interface_name
            ip address ipv4_address/subnetmask
        exit
        subscriber default
        exit
        aaa group default
        exit
        gtpp group default
        ip domain-lookup
        ip name-servers ipv4-address
        dns-client dns_client_name
            bind address ipv4_address
        exit
```

Configuring Local Breakout

Optionally, configure the local breakout - enhanced, or local breakout - basic, or flow-based (with or without external NAT) local breakout model for an APN (assuming that a P-GW service is configured) by applying the appropriate example configuration below:
Important

The Local Breakout (LBO) feature is license dependent. Each LBO models require separate feature licenses. While the LBO - Basic and Flow-based LBO licenses can co-exist, they are mutually exclusive with the LBO - Enhanced license. Contact your local Cisco account representative for licensing requirements.

Local Breakout - Enhanced

```config
context context_name
cgw-service service_name
   associate pgw-service service_name
   exit
exit
apn-profile profile_name
   local-offload
   end
```

Local Breakout - Basic

```config
apn-profile apn_profile_name
   local-offload
   ip address pool name pool_name
   ip context-name vpn_context_name
dns primary ipv4_address
dns secondary ipv4_address
   ip access-group access_list_name [ in | out ]
active-charging rulebase rulebase_name
   exit
context context_name
   ip pool pool_name ip_address/mask public priority subscriber-gw-address router_ip_address
   ip access-list access_list_name
      redirect css service acs_service_name any
      exit
exit
active-charging service acs_service_name
   access-ruledef access_ruledef_name
      ip any-match = TRUE
      exit
fw-and-nat policy policy_name
   access-rule priority priority access-ruledef access_ruledef_name permit nat-realm nat_realm
      exit
rulebase rulebase_name
   fw-and-nat default-policy policy_name
   end
```

Flow-based Local Breakout

```config
apn-profile apn_profile_name
```
local-offload flow
  ip context-name vpn_context_name
  ip access-group access_list_name [ in | out ]
  active-charge rulebase rulebase_name
exit
context context_name
  ip access-list access_list_name
    redirect css service acs_service_name any
exit
exit

After applying the above initial configuration for Flow-based LBO, you can configure either a flow-based LBO whitelist or a blacklist.

Flow-based LBO with External NAT

SaMOG can also perform flow-based LBO with external NAT devices based on nex-hop. Configure flow-based LBO with an external NAT by applying the example configuration below:

```
config
  active-charge service acs_service_name
  rulebase rulebase_name
  action priority action_priority_1
  ruledef ruledef_name_1
    charging-action charging_action_name
  exit
  ruledef ruledef_name_2
    charging-action charging_action_name
    nexthop-forwarding-address ipv4_address
exit
exit
  # To configure IPv6 Access List
  context context_name
  ipv6 access-list ipv6_acl_name
  redirect css service css_service_name any
exit
exit
  # To configure the APN profile to use the IPv6 access list
  apn-profile apn_profile_name
  ip access-group ipv6_acl_name in
  ip access-group ipv6_acl_name out
  dns ipv6 { primary | secondary } ipv6_address
end
```

Flow-based LBO Whitelist

```
active-charge service acs_service_name
  access-rulled access_rulled_name
    ip dst-address = ipv4_destination_address[/mask ]
exit
fw-and-nat policy policy_name
```
Configuring Web-based Authorization

**Important**

The Web Authorization feature is license dependent. Contact your local Cisco account representative for licensing requirements.

Optionally, configure the SaMOG web-based authorization by applying the example configuration below.

### HTTP Redirection for Web-based Authorization

For HTTP redirection, apply the following rulebase, ruledef and charging action example:

```config
cfg
  active-charging-service acs_service_name
  # Rule to analyze HTTP packets
  ruledef http_ruledef_name
tcp either-port = 80
tcp either-port = 8080
rule-application-routing
exit
```

Notes:

- The `nat_realm_name` is the IP pool used by the NAT service for dynamic NATting. This IP pool may have one-to-one or many-to-one users mapping to conserve IP addresses.

---

**Flow-based LBO Blacklist**

```config
active-charging-service acs_service_name
access-ruledef access_ruledef_name
  ip dst-address = ipv4_destination_address[/mask ]
exit
fw-and-nat policy policy_name
access-rule priority priority
access-ruledef access_ruledef_name permit nat-realm nat_realm_name
access-rule no-ruledef-matches uplink action permit nat-realm nat_realm_name
access-rule no-ruledef-matches downlink action permit nat-realm nat_realm_name
exit
rulebase rulebase_name
fw-and-nat default-policy policy_name
end
```

Notes:

- The `nat_realm_name` is the IP pool used by the NAT service for dynamic NATting. This IP pool may have one-to-one or many-to-one users mapping to conserve IP addresses.
HTTPS Redirection for Web-based Authorization

For HTTPS redirection, as the HTTPS packets are encrypted using SSL/TLS between the client and server, the ACS service will not be able to perform HTTP request inspection. All HTTPS packets are redirected to an external web portal using Layer 3/Layer 4 redirection rules. The web portal performs an SSL handshake with the UE and redirects for authentication.

Apply the following rulebase, ruledef and charging action example for HTTPS redirection:

```
config
    active-charging service acs_service_name
    #Rule to allow DNS packets
    ruledef is_dns_ruledef_name
        udp either-port = 53
        tcp either-port = 53
        multi-line-or all-lines
        exit
    end
    #Rule to check if packet is a DNS packet
    ruledef is_DNS_ruledef_name
        udp either-port = port_number
        tcp either-port = port_number
        multi-line-or all-lines
        exit
    #Rule to check if packet is destined to HTTP portal (to avoid redirect loop)
    ruledef is_redirected_ruledef_name
        ip server-ip-address = http_web_portal_ipv4_address/mask
        exit
    #Rule for HTTP redirection to HTTP portal
    ruledef http_redirect_ruledef_name
        http any-match = TRUE
        ip any-match = TRUE
        multi-line-or all-lines
        exit
    #Action to allow packets without throttling at ECS
    charging-action allow_charging_action_name
        content-id content_id_2
        exit
    #Action to perform HTTP 302 redirection
    charging-action page_redirect_charging_action_name
        content-id content_id_3
        flow action redirect-url http_web_portal_url
        exit
    #Rulebase with all above rules and actions
    rulebase rulebase_name
        retransmissions-counted
        #Run protocol analyzers
        route priority route_priority ruledef http_ruledef_name analyzer http
        #Take action based on protocol analyzer result
        action priority action_priority ruledef is_DNS_ruledef_name charging-action
            allow_charging_action_name
        action priority action_priority ruledef is_redirected_ruledef_name charging-action
            allow_charging_action_name
        action priority action_priority ruledef http_redirect_ruledef_name charging-action
            page_redirect_charging_action_name
        end
```
# Rule to check if the packet is destined to the web portal, to avoid redirect loop
ruledef is_redirect_ruledef_name
    ip server-ip-address = web_portal_ip_address
exit
# Rule to check if the packet is an HTTPS packet
ruledef is_https_ruledef_name
    tcp either-port = 443
    multi-line-or-all-lines
exit
# Action to allow packets without throttling at ECS
charging-action allow_charging_action_name
    content-id content_id_1
exit
# Charging action to redirect all HTTPS packets (including initial TCP SYN/SYNACK/ACK) to web portal
charging-action l4_redirect_charging_action_name
    content-id content_id_2
    flow action readdress server web_portal_ip_address port port_number
exit
rulebase rulebase_name

l4_redirect_charging_action_name

Once the ruledef, charging action and rulebase are configured based on HTTP or HTTPS redirection, apply the rest of the configuration for web authorization as specified below:

configure
    operator-policy { default | name policy_name }
    apn webauth-apn-profile apn_profile_name
exit
apn-profile profile_name
    active-charging rulebase rulebase_name
    dns { primary | secondary } IPv4_address
    dhcp lease { short duration | time duration }
    ip address pool name pool_name
    ip context-name context_name
    ip access-group group_name [ in | out ]
    ipv6 address prefix-pool pool_name
exit
call-control-profile profile_name
    timeout imsi cache timer_value
    subscriber multi-device
    authenticate context context_name auth-method { [ eap ] [ non-eap ] }
end

Configuring and Binding the Interfaces

The interfaces created previously now must be bound to physical ports. Bind the system interfaces by applying the example configuration below.

config
    port ethernet slot no/port no
Enabling Logging

Optional. Enable event logging for the SaMOG Gateway by applying the example configuration below from the Command Line Interface Exec Mode.

```plaintext
[local]asr5000#  logging filter active facility mrme level error_reporting_level
[local]asr5500#  logging filter active facility cgw level error_reporting_level
[local]asr5500#  logging filter active facility ipsmgr level error_reporting_level
[local]asr5500#  logging filter active facility radius-coa level error_reporting_level
[local]asr5500#  logging filter active facility radius-auth level error_reporting_level
[local]asr5500#  logging filter active facility radius-acct level error_reporting_level
[local]asr5500#  logging filter active facility diabase level error_reporting_level
[local]asr5500#  logging filter active facility diameter-auth level error_reporting_level
[local]asr5500#  logging filter active facility aaamgr level error_reporting_level
[local]asr5500#  logging filter active facility aamgr level error_reporting_level
[local]asr5500#  logging filter active facility mobile-ipv6 level error_reporting_level
[local]asr5500#  logging filter active facility hamgr level error_reporting_level
[local]asr5500#  logging filter active facility ham diameter-ecs level error_reporting_level
[local]asr5500#  logging filter active facility egtpc level error_reporting_level
[local]asr5500#  logging filter active facility egtpmgr level error_reporting_level
```

Enabling SNMP Traps

Optional. Enable the sending of SaMOG gateway-related SNMP traps by applying the example configuration below.

```plaintext
config context samog_context_name
    snmp trap enable SaMOGServiceStart
    snmp trap enable SaMOGServiceStop
    snmp trap enable CGWServiceStart
    snmp trap enable CGWServiceStop
end
```
To disable the generation of an SNMP trap:

```conf
config
context samog_context_name
    snmp trap suppress trap_name
end
```

## Configuring Bulk Statistics

Use the following configuration example to enable SaMOG bulk statistics:

```conf
config
    bulkstats collection
    bulkstats mode
    sample-interval minutes
    transfer-interval minutes
    file no
    remote file format format /localdisk/bulkstats/bulkstat%date%%time%.txt
    receiver ipv4_or_ipv6_address primary mechanism sftp login login_name encrypted
password samog schema schema_name format schema_format
```

Notes:

- The `bulkstats collection` command in this example enables bulk statistics, and the system begins collecting pre-defined bulk statistical information.
- The `bulkstats mode` command enters Bulk Statistics Configuration Mode, where you define the statistics to collect.
- The `sample-interval` command specifies the time interval, in minutes, to collect the defined statistics. The `minutes` value can be in the range of 1 to 1440 minutes. The default value is 15 minutes.
- The `transfer-interval` command specifies the time interval, in minutes, to transfer the collected statistics to the receiver (the collection server). The `minutes` value can be in the range of 1 to 999999 minutes. The default value is 480 minutes.
- The `file` command specifies a file in which to collect the bulk statistics. A bulk statistics file is used to group bulk statistics schema, delivery options, and receiver configuration. The `number` can be in the range of 1 to 4.
- The `receiver` command in this example specifies a primary and secondary collection server, the transfer mechanism (in this example, ftp), and a login name and password.
- The `samog schema` command specifies that the SaMOG schema is used to gather statistics. The `schema_name` is an arbitrary name (in the range of 1 to 31 characters) to use as a label for the collected statistics defined by the `format` option. The `format` option defines within quotation marks the list of variables in the SaMOG schema to collect. The format string can be in the range of 1 to 3599.

For descriptions of the SaMOG schema variables, see "SaMOG Schema Statistics" in the Statistics and Counters Reference. For more information on configuring bulk statistics, see the System Administration Guide.

### Saving the Configuration

Save the SaMOG configuration file to flash memory, an external memory device, and/or a network location using the Exec mode command `save configuration`.
For additional information on how to verify and save configuration files, see the System Administration Guide and the Command Line Interface Reference.
Monitoring the SaMOG Gateway

This chapter provides information for monitoring the status and performance of the SaMOG (S2a Mobility Over GTP) Gateway using the `show` commands found in the CLI (Command Line Interface). These commands have many related keywords that allow them to provide useful information on all aspects of the system ranging from current software configuration through call activity and status.

The selection of `show` commands listed in this chapter is intended to provide the most useful and in-depth information for monitoring the system. For additional information on these and other `show` commands and keywords, refer to the Command Line Interface Reference.

The system also supports the sending of Simple Network Management Protocol (SNMP) traps that indicate status and alarm conditions. See the SNMP MIB Reference for a detailed listing of these traps.

- Monitoring SaMOG Gateway Status and Performance, page 99
- Clearing Statistics and Counters, page 102

Monitoring SaMOG Gateway Status and Performance

The following table contains the CLI commands used to monitor the status of the SaMOG Gateway features and functions. Output descriptions for most of the commands are located in the Statistics and Counters Reference.

| View session recovery status.                               | show session recovery status [ verbose ]                                                                         |

**View Session Disconnect Reasons**

| View session disconnect reasons.   | show session disconnect-reasons                                                                                   |
Clearing Statistics and Counters

It may be necessary to periodically clear statistics and counters in order to gather new information. The system provides the ability to clear statistics and counters based on their grouping.

Statistics and counters can be cleared using the CLI `clear` command. Refer to the Command Line Interface Reference for detailed information on using this command.
AAA Server-provided 3GPP-User-Location-Information Support

The following topics are discussed:

- Feature Description, page 103
- How AAA Server-provided 3GPP-User-Location-Information Works, page 104
- Configuring AAA Server-provided 3GPP-User-Location-Information, page 105
- Monitoring and Troubleshooting, page 106

Feature Description

Overview

This feature enables the SaMOG Gateway to receive the last known LTE location of the subscriber in the 3GPP-User-Location-Info AVP from the Diameter-based AAA server over the STa interface. This information is then used by SaMOG in the Create Session Request (CSR) messages over the S2a interface. The 3GPP-User-Location-Info AVP is received by SaMOG when the aaa-custom23 dictionary is available.

With the 3GPP-User-Location-Info AVP, SaMOG can then:

- Use the PLMN values (MCC/MNC) in the Serving-Network IE in the CSR messages.
- Populate the User-Location-Information (ULI) IE in the CSR messages.

---

Important

The aaa-custom23 dictionary is customer specific. For more information, contact your Cisco account representative.
Relationship to Other Features

Lawful Intercept

The PLMN values received in the 3GPP-User-Location-Information AVP will be used for lawful intercept purposes.

Offline Charging

The PLMN values received in the 3GPP-User-Location-Information AVP will be used for offline charging (CDR interface).

How AAA Server-provided 3GPP-User-Location-Information Works

Architecture

The AAA Server shares the last known LTE location of the subscriber through the Geographic Location Type field in the 3GPP-User-Location-Information AVP as specified in 3GPP TS 29.061:

- **TAI** – When the value of the Geographic Location Type field is 128, the Geographic Location field will contain the PLMN and Tracking Area Code (TAC) values.
- **ECGI** – When the value of the Geographic Location Type field is 129, the Geographic Location field will contain the PLMN and E-UTRAN Cell Identifier (ECI) values.
- **TAI-ECGI** – Value of the Geographic Location Type field is 130.

On receiving the 3GPP-User-Location-Info AVP from the AAA Server, SaMOG can do one or both of the following:

- When the `samog-s2a-gtpv2 send uli` command under the Call Control Profile Configuration mode is enabled, SaMOG populates the ULI IE in the Create Session Request message over the S2a interface.
- When the `samog-s2a-gtpv2 send serving-network value uli` command under the Call Control Profile Configuration Mode is enabled, SaMOG forwards the Serving-Network Information Element (IE) in the Create Session Request message over the S2a interface.

The structure of the ULI IE, and ECGI and TAI values are as specified in 3GPP TS 29.274.

The 3GPP-User-Location-Info AVP is non-standard over the STa interface, and ULI IE is non-standard over the S2a interface.

Standards Compliance

This feature complies with the following standards:
• 3GPP TS: 29.061 - "Interworking between the Public Land Mobile Network (PLMN) supporting packet based services and Packet Data Networks (PDN)"

• 3GPP TS: 29.274 - “3GPP Evolved Packet System (EPS); Evolved General Packet Radio Service (GPRS) Tunnelling Protocol for Control plane (GTPv2-C); Stage 3”

### Configuring AAA Server-provided 3GPP-User-Location-Information

#### Configuring SaMOG to Forward the ULI IE

Use the following configuration to configure SaMOG to forward the User-Location-Information (ULI) Information Element (IE) in the CSR message over the S2a interface.

```
config
call-control-profile profile_name
  samog-s2a-gtpv2 send uli
end
```

**Notes:**

- **Default:** Disabled
- If previously configured, use the `no samog-s2a-gtpv2 send uli` command to disable the configuration.

#### Configuring SaMOG to Forward the Serving-Network IE

Use the following configuration to configure SaMOG to forward the Serving-Network Information Element (IE) in the CSR message over the S2a interface.

