Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Configuring Link Latency

- The controller displays the current round-trip time as well as a running minimum and maximum round-trip time. The minimum and maximum times continue to run as long as the controller is up or can be cleared and allowed to restart.
- You can configure link latency for a specific access point using the controller GUI or CLI or for all access points joined to the controller using the CLI.

Restrictions for Configuring Link Latency

- Link latency calculates the Control and Provisioning of Wireless Access Points (CAPWAP) response time between the access point and the controller. It does not measure network latency or ping responses.

Information About Configuring Link Latency

You can configure link latency on the controller to measure the link between an access point and the controller. You can use this feature with all access points that are joined to the controller where the link can be a slow or unreliable WAN connection.

TCP MSS

If the client's maximum segment size (MSS) in a Transmission Control Protocol (TCP) three-way handshake is greater than the maximum transmission unit can handle, the client might experience reduced throughput and the fragmentation of packets. To avoid this problem, you can specify the MSS for all access points that are joined to the controller or for a specific access point.

When you enable this feature, the access point selects the MSS for TCP packets to and from wireless clients in its data path. If the MSS of these packets is greater than the value that you configured or greater than the default value for the CAPWAP tunnel, the access point changes the MSS to the new configured value.

Link Tests

A link test is used to determine the quality of the radio link between two devices. Two types of link-test packets are transmitted during a link test: request and response. Any radio receiving a link-test request packet fills in the appropriate text boxes and echoes the packet back to the sender with the response type set.

The radio link quality in the client-to-access point direction can differ from that in the access point-to-client direction due to the asymmetrical distribution of the transmit power and receive sensitivity on both sides. Two types of link tests can be performed: a ping test and a CCX link test.

With the *ping link test*, the controller can test link quality only in the client-to-access point direction. The RF parameters of the ping reply packets received by the access point are polled by the controller to determine the client-to-access point link quality.

With the *CCX link test*, the controller can also test the link quality in the access point-to-client direction. The controller issues link-test requests to the client, and the client records the RF parameters (received signal strength indicator [RSSI], signal-to-noise ratio [SNR], and so on) of the received request packet in the response packet. Both the link-test requestor and responder roles are implemented on the access point and controller. Not only can the access point or controller initiate a link test to a CCX v4 or v5 client, but a CCX v4 or v5 client can initiate a link test to the access point or controller.

The controller shows the link-quality metrics for CCX link tests in both directions (out— the access point to the client; in— the client to the access point):

- Signal strength in the form of RSSI (minimum, maximum, and average)
- Signal quality in the form of SNR (minimum, maximum, and average)

- Total number of packets that are retried
- Maximum retry count for a single packet
- Number of lost packets
- Data rate of a successfully transmitted packet

The controller shows this metric regardless of direction:

- Link test request/reply round-trip time (minimum, maximum, and average)

The controller software supports CCX versions 1 through 5. CCX support is enabled automatically for every WLAN on the controller and cannot be disabled. The controller stores the CCX version of the client in its client database and uses it to limit the features for this client. If a client does not support CCXv4 or v5, the controller performs a ping link test on the client. If a client supports CCXv4 or v5, the controller performs a CCX link test on the client. If a client times out during a CCX link test, the controller switches to the ping link test automatically.

How to Configure Link Latency

Configuring Link Latency (CLI)

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ap link-latency**
4. **ap tcp-adjust-mss size *size***
5. **show ap name *Cisco_AP* config general**
6. **ap name *Cisco_AP* link-latency [reset]**
7. **show ap name *Cisco_AP* config general**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Controller# enable	Enters privileged EXEC mode.
Step 2	configure terminal Example: Controller# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 3	ap link-latency Example: <pre>Controller(config)# ap link-latency</pre>	<p>Enables link latency for all access points that are currently associated with the controller.</p> <p>Note To disable link latency for all the access points that are associated with the controller, use the no ap link-latency command.</p> <p>Note These commands enable or disable link latency only for access points that are currently joined to the controller. You have to enable or disable link latency for the access points that join in the future.</p> <p>Note To enable or disable link latency for specific access points that are associated with the controller, enter the following commands in Privileged EXEC mode:</p> <ul style="list-style-type: none"> • ap name Cisco_AP link-latency—Enables link latency. • ap name Cisco_AP no link-latency—Disables link latency.
Step 4	ap tcp-adjust-mss size size Example: <pre>Controller(config)# ap tcp-adjust-mss size 537</pre>	Configures TCP MSS adjust size for all access points. The range is from 536 to 1363.
Step 5	show ap name Cisco_AP config general Example: <pre>Controller(config)# show ap name AP02 config general</pre>	<p>Displays the general configuration details of the access point. These configuration details contain the link latency results that correspond to the access point that you specify in the command.</p> <p>The output of this command contains the following link latency results:</p> <ul style="list-style-type: none"> • Current Delay—The current round-trip time (in milliseconds) of CAPWAP heartbeat packets from the access point to the controller and back. • Maximum Delay—Since the time that link latency has been enabled or reset, the maximum round-trip time (in milliseconds) of CAPWAP heartbeat packets from the access point to the controller and back. • Minimum Delay—Since the time that link latency has been enabled or reset, the minimum round-trip time (in milliseconds) of CAPWAP heartbeat packets from the access point to the controller and back.
Step 6	ap name Cisco_AP link-latency [reset] Example: <pre>Controller(config)# ap name AP02 link-latency reset</pre>	Clears the current, minimum, and maximum link latency statistics on the controller for a specific access point.
Step 7	show ap name Cisco_AP config general Example: <pre>Controller(config)# show ap name AP02 config general</pre>	Displays the general configuration details of the access point. Use this command to see the result of the reset operation.