```
config
  call-control-profile profile_name
    [ no ] samog-s2a-gtpv2 send serving-network value uli
end
```

**Notes:**

- **Default:** Disabled
- If previously configured, use the `no samog-s2a-gtpv2 send serving-network value uli` command to disable the configuration.

Civic Address in TWAN-Identifier IE

The following topics are discussed:

- Feature Description, page 109
- How Civic Address in TWAN-Identifier IE Works, page 110
- Configuring Civic Address in TWAN-Identifier IE, page 111
- Monitoring and Troubleshooting, page 112

Feature Description

Overview

In earlier releases, SaMOG could send either the AP-Group-Name or the SSID value in the TWAN-Identifier IE in the Create Session Request (CSR) message. From Release 21.1 and later, operators can provision the SaMOG Gateway to forward AP-MAC, SSID, and AP-Group-Name triplet information in the TWAN-Identifier IE received from the access network to P-GW, Lawful Intercept (LI) services.

This feature enables the AP-Group-Name information to be encoded in the Civic-Address-Information IE within the TWAN-Identifier IE as defined in RFC 4776. The TWAN-Identifier will contain:

- AP-MAC to be encoded in the BSSID attribute
- SSID to be encoded in the SSID attribute
- AP-Group-Name to be encoded in the civic-addr attribute

On receiving the Civic Address Information IE within the TWAN-Identifier IE, P-GW can forward the IE towards PCRF (Gx) and OCS (Gy).

This feature is currently supported on the S2a GTPv2 protocol for RADIUS Authentication-based session triggers.

Important

When this feature is enabled, the memory utilization of the AAAMgr will increase slightly.
How Civic Address in TWAN-Identifier IE Works

Architecture

SaMOG can receive the AP-Group-Name in the Called-Station-ID (RADIUS) AVP from the WLAN access network in following formats:

- `mac<MAC>:grp<AP-Group-Name>`
- `grp<AP-Group-Name>:<SSID>`
- `cgi<CGI>:grp<AP-Group-Name>`
- `cgi<CGI>:mac<MAC>:grp<AP-Group-Name>`
- `<MAC>:<SSID>:<AP-Group-Name>`

The AP group name is encoded in the Civic Address as per RFC 4776. For this feature, the Civic Address Type (CAType) format used is NAM (name).

Encoding

**S2a Interface**

The SaMOG Gateway encodes the TWAN-Identifier IE with the Civic-Address-Information field as specified in RFC 4776, and 3GPP TS: 29.274. By default, the two digit country code in the civic location option will be encoded as IN.

**LI Interface**

Encoding for LI interface will be performed by SaMOG and P-GW as specified in 3GPP TS:29.274, and 3GPP TS: 33.108.

For more information, refer Lawful Intercept with the SaMOG Service chapter in the Lawful Intercept Configuration guide.

**Gx Interface**

The P-GW receives the Civic address IE in TWAN-Identifier IE from SaMOG over the S2a interface, and encodes the Civic address value in TWAN-Identifier attribute in Gx interface. Encoding for this AVP is as specified in 3GPP TS 29.274. The standard Gx dictionary, `r8-gx-standard` is used.

**Gy Interface**

A Civic-Addr vendor specific AVP is used in the non-standard custom dictionary, `dcca-custom33` to encode the civic address value in the Gy interface by P-GW.

---

**Important**

The `dcca-custom33` dictionary is customer specific. For more information, contact your Cisco account representative.
Gz Interface

P-GW (P-GW records) encodes the AP-Group-Name within the civicAddress attribute in the TWANUserLocationInfo and forwards it over the Gz interface using a non-standard custom dictionary, custom53.

Important

The custom53 dictionary is customer specific. For more information, contact your Cisco account representative.

Limitations

- If the maximum length of the AP-Group-Name exceeds 32 bytes, SaMOG will not include the AP group name in the Civic Address Information field of the TWAN-Identifier IE.
- It is recommended to avoid configuring SaMOG to send the AP-Group-Name in both SSID and Civic Address Information fields. If configured, SaMOG will send the AP-Group-Name in the SSID field and the Civic Address Information field.

Standards Compliance

This feature complies with the following standards:

- RFC 4776: "Dynamic Host Configuration Protocol (DHCPv4 and DHCPv6) Option for Civic Addresses Configuration Information"
- 3GPP TS: 29.274: "3GPP Evolved Packet System (EPS); Evolved General Packet Radio Service (GPRS) Tunnelling Protocol for Control plane (GTPv2-C)"

Configuring Civic Address in TWAN-Identifier IE

Enabling Civic Address in TWAN-Identifier on the S2a Interface

Use the following configuration to enable SaMOG to forward the AP-Group-Name value in the Civic Address Information field of the TWAN-Identifier IE over the S2a interface.

```
config
call-control-profile profile_name
  samog-s2a-gtpv2 send twan-identifier civic-addr-fld ca-type name value ap-group-name
end
```

Notes:

- If previously configured, use the no samog-s2a-gtpv2 send twan-identifier civic-addr-fld command to remove and restore the configuration to its default value.
- Default: Disabled
Monitoring and Troubleshooting

Civic Address in TWAN-Identifier IE Show Command(s) and/or Outputs

**show call-control-profile full name**

The following fields are available to the output of the `show call-control-profile full name profile_name` command in support of this feature:

Samog-S2a-GTPv2:
- TWAN-IDENTIFIER IE:
  - SSID Value Type: SSID
  - Civic Address Information: CAtype-23 (NAME): AP GROUP NAME
- TWAN User Location Information:
  - SSID Value Type: SSID
  - Civic Address Information: CAtype-23 (NAME): AP GROUP NAME

Feature Description

SaMOG supports dedicated bearer over S2A interface over GTPv2 protocol.

This release provides basic support for network initiated dedicated bearer. The additional procedures and features mentioned in release 13 3GPP TS 23.402/29.274 are not provided. SaMOG will support dedicated bearer creation in Transparent Single Mode.

Flows

This section provides various call flows that illustrate PGW and HSS initiated Bearer Modification.
1 If dynamic PCC is deployed, the PCRF sends a PCC decision provision (QoS policy) message to the P-GW. If the Application function, (e.g. P-CSCF) requests it. If dynamic PCC is not deployed, the PDN GW may apply local QoS policy.

2 The P-GW uses this QoS policy to assign the S2a bearer QoS, i.e., it assigns the values to the bearer level QoS parameters QCI, ARP, GBR and MBR. If this dedicated bearer is created as part of the handover from 3GPP access with GTP-based S5/S8, then the PDN GW applies the Charging ID already in use for the corresponding dedicated bearer while the UE was in 3GPP access (i.e. bearer with the same QCI and ARP as in 3GPP access). Otherwise, the PDN GW generates a new Charging ID for the dedicated bearer. The PDN GW sends a Create Bearer Request message (IMSI, EPS bearer QoS, TFT, PDN GW Address for the user plane, PDN GW TEID of the user plane, Charging Id, LBI) to the trusted WLAN access network - SaMOG. The Linked EPS bearer Identity (LBI) is the EPS bearer Identity of the default bearer.

3 SaMOG specific resource allocation/modification procedure are executed in this step.

4 The SaMOG selects an EPS bearer Identity, un assigned to the UE. Then stores the EPS bearer Identity and links the dedicated bearer to the default bearer indicated by the Linked Bearer Identity (LBI). SaMOG uses the uplink packet filter (UL TFT) to determine the mapping of uplink traffic flows to the S2a bearer. SaMOG then acknowledges the S2a bearer activation to the PGW by sending a Create Bearer Response (EPS bearer Identity, SaMOG Address for the user plane, SaMOG TEID of the user plane) message.

5 If the dedicated bearer activation procedure was triggered by a PCC Decision Provision message from the PCRF, the PDN GW indicates to the PCRF whether the requested PCC decision (QoS policy) could be enforced or not, allowing the completion of the PCRF-Initiated IP CAN Session Modification procedure.
If dynamic PCC is deployed, the P-GW initiated Bearer Deactivation procedure may for example be triggered due to 'IP CAN session Modification procedure'. In this case, the resources associated with the PDN connection in the P-GW are released. If requested by the Application Function (e.g. P-CSCF).

The P-GW sends a Delete Bearer Request message (EPS Bearer Identity, Cause) to the SaMOG. This message can include an indication that all bearers belonging to that PDN connection shall be released.

SaMOG specific resources will be released for the bearer.

SaMOG deletes the bearer contexts related to the Delete Bearer Request, and acknowledges the bearer deactivation to the P-GW by sending a Delete Bearer Response (EPS Bearer Identity) message.

The P-GW deletes the bearer context related to the deactivated S2a bearer. If the dedicated bearer deactivation procedure was triggered by receiving a PCC decision message from the PCRF, the P-GW indicates to the PCRF whether the requested PCC decision was successfully enforced by completing the PCRF-initiated IP CAN Session Modification procedure or the PCEF initiated IP-CAN Session Modification procedure.
This procedure can be used to deactivate an S2a dedicated bearer or deactivate all S2a bearers belonging to a PDN address, for e.g., due to IP CAN session modification requests from the PCRF. If the default S2a bearer belonging to a PDN connection is deactivated, the P-GW deactivates all S2a bearers belonging to the PDN connection.

**Important**

**HSS Initiated Bearer Modification**

1. The HSS updates the User Profile. (RAR from Diameter to SaMOG)

2. If the QCI and/or ARP and/or subscribed APN-AMBR has been modified and there is a related active PDN connection with the modified QoS Profile, then SaMOG sends the Modify Bearer Command (EPS bearer Identity, EPS bearer QoS, APN AMBR) message to the P-GW. The EPS bearer Identity identifies the default bearer of the affected PDN connection. The EPS bearer QoS contains the EPS subscribed QoS profile to be updated.

3. If PCC infrastructure is deployed, the P-GW informs the PCRF about the updated EPS bearer QoS. The PCRF sends the new updated PCC decision to the P-GW.

4. The PCRF may modify the APN-AMBR and the QoS parameters (QCI and ARP) associated with the default bearer in the response to the P-GW.

5. The P-GW modifies the default bearer of each PDN connection corresponding to the APN for which subscribed QoS has been modified. If the subscribed ARP parameter has been changed, the P-GW shall also modify all dedicated S2a bearers having the previously subscribed ARP value unless superseded by
PCRF decision. The P-GW then sends the Update Bearer Request (EPS bearer Identity, EPS bearer QoS, TFT, APN AMBR) message to the SaMOG.

6  SaMOG will perform resource allocation/modification procedures.

7  SaMOG acknowledges the bearer modification to the P-GW by sending an Update Bearer Response (EPS bearer Identity) message. If the bearer modification fails the P-GW deletes the concerned S2a Bearer. P-GW indicates to the PCRF whether the requested PCC decision was enforced or not by sending a Provision Ack message

Limitations

Following are the know limitations of this feature:

• Support is available only for network-initiated dedicated bearer creation.
• LI and CDR support is not provided for dedicated bearer in SaMOG.
• Dedicated bearer support for LBO flow call model is not available.
• 3GPP-24.008 length field in TFT IE is only one Octet, as a result of this maximum length can be only 256, but in update bearer (message) more packet filters can be added to increase the size of TFT up to 960 (16 * 60 = 960). In this release, SaMOG only supports 504 size TFT per bearer.

Monitoring and Troubleshooting

Dedicated Bearer Support Show Command(s) and /or Outputs

show samog service statistic

Chapter 7

DHCP, RADIUS Accounting, and PMIPv6 based Session Triggers on GTPv2 over S2a Interface

The following topics are discussed:

- Feature Description, page 131
- Configuring Session Triggers on GTPv2 Over S2a Interface, page 132
- Monitoring and Troubleshooting, page 132

Feature Description

This feature enables support for GTPv2 protocol on the S2a interface for DHCP, RADIUS Accounting, and PMIPv6-based session triggers for non-UICC devices.

For session triggers using the GTPv2 protocol over the S2a interface, the IMSI field in the Create-Session-Request (CSR) message will contain the decimal equivalent of the MAC address of the UE. The UE's MN-NAI value (from the AAA Server) in the PAP container within the PCO IE in the CSR message is sent to the local P-GW, and to the PCRF server over the Gx interface. SaMOG can be configured to send the MN-NAI value in the PAP-PCO IE using the `samog-s2a-gtpv2 send pco pap value mn-nai` command under the Call Control Profile Configuration Mode. The local P-GW can be configured to send the MN-NAI value in the Subscription-ID AVP with MSISDN in CCR-I or CCR-U towards PCRF on the Gx interface using the `subscription-id service-type samog-epdg nai` command under the Policy Control Configuration Mode.

Standards Compliance

This feature complies with the following standards:

- **3GPP TS 23.402** - "3rd Generation Partnership Project; Technical Specification Group Services and System Aspects; Architecture enhancements for non-3GPP accesses"
- **3GPP TS 29.274** - "3rd Generation Partnership Project; Technical Specification Group Core Network and Terminals; 3GPP Evolved Packet System (EPS); Evolved General Packet Radio Service (GPRS) Tunnelling Protocol for Control plane (GTPv2-C); Stage 3"
Configuring Session Triggers on GTPv2 Over S2a Interface

Enabling MN-NAI in PCO-PAP

Use the following configuration to enable SaMOG to forward the UE’s MN-NAI value in the PAP container within the PCO IE in the CSR message to P-GW:

```
configure
  call-control-profile profile_name
    samog-s2a-gtpv2 send pco pap value mn-nai
end
```

Notes:

- If previously configured, use the `no samog-s2a-gtpv2 send pco pap value mn-nai` command to remove and restore the configuration to its default value.
- Default: Disabled

Monitoring and Troubleshooting

Show Command(s) and/or Outputs

DHCP Trigger-based Session Creation

This feature enables the SaMOG Gateway to create sessions on receiving DHCP Discover or DHCP Request messages for a subscriber over the EoGRE tunnel.

The following sections provide more detailed information:

- Feature Description, page 133
- How DHCP Trigger-based Session Creation Works, page 134
- Configuring DHCP Trigger-based Session Creation, page 137
- Monitoring and Troubleshooting DHCP Trigger-based Session Creation, page 139

Feature Description

Overview

In traditional internet deployment architectures, the service provider provide WiFi access to subscribers based on web-based authentication. These deployment architecture might use access points (AP) which are incapable of RADIUS-based authentication triggers. These access points are only capable of relaying DHCP messages between the subscriber’s user equipment (UE) and the DHCP server, to obtain the IP address for the UE, after which the AP forwards data packets between the UE and the default gateway.

With this feature, the SaMOG Gateway can initiate session creation when a DHCP message is received from the AP over the EoGRE tunnel. This feature integrates SaMOG as a gateway in deployment architectures where the AP/WLC cannot initiate RADIUS (Access-Request) messages.

DHCP Relay Agent Information Option

The SaMOG Gateway supports DHCP Relay Agent Information Option (option 82) to determine the AP’s location information. This enables the SaMOG Gateway to select policies for the subscriber based on the location information, and share the serving AP’s location information with the AAA server during authentication.
License Requirements

The DHCP trigger-based session creation feature does not require a separate license. However, a Local Breakout - Enhanced license is required to configure a local P-GW.

Contact your Cisco account representative for detailed information on specific licensing requirements.

How DHCP Trigger-based Session Creation Works

The following figure provides the deployment architecture for DHCP trigger-based session creation:

![Figure 17: DHCP Trigger-based Session Creation Architecture](image)

The following is the sequence of events for a DHCP trigger-based session creation deployment model:

1. The UE communicates with the AP/RG over the 802.11 link for WiFi association and data transmission. The AP receives the control (DHCP, ARP, etc.) and data packets from the UE and forwards them over the EoGRE tunnel to the SaMOG Gateway.

2. On receiving the DHCP Request or DHCP Discover message sent by the UE from the AP over the EoGRE tunnel, the SaMOG Gateway acts as the RADIUS client and sends a RADIUS Access-Request to the AAA server to obtain the subscriber information based on the UE MAC address (received in L2 DHCP packet).

3. On obtaining the subscriber information (APN name, NAI (in MAC@realm format), etc.) from the AAA server, the SaMOG Gateway uses the Local Breakout (LBO) - Enhanced feature and initiates a PMIPv6 based S2a session with the local P-GW.

4. The local P-GW obtains the HTTP redirection rules from the PCRF over the Gx interface. For more information on the Local Breakout feature, refer Local Breakout-Enhanced section of this guide.

5. The local P-GW assigns an IPv4 address and forwards it to the SaMOG Gateway. The SaMOG Gateway in turn forwards the IPv4 address in the DHCP Offer/Reply message to the AP over the EoGRE tunnel. The AP forwards this message to the UE.
Any UE initiated traffic is then forwarded to a web authentication portal through the AP, SaMOG Gateway, and the local P-GW (LBO).

The UE is presented with a web portal for subscriber authentication. The web portal authenticates the subscriber credentials with the AAA server, and informs the PCRF.

The PCRF responds to the web portal with an RAR message on the Gx interface to remove the HTTP redirection rules.

All UE traffic is henceforth directed to the Internet.

DHCP Relay Agent Information Option (option 82)

The SaMOG Gateway receives the location information in the AP-MAC or AP-MAC:SSID format in either the Circuit-ID (1) or Remote-ID (2) sub-option in the DHCP Relay Agent Information Option (option 82). Currently, the maximum supported length for DHCP option 82 is 64 bytes, and the maximum SSID value supported is 32 bytes. Formats other than AP-MAC or AP-MAC:SSID is considered as an opaque value. The SaMOG Gateway validates the Circuit-ID or Remote-ID sub-options based on the CLI configured under the TWAN Profile Configuration mode. For more configuration information, refer Configuring DHCP Trigger-based Session Creation, on page 137.

When the sub-option contains the location information in AP-MAC:SSID format, the SaMOG Gateway uses the SSID for policy selection, and selects the AAA server based on the policy.

During subscriber authentication with the AAA server, the SaMOG Gateway includes the processed Circuit-ID or Remote-ID values (AP-MAC, AP-MAC:SSID, or opaque value) in Called-station-ID attribute in the Access-Request message towards the AAA server. While responding to the DHCP Discover/Request messages containing the DHCP Relay Agent Information Option (option 82), the SaMOG Gateway copies the DHCP option 82 value as it is in the DHCP-Offer/Ack messages.

Currently, the SaMOG Gateway supports AP-MAC and AP-MAC/SSID options in the following formats:

**AP-MAC** (separated by hyphen (-), colon (:), or period (.)):
- XX-XX-XX-XX-XX-XX
- XX:XX:XX:XX:XX:XX
- XXXX.XXXX.XXXX

Other AP-MAC formats are not parsed.

**AP-MAC and SSID** (separated by colon (:)) or semi-colon (;)):
- XX-XX-XX-XX-XX-XX:SSID
- XX-XX-XX-XX-XX-XX;SSID
- XX:XX:XX:XX:XX:XX:SSID
- XX:XX:XX:XX:XX:XX;SSID
- XXXX.XXXX.XXXX:SSID
- XXXX.XXXX.XXXX;SSID
Access Point without DHCP Relay Agent Information Option (option 82) Support

Where an access point does not support DHCP Relay Agent Information Option (option 82), the SaMOG Gateway maps the VLAN-ID with the NAS-Identifier AVP, and the EoGRE end point IP address with the NAS-Port-ID AVP. The NAS-Identifier and NAS-Port-ID AVPs are then shared with the RADIUS-based AAA server in the Access-Request message. The AAA server uses the information in these AVPs to identify the AP location and select the appropriate portal for the subscriber. When the DHCP discover/request message does not contain VLAN tagging, the AAA server uses the NAS-Port-ID AVP to identify the AP location.

The SaMOG Gateway can be configured to send the mapped RADIUS attributes to the AAA server using the `radius attribute authentication nas-identifier` and `radius attribute authentication nas-port-id` commands under the Global Context Configuration or AAA Server Group Configuration Modes. For more information, refer Configuring DHCP-based Session Location (AP Without DHCP Relay Agent Information Option (option 82) Support), on page 137.

Limitations

Architectural Limitations

- Network initiated session disconnection cannot be communicated to the UE or AP as RADIUS support is not available on the AP.
- DHCP Trigger-based session creation can be achieved using a local P-GW (LBO - Enhanced) only. Using an external P-GW is not supported in this release.
- The SaMOG Gateway and P-GW communicate over the PMIPv6 protocol only. Other network protocols are currently not supported.
- The location attributes can be sent in either the Circuit-ID or the Remote-ID sub-option of option 82. Location attributes cannot be sent in both the sub-options.
- To support Cisco specific AVPs (mn-apn, mn-nai, etc), the recommended dictionary towards the RADIUS AAA server is Custom71.

Configuration Limitations

- The bind address for the MRME and CGW must be the same in order for the IPSGMGR to receive the MRME bind address and obtain the DHCP discover messages over the EoGRE tunnel with the tunnel end points as WLC and CGW/MRME bind address.
- The EoGRE access type configuration is mandatory for this feature. PMIPv6 or L3IP access type configuration will result in configuration error in the TWAN profile.
- Only one TWAN profile must have a DHCP session trigger enabled. If multiple TWAN profile configurations have DHCP session trigger enabled, the first configured TWAN profile with the DHCP session trigger is used.
Standards Compliance

This feature complies with the following standards:

- RFC 2131 (Handling of DHCP messages)
- RFC 3046 (DHCP Relay Agent Information Option)

The interface between the AP/WLC and the SaMOG Gateway is currently not standardized, and does not require any compliance.

Configuring DHCP Trigger-based Session Creation

Configuring TWAN Profile for DHCP Triggered Session Creation

Use the following configuration to enable DHCP trigger-based session creation:

```plaintext
configure
twan-profile twan_profile_name
  access-type eogre
  session-trigger { dhcp location { circuit-id | remote-id } | radius }
end
```

Notes:

- Use the `session-trigger` command under the TWAN Profile Configuration Mode to enable DHCP trigger-based session creation.
- Use the sub-option `circuit-id` or `remote-id` for the SaMOG Gateway to choose the UE location from the DHCP-Relay-Agent-Info option (DHCP option 82).
- Use the `default session-trigger` command to reset the configuration to its default value.
- If previously configured, use the `no session-trigger dhcp location` command to remove the configuration.
- Default: RADIUS-based session creation
- If the TWAN profile is configured with a DHCP session trigger, the access type must be EoGRE.
- At least one TWAN profile should have the DHCP session trigger enabled. If multiple TWAN profile configurations have DHCP session trigger enabled, the SaMOG Gateway will use the first configured TWAN profile with DHCP session trigger.

Configuring DHCP-based Session Location (AP Without DHCP Relay Agent Information Option (option 82) Support)

Use the following configuration to enable the SaMOG Gateway to send the mapped RADIUS attributes to the AAA server.
For Default AAA Server Group:

```bash
configure
context context_name
    radius attribute authentication nas-identifier
    radius attribute authentication nas-port-id
end
```

For Specific AAA Server Group:

```bash
configure
context context_name
    aaa group group_name
        radius attribute authentication nas-identifier
        radius attribute authentication nas-port-id
end
```

Notes:

- If previously configured, use the `no radius attribute authentication nas-identifier` command and `no radius attribute authentication nas-port-id` commands to remove the configuration.

- By default, nas-identifier is enabled and nas-port-id is disabled.

- If these commands are configured under the Global Context Configuration Mode, the configuration will be applicable to the default AAA server group.

- If these commands are configured under the respective AAA server group, the configuration will be applicable to that AAA server group only.

- For expected functionality, both `nas-identifier` and `nas-port-id` keywords must be enabled.

- When `radius attribute authentication nas-identifier` is configured, also configuring `radius attribute nas-identifier` under the Global Context Configuration or AAA Server Group Configuration Mode will overwrite the VLAN ID received from the UE.

### Verifying Configuration for DHCP Trigger-based Session Creation

Use the `show subscribers samog-only` command to verify if a subscriber session is triggered on receiving DHCP messages.

```
show subscribers samog-only full
```

Session Trigger Type: DHCP

Use the `shown twan-profile` command to verify if DHCP trigger-based session creation is enabled for the TWAN profile.

```
show twan-profile name twan_profile_name
```

Session Trigger Type: DHCP
Monitoring and Troubleshooting DHCP Trigger-based Session Creation

DSCP Marking

This feature enables the SaMOG Gateway to perform DSCP marking on the uplink and downlink data packets on S2a and WLAN interfaces. The following sections provide more detailed information:

- Feature Description, page 143
- How DSCP Marking Works, page 144
- Configuring DSCP Marking, page 146
- Monitoring and Troubleshooting DSCP Marking, page 150

Feature Description

Overview

The SaMOG Gateway supports DSCP marking on the uplink and downlink data packets. Service providers can use this feature to prioritize traffic across intermediate routers and deliver QoS services to subscribers. In an ePDG and SaMOG cascading network architecture for a Voice over WiFi (VoWiFi) over WLAN access, the SaMOG Gateway performs DSCP marking and prioritization to VoWiFi traffic using the Flow-based Local Breakout (LBO).

DSCP marking is supported on the EoGRE, PMIPv6, and L3-IP network access types, and GTP-U (GGSN-GTPv1 and PGW-GTPv2) and GRE (PMIPv6-based S2a) S2a-U variants on the network side. SaMOG can perform DSCP marking on IPv4, IPv6, and dual PDNs.
Relationship to Other Features

Flow-based Local Breakout

In an ePDG cascading architecture with SaMOG for VoWiFi over trusted WLAN access, DSCP marking in the SaMOG Flow-based LBO model ensures that the desired DSCP marking is performed by ePDG in the downlink packets towards the TWAN in the access network.

Session Recovery

The QCI-QoS-Map table will be restored for the recreated session after session recovery. DSCP values are applied to the consecutive traffic based on the QCI-QoS mapping table configuration during the time of session recovery.

Web Authorization

DSCP marking will not be performed to the traffic redirected to the web portal during the pre-authentication phase. The traffic from the UE session in this phase is intended for session establishment and authorization, and has no QCI value. DSCP marking will be performed on the subscriber traffic during the TAL phase.

During reauthorization, if the QCI value is modified for the subscriber call, the new QCI’s DSCP value will be applied.

How DSCP Marking Works

Architecture

The SaMOG Gateway performs DSCP marking on the data traffic based on the QCI value derived for the subscriber’s call. The QCI value is obtained based on the following order of priority:

- QoS negotiated with internal P-GW
- AAA server supplied QoS value

The QCI-QOS mapping table for DSCP marking can be configured using the qci qci_value [ uplink | downlink ] encaps-header { copy-inner | copy-outer | dscp-marking dscp_hex_value } command under the QCI-QOS Mapping Table Configuration Mode. This configuration enables the SaMOG Gateway to mark the DSCP value in the outermost IP packet sent out of SaMOG (i.e., EoGRE/GRE/GTPU tunnel’s IP header).

A default DSCP value of 0x00 is marked on all uplink and downlink data traffic during the following scenarios:

- When no QCI-QoS mapping table is mapped (for the APN profile or CGW service).
- When no QCI-specific DSCP marking is configured under the QCI-QoS mapping table.
**QCI-QoS Mapping Table Selection**

The DSCP marking is performed based on the QCI-QoS mapping table configuration under the Context Configuration mode. The QCI-QoS mapping table is mapped to the subscriber call in the following order of priority:

- Mapping under the APN Profile Configuration Mode
- Mapping under the CGW Service Configuration Mode

The SaMOG Gateway will use the QCI-QoS mapping table configured for the APN profile for the subscriber session call. If no table is associated, SaMOG will look for the QCI-QoS mapping table configured for the CGW service.

For more configuration information, refer Configuring DSCP Marking, on page 146.

**DSCP Configuration Change**

When the DSCP configuration for a QCI changes, the new QCI/DSCP configuration will be applied to new calls only. The new DSCP marking will not be applied to subscriber calls that are currently active.

When session recovery occurs after the QCI-QoS mapping table is modified, the SaMOG gateway uses the latest CLI configuration.

**Modifying the QCI Value**

The QCI value for the SaMOG bearer can be modified in one of the following ways:

- From the AAA server using the RAR/CoA messages
- From the P-GW using the Update-Bearer-Request message

The new QCI value for the SaMOG bearer is then applied to all consecutive data traffic.

**QCI Value for Flow-based LBO Model**

The traffic sent to the flow-based LBO network uses the QCI value configured using the local-offload flow qci qci_value command under the APN Profile Configuration Mode.

If the configured QCI value is between 128 and 254, the DSCP configuration using the operator-defined-qci command under the QCI-QoS Mapping Table Configuration Mode mapped to the APN profile is used.

If the QCI value is between 1 and 9, the DSCP configuration using the qci command under the QCI-QOS Mapping Table Configuration Mode mapped to the APN profile is used.

For more configuration information, refer Configuring DSCP Marking, on page 146.

**QCI Value for LBO – Enhanced Model**

The QCI value for the LBO – Enhanced model is obtained based on the negotiated QCI-QoS value from the internal or external P-GW.
Limitations

This following limitations apply to the DSCP Marking feature:

- Currently, SaMOG supports DSCP marking on Flow-based LBO and LBO – Enhanced models. LBO Basic is not supported.
- DSCP marking cannot be performed on control signalling messages.

Configuring DSCP Marking

Associating the QCI-QoS Mapping Table

Use the following configuration to associate the QCI-QoS mapping table with the specified APN profile or CGW Service.

For APN Profile:
```
config
    apn-profile profile_name
    associate qci-qos-mapping mapping_table_name
end
```

For CGW Service:
```
config
    context context_name
    cgw-service service_name
    associate qci-qos-mapping mapping_table_name
end
```

Notes:
- By default, this configuration is disabled.
- To remove the configuration:
  - APN Profile Configuration mode: use the remove associate qci-qos-mapping command.
  - CGW Service Configuration mode: Use the no associate qci-qos-mapping command.

- mapping_table_name must be an alphanumeric string between 1 and 63 characters.

Configuring Downlink DSCP Marking

Use the following configuration to configure DSCP marking for downlink packets.
```
config
    qci-qos-mapping mapping_table_name
        qci qci_value downlink encaps-header { copy-inner | copy-outer | dscp-marking dscp_hex_value }
    end
```

Notes:
• Use the `no qci qci_value` command to remove the configuration.

  `qci_value` must be an integer from 1 through 9.

• **encaps-header**: Specifies that the DSCP marking must be set on the encapsulation header for IP-in-IP, GRE, or GTP encapsulation.

• **copy-inner**: Specifies to copy the DSCP value from the inner IP packet’s header in the S2a-u (GTP-U/PMIP-GRE) to the outer tunnel header towards UE (EoGRE/PMIP-GRE/Direct-IP).

• **copy-outer**: Specifies to copy the DSCP value from the outer tunnel header of the S2a-u (GTP-U/PMIP-GRE) to the outer tunnel header towards UE (EoGRE/PMIP-GRE/Direct-IP).

• **dscp-marking dscp_hex_value**: Specifies to enable marking of the specified `dscp_hex_value` in the uplink direction per QCI.

  * `dscp_hex_value` must be a hexadecimal number from 0x00 through 0x3F.

• When this configuration does not exist for the subscriber session’s QCI, SaMOG will not perform DSCP marking to the uplink packets, and 0x00 (best effort) value will be marked.

## Configuring Uplink DSCP Marking

Use the following configuration to configure DSCP marking for uplink packets

```
config
  qci-qos-mapping mapping_table_name
    qci qci_value uplink encaps-header { copy-inner | copy-outer | dscp-marking dscp_hex_value }
  }
end
```

**Notes:**

• Use the `no qci qci_value` command to remove the configuration.

  `qci_value` must be an integer from 1 through 9.

• **encaps-header**: Specifies that the DSCP marking must be set on the encapsulation header for IP-in-IP, GRE, or GTP encapsulation.

• **copy-inner**: Specifies to copy the DSCP value from the inner IP packet’s header from the UE (EoGRE/PMIP-GRE/Direct-IP) to the outer tunnel in the S2a-u (GTP-U/PMIP-GRE) towards P-GW.

• **copy-outer**: Specifies to copy the DSCP value from the outer tunnel header from the UE (EoGRE/PMIP-GRE/Direct-IP) to the outer tunnel in the S2a-u (GTP-U/PMIP-GRE) towards P-GW.

• **dscp-marking dscp_hex_value**: Specifies to enable marking of the specified `dscp_hex_value` in the uplink direction per QCI.

  * `dscp_hex_value` must be a hexadecimal number from 0x00 through 0x3F.

• When this configuration does not exist for the subscriber session’s QCI, SaMOG will not perform DSCP marking to the uplink packets, and 0x00 (best effort) value will be marked.
Configuring QCI Value for Flow-based Local Breakout

Use the following configuration to specify the QCI for flow-based Local Breakout (LBO).

```
config
  apn-profile profile_name
    local-offload flow qci qci_value
end
```

Notes:

- By default, this configuration is disabled.
- Use the `no local-offload flow qci` command to remove the configuration.
- `qci_value` must be an integer from 1 through 9, or 128 through 254.
  - For QCI range configured from 128 through 254, the DSCP configuration using the `operator-defined-qci` command (refer Configuring Downlink DSCP Marking for Flow-based Local Breakout, on page 148 and Configuring Uplink DSCP Marking for Flow-based Local Breakout, on page 149) under the QCI-QoS Mapping Table Configuration Mode mapped to this APN profile is used.
  - For QCI range configured from 1 through 9, the DSCP configuration using the `qci` command (refer Configuring Downlink DSCP Marking, on page 146 and Configuring Uplink DSCP Marking, on page 147) under the QCI-QoS Mapping Table Configuration Mode mapped to this APN profile is used.

Configuring Downlink DSCP Marking for Flow-based Local Breakout

Use the following configuration to configure DSCP marking for downlink packets using flow-based LBO.

```
config
  qci-qos-mapping mapping_table_name
    operator-defined-qci qci_value { gbr | non-gbr } downlink encaps-header { copy-inner | copy-outer | dscp-marking dscp_hex_value }
end
```

Notes:

- Use the `no operator-defined-qci qci_value` command to remove the configuration.
- `qci_value` must be an integer from 128 through 254.
- `gbr`: Specifies that the QCI type is Guaranteed Bit Rate (GBR).
- `non-gbr`: Specifies that the QCI type is non-Guaranteed Bit Rate (GBR).
- `encaps-header`: Specifies that the DSCP marking must be set on the encapsulation header for IP-in-IP, GRE, or GTP encapsulation.
- `copy-inner | copy-outer`: Specifies to copy the DSCP value from the IP packet's header from the LBO network towards the IP header in the access side network (EoGRE/PMIP-GRE/Direct-IP).
- `dscp-marking dscp_hex_value`: Specifies to enable marking of the specified `dscp_hex_value` in the downlink direction per LBO QCI.
• *dscp_hex_value* must be a hexadecimal number from 0x00 through 0x3F.

• When this configuration does not exist, SaMOG will not perform DSCP marking to the downlink packets for the flow-based LBO.

## Configuring Uplink DSCP Marking for Flow-based Local Breakout

Use the following configuration to configure DSCP marking for uplink packets using flow-based LBO.

```plaintext
config
  qci-qos-mapping mapping_table_name
    operator-defined-qci qci_value { gbr | non-gbr } uplink encaps-header { copy-inner | copy-outer |
      dscp-marking dscp_hex_value }
end
```

Notes:

• Use the no operator-defined-qci qci_value command to remove the configuration.

• *qci_value* must be an integer from 128 through 254.

• *gbr*: Specifies that the QCI type is Guaranteed Bit Rate (GBR).

• *non-gbr*: Specifies that the QCI type is non-Guaranteed Bit Rate (GBR).

• *encaps-header*: Specifies that the DSCP marking must be set on the encapsulation header for IP-in-IP, GRE, or GTP encapsulation.

• *copy-inner*: Specifies to copy the DSCP value from the inner IP packet’s header from the UE (EoGRE/PMIP-GRE/Direct-IP) to the LBO IP header towards the LBO network.

• *copy-outer*: Specifies to copy the DSCP value from the IP packet’s header from the outer tunnel header from the UE (EoGRE/PMIP-GRE/Direct-IP) to the LBO IP header towards the LBO network.

• *dscp-marking dscp_hex_value*: Specifies to enable marking of the specified *dscp_hex_value* in the uplink direction per LBO QCI.

  • *dscp_hex_value* must be a hexadecimal number from 0x00 through 0x3F.

• When this configuration does not exist, SaMOG will not perform DSCP marking to the uplink packets for the flow-based LBO.
Monitoring and Troubleshooting DSCP Marking

DSCP Marking Show Command(s) and/or Outputs

**show apn-profile full**

The information is available in the output of the `show apn-profile full { all | name profile_name }` command in support of this feature:

- **Local Offload**: Enabled
- **Type**: Flow
- **QCI**: 129

<table>
<thead>
<tr>

MAC Address in Decimal Format for P-GW

This feature enables the SaMOG Gateway to encode the User Equipment's MAC address in the IMEISV IE value in decimal format, in order to support inter-operability with P-GW from third party vendors. The following sections provide more detailed information:

- Feature Description, page 153
- How it Works, page 153
- Configuring MAC Address Encoding in Decimal Format, page 155

Feature Description

During call establishment, the SaMOG Gateway encodes the UE MAC address in the IMEISV IE value to decimal format and sends the Create Session Request message with the encoded value to P-GW. This ensures inter-operability between SaMOG and some third party vendor's P-GW that requires the UE MAC address in decimal format.

This feature can be configured by enabling the decimal keyword in the samog-gtpv1 and samog-s2a-gtpv2 commands under the Call Control Profile Configuration Mode. For more configuration information, refer Configuring MAC Address Encoding, on page 155.

How it Works

Architecture

The IMEI is a 15 digit decimal number that consists of a 14 digit value and 1 check digit, while the IMEISV field is a 16 digit decimal number that consists of a 14 digit value and 2 digit software version. The User Equipment's (UE) MAC address is a 6 byte or a 48 bit hexa-decimal value. As the maximum value of 6 bytes exceeds the 15 digit value in the IMEI field, 2 bits of the UE MAC address are removed and the remaining bits are left shifted. The SaMOG Gateway converts this value into decimal format and sends it to P-GW.

The following figure displays the bit representation and conversion of the MAC address:
The b1 bit represents the MAC address as unicast or multicast, and the b2 bit represents the MAC address as globally unique or locally administered.

Examples:

• UE MAC Address: 8AF9ABD5C613  
  After bits 1 and 2 are removed: 22F9ABD5C613  
  Decimal converted value: 38455725114899  
  TBCD encoded value (sent to P-GW): 83547552118499F0

• UE MAC Address: FFFFFFFFEFFF  
  After bits 1 and 2 are removed: 3FFFFFFFEFFF  
  Decimal converted value: 70368744177663  
  TBCD encoded value (sent to P-GW): 07637844716736F0

• UE MAC Address: 0034567890AB  
  After bits 1 and 2 are removed: 0034567890AB  
  Decimal converted value: 224789041323  
  TBCD encoded value (sent to P-GW): 00227498403132F0

Standards Compliance

The interface between the SaMOG Gateway and P-GW complies with the following 3GPP standards:

• 3GPP TS 23.002
• 3GPP TS 29.060
• 3GPP TS 29.274

Configuring MAC Address Encoding in Decimal Format

Configuring MAC Address Encoding

Use the `decimal` keyword in the `samog-gtpv1` and `samog-s2a-gtpv2` commands under the Call Control Profile Configuration mode to enable SaMOG Gateway to encode the IMEI attribute in decimal format to send to P-GW.

```plaintext
configure
call-control-profile profile_name
   samog-gtpv1 send imeisv value ue-mac decimal
   samog-s2a-gtpv2 send imeisv value ue-mac decimal
end
```

• By default, SaMOG sends the IMEISV value in hexa-decimal format.
• Use the `no samog-gtpv1 send imeisv` and `no samog-s2a-gtpv2 send imeisv` commands to disable decimal encoding.
• For further information on the other command keywords and the use of the command prefixes, refer to the Command Line Interface Reference for Release 20.0.

Verifying Configuration

Use the `show call-control-profile` command to verify the configuration of this feature.

```plaintext
show call-control-profile full name profile_name

Samog-GTPv1:
Sending IMEI(SV) IE : Enabled
IMEI(SV) IE Value Type : UE MAC in Decimal
Samog-S2a-GTPv2:
Sending IMEI(SV) IE : Enabled
IMEI(SV) IE Value Type : UE MAC in Decimal
```
CHAPTER 11

MN-NAI Support for Web Authorization Calls

This chapter describes MN-NAI support for web authorization calls in the following sections:

- Feature Summary and Revision History, page 157
- Feature Description, page 158
- How It Works, page 158
- Monitoring and Troubleshooting, page 166

Feature Description

MN-NAI based authentication is supported for Web Authorization calls.

Earlier, SaMOG only supported IMSI based pre-authentication to post-authentication transition. Now, MN-NAI based pre-authentication to post-authentication transition is also supported.

SaMOG now supports pre-Authentication to post-Authentication transition for DHCP and PMIPv6 triggered sessions. The output for the `show subscribers samog-only full` command is modified to show the pre and post-authentication phases for DHCP and PMIPv6 triggered calls. For DHCP and PMIPv6 triggered calls, the UE-MAC is displayed as Username in the output when the `show subscribers samog-only full` and `show subscribers samog-only all` commands are executed.

For DHCP and PMIPv6 triggered sessions, SaMOG directs a TAL setup towards a local P-GW when an incoming Accept-Accept request contains an IMSI or MN-NAI value as a user identity. If the Accept-Accept request does not contain any user identity, the SaMOG processes the request as a pre-authentication call.

How It Works

The MN-NAI Web Authorization Calls supports:

- MN-NAI in the CoA request.
- Pre-authentication phase for DHCP and PMIPv6 triggered sessions.

The above implementations are applicable for both LBO-Basic and LBO-Enhanced models.

LBO Enhanced (also called as LBO Heavy): Uses a local P-GW/GGSN service locally to offload traffic to the internet. The UE’s IP address is allocated by a local P-GW/GGSN service.

LBO Basic (also called as LBO Lite): Does not use a local P-GW/GGSN service. Here, the SaMOG itself offloads data to the internet. The UE’s IP address is allocated by an SaMOG service.

MN-NAI is also applicable for DHCP and PMIPv6 triggered sessions. The session establishment call flows for DHCP and PMIPv6 triggered sessions are discussed in the Call Flows section.

Note

From Release 21.4 onwards, the existing call flows for DHCP and PMIPv6 triggered sessions are not supported.

For more information on DHCP and PMIPv6 triggered sessions, refer to `DHCP Trigger-based Session Creation` and `PMIPv6-based Session Creation` chapters in the `SaMOG Administration Guide` respectively.

Call Flows

This section provides various call flows that illustrate the procedures used during DHCP and PMIPv6 triggered session establishment.
RADIUS Triggered - Web Authorization Call/Session Establishment

The figure below shows the detailed session establishment flow for a RADIUS triggered session. The table that follows the figure describes each step in the flow.

**Figure 18: RADIUS Triggered Session Establishment Call Flow**

</tr>
</tbody>
</table>
| 05   | SaMOG triggers the following procedures before sending an Access-Accept message to WLC:  
  - Allocate IP address from the local pool.  
  - Initiate the Web-Auth and Pre-Auth timer.  
  - Install L4/L7 Redirect Rules.  
  The local P-GW assigns an IPv4 address and forwards it to the SaMOG Gateway. |
| 06   | SaMOG sends Access-Accept to WLC. |
| 07   | WLC sends 802.1x association response to UE. MAC based authentication between UE and AP/WLC is now complete. |
| 08   | UE performs L3 Attach procedures by initiating DHCP/IPv6-ND messages to WLC for fetching the IP Address or the IPv6-prefix. |
| 09   | WLC initiates EoGRE/PMIPv6 procedures towards SaMOG for L3 Attach. |
| 10   | Accounting is enabled on WLC and SaMOG is configured as an accounting server on the WLC. |
| 11   | SaMOG forwards an accounting start request towards AAA. AAA then associates the UE MAC Address and UE IP Address. AAA sends a Accounting Start Response, which will be forwarded by SaMOG towards WLC. |
| 12   | Web-based authentication takes place between UE and Portal Server. |
| 13   | After the user is authenticated, portal server fetches MSISDN, IMSI or MN-NAI information of the user. Portal sends CoA request (user-name, IMSI or MSISDN, UE IP Address) towards AAA. AAA associates the UE MAC Address and UE IP Address with the IMSI, MSISDN or MN-NAI value. It sends MAP request towards HSS to fetch the UE subscription details |
| 14   | AAA associates the UE MAC address, UE Subscription with the IMSI, MSISDN or MN-NAI value of the subscriber. |
| 15   | Further to this, AAA will be able to provide UE subscription details to SaMOG for a MAC based look-up. AAA caches this information as per operator policy, so that UE need not be redirected to the portal server every time. |
| 16   | SaMOG processes the received RADIUS CoA based on locally configured web-authentication APN-profile, SaMOG looks for IMSI or MN-NAI value in CoA. If IMSI or MN-NAI is part of CoA packet, SaMOG removes the L4-Redirection rules, and also removes the DL NPU flow for the allocated IP addresses. |
**DHCP-triggered Web Authorization Call/Session Establishment**

The following figure illustrates a detailed session establishment flow for a DHCP triggered session.

SaMOG retains the allocated IP addresses, and stops the webauth_preauth_timer. |
| 14    | SaMOG initiates a GTPv2 CSReq for static IP address allocation with a.b.c.d and p:q:r:s::/64 for provided the vIMSI or MN-NAI value towards Local LBO based on received subscriber profile or locally configured APN-profile in case subscriber-profile is not received as part of RADIUS CoA. |
| 15    | SaMOG receives a GTPv2 CSResp from Local LBO with the allocated IP addresses of the end user. |
| 16    | SaMOG forwards the packet through the Local LBO; through the GTP-U Tunnel. |
Limitations

SaMOG does not support RADIUS Accounting Triggered sessions for Web Authentication. This is under development and intended for future use. In Release 21.4, only TAL (post-authentication phase) is supported for RADIUS Accounting triggered sessions.

Monitoring and Troubleshooting

This section provides information on the show commands available to support the MN-NAI Support for Web Authorization Calls.

Show Command(s) and/or Outputs

**show subscribers samog-only full**

The following new fields are added to the output of this command for DHCP and PMIPv6 session triggers during the pre-authentication phase:

- **DHCP Trigger**
  - Web authorization phase
  - IP pool name
  - IPv6 pool name
  - IP context name
  - Rulebase name
  - Access-list Name
  - Post-pre switch

- **PMIPv6 Trigger**
  - Web authorization phase
  - IP pool name
  - IPv6 pool name
  - IP context name
  - Rulebase name
  - Access-list Name
  - Post-pre switch
PMIPv6-based Session Creation

The following topics are discussed:

- Feature Description, page 167
- How PMIPv6-based Session Creation Works, page 168
- Configuring PMIPv6-based Session Creation, page 172
- Monitoring and Troubleshooting PMIPv6-based Session Creation, page 173

Feature Description

Overview

SaMOG supports Radius Access-Request, Radius Accounting-Request and DHCP messages as the triggers for session creation.

Based on the AP/WLC capabilities, SaMOG can support session establishment in the following ways:

- When the AP/WLC is capable of RADIUS-based authentication, SaMOG acts as a AAA server and initiates session creation when it receives a RADIUS Access-Request from the AP/WLC.
- When the AP/WLC is capable of only forwarding DHCP messages from the UE through an EoGRE tunnel, SaMOG initiates session creation on receiving DHCP Discover and DHCP Request messages from the AP/WLC.
- When the AP/WLC is not capable of establishing EoGRE connections, is configured with a DHCP server, and the UE IP is allocated by the AP, SaMOG acts as an accounting server and allocates an IP. SaMOG then performs NAT between the IP allocated by the AP, and the IP allocated by SaMOG to establish a session for the subscriber.

With this feature, the SaMOG Gateway can also initiate session creation when it receives a PMIPv6 (PBU) message from the access point (AP). This feature integrates SaMOG as a gateway in deployment architectures where the AP/WLC can only initiate PMIPv6 messages, and not RADIUS or DHCP messages.
License Requirements

The following licenses are required for this feature:

- SaMOG General license (3G and 4G)
- SaMOG Local Breakout - Enhanced license to configure a local P-GW

Relationship to Other Features

DHCP-triggered and RADIUS-based Session Creation

DHCP-triggered and RADIUS (Access and Accounting) triggered sessions can co-exist with the PMIPv6-based sessions if the AP initiating the sessions are on different TWAN profiles. These TWAN profiles must have a corresponding session trigger configured.

Session Recovery

The PMIPv6-based sessions can be recovered for both unplanned failures and planned migrations.

How PMIPv6-based Session Creation Works

Architecture

The following is the sequence of events for a PMIP-based session creation deployment model:

- The UE communicates with the AP/WLC over the 802.11 link for WiFi association and data transmission. The AP/WLC forms a PMIPv6 Proxy Binding Update (PBU) message with the UE MAC in the Username part of NAI or UE MAC as NAI (MAC@realm or MAC).
- The AP/WLC sends the PBU message to SaMOG over the GRE (PMIPv6) tunnel.
- On receiving the PBU message, SaMOG performs RADIUS-based authentication with the 3GPP AAA server.
- The SaMOG Gateway then uses the Local Breakout (LBO) - Enhanced feature to allocate an IPv4 address and forwards it in the PBU message to the AP.
- The AP forwards this message to the UE.
- Any UE initiated traffic is then forwarded to a web authentication portal through the AP, SaMOG Gateway, and the local P-GW (LBO).
- The UE is presented with a web portal for subscriber authentication. The web portal authenticates the subscriber credentials with the AAA server, and informs the PCRF.
- The PCRF responds to the web portal with an RAR message on the Gx interface to remove the HTTP redirection rules.
• All UE traffic is henceforth directed to the Internet.

Limitations

Architectural Limitations

• This feature supports RADIUS-based authentication between SaMOG and the 3GPP AAA Server. Diameter-based authentication is currently not supported.

• With this feature, the AP will not send the SSID or location information in the PBU message.

• Only IPv4 address allocation is supported for the UE. IPv6 and IPv4v6 PDN types are currently not supported.

• All interfaces towards all external nodes will be IPv4 address only. IPv6 transport on any interface with external nodes is currently not supported.
PMIPv6-based Session Establishment

The figure below shows the detailed session establishment flow for a PMIPv6-based session. The table that follows the figure describes each step in the flow.

Figure 21: PMIPv6-based Session Establishment Call Flow
### Table 34: PMIPv6-based Session Establishment

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>UE performs 802.11 association with the AP.</td>
</tr>
<tr>
<td>02</td>
<td>AP forms a PBU and sends it to SaMOG. The message has the following parameter: UE MAC address in the Username part of NAI, or NAI can be only UE MAC (MAC@realm or MAC).</td>
</tr>
<tr>
<td>03</td>
<td>SaMOG caches the PBU message and maps its contents to the Radius Access-Request message towards the AAA Server.</td>
</tr>
<tr>
<td>04</td>
<td>AAA server determines that the UE MAC is not authenticated and sends an Access-Accept message with an access point name (APN) and NAI in the MAC@realm format. These values are received using CS-AVPair attributes similar to DHCP/Radius Accounting triggered sessions.</td>
</tr>
<tr>
<td>05</td>
<td>SaMOG initiates a PMIPv6 Proxy Binding Update (PBU) message towards the Local Gateway (LGW) to setup the network side of the call. The MNID of the PBU is the NAI received from the AAA Server.</td>
</tr>
<tr>
<td>06</td>
<td>LGW sends CCR-I towards the PCRF, and includes the NAI/MNID received from SaMOG in the PBU.</td>
</tr>
<tr>
<td>07</td>
<td>PCRF determines that the subscriber is not authenticated and sends a CCA-I with Layer 7 (L7) redirection rulebase name.</td>
</tr>
<tr>
<td>08</td>
<td>LGW installs the L7 redirection rule and proceeds with session creation.</td>
</tr>
<tr>
<td>09</td>
<td>LGW allocates an IP address for the UE, and sends the same in Proxy Binding Answer (PBA) message towards SaMOG.</td>
</tr>
<tr>
<td>10</td>
<td>SaMOG completes the session creation by sending the PBA message to the AP.</td>
</tr>
<tr>
<td>11</td>
<td>UE attempts to access the HTTP page, and the HTTP packet reaches the LGW through SaMOG.</td>
</tr>
<tr>
<td>12</td>
<td>As the L7 redirection rule on the LGW is active, the LGW intercepts the HTTP packet.</td>
</tr>
<tr>
<td>13</td>
<td>LGW responds with a HTTP 302 response and provides the URL of the web authentication portal to the UE.</td>
</tr>
<tr>
<td>14</td>
<td>UE sends the HTTP GET request to the web portal through SaMOG and LGW.</td>
</tr>
<tr>
<td>15</td>
<td>The web portal presents the login page to the UE to enter the username and password.</td>
</tr>
<tr>
<td>16</td>
<td>Subscriber enters the username and password to perform web authentication.</td>
</tr>
</tbody>
</table>
The web portal invokes the PCRF API to share the username, password, and the source IP address of the packet.

PCRF validates the subscriber credentials and marks the UE MAC corresponding to the IP address as authenticated.

PCRF indicates authentication success to the web portal. The web portal then sends a HTTP 302 response to the UE with redirect to the originally accessed web page.

PCRF sends an RAR message on the Gx interface to indicate the removal of redirection rule.

LGW acknowledges with an RAA message.

LGW removes the L7 redirection rule for the UE session.

LGW sends a CCR-U message to PCRF to get quota information for the authenticated session.

PCRF sends the requested information in the CCA-U message.

UE attempts to connect to the originally accessed web page again. As the L7 rule is not present at the LGW this time, the packets are sent to the Internet.

<table>

</tbody>
</table>

Configuring PMIPv6-based Session Creation

Enabling PMIPv6-based Session Creation Trigger

Use the following configuration to enable PMIPv6-based session creation:

```
configure
c   context context_name
t      twan-profile profile_name
      session-trigger pmipv6
end
```

Notes:

- Use the `default session-trigger` command to reset the configuration to its default value.
- Default: RADIUS (authentication)-based session trigger
Monitoring and Troubleshooting PMIPv6-based Session Creation

CHAPTER 13

RADIUS Accounting-based Session Creation

This feature enables the SaMOG Gateway to create sessions on receiving a RADIUS Accounting-Start messages for subscribers.

The following sections provide more detailed information:

• Feature Description, page 177
• How RADIUS Accounting-based Session Creation Works, page 179
• Configuring RADIUS Accounting-based Session Creation, page 184
• Monitoring and Troubleshooting RADIUS Accounting-based Session Creation, page 185

Feature Description

Overview

The SaMOG Gateway can create sessions based on either of the following messages as a trigger:

RADIUS Access-Request messages: The Access Points (AP) or WLCs are configured with the SaMOG Gateway acting as the AAA Server. When the subscriber's user equipment (UE) performs an 802.11 association, these APs or WLCs trigger a RADIUS Access-Request message towards the SaMOG Gateway.

DHCP messages: The AP or WLC forwards DHCP messages (DHCP discover or DHCP Request) from the UE to the SaMOG Gateway over the EoGRE tunnel. The SaMOG Gateway uses this DHCP message as a trigger to initiate a session. This method of session creation is suited in networks where the AP or WLC is not capable of forwarding RADIUS messages.

RADIUS Accounting-based Session Creation

With the RADIUS Accounting-based Session Creation feature, sessions can be created when the APs forward a RADIUS Accounting-Start message with the allocated UE's IP address towards the accounting server. This method of session creation is suited in networks where the APs do not have EoGRE capabilities. These APs are configured with DHCP servers and the UE's IP address is allocated locally by the AP.
The SaMOG Gateway performs RADIUS-based authentication towards 3GPP AAA server by mapping parameters received in RADIUS Accounting request from the AP to a RADIUS Access-Request message towards the AAA server. The SaMOG Gateway perform APN-based local offload, using a Local P-GW for all accounting triggered sessions. The local P-GW allocates an IP address for the session. SaMOG performs a static NAT between the UE’s IP address (shared by the AP in the Framed-IP-Address attribute of the accounting message) and the IP address assigned by the local P-GW.

**Relationship to Other Features**

**DHCP Triggered and RADIUS (Authentication)-based Session Creation**

DHCP triggered and RADIUS (authentication) triggered sessions can co-exist with the RADIUS Accounting-based sessions if the AP initiating the sessions are on different TWAN profiles. These TWAN profiles must have a corresponding session trigger configured.

**Session Recovery**

The RADIUS Accounting-based sessions can be recovered for both unplanned failures and planned migrations.

**Web Authorization**

The SaMOG Gateway supports RADIUS Accounting-based session creation on the TAL phase of both Web Authorization and Optimized Web Authorization features. Session redirection is performed using the local P-GW.
How RADIUS Accounting-based Session Creation Works

Architecture

The following figure provides the deployment architecture for RADIUS Accounting-based session creation:

Figure 22: RADIUS Accounting-based Session Creation

The following are the sequence of events for a RADIUS Accounting-based session creation deployment model:

1. The AP allocates an IP address from a local DHCP server. SaMOG acts as an Accounting server for the AP.
2. Once the IP address is allocated, the AP sends an Accounting Start message to SaMOG with the allocated IP address in the Framed-IP-Address attribute.
3. SaMOG accepts the Radius Accounting Start message as a session trigger and performs authentication with a 3GPP AAA server.
4. The AAA server sends the UE details (received in the Accounting message) to the PCRF, and also forwards the NAI information to SaMOG based on the UE location.
5. On successful authentication, SaMOG establishes a connection with the local P-GW using PMIPv6 control protocol and obtains the IP address.
6. SaMOG uses the NAI information received from the AAA server in the PMIPv6 PBU message. This information is used by the local P-GW in the Gx messaging towards PCRF during session creation.
7. The local P-GW sends the redirection rules and other policies to the local P-GW based on the NAI information.
8. Once the session with the local P-GW is successfully established, SaMOG installs a static NAT between the UE’s IP address and the IP address provided by the local P-GW.
9. SaMOG can now respond to Accounting Start messages, and the UE starts sending data over L3IP access towards SaMOG.
10 This data then NATTed towards the local P-GW and routed to the internet or redirected by the local P-GW as per the installed policy.

11 The downlink data is sent to SaMOG by the local P-GW and a reverse NAT is performed before forwarding the packets to the AP.
Flows

Session Establishment

The figure below shows the detailed session establishment flow for a RADIUS accounting-based session. The table that follows the figure describes each step in the flow.

*Figure 23: RADIUS Accounting-based Session Establishment Call Flow*
Table 38: RADIUS Accounting-based Session Establishment

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>UE performs 802.11 association with the AP and attaches to the open SSID.</td>
</tr>
<tr>
<td>02</td>
<td>UE sends DHCP Discover message to AP to get an IP address.</td>
</tr>
<tr>
<td>03</td>
<td>AP gets an IP address (For example, IP1) from a local DHCP server.</td>
</tr>
<tr>
<td>04</td>
<td>AP completes the DHCP transaction with the UE, and sends the IP (IP1) address to the UE in the DHCP offer/DHCP Reply message.</td>
</tr>
</tbody>
</table>
| 05   | AP sends a Radius Accounting Start message to SaMOG with the following parameters:  
  - UE MAC address in the Username and Calling Station-Id attribute.  
  - Optional: VLAN ID in the NAS-Identifier attribute.  
  - IP address (allocated by local DHCP server: IP1) in the Framed-IP-Address attribute.  
  - AP-MAC and SSID in the Called-Station-Id attribute. |
| 06   | SaMOG caches the Accounting Start message and maps its contents to the Radius Access-Request message towards a AAA server. The Framed-IP-Address received in Accounting Start message is not sent towards the AAA server and the AP IP address (Radius endpoint address/source address of the Accounting Start message) is included in NAS-Port-Id attribute of the Access-Request.  
The AAA server determines that the UE MAC is not authenticated and sends Access-Accept message with an access point name (APN) and NAI in the MAC@realm format.  
These values are received using CS-AVPair attributes similar to DHCP triggered sessions. |
<p>| 07   | SaMOG initiates a PMIPv6 Proxy Binding Update (PBU) message towards the local P-GW to setup the network side of the call. The MNID of the PBU is the NAI received from the AAA server. |
| 08   | The local P-GW sends CCR-I towards the PCRF, and includes the NAI/MNID received from SaMOG in the PBU message. |
| 09   | PCRF determines that the subscriber is not authenticated and sends a CCA-I with the L7 redirection rulebase name. |
| 10   | The local P-GW installs the L7 redirection rule and proceeds with session creation. |
| 11   | The local P-GW allocates an IP address (For example, IP2) for the UE and sends the IP address in the Proxy Binding Answer (PBA) message towards SaMOG. |
| 12   | SaMOG maps the static NAT between the IP address (IP1) received in the Accounting Start message from AP, and the IP address (IP2) sent by the local P-GW to the NAT table. |
| 13   | SaMOG completes session creation by sending the Accounting Response message to the AP. |</p>
<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>14</td>
<td>The local P-GW sends an Accounting Start message towards the AAA server with the UE MAC and the Framed-IP-Address (with IP2).</td>
</tr>
<tr>
<td>15</td>
<td>The AAA server sends an Accounting Start response to the local P-GW.</td>
</tr>
<tr>
<td>16</td>
<td>The UE attempts to access the HTTP page, and the HTTP packet reaches the local P-GW through SaMOG. SaMOG performs static NAT to change the source IP address of the packet from IP1 to IP2 and forwards it to the local P-GW over the GRE tunnel.</td>
</tr>
<tr>
<td>17</td>
<td>As the L7 redirection rule on the local P-GW is active, HTTP packet is intercepted.</td>
</tr>
<tr>
<td>18</td>
<td>The local P-GW responds with a HTTP 302 response, and provides the URL of the authentication portal to the UE. SaMOG performs reverse NAT on this packet before forwarding it to the UE.</td>
</tr>
<tr>
<td>19</td>
<td>UE sends the HTTP GET request to the portal through SaMOG and the local P-GW.</td>
</tr>
<tr>
<td>20</td>
<td>The portal presents the login page to the UE to enter the username and password.</td>
</tr>
<tr>
<td>21</td>
<td>The subscriber enters the username and password to perform web authentication.</td>
</tr>
<tr>
<td>22</td>
<td>The portal shares the username, password and the source IP address (IP2) of the packet to the PCRF.</td>
</tr>
<tr>
<td>23</td>
<td>The PCRF validates the user credentials and marks the UE MAC corresponding to IP2 as authenticated.</td>
</tr>
<tr>
<td>24</td>
<td>The PCRF indicates authentication success to the portal. The portal then sends an HTTP 302 response to the UE with a redirect to the originally accessed web page.</td>
</tr>
<tr>
<td>25</td>
<td>The PCRF sends an RAR message on the Gx interface to indicate removal of redirection rule.</td>
</tr>
<tr>
<td>26</td>
<td>The local P-GW acknowledges the RAR message with an RAA message.</td>
</tr>
<tr>
<td>27</td>
<td>The local P-GW removes the L7 redirection rule for the UE session.</td>
</tr>
<tr>
<td>28</td>
<td>The local P-GW sends a CCR-U message to PCRF to get the quota information for the authenticated session.</td>
</tr>
<tr>
<td>29</td>
<td>The PCRF responds with a CCA-U message with the requested information.</td>
</tr>
<tr>
<td>30</td>
<td>UE now attempts to connect to the originally accessed web page again. As the L7 rule is not present at the local P-GW, the packets are sent to the Internet.</td>
</tr>
</tbody>
</table>
Standards Compliance

This feature complies with the following standard(s):

- RFC 2866 (RADIUS Accounting)

Configuring RADIUS Accounting-based Session Creation

Enabling RADIUS Accounting-based Session Creation Trigger

Use the following configuration to enable RADIUS Accounting-based session creation:

```text
config
c
context context_name
twan-profile profile_name
  session-trigger radius acct
end
```

Notes:

- Use the `default session-trigger` command to reset the configuration to its default value.
- Default: RADIUS (authentication)-based session trigger

Configuring Access Type and UE Address

Use the following configuration to configure the access type and UE address for RADIUS accounting-based session creation:

```text
config
c
context context_name
twan-profile profile_name
  ue-address twan
  access-type ip
end
```

Notes:

- Use the `ue-address twan` command to enable SaMOG to receive the TWAN UE address through the Accounting Start Framed-IP-Address message.
- Use the `access-type ip` command to specify that all RADIUS clients under the TWAN profile will use the Layer 3 IP (L3IP) access type.
Monitoring and Troubleshooting RADIUS Accounting-based Session Creation

RADIUS Authentication-based non-UICC Sessions on PMIPv6 over S2a Interface

The following topics are discussed:

- Feature Description, page 189
- How RADIUS Authentication-based Sessions on PMIPv6 over S2a Interface Work, page 191

Feature Description

Overview

In Release 21.0 and earlier, for non-UICC devices, SaMOG supported the PMIPv6 protocol over the S2a interface for DHCP and RADIUS Accounting-based sessions.

In Release 21.1 and later, SaMOG supports the PMIPv6 protocol over the S2a interface for RADIUS Authentication triggered sessions also. This ensures that SaMOG can seamlessly handover non-UICC UE sessions that move from access points (AP) of one access type to another.

SaMOG forwards the MN-NAI value received from the AAA Server towards the Cisco WLC in the Access-Accept message. The Cisco WLC can use the same message in the PBU message towards SaMOG. For non-Cisco WLCs, the WLC may initiate a PBU message with the UE's MAC address (in any MAC format separated by '-', '.', ':') in the NAI attribute. SaMOG can then perform session lookup.

Web Authorization - Pre-Authentication Phase

In release 21.0 and earlier, during RADIUS authentication-based session creation, when the AAA server does not send the IMSI information in the Access-Accept message to SaMOG, SaMOG treats the call type as pre-authentication phase.

In release 21.1 and later, SaMOG applies the following logic to determine the call type as pre-authentication or Transparent Auto Logon (TAL) phase:

- If the IMSI information is included in the Access-Accept message from the AAA server, the call type will be considered as TAL phase (MN-NAI information can be included or excluded).
• If the IMSI information is not present and the MN-NAI information is present in the Acess-Accept message from the AAA server:
  ◦ SaMOG considers the call type to be TAL phase if the S2a protocol is PMIPv6.
  ◦ SaMOG considers the call type to be TAL phase, if the session trigger is DHCP or Accounting.
  ◦ SaMOG considers the call type to be pre-authentication phase if PMIPv6 is not the S2a protocol.

• If both IMSI and MN-NAI information is not present in the Access-Accept message from the AAA server, the call type will be considered as pre-authentication phase.

License Requirements

The following licenses are required for this feature:

• SaMOG General license (3G and 4G)
• SaMOG Local Breakout - Enhanced license to configure a local P-GW
• SaMOG Web Authorization license

Contact your Cisco account representative for detailed information on specific licensing requirements.
How RADIUS Authentication-based Sessions on PMIPv6 over S2a Interface Work

Flows

**RADIUS PMIPv6-based Session Establishment with S2a-PMIPv6 LBO**

The figure below shows the detailed session establishment flow for a RADIUS PMIPv6-based WLC with S2a-PMIPv6 Local Breakout session. The table that follows the figure describes each step in the flow.

*Figure 24: RADIUS PMIPv6-based Session Establishment with S2a-PMIPv6 LBO Call Flow*
Table 42: *RADIUS PMIPv6-based Session Establishment with S2a-PMIPv6 LBO*

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>UE performs 802.11 association with the AP, and attaches to the open SSID.</td>
</tr>
</tbody>
</table>
| 02   | AP forms a Radius Access Request (RAR) message and sends it to SaMOG. The RAR message has the following parameter:  
  - UE MAC address in the Username and Calling-Station-Id attribute  
  - (Optional) VLAN ID in the NAS-Identifier attribute  
  - AP-MAC and SSID in the Called-Station-Id attribute |
| 03   | SaMOG caches the Access Request message from the AP/WLC and maps its contents to the Radius Access-Request message towards the AAA Server. The AP’s IP address (Radius endpoint address/source address of the Access-Request message) is included in NAS-Port-Id attribute of the Access-Request message. |
| 04   | AAA server determines that the UE MAC is not authenticated and sends an Access-Accept message with an access point name (APN) and NAI in the MAC@realm format. These values are received using the CS-AVPair attributes similar to DHCP-triggered sessions. |
| 05   | SaMOG initiates a PMIPv6 Proxy Binding Update (PBU) message towards the Local Gateway (LGW) to setup the network side of the call. The MNID of the PBU is the NAI received from the AAA Server. |
| 06   | LGW sends CCR-I towards the PCRF, and includes the NAI/MNID received from SaMOG in the PBU. |
| 07   | PCRF determines that the subscriber is not authenticated and sends a CCA-I with Layer 7 (L7) redirection rulebase name. |
| 08   | LGW installs the L7 redirection rule and proceeds with session creation. |
| 09   | LGW allocates an IP address for the UE, and sends the same in Proxy Binding Answer (PBA) message towards SaMOG. |
| 10   | SaMOG completes the session creation by sending an Access-Accept message to the WLC with the MN-NAI attribute in MAC@realm format, as received from the AAA Server. |
| 11   | Cisco WLC sends a Proxy Binding Update (PBU) message with the NAI in MAC@realm format as received from SaMOG. Non-Cisco WLC sends a Proxy Binding Update (PBU) message with the NAI in MAC format. |
| 12   | SaMOG validates the NAI value received from the WLC. Upon successful validation of the NAI value, SaMOG sends a Proxy Binding Answer (PBA) message towards WLC. |
| 13   | LGW sends an Accounting Start message with the UE MAC and the Framed-IP-Address in the message towards the AAA Server. |
AAA server sends Accounting Start response to the LGW.

15. UE attempts to access the HTTP page. The HTTP packet reaches the LGW through SaMOG. SaMOG forwards the packet to the LGW over the GRE tunnel.

16. As the L7 redirection rule on LGW is active, the HTTP packet is intercepted. LGW responds with an HTTP 302 response and provides the URL of the authentication portal to the UE. SaMOG forwards it to the UE.

17. UE sends an HTTP GET request to the portal through SaMOG and LGW.

18. The web portal presents the login page to the UE to enter the username and password.

19. Subscriber enters the username and password to perform web authentication.

20. The web portal invokes the PCRF API to share the username, password, and the source IP address of the packet. PCRF validates the user credentials and marks the UE MAC corresponding to the IP as authenticated.

21. The PCRF indicates an authentication success to the web portal. The web portal sends an HTTP 302 response to the UE with redirect to the originally accessed web page.

22. PCRF sends an RAR message on the Gx Interface to remove the redirection rule. LGW acknowledges the RAR with an RAA message. LGW removes the L7 redirection rule for the UE session. LGW sends a CCR-U message to the PCRF to get the quota information for the authenticated session. PCRF sends back a CCA-U message with the requested information.

23. UE attempts to reach the originally accessed web page again.

24. As the L7 rule is no longer present at the LGW, and the packets are sent to the Internet.

Limitations

Architectural Limitations

- This feature currently supports RADIUS-based AAA Server only.
- Only IPv4 address allocation is supported for the UE. IPv6 and IPv4v6 PDN types are currently not supported.
- All interfaces towards all external nodes will be IPv4 address only. IPv6 transport on any interface with external nodes is currently not supported.
Standards Compliance

This feature complies with the following standards:

- **3GPP TS 23.402** - "3rd Generation Partnership Project; Technical Specification Group Services and System Aspects; Architecture enhancements for non-3GPP accesses"

- **3GPP TS 29.274** - "3rd Generation Partnership Project; Technical Specification Group Core Network and Terminals; 3GPP Evolved Packet System (EPS); Evolved General Packet Radio Service (GPRS) Tunnelling Protocol for Control plane (GTPv2-C); Stage 3"
CHAPTER 15

RADIUS-based Web Authorization with Local Breakout - Basic

The following topics are discussed:

- Feature Description, page 195
- How RADIUS-based Web Authorization with LBO Basic Works, page 196
- Configuring RADIUS-based Web Authorization with LBO – Basic, page 202
- Monitoring and Troubleshooting, page 205

Feature Description

Overview

In earlier releases, the SaMOG Gateway supports the Web Authorization and Local Breakout features:

- The Web Authorization feature enables SaMOG to register the subscriber's non-SIM UEs by authenticating the subscriber through a web portal (using username and password). In the pre-authentication phase, SaMOG allocates the IP address to the UE. In the TAL/post-authentication phase, the P-GW allocates the IP address to the UE.

- The Local Breakout – Basic feature enables SaMOG to connect subscriber's UE directly to the Internet without employing a local or external P-GW. The UE's IP address is allocated using an IP pool configured locally (or provided by the AAA Server).

For more information on the Web Authorization and Local Breakout – Basic features, refer the SaMOG Administration Guide.

This feature integrates SaMOG as a gateway in deployment architectures where service providers (such as cable operators) can connect subscriber's non-SIM UEs to the Internet without an external P-GW, using policies and rules provided by the RADIUS-based AAA server. Gx and Gy interface's capabilities are not required on these networks. The subscribers of the non-SIM devices are authenticated using web authorization, and connected to the Internet Service Provider (ISP) using Local Breakout – Basic.
License Requirements

The following licenses are required for RADIUS-based web authorization with LBO – Basic:

- SaMOG Local Breakout – Basic license
- SaMOG Web Authorization license
- Enhanced Charging Bundle (ECS) license
- (Optional) Application Detection and Control (ADC) license – To enable ADC related features

Contact your Cisco account representative for detailed information on specific licensing requirements.

Relationship to Other Features

Application Detection and Control (ADC)

This feature can support ADC functionalities when the ADC license is installed.

How RADIUS-based Web Authorization with LBO Basic Works

Architecture

Web Authorization

Pre-Authentication Phase

During the pre-authentication phase of web authorization, the Access-Accept message from the RADIUS-based AAA server contains the following attributes to enable SaMOG to assign IP address the UE and redirect the subscriber to the web portal:

- User-Name (UE MAC) – This is a mandatory attribute.
- SN1-Rulebase (Rulebase name in Starent VSA) – SaMOG redirects traffic to the web portal for subscriber authentication based on the configured rulebase, and its related ruledef and charging action. The rulebase can also be configured under the APN profile for SaMOG to use when the AAA Server does not share the rulebase. When both the rulebases exist, SaMOG will use the rulebase provided by the AAA Server.
- SN1-VPN-Name (Context name in the Starent VSA) – SaMOG allocates IPv4 or IPv6 address to the UE based on the IP pool configured for the context. The context can also be configured locally under the APN profile for SaMOG to use when the AAA Server does not share the context name.
- Framed-Pool (Pool name) – To indicate IPv4 and IPv6 pools, the AAA Server can send more than one IP pool name to SaMOG. SaMOG selects the pool configured under the context when the AAA Server does not share the pool name.
**Filter-ID (ACL name)** – This attribute contains the allowed ACL for the UE.

**Post-Authentication Phase**

After the pre-authentication phase, SaMOG awaits the IMSI or MN-NAI attribute from the AAA Server in the CoA message. This CoA message acts as the post-authentication trigger. On receiving the CoA message, SaMOG removes the redirection rule and installs new rules from the CoA message. If the CoA message is not received within 5 minutes (timer expiry of 300 seconds), SaMOG disconnects the session.

**DSCP Marking**

SaMOG supports DSCP marking in the web authorization post-authentication or direct TAL phase for uplink and downlink traffic. The QCI value is obtained in one of the following ways:

- The qci-qos-mapping table can be configured with the QCI value using the `qos default-bearer qci qci_value` under the APN Profile Configuration Mode. The QCI value can also be configured for the CGW service. Operator-defined DSCP marking, copy inner and copy outer options are supported.
- DSCP marking configured in the charging-action associated with a rulebase (using the Enhanced Charging Service). DSCP marking can be performed during pre-authentication and post-authentication phases.
- Default QCI value of 9.

When the qci-qos-mapping definition and configuration for DSCP marking under the charging-action exist, SaMOG will prefer the configuration for DSCP marking under the charging-action.

The following decision table provides various combinations of QCI configurations in the network, and the QCI value selection by SaMOG:

<table>
<thead>
<tr>
<th>QCI received from AAA Server</th>
<th>QCI configured under APN profile</th>
<th>Charging action enabled with DSCP configuration</th>
<th>DSCP Marking (QCI value for the qci-qos-mapping table)</th>
</tr>

<td>Value configured under Charging Action</td>
</tr>
</tbody>
</table>
SaMOG as an Accounting Client

SaMOG can perform the functionalities of an accounting client when access points do not have this capability. Use the `accounting mode radius-diameter` command under the Call Control Profile Configuration Mode to enable SaMOG to act as an accounting client. When enabled, SaMOG supports WLAN attributes like calling-station-id and called-station-id in the RADIUS accounting messages.
Flows

The figure below shows the detailed RADIUS-based web authorization flow with LBO – basic. The table that follows the figure describes each step in the flow.

Figure 25: RADIUS-based Web Authorization with LBO – Basic Call Flow
### Table 43: RADIUS-based Web Authorization with LBO – Basic

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>UE sends 802.1x association request to AP/WLC with the SSID/Open-SSID information that it wishes to associate with.</td>
</tr>
<tr>
<td>02</td>
<td>On the WLC, the SSID is configured with MAC-based authentication, and SaMOG as the RADIUS Server. The WLC sends an Access-Request (user-name=UE-MAC, called-station-id=AP-MAC:SSID, Calling-Station-Id=UE-MAC) message to SaMOG without the EAP payload.</td>
</tr>
<tr>
<td>03</td>
<td>On SaMOG, an SSID-based policy is applied. If applicable, the operator policy allows Non-EAP based authentication. SaMOG fetches the AAA authentication server information from the policy. SaMOG initiates the authentication process by sending the Access-Request message received from the AP/WLC to the AAA server.</td>
</tr>
<tr>
<td>04</td>
<td>On the AAA Server, a MAC-based session lookup takes place as the user session is not found. Since the AAA Server is configured to allow user sessions, it sends an Access-Accept message to SaMOG. The subscription details will not be available on the AAA Server at this point. So the AAA Server sends only the user-name AVP in Access-Accept message. Optionally, the AAA server can provide the Filter-Id AVP and SN1-Rulebase AVPs for redirection along with SN1-IP-Pool-Name, SN1-VPN-Name, SN1-Primary/Secondary-DNS-Server, Framed-IPv6-Pool, SN1-IPv6-Primary/Secondary/DNS parameters.</td>
</tr>
</tbody>
</table>
| 05   | Since the AAA Server does not provide the APN, SaMOG fetches the default web authorization APN profile associated to the operator policy. This APN profile is configured for IP address allocation and traffic redirection (if rulebase is not provided by the AAA Server). SaMOG performs the following procedures before sending the Access-Accept message to WLC:  
  - Reserves IP Address (a.b.c.d and p:q:r:s::/64) from the local IP/IPv6 pool for UE.  
  - Installs L4/L7 redirection rules to redirect the user traffic to the web portal and installs downlink NPU flow for the allocated ip-address and ipv6-prefix.  
  - Initiates webauth_preauth_timer with a timeout value of 5 minutes. Post-authorization phase will be triggered within this timer. |
<p>| 06   | SaMOG forwards the RADIUS Access-Accept message to the AP/WLC. |
| 07   | The WLC/AP sends an 802.1x association response to the UE. MAC-based authentication between the UE and AP/WLC is complete. |
| 08   | UE initiates an L3 attach procedure by sending a DHCP-Discover. SaMOG receives the same through the EoGRE tunnel. |
| 09   | SaMOG sends the allocated IPv4 address, default gateway address, and the lease duration through the DHCP-Offer message to the UE. |</p>
<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>SaMOG sends DHCP-Request with a request IP as received in DHCP-Offer. SaMOG responds with a DHCP-Reply confirming the allotment of IP address.</td>
</tr>
<tr>
<td>11</td>
<td>UE sends the ARP-Request message to resolve the MAC address of the default gateway.</td>
</tr>
<tr>
<td>12</td>
<td>SaMOG sends ARP-Reply message to the UE with the virtual MAC address that is configured in the APN profile.</td>
</tr>
<tr>
<td>13</td>
<td>For IPv6/Dual stack, the UE sends a Router Solicitation to obtain the IPv6 address/prefix.</td>
</tr>
<tr>
<td>14</td>
<td>SaMOG responds to the UE with a Router Advertisement containing the IPv6 prefix.</td>
</tr>
<tr>
<td>15</td>
<td>UE sends a Neighbor Solicitation to determine the link-layer address of SaMOG.</td>
</tr>
<tr>
<td>16</td>
<td>SaMOG sends a Neighbor Advertisement to the UE with its link-layer address. The UE may also send a DHCPv6-Info-Request to obtain the DNS server addresses at this stage. If received, SaMOG sends a DHCPv6-Info-Reply with the DNS server addresses configured under the APN profile.</td>
</tr>
<tr>
<td>17</td>
<td>UE initiates data packets.</td>
</tr>
<tr>
<td>18</td>
<td>SaMOG receives the data packets from the UE through the EoGRE tunnel.</td>
</tr>
<tr>
<td>19</td>
<td>SaMOG redirects the traffic to a web portal as per the redirection rules installed (Step 5). If L4 rules are applied, SaMOG changes the destination address to the IP address of the portal, and forwards the packets. If L7 rules are applied, SaMOG redirects the packets to the IP address of the portal without modifying the destination address.</td>
</tr>
<tr>
<td>20</td>
<td>UE provides the subscriber’s credentials for authorization.</td>
</tr>
<tr>
<td>21</td>
<td>Web-based authorization takes place between the UE and the portal server.</td>
</tr>
<tr>
<td>22</td>
<td>Portal server indicates the successful authentication status with the AAA server.</td>
</tr>
<tr>
<td>23</td>
<td>Post successful authentication, the AAA server triggers post-authorization phase by sending a CoA with the IMSI/MN-NAI and new rulebase in the SN1-Rulebase AVP. If CoA doesn’t contain IMSI/MN-NAI identifier, SaMOG will not consider the CoA as a post-authorization trigger.</td>
</tr>
<tr>
<td>24</td>
<td>SaMOG sends CoA-Acknowledgement to the AAA Server.</td>
</tr>
<tr>
<td>25</td>
<td>SaMOG removes the redirection rules and installs the new rulebase received in the CoA message. SaMOG will offload the traffic locally with certain ECS capabilities.</td>
</tr>
<tr>
<td>26</td>
<td>SaMOG sends an Accounting-Request (Acct-Status-Type: Start) to the accounting server, if SaMOG has been configured to act as the Accounting client.</td>
</tr>
<tr>
<td>Step</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td>27</td>
<td>The Accounting Server sends an Accounting-Response to SaMOG.</td>
</tr>
<tr>
<td>28</td>
<td>UE initiates data packets.</td>
</tr>
<tr>
<td>29</td>
<td>SaMOG receives the data packets through the EoGRE tunnel.</td>
</tr>
<tr>
<td>30</td>
<td>SaMOG locally offloads the traffic to ISP without any redirection. SaMOG enforces any ECS capabilities like DSCP marking, rate limiting, MSS overwriting, and so on.</td>
</tr>
<tr>
<td>31</td>
<td>When the accounting interim conditions (volume/interval) configured under the AAA group are met, SaMOG sends an Accounting-Request (Acct-Status-Type: Interim) to the Accounting Server.</td>
</tr>
<tr>
<td>32</td>
<td>The Accounting Server sends an Accounting-Response to SaMOG.</td>
</tr>
<tr>
<td>33</td>
<td>(Optional) The AAA Server could send more CoA messages to SaMOG to install new rules.</td>
</tr>
<tr>
<td>34</td>
<td>SaMOG installs the new rules received in the CoA message.</td>
</tr>
<tr>
<td>35</td>
<td>Upon UE detach, SaMOG sends an Accounting-Request (Acct-Status-Type: Stop) message to the Accounting Server.</td>
</tr>
<tr>
<td>36</td>
<td>The Accounting Server sends an Accounting-Response message to SaMOG.</td>
</tr>
</tbody>
</table>

### Configuring RADIUS-based Web Authorization with LBO – Basic

#### Configuring Local Breakout – Basic

The following is a sample configuration to enable Local Breakout – Basic:

```plaintext
lte-policy
   subscriber-map smap
      precedence 1 match-criteria all operator-policy-name oppolicywebauthdia

operator-policy name oppolicywebauthdia
   associate call-control-profile cc-profwebauthdia
   apn webauth-apn-profile apnprfwebauth

call-control-profile cc-profwebauthdia
   accounting context aaa aaa-group accounting1
   authenticate context aaa aaa-group STawebauth auth-method eap non-eap
   #exit

apn-profile apnprfwebauth
   ip access-group acl-lbo-flow in
   ip access-group acl-lbo-flow out
   ip address pool name lbo-pool-1
   active-charging rulebase rb_lite
   ip context-name lbo-gi
   local-offload
twan default-gateway 12.0.0.10/8
```

---

**RADIUS-based Web Authorization with Local Breakout - Basic**

**Configuring Local Breakout – Basic**

The following is a sample configuration to enable Local Breakout – Basic:

```plaintext
lte-policy
   subscriber-map smap
      precedence 1 match-criteria all operator-policy-name oppolicywebauthdia

operator-policy name oppolicywebauthdia
   associate call-control-profile cc-profwebauthdia
   apn webauth-apn-profile apnprfwebauth

call-control-profile cc-profwebauthdia
   accounting context aaa aaa-group accounting1
   authenticate context aaa aaa-group STawebauth auth-method eap non-eap
   #exit

apn-profile apnprfwebauth
   ip access-group acl-lbo-flow in
   ip access-group acl-lbo-flow out
   ip address pool name lbo-pool-1
   active-charging rulebase rb_lite
   ip context-name lbo-gi
   local-offload
twan default-gateway 12.0.0.10/8
```
Configuring DSCP Marking by SaMOG

The following is a sample configuration for SaMOG to mark DSCP values:

```plaintext
config
  qci-qos-mapping qci_qos_map_name
    qci qci_value_1 downlink encaps-header copy-inner
    qci qci_value_1 uplink encaps-header copy-inner
    qci qci_value_1 downlink encaps-header copy-outer
    qci qci_value_1 uplink encaps-header copy-outer
    qci qci_value_2 downlink encaps-header dscp-marking value1
    qci qci_value_2 uplink encaps-header dscp-marking value2
end

config
  apn-profile profile-name
    associate qci-qos-mapping qci_qos_map_name
end

config
  context context_name
    cgw-service service_name
      associate qci-qos-mapping qci_qos_map_name
end
```

Important: The DSCP marking configuration under the APN Profile Configuration Mode takes priority over the DSCP marking configuration under the CGW Service Configuration Mode.
Configuring DSCP Marking by ECS

The following is a sample configuration for the AAA server to send a rulebase in the Access-Accept/CoA message. The APN profile can also be configured with the rulebase with DSCP marking as ef (expedite forwarding) in both uplink and downlink traffic:

```bash
rulebase rulebase_name
   action priority action_priority ruledef ruledef_name charging-action charging_action_name

ruledef ruledef_name
   ip any-match = TRUE

charging-action charging_action_name
   content-id id
   ip tos ef uplink
   ip tos ef downlink
```

Configuring SaMOG to act as the RADIUS Accounting Client

The following is a sample configuration to enable SaMOG to act as the RADIUS accounting client:

```bash
call-control-profile call_control_profile_name
   accounting mode radius-diameter
   associate accounting-policy accounting_policy_name
   accounting context aaa aaa-group aaa_group_name
   authenticate context aaa aaa-group aaa_group_name auth-type radius auth-method eap
   non-eap
   exit

aaa group accounting_policy_name
   radius attribute nas-ip-address address ip_address
   radius dictionary custom71
   radius accounting server ip_address key key port port_number
   radius accounting interim interval interim_interval
   radius accounting interim volume total interim_volume
   exit

policy accounting accounting_policy_name
   cc profile 2 interval interval
   cc profile 2 volume total total
   cc profile 8 interval interval
   cc profile 8 volume total total
   exit
```
Monitoring and Troubleshooting

RADIUS-based Web Authorization with LBO Basic Show Command(s) and/or Outputs

**show subscriber samog-only full**

The following field is available in the output of the `show subscriber samog-only full` command in support of this feature:

**CGW Subscriber Info:**

```
---------------------
QCI : 9
```

*Table 44: show subscriber samog-only full Command Output Descriptions*

<tr>
<td>QCI</td>
<td>Subscriber's QCI value.</td>
</tr>
</tbody>
</table>
SaMOG Gateway Offline Charging

The SaMOG Gateway supports generation of CDR files for offline charging. In Offline Charging, charging information is collected concurrently with resource usage and passed through a chain of logical charging functions. At the end of the process, CDR files are generated by the network and transferred to the network operator's Billing Domain.

Figure 26: 3GPP Offline Charging Architecture

The Charging Trigger Function (CTF) generates charging events and forwards them to the Charging Data Function (CDF). The CDF then generates CDRs and transfers it to the Charging Gateway Function (CGF). Finally, the CGF creates CDR files and forwards them to the Billing Domain.

The SaMOG Gateway integrates with the CTF and CDF functions, generates CDRs based on the triggered events, and sends the same to the CGF over the Gz/Wz interface (using the GTPP protocol).

- **SaMOG CDR Formats, page 208**
- **Triggers for Generation of Charging Records, page 215**
- **Configuring the SaMOG CDRs, page 216**
SaMOG CDR Formats

As 3GPP specifications does not define a CDR format for SaMOG, the S-GW CDR and SGSN CDR record formats are used to define the CDR formats. The record format can be selected using a CLI command under the GTPP Group Configuration Mode. By default, for an SaMOG general license, the S-GW record type is used, and for an SaMOG 3G license, the SGSN (SGSNPDRecord) record type is used.

This section provides a reference for the S-GW and SGSN CDR fields supported by SaMOG.

The category column in all tables use keys described in the following table.

**Table 45: Dictionary Table Key**

<table>
<thead>
<tr>
<th>Abbreviation</th>
<th>Meaning</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>M</td>
<td>Mandatory</td>
<td>A field that must be present in the CDR</td>
</tr>
<tr>
<td>C</td>
<td>Conditional</td>
<td>A field that must be present in the CDR if certain conditions are met.</td>
</tr>
<tr>
<td>OM</td>
<td>Operator Provisionable:</td>
<td>A field that an operator has provisioned and must be included in the CDR</td>
</tr>
<tr>

**Triggers for Generation of Charging Records**

The following section describes the triggers for the generation of partial and final SaMOG CDRs. SaMOG CDRs are updated (not closed) for any of the following conditions:

- **QoS Change:** When a QoS change is detected, the "List of Traffic Data Volumes" is added to the CDR.
- **Tarrif Time Change:** When the tarrif time changes, the "List of Traffic Data Volumes" is added to the CDR.
- **CDR Closure:** The "List of Traffic Data Volumes" is added to the CDR when this event occurs.
The "List of Traffic Volumes" attribute in the SaMOG CDR consists of a set of containers that are added when specific trigger conditions are met. The volume count per IP CAN bearer is also identified and separated for uplink and downlink traffic when the trigger condition occurs.

The SAMOG CDRs are closed as the final record for a subscriber session for the following events:

- End of IP-CAN bearer: The CDR is closed when the IP-CAN bearer is deactivated. The trigger condition includes:
  - UE detach
  - AAA detach
  - PGW/GGSN detach
  - any abnormal release
  - Admin clear

The following events trigger closure and sending of a partial SaMOG CDR:

- Volume Limit: The CDR is partially closed when the configured volume threshold is exceeded.
- Time Limit: The CDR is partially closed when the configured interval is reached.
- Maximum number of charging condition changes: The CDR is partially closed when the LOTV container exceeds its limit.
- Management intervention

### Configuring the SaMOG CDRs

The SaMOG Gateway uses the custom24 GTPP dictionary to generate SGW and SGSN CDRs. The following table lists the configuration commands related to creating and formatting the CDRs. These commands appear at different portions of the system configuration file.

- `gtpp group <name>` - These are commands specified within the billing context.

<table>
<thead>
<tr>
<th>Command</th>
<th>Default</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trigger-related Configuration</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>gtpp group &lt;name&gt;</code> in Billing Context</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>gtpp trigger volume-limit</code></td>
<td>Enabled</td>
<td>When this trigger is disabled, no partial record closure occurs when the volume limit is reached.</td>
</tr>
<tr>
<td><code>gtpp trigger time-limit</code></td>
<td>Enabled</td>
<td>When this trigger is disabled, no partial record closure occurs when the configured time limit is reached.</td>
</tr>
</tbody>
</table>
### Command

</tr>
</thead>
<tbody>
<tr>
<td>gtp trigger tariff-time-change</td>
<td>Enabled</td>
<td>When this trigger is disabled, container closure does not occur for a tariff-time change.</td>
</tr>
<tr>
<td>gtpp trigger qos-change</td>
<td>Enabled</td>
<td>Disabling this trigger ignores a qos-change and does not open a new CDR for it.</td>
</tr>
</tbody>
</table>

### CDR Attribute-related Configuration

<table>
<thead>
<tr>
<th>Command</th>
<th>Default</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>gtp attribute diagnostics</td>
<td>No</td>
<td>Includes the Diagnostic field in the CDR that is created when PDP contexts are released.</td>
</tr>
<tr>
<td>gtp attribute duration-ms</td>
<td>No</td>
<td>Specifying this option results in mandatory &quot;Duration&quot; field in the CDR to be recorded in milliseconds rather than seconds.</td>
</tr>
<tr>
<td>gtp attribute local-record-sequence-number</td>
<td>No</td>
<td>Specifying this option includes optional fields &quot;Local Record Sequence Number&quot; and &quot;Node-ID&quot; in the CDR. Since the &quot;Local Record Sequence Number&quot; has to be unique within one node (identified by &quot;Node-ID&quot;), &quot;Node-ID&quot; field will consist of sessMgr Recovery count + AAA Manager identifier + the name of the GSN service. Since each AAA Manager generate S-CDRs independently, the &quot;Local Record Sequence Number&quot; and &quot;Node ID&quot; fields will uniquely identify a CDR.</td>
</tr>
<tr>
<td>gtp attribute msisdn</td>
<td>Enabled</td>
<td>Specifying this option includes field &quot;MSISDN&quot; in the CDR.</td>
</tr>
<tr>
<td>gtp attribute node-id-suffix &lt;string&gt;</td>
<td>No</td>
<td>String between 1 and 16 characters Specifies the string suffix to use in the NodeID field of S- CDRs. With the default setting of &quot;no&quot;, the SaMOG Gateway uses the GTPP context name for the Node ID field.</td>
</tr>
<tr>
<td>gtp attribute record-type {sgwrecord</td>
<td>sgsnpdprecord}</td>
<td>No</td>
</tr>
<tr>
<td>gtp attribute twanuli</td>
<td>Disabled</td>
<td>Specifying this option includes the &quot;TWAN User Location Information&quot; in the S-GW CDRs. <strong>Important</strong> SaMOG services and standalone S-GW services must not share a GTPP group that has the <strong>gtp attribute twanuli</strong> command configured. Instead, configure the command under different GTPP groups for each service.</td>
</tr>
</tbody>
</table>

**Policy Accounting** in Source Context
### Command

<table>
<thead>
<tr>
<th>Command</th>
<th>Default</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>cc profile &lt;index&gt; buckets &lt;number&gt;</code></td>
<td>index = 0-15 number = 4</td>
<td>Specifies the number of traffic volume container changes due to QoS changes or tariff time that can occur before an accounting record is closed.</td>
</tr>
<tr>
<td><code>cc profile &lt;index&gt; interval &lt;seconds&gt;</code></td>

SaMOG Inter-Chassis Session Recovery

This chapter describes the license-enabled inter-chassis session recovery feature on the SaMOG gateway.

- Feature Description, page 221
- How It Works, page 222

Feature Description

SaMOG is capable of providing chassis-level and geographic-level redundancy and can recover fully created sessions in the event of a chassis failure.

The Cisco ASR 5x00 and virtualized platforms provide industry leading carrier class redundancy. The systems protects against all single points of failure (hardware and software) and attempts to recover to an operational state when multiple simultaneous failures occur.

The system provides several levels of system redundancy:

- Under normal N+1 packet processing card hardware redundancy, if a catastrophic packet processing card failure occurs all affected calls are migrated to the standby packet processing card if possible. Calls which cannot be migrated are gracefully terminated with proper call-termination signaling and accounting records are generated with statistics accurate to the last internal checkpoint.

- If the Session Recovery feature is enabled, any total packet processing card failure will cause a packet processing card switchover and all established sessions for supported call-types are recovered without any loss of session.

Even though Cisco provides excellent intra-chassis redundancy with these two schemes, certain catastrophic failures which can cause total chassis outages, such as IP routing failures, line-cuts, loss of power, or physical destruction of the chassis, cannot be protected by this scheme. In such cases, the SaMOG Inter-Chassis Session Recovery (ICSR) feature provides geographic redundancy between sites. This has the benefit of not only providing enhanced subscriber experience even during catastrophic outages, but can also protect other systems such as the RAN from subscriber reactivation storms.

ICSR allows for continuous call processing without interrupting subscriber services. This is accomplished through the use of redundant chassis. The chassis are configured as primary and backup with one being active and one in recovery mode. A checkpoint duration timer is used to control when subscriber data is sent from the active chassis to the inactive chassis. If the active chassis handling the call traffic goes out of service, the inactive chassis transitions to the active state and continues processing the call traffic without interrupting the
subscriber session. The chassis determines which is active through a propriety TCP-based connection called a redundancy link. This link is used to exchange Hello messages between the primary and backup chassis and must be maintained for proper system operation.

How It Works

Inter-chassis Communication

Chassis configured to support ICSR communicate using periodic Hello messages. These messages are sent by each chassis to notify the peer of its current state. The Hello message contains information about the chassis such as its configuration and priority. A dead interval is used to set a time limit for a Hello message to be received from the chassis' peer. If the standby chassis does not receive a Hello message from the active chassis within the dead interval, the standby chassis transitions to the active state. In situations where the redundancy link goes out of service, a priority scheme is used to determine which chassis processes the session. The following priority scheme is used:

- route modifier
- chassis priority
- SPI MAC address

Checkpoint Messages

Checkpoint messages are sent from the active chassis to the inactive chassis at specific intervals and contain all the information needed to recreate the sessions on the standby chassis, if that chassis were to become active. Once a session exceeds the checkpoint duration, checkpoint data is collected on the session. The checkpoint parameter determines the amount of time a session must be active before it is included in the checkpoint message.

Important

For more information on inter-chassis session recovery support, refer to the Interchassis Session Recovery chapter in the System Administration Guide.

Limitations

This section identifies limitations, restrictions, and dependencies for the SaMOG ICSR feature:

- In this release, ICSR support is available only for the following sessions types:
  - PMIPv6 access-type and GTPv2 network type sessions with DIAMETER-based authentication.
  - EoGRE access-type and GTPv2 network type sessions with DIAMETER-based authentication.

- ICSR support is not available for recovering CDR information and SaMOG Local Breakout (LBO) sessions (flow-based and LBO Basic).
• ICSR support is not available for multiple SaMOG services configuration.
SaMOG Local Break Out

The SaMOG Local Breakout (LBO) feature enables subscribers to access the Internet without connecting to the EPC or 3G core. SaMOG currently supports the following LBO models:

- Local Breakout - Enhanced, page 225
- Local Breakout - Basic, page 234
- Flow-based Local Breakout, page 237

Local Breakout - Enhanced

The Local Breakout (LBO) - Enhanced model is implemented by configuring a local P-GW or a local GGSN. All subscribers of a particular APN will be locally broken out without connecting to the P-GW or GGSN over the S2a interface. SaMOG performs IP allocation locally. This capability helps APNs whose data traffic can connect to the Internet immediately after authentication, instead of being sent to the 3GPP backbone.

License Requirements

The Local Breakout - Enhanced model requires a separate LBO - Enhanced feature license. This license is mutually exclusive with the LBO - Basic and Flow-based LBO licenses.

**SaMOG 3G license:** Only a GGSN service can be configured and associated with the CGW service.

**SaMOG general license:** Either a GGSN service or a P-GW service can be configured and associated with the CGW service.

Overview

The following figure provides a high level architecture of the Local Breakout feature:
The APN provided by the AAA server is mapped to the locally configured P-GW or GGSN service IP. This eliminates the need for a DNS. The local P-GW or local GGSN assigns the IP using a locally configured IP pool after receiving the subscriber information from the AAA server. The subscriber information is received from the SaMOG service to the local P-GW service or local GGSN service through a GTP tunnel. This tunnel is set up within the same chassis.

The SaMOG Gateway decides whether an APN should be locally broken out based on the following parameters:

- A configuration in the APN profile indicating if LBO is enabled for the APN.
- Whether a "DEA-Flags" is received in the DEA messages on the STa interface. If DEA-Flags are received, SaMOG will verify if the "NSWO-Authorization" flag is set.

If the APN profile is configured for LBO, and either no "DEA-Flags" are received in the DEA messages, or "DEA-Flags" is received with the "NSWO-Authorization" flag set, SaMOG performs LBO for that APN.

**LBO Decision based on AAA Policy and Local Policy**

The decision on whether LBO can be done for a call is based on the following factors:

- A DIAMETER-based server can provide the following information:
The MIP6 FEATURE VECTOR AVP in DEA message can have the GTPV2_SUPPORTED flag set to indicate that the AAA server authorizes the GTP call through the EPC core (GGSN/PGW).

The Bit 0 of the DEA_FLAG AVP (NSWO Authorization) is set to indicate that LBO is authorized for a session by the AAA server.

- The DIAMETER AAA server sends the APN information in the APN-Configuration AVP in DEA. This AVP may however be absent in case the AAA server authorizes only LBO, to indicate that any APN can be used for LBO for the subscriber.

- The operator can configure "local-offload" for each APN supporting LBO under the APN profile. However, the authorization from the AAA server will always be given preference over the local configuration. Local configuration will be used to take a decision when AAA server authorizes GTP as well as LBO for a call.

The following table indicates different scenarios where the occurrence of LBO is determined:

<table>
<thead>
<tr>

</table>
Prepaid LBO Support

The SaMOG Gateway also supports Local Breakout (LBO) that enables time- and quota-based control to support prepaid subscribers. SaMOG interfaces with the Enhanced Charging Services (ECS) using the Gy interface for prepaid subscribers, and AAA for voucher-based subscribers. LBO for prepaid subscribers is supported on both PMIPv6 and EoGRE access types.

When a GTP session with the local P-GW or GGSN is set up, the local P-GW or GGSN service communicates with ECS to obtain the time and quota limits of the subscriber to establish connection. The time and quota limits are obtained with the Gy interface forwarding the CCR-I message to the Diameter Credit Control Application (DCCA) server. Until the time or volume quota is reached, the local P-GW or GGSN forwards the CCR-U message to DCCA in order to refresh the permitted time or volume quota allowed. When the UE terminates the session, the internal P-GW forwards the final service usage to ECS, and SaMOG completes the session.
Call Flows with Local Breakout - Enhanced

Attach Procedure

Figure 27: Attach Procedure Call Flow

Table 49: Attach Procedure Call Flow Descriptions

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>UE associates with AP and WLC.</td>
</tr>
</tbody>
</table>
Step | Description
--- | ---
2 | WLC starts EAP based authentication with UE and requests for the permanent identity of the user.
3 | UE responds with the permanent identity (IMSI) stored on the SIM.
4 | WLC requests SaMOG for authentication using Radius Access Request message.
5 | SaMOG uses the STa interface towards 3GPP HSS to fetch subscriber authentication challenge. If LBO is enabled, SaMOG forwards DER-Flags (in the DER msg) with "NSWO-Capability" bit set to '1' to indicate to AAA that it supports LBO. Else, it sends the DER-Flags with "NSWO-Capability" bit set to '0'.
6 | HSS returns the authentication parameters to SaMOG for the subscriber. The DEA message may contain DEA-Flags.
7 | SaMOG sends Radius-Access-Challenge message to the WLC.
8 | WLC in turn sends authentication challenge to UE.
9 | UE responds with challenge response.
10 | WLC initiates Radius Access Requests towards SaMOG with challenge response.
11 | SaMOG originates STa AARequest towards HSS. If LBO is enabled, SaMOG sends DER-Flags (in the DER msg) with "NSWO-Capability" bit set to '1' to indicate to AAA that it supports LBO. Else, it sends the DER-Flags with "NSWO-Capability" bit set to '0'.
12 | HSS authenticates the subscriber and also returns the subscriber profile information to MRME. The profile information will contain the Default QoS profile, Default APN, APN-AMBR, and Charging Characteristics.
13 | If the APN profile requires LBO for the APN, either of the following conditions is met:
- DEA-Flags not received
- DEA-Flags received with the "NSWO-Authorization" bit set to 1.

The P-GW service is then associated with the SaMOG service, and the associated P-GW IP address is used for LBO. Or, if a static IP address is provided by AAA, the address is used for allocation.

If neither of the conditions above is met, DNS resolution is performed to determine the P-GW address.
14 | SaMOG sends Radius-Access-Accept message towards WLC with some of the information mentioned in Step12 (APN Name, PDN-GW/LGW address).
15 | EAP Success is sent to the UE.
Step | Description
--- | ---
16 | For access-type EoGRE, UE sends DHCP Discover to SaMOG via. WLC. For access-type PIMP, WLC originates the PMIPv6 Proxy-Binding-Update message to SaMOG with the information from Step 13. Additionally, WLC allocates a GRE tunnel ID for downlink data transfer and includes it in PBU message.
17 | For access-type EoGRE, the IP address allocated in Step 13 via. the associated P-GW is sent in the DHCP Offer msg. For access-type PMIPv6, the IP address allocated in Step 13 via. the associated P-GW is sent in the PBA message. The SaMOG service will setup the GRE tunnel and include the GRE tunnel ID for uplink data transfer.
18 | For access-type EoGRE, the DHCP Request and DHCP Ack messages are forwarded to complete the IP address allocation. For access-type PMIPv6, WLC acts as DHCP server to the UE, and assigns the IP address received in PBA.
**UE Initiated Detach**

*Figure 28: UE Initiated Detach Call Flow*

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>UE initiates DHCP Release or L2 layer detach towards wireless network.</td>
</tr>
</tbody>
</table>
| 2    | If access-type is EoGRE, UE sends a "DHCP Release" message to SaMOG.  
If the access-type is PMIPv6, WLC sends a PBU (De-registration) to SaMOG. |
| 3    | SaMOG sends a "Radius POD" to WLC. |
| 4    | WLC initiates Radius-Accounting-Stop message to SaMOG. |
| 5-6  | SaMOG in turn initiates STa Termination request to HSS, and receives a STa Termination response back from HSS. |
| 7    | SaMOG sends Radius-Accounting-Stop Response message to WLC. |
### Step 8
For access-type PMIPv6, SaMOG sends back PMIPv6 Proxy Binding.

### Step 9
If the APN has been locally broken out, the allocated IP address is returned back to the P-GW IP pool. The session and associated IP-GRE/EoGRE tunnel is cleared.

<td>SaMOG sends Radius-Accounting-Stop Response message to WLC.</td>
</tr>
</tbody>
</table>
### Limitations, Restrictions, and Dependencies

The following limitations, restrictions, and dependencies apply for the Local Breakout - Enhanced model:

- When an LBO session or GTP session is setup to an EPC/3G core, the mobility protocol or local breakout cannot be changed dynamically during reattach, even if the new authentication indicates the scope for such change. If the AAA server withdraws permission for the current mobility protocol/LBO, the session will be closed.

- In release 16.0, the Local Breakout feature supports 4G (GTPv2) sessions only.

- Prepaid support for Local Breakout feature using the AAA interface is limited to session-timeout AVP to control the session duration for voucher-based users. No additional support will be available on the AAA interface.

- For the LBO prepaid support, the SaMOG Gateway generates S-GW CDRs. Any packet drops on the interface P-GW service due to online credit control will still be counted in SGW-CDRs. However, operators can consider enabling P-GW CDRs in the internal P-GW as required.

### Local Breakout - Basic

The Local Breakout (LBO) - Basic model enables SaMOG to connect the subscriber's User Equipment (UE) directly to the Internet without employing a local or external P-GW or GGSN service. The UE's IP address is allocated using an IP pool configured locally (or provided by the AAA server). The LBO basic model can be used with or without a Network Address Translation (NAT) service. If dynamic NAT is enabled for a subscriber, SaMOG allocates a global IP address from a pool, and replaces the source IP address of the data packet with this address.

### License Requirements

The LBO - Basic model requires a separate feature license. This license is mutually exclusive with the LBO - Enhanced license, and can co-exist with the Flow-based LBO license.

SaMOG forwards it to the AAA accounting server, and the response from the accounting server is forwarded back to WLC.</td>
</tr>
<tr>
<td>15</td>
<td>Uplink data packet with the source IP address (a.b.c.d) is sent to WLC through the CAPWAP tunnel by UE.</td>
</tr>
<tr>
<td>16</td>
<td>WLC encapsulates the same packet into GRE/EoGRE tunnel or as L3IP, and sends it to SaMOG.</td>
</tr>
<tr>
<td>17</td>
<td>SaMOG performs dynamic NAT on this packet, allocates a global IP address from a pool (p.q.r.s), and replaces the source IP address of data packet with this address.</td>
</tr>
</tbody>
</table>
SaMOG routes the modified packet to the Internet.

The downlink packet contains the destination address set to p.q.r.s from the Internet to SaMOG.

SaMOG performs a reverse NAT, and replaces the address (a.b.c.d) as the destination address of the packet.

The modified packet is forwarded through the GRE/EoGRE tunnel as an L3IP to WLC.

WLC forwards the packet to the UE.

If NAT policy is not applied for the session (i.e. if ACLs are not provided, or if Rulebase is not provided, or if Rulebase doesn't contain NAT policy), the uplink data packets are directly offloaded to the Internet without NATting, and consequently reverse NAT is not applied for downlink packets from Internet, as NAT is not mandatory for LBO Basic.

---

**Flow-based Local Breakout**

The Flow-based Local Breakout (LBO) model enables SaMOG to selectively offload certain user data directly to the Internet without employing an external or internal P-GW or GGSN service, and forward the remaining traffic to an external P-GW or GGSN (via the S2a tunnel) depending on configured Layer 4 rules. The User Equipment's (UE) IP address is allocated by the external P-GW or GGSN service. SaMOG applies NAT addressing to all traffic that are offloaded directly to the Internet to differentiate between packets intended for local offload, and packets intended to be forwarded to P-GW or GGSN.

**License Requirements**

The Flow-based LBO model requires a separate feature license. This license is mutually exclusive with the LBO - Enhanced license, and can co-exist with the LBO - Basic license.

**Flow-based LBO models**

SaMOG applies Layer 4 rules to the data traffic using Access Control Lists (ACLs) to determine the part of traffic to be offloaded directly or sent to the P-GW or GGSN service. This decision can be based off an ACL whitelist or an ACL blacklist. While the ACL whitelist identifies the data to be forwarded to the P-GW or GGSN service, the ACL blacklist identifies the data to be locally offloaded.
Flow-based LBO using a Whitelist

A flow-based LBO using a whitelist is ideal in situations when a subscriber signs up for some premium content, and this content must be charged differently. SaMOG uses the ACL to route all traffic intended for the premium content server to be forwarded to P-GW or GGSN where special charging is applied using the Gx/Gy interface. SaMOG offloads the rest of the traffic that does not match the ACL directly to the Internet.

Flow-based LBO using a Blacklist

A flow-based LBO using blacklist is ideal in situations when SaMOG is deployed in a vicinity where a large number of subscribers access the same content (for example, a streaming video of an event in a stadium where the server is locally hosted). SaMOG offloads this content directly from the local server, and all other data traffic is routed to the P-GW or GGSN service.

**Limitations, Restrictions, and Dependancies**

The following limitations, restrictions, and dependancies apply for the Local Breakout - Basic model:

- For an L3IP access type, the IP address assigned by the P-GW or GGSN must be routable on the WLAN. SaMOG does not assign a separate IP address for the UE.
- The Flow-based LBO model will always require NAT to route the UE packets on the Internet directly.
SaMOG Local P-GW Selection

This feature enables the SaMOG Gateway to configure and use local P-GW addresses either as a fall-back selection method or as the preferred selection method.

The following sections provide more detailed information:

• Feature Description, page 245
• How Local P-GW Address Support Works, page 246
• Configuring Local P-GW Selection, page 249
• Monitoring Local P-GW Selection, page 251

Feature Description

The SaMOG Gateway allocates P-GW to provide PDN connectivity to the User Equipment (UEs). The P-GW address is either selected based on the address provided by the AAA server (static selection) or by using DNS resolution (dynamic selection). With this feature, the SaMOG Gateway can support P-GW addresses that are configured locally under the APN Profile Configuration Mode. SaMOG can use these locally configured P-GW addresses in one of the following ways:

• As a fall-back selection method
• As preferred selection method

Local P-GW as a Fall-back Selection Method

1 When AAA Server identifies the P-GW selection method as Dynamic and if the local P-GW address is configured under the APN Profile, the SaMOG Gateway will perform local P-GW selection in the following scenarios:

• The P-GW addresses received by DNS resolution are unreachable.
• The DNS server is unreachable, or the DNS query is rejected.
• DNS resolution is not configured, and/or the AAA server does not send the P-GW address.
When AAA Server identifies the P-GW selection method as static (P-GW IP Address or P-GW FQDN): If the local P-GW address(es) are configured under the APN Profile and also P-GW selection fallback for P-GW ID is configured under mrme-service, the SaMOG Gateway will perform local P-GW selection in the following scenarios:

- The P-GW address mentioned by AAA server or received by DNS resolution (P-GW FQDN) is unreachable
- The DNS server is unreachable, or the DNS query is rejected (for P-GW FQDN).
- DNS resolution is not configured (for P-GW FQDN).

Local P-GW as the Preferred Selection Method

The SaMOG Gateway can be configured to use the local P-GW addresses for P-GW node selection as the preferred selection method.

This method is applicable only when the AAA server mentions the selection method as dynamic and the "local-configuration-preferred" configuration is enabled under mrme-service.

Note

This configuration is not effective when the AAA server mentions the selection method as static.

How Local P-GW Address Support Works

The SaMOG Gateway performs local P-GW address selection based on the weight that is configured for each P-GW address (similar to DNS resolution of P-GW addresses). Only the first P-GW address is selected based on its weight. The rest of the addresses are selected on a round-robin basis starting from the next available P-GW address, rounding to the P-GW address before the first selected P-GW address. A maximum of 16 IPv4 and/or IPv6 local P-GW addresses can be configured.

Limitations

- In this release, the SaMOG Gateway does not support dual bind (IPv4 and IPv6) address for EGTP service (or GTPU service).
- The PGW-Fallback is supported only for GTPv2 Network Protocol.

1. SaMOG performs DNS resolution on APN FQDN, If resolved PGWs are not reachable then
2. SaMOG tries to establish session with locally configured PGW Addresses.
**Configuring Local P-GW Selection**

**Configuring Local P-GW Resolution**

Use the `pgw-address` command under the APN Profile Configuration Mode to define local P-GW addresses for load balancing.

```plaintext
configure
    apn-profile profile-name
        pgw-address ipv4_address | ipv6_address weight weight [primary | secondary ]
    no pgw-address ipv4_address | ipv6_address
end
```

**Notes:**

- Use the `no pgw-address ipv4_address | ipv6_address` command to disable the P-GW address(es) configured for an APN profile.

  * `ipv4_address` must be an IPv4 address expressed in dotted-decimal notation.
  * `ipv6_address` must be an IPv6 address expressed in colon (or double-colon) notation.

- `weight weight`
  
  Configures the weight for the IPv4 or IPv6 address.
  
  `weight` is an integer from 1 to 100.

- `primary | secondary`

  * `primary`: Configures the primary P-GW for S2b interface.
  * `secondary`: Configures the primary P-GW for S2b interface.

- A maximum of 16 P-GW IPv4 and/or IPv6 addresses can be configured for an APN profile.

- When multiple P-GW addresses are configured, only the first P-GW will be selected based on the weight. The rest of the P-GW addresses are selected using the round-robin mechanism.
Configuring Preferred Selection as Local P-GW

Use the `pgw-selection` command under the MRME Service Configuration Mode to set the P-GW address selection from a local configuration as the preferred selection mechanism.

```bash
configure
  context context_name
    mrme-service service_name
      pgw-selection local-configuration-preferred
  end
```

Notes:

- Use the `no pgw-selection local-configuration-preferred` command to disable this command.
- By default, this command is disabled. The SaMOG Gateway uses DNS-based P-GW selection (dynamic selection) as the preferred selection method.

Configuring Local P-GW Fallback for Static Selection Method

Use the `pgw-selection` command under the MRME Service Configuration Mode to set the P-GW address selection from a local configuration as static selection method.

```bash
configure
  context context_name
    mrme-service service_name
      pgw-selection fallback pgw-id
  end
```

Notes:

- Use the `no pgw-selection fallback pgw-id` command to disable this command.
- By default, this command is disabled.

Verifying Configuration for Local P-GW Support

```bash
show apn-profile full all
```

Use the `show apn-profile` command to verify the configured P-GW IP address(es).

```
P-GW:
  IP-Address : 6666::200:1
  S5-S8-Protocol : N/A
  Weight : 1
  IP-Address : 6666::a00:1
  S5-S8-Protocol : N/A
  Weight : 17
```

```bash
show mrme-service name mrme_service_name
```

Use the `show mrme-service name` command to verify the status of the local P-GW selection configuration.

```
Preferred PGW selection mechanism : Local
PGW-ID selection fallback : Enabled
```
Monitoring Local P-GW Selection

This section provides information on the show commands available to monitor the local P-GW selection.

Local P-GW Selection Show Command(s) and/or Outputs

show samog-service statistics

The following fields are available to the output of the show samog-service statistics command in support of this feature.

Local PGW Fallback Stats:
Attempted: 0
Success: 0
No Alternate GW: 0

Feature Description

The PCAP trace output of the `monitor subscriber` and `monitor protocol` commands can be exported as a hexdump file for SaMOG sessions. The hexdump capture can be stored in a text file in a hard disk, and later transferred to an external server through SFTP using a PUSH or PULL method.

PCAP trace and hexdump file collection can be enabled or disabled under the `monitor protocol` and `monitor subscriber` commands.

For SaMOG, hexdump captures can be enabled for the following protocols:

- GTPv1
- GTPv2
- GTPU
- User L3
- Diameter
- Radius
- EoGRE
- PMIPv6

SaMOG subscriber information for PCAP trace can be specified using the following filters:

- By MSID/IMSI
- By callid
- By username
- Next-Call
- By IMEI
- By MSISDN
- Next-SAMOG Call

For more information on PCAP Trace, Refer the `Packet Capture (PCAP) Trace` chapter in the *ASR5500 System Administration Guide*. 
Seamless Session Handover

The following topics are discussed:

- Feature Description, page 255
- How Seamless Session Handover Works, page 256
- Monitoring and Troubleshooting Seamless Session Handover, page 260

Feature Description

Overview

This feature enables SaMOG to switch the access type (PMIPv6/EoGRE) seamlessly and preserve the session when subscribers move between access points with different session trigger types.

The SaMOG Gateway can:

- Seamlessly switch the access type from PMIPv6 (PMIPv6-based session creation) to EoGRE, based on the DHCP Discover, DHCP Request, or Direct Data Traffic on the EoGRE tunnel.
- Seamlessly switch the access type from EoGRE (DHCP trigger-based session creation) to PMIPv6, based on the PBU message from the AP.
How Seamless Session Handover Works

Flows

PMIPv6 to EoGRE (DHCP-triggered) Handover

PMIPv6 to EoGRE (data-triggered) Handover

The figure below shows the detailed handover procedure from PMIPv6 to EoGRE (data-triggered).

**Figure 34: PMIPv6 to EoGRE (data-triggered) Handover Call Flow**

### Table 58: PMIPv6 to EoGRE (data-triggered) Handover

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
</table>
| 01   | PMIPv6-triggered session is established. For more information on the PMIPv6-based session establishment, refer the **PMIPv6-based Session Creation** section of this guide.  
As the TWAN profile for DHCP-triggered session is associated with the MRME service, EoGRE (UE MAC) based flows are installed during the PMIPv6-triggered session setup. |
| 02   | UE moves (hand-off) to a new Residential Gateway (RG) that supports EoGRE. |
| 03   | UE continues to send data traffic through the new RG. |
| 04   | RG forwards the data traffic to SaMOG through the EoGRE tunnel. |
SaMOG detects that the UE has moved to a new RG (hand-off) and switches the data path from the PMIPv6 GRE tunnel to EoGRE tunnel for the UE session. SaMOG also updates the session type to EoGRE/DHCP-triggered.

Data is transferred between the UE and ISP (through SaMOG and the RG).

SaMOG initiates a clean-up of the previous PMIPv6 access side session with the old AP/WLC. SaMOG sends a Binding Revocation Indication (BRI) message to the old AP/WLC.

The old AP/WLC sends a BRI Ack message to SaMOG.

SaMOG cleans up the PMIPv6 session.

**EoGRE to PMIPv6 (PBU-triggered) Handover**

The figure below shows the detailed handover procedure from EoGRE to PMIPv6 (PBU-triggered).

</tbody>
</table>
### Limitations

**Architectural Limitations**

- This feature supports RADIUS-based authentication between SaMOG and the 3GPP AAA Server. Diameter-based authentication is currently not supported.

- This feature supports PMIPv6-based S2a interface towards the local gateway. GTPv1 and GTPv2 are currently not supported.

- Only IPv4 address allocation is supported for the UE. IPv6 and IPv4v6 PDN types are currently not supported.

- All interfaces towards all external nodes will be IPv4 address only. IPv6 transport on any interface with external nodes is currently not supported.

- The AP will not convey the user location and SSID information to SaMOG.

### Monitoring and Troubleshooting Seamless Session Handover

Static Serving PLMN Configuration

The following topics are discussed:

- Feature Description, page 265
- How Static Serving PLMN Works, page 265
- Configuring Static Serving PLMN, page 266
- Monitoring and Troubleshooting Static Serving PLMN Configuration, page 267

Feature Description

Overview

The static serving PLMN configuration feature enables subscribers connecting from different operator sub-zones to be grouped and treated as a home user instead of a visited user. These subscribers can then be served by one SaMOG/P-GW for offloading traffic. This feature can be enabled using the `serving-plmn id` command under the Call Control Profile Configuration Mode.

How Static Serving PLMN Works

Architecture

When the serving PLMN ID (MNC/MCC) is configured under the Call Control Profile Configuration Mode (typically with the same serving PLMN ID of the serving P-GW), SaMOG provides higher priority to this configuration. The configured PLMN will be then be sent to P-GW in the Serving-Network IE of the Create Session Request (CSR) message. These subscribers will be treated as home users even if they belong to different operator sub-zones, and can be served by one SaMOG/P-GW.

In Release 21.1 and later, the PLMN ID for UICC and non-UICC devices is selected based on the following order of priority:
• The `serving-plmn` configuration under the Call Control Profile Configuration Mode.

• The `plmn` configuration under the SaMOG Service Configuration Mode.

• The `User-Name` from the EAP-Identity, Authentication, or Accounting messages if the realm (serving PLMN's realm) part of User-Name is in 3GPP format.

In Release 21.0 and earlier, the PLMN ID for UICC and non-UICC devices is selected based on the following order of priority:

• The `User-Name` from the EAP-Identity, Authentication, or Accounting messages if the realm (serving PLMN's realm) part of User-Name is in 3GPP format.

• The `plmn` configuration under the SaMOG Service Configuration Mode.

Limitations

Architectural Limitations

• As there is no serving-plmn field in a PMIPv6 interface, static serving PLMN is not supported on the PMIPv6-based S2a interface.

• Static serving PLMN is not supported with DHCP trigger-based and Accounting-based session creation features as these features require PMIPv6-based S2a interface.

Configuring Static Serving PLMN

Use the following configuration to configure a static serving node PLMN Identifier (MCC and MNC) for a Call Control Profile:

```plaintext
configure
call-control-profile profile_name
    serving-plmn id mcc mcc_value mnc mnc_value
end
```

Notes:

• Use the `remove serving-plmn id` command to remove the static serving node PLMN ID configuration from the Call Control Profile.

• `mcc_value` must be an integer between 100 and 999.

• `mnc_value` must be an integer between 0 and 999.
Monitoring and Troubleshooting Static Serving PLMN Configuration

Feature Description

Overview

The SaMOG Gateway supports the Web Authorization feature that enables SaMOG to register the subscriber's non-SIM UEs by authenticating the subscriber through a web portal (using username and password). On successful authentication, the AAA server stores the subscriber profile (APN, IMSI, QoS) from the HLR/HSS for the subscriber's device, and SaMOG establishes the network connection for the UE.

The Web Authorization feature has two phases:

• Pre-Authentication Phase – SaMOG allocates the IP address for the UE locally, and redirects the UE traffic to a web portal for subscriber authentication.

• Post-Authentication/Transparent Auto Logon (TAL) phase – P-GW allocates the IP address to the UE.

During transition between the two phases, the subscriber session disconnects. The Web Authorization feature can also be configured where the transition between the pre-authentication and post-authentication phases are achieved without session disconnection (optimized Web Authorization feature).

Refer the Web Authorization and Optimized Web Authorization sections in the SaMOG Administration Guide for more information on these features.

The Web Authorization Session Logout feature provides additional functionality to the Web Authorization feature. In release 21.1 and earlier, when the subscriber logs out of the portal or exhausts the quota, SaMOG clears the subscriber session on receiving a trigger from the P-GW or PCRF.

In Release 21.2 and later, SaMOG does not clear the subscriber session when the subscriber logs out of the portal or exhausts the quota. The subscriber session is instead moved from the post-authentication phase to the pre-authentication phase, and retained until the subscriber logs back in, or the timeout period (configurable) expires. This functionality enables operators to provide session stickiness for subscribers by retaining the subscriber’s Wi-Fi network connection.
License Requirements

The Web Authorization Session Logout feature requires the following licenses:

- SaMOG General license
- SaMOG Web Authorization feature license (to configure web authorization)
- SaMOG Local Breakout feature license (to configure a local P-GW)

Contact your Cisco account representative for detailed information on specific licensing requirements.

How Web Authorization Session Logout Works

Architecture

When the subscriber logs out from the web portal or exhausts the quota, the AAA Server initiates a subscription change request to SaMOG. The AAA Server does not include the APN subscription, vIMSI, or NAI information for the session (portal redirection rulebase, ACL name, IP pool name and Gi context names are optionally shared). On receiving the subscription change request without the user identity information, SaMOG verifies if the subscriber session is in post-authentication phase. SaMOG then switches the session back to the pre-authentication phase by initiating an address transfer from the local P-GW (through the VPN manager) to SaMOG, and installing the redirection rules and ACLs. CDRs used during the post-authentication phase are released when the session moves to the pre-authentication phase. New CDRs are used if the session moves back to the post-authentication phase.

The subscriber session will be retained in the pre-authentication phase until the subscriber re-authenticates through the web portal, or the session in the pre-authentication phase timeout period expires. The timeout period can be configured using the `disconnect preauth-wait-time` command under the MRME Configuration Mode.

Limitations

Architectural Limitations

- This feature is currently not support on GTPv1 and PMIPv6 towards P-GW.
- Only AAA Diameter-based authentication is supported. AAA Radius-based authentication is currently not supported.
- Inter-chassis session recovery (ICSR) is currently not supported with this feature.
Flows

Post-authentication to Pre-authentication

The figure below shows the detailed flow for the subscriber session moving from the post-authentication phase to the pre-authentication phase. The table that follows the figure describes each step in the flow.

Figure 36: Post-Authentication to Pre-Authentication Call Flow

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Subscriber session is established using web authorization.</td>
</tr>
<tr>
<td>2</td>
<td>Subscriber logs out from the portal, or exhausts the quota limit for the session.</td>
</tr>
<tr>
<td>Step</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td>3</td>
<td>The Diameter Server initiates an RAR message to SaMOG for the session.</td>
</tr>
<tr>
<td>4</td>
<td>SaMOG responds with an AAR message to the Diameter Server.</td>
</tr>
</tbody>
</table>
| 5    | The Diameter Server initiates the AAA towards SaMOG where,  
|      | • The Diameter Server does not share the user identity (no IMSI or NAI).  
|      | • (optional) Parameters like the redirection rule name, ACL name, IP pool name (IPv4/IPv6)  
|      | and Gi context name are included. |
| 6    | SaMOG receives the subscription change request without the user identity from the AAA Server. If the subscriber session is in the post-authentication phase, SaMOG initiates the process to move the session from post-authentication to pre-authentication phase.  
|      | • If the AAA Server does not share the rule name, ACL name, IP pool name or context name, SaMOG takes these information from the Web authorization profile.  
|      | • SaMOG transfers the user-allocated IP address (IPv4, IPv6, or IPv4v6) from the P-GW to SaMOG through the VPN manager.  
|      | • SaMOG also initiates an ECS session creation with the redirection rule base and ACLs.  
|      | • On receiving the address allocation request, the VPN manager initiates an abort request to the P-GW. |
| 7    | On receiving the abort request from the VPN manager, P-GW sends a Delete Bearer Request (DBR) to SaMOG. |
| 8    | SaMOG responds to the DBR and cleans up the EGTPC/GTPU interfaces. The session, however, is not deleted. |
| 9    | The VPN manager provides the addresses requested by SaMOG. SaMOG initiates a FLOW creation for the IPs, and receives the downlink traffic from the ISP for the UE addresses. |
| 10   | SaMOG switches the session from post-authentication to pre-authentication on receiving the FLOW creation success notification from the NPU manager. |
| 11   | The subscriber is now redirected to the web portal for authorization. Once the subscriber successfully authenticates their identity, pre-authentication to post-authentication procedures are initiated. The AAA Server sends a re-authorization trigger to move the UE back to the post-authentication phase and provide the subscriber with access to the Internet. |
Configuring Web Authorization Session Logout

Configuring the Pre-Authentication Wait Timer

Use the following configuration to configure the timeout for the subscriber’s session after the session moves from the post-authentication phase to the pre-authentication phase:

```
config
    context context_name
    mrme-service service_name
    disconnect preauth-wait-time minutes
end
```

Notes:

- Use the `default disconnect preauth-wait-time` command to restore the configuration to its default value.
- Default: 5 minutes
- `minutes` must be an integer from 1 through 60.

Monitoring and Troubleshooting Web Authorization Session Logout

Show Command(s) and/or Outputs

```
show samog-service statistics
```

The following fields are available to the output of the `show subscribers samog-service statistics` command in support of this feature:

```
MRME Service Stats:
Non-EAP Session Stats:
Post-to-Pre:
    Attempted: 1 Success: 1
    Failure: 0
```

Table 63: `show subscribers samog-service statistics` Command Output Descriptions