Configuring Link Latency (GUI)

-
- Step 1** Choose **Configuration > Wireless > Access Points > All APs**.
The **All APs** page appears with a list of access points.
- Step 2** Click the name of the access point.
The **AP > Edit** page appears.
- Step 3** Click the **Advanced** tab.
- Step 4** In the **Link Latency** area, select or unselect the **Enable Link Latency** check box.
Note You can select the **Enable Link Latency** check box to enable link latency for this access point or unselect it to prevent the access point from sending the round-trip time to the controller after every echo response is received. The default state is unselected.
- Step 5** Click **Apply**.
- Step 6** When a message box appears that indicates that AP Parameters are modified successfully, click **OK**.
- Step 7** When the **All APs** page is displayed, click the access point that you have modified earlier.
The **AP > Edit** page appears.
- Step 8** Click the **Advanced** tab.
In the **Link Latency** area, the following link latency and data latency results are displayed:
- **Current(mSec)**—The current round-trip time (in milliseconds) of CAPWAP heartbeat packets or data packets from the access point to the controller and back.
 - **Minimum(mSec)**—Since the time that link latency has been enabled or reset, the minimum round-trip time (in milliseconds) of CAPWAP heartbeat packets or data packets from the access point to the controller and back.
 - **Maximum(mSec)**—Since the time that link latency has been enabled or reset, the maximum round-trip time (in milliseconds) of CAPWAP heartbeat packets or data packets from the access point to the controller and back.
- Step 9** Click **Reset Link Latency** to clear the current, minimum, and maximum link latency and data latency statistics on the controller for this access point.
Note After the page refreshes and the **All APs** page is displayed again, click the **Advanced** tab. The updated statistics appear in the **Minimum** and **Maximum** text boxes.
-

How to Configure TCP MSS

Configuring TCP MSS (CLI)

SUMMARY STEPS

1. `configure terminal`
2. `ap tcp-adjust-mss size size_value`
3. `reload`
4. `show ap tcp-adjust-mss`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<code>configure terminal</code> Example: <code>Controller# configure terminal</code>	Enters global configuration mode.
Step 2	<code>ap tcp-adjust-mss size <i>size_value</i></code> Example: <code>Controller(config)# ap tcp-adjust-mss size 537</code>	Enables the TCP MSS on the particular access point that you specify. Note To enable TCP MSS on all the access points that are associated with the controller, enter the <code>ap tcp-adjust-mss size <i>size_value</i></code> command, where the size parameter is from 536 to 1363 bytes. The default value varies for different clients.
Step 3	<code>reload</code> Example: <code>Controller# reload</code>	Reboots the controller in order for your change to take effect.
Step 4	<code>show ap tcp-adjust-mss</code> Example: <code>Controller# show ap tcp-adjust-mss</code>	Displays the current TCP MSS setting for all the access points that are associated with the controller. Note To display the TCP MSS settings that correspond to a specific access point, enter the <code>show ap name <i>Cisco_AP</i> tcp-adjust-mss</code> command.

Configuring TCP MSS (GUI)

- Step 1** Choose **Configuration > Wireless > Access Points > Global AP Configuration**.

The **Global Configuration** page is displayed.

- Step 2** In the **TCP MSS** area, select the **Global TCP Adjust MSS** check box and set the MSS for all access points that are associated with the controller. The valid range is from 536 to 1363 bytes.
- Step 3** Click **Apply**.
- Step 4** Click **Save Configuration**.

Performing a Link Test (CLI)

Note

The procedure to perform this task using the controller GUI is not currently available.

SUMMARY STEPS

1. **test wireless linktest** *mac_address*
2. **configure terminal**
3. **wireless linktest frame-size** *frame_size*
4. **wireless linktest number-of-frames** *number_of_frames*
5. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	test wireless linktest <i>mac_address</i> Example: Controller# test wireless linktest 00:0d:88:c5:8a:d1	Runs a link test.
Step 2	configure terminal Example: Controller# configure terminal	Enters global configuration mode.
Step 3	wireless linktest frame-size <i>frame_size</i> Example: Controller(config)# wireless linktest frame-size 41	Configures the link test frame size for each packet.
Step 4	wireless linktest number-of-frames <i>number_of_frames</i> Example: Controller(config)# wireless linktest number-of-frames 50	Configures the number of frames to send for the link test.

	Command or Action	Purpose
Step 5	end Example: Controller(config)# end	Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Configuration Examples for Configuring Link Latency

Running a Link Test: Example

This example shows how to run a link test:

```

Controller# test wireless linktest 6470.0227.ca55
Controller# show wireless linktest statistic

Link Test to 64700227CA55 with 500 frame-size.
Client MAC Address           : 6470.0227.ca55
AP Mac Address               : 44e4.d901.19c0
Link Test Packets Sent       : 20
Link Test Packets Received   : 20
Link Test Pkts Lost(Total/AP->Clnt/Clnt->AP) : 0/0/0
Link Test Pkts round trip time (min/max/avg) : 9ms/31ms/14ms
RSSI at AP (min/max/average) : -53dBm/-51dBm/-52dBm
RSSI at Client (min/max/average) : -48dBm/-40dBm/-44dBm

```

Displaying Link Latency Information: Example

This example shows how to display general configuration details of the access point. These configuration details contain the link latency results that correspond to the access point that you specify in the command.

```

Controller# show ap name AP01 config general

Cisco AP Name                : AP01
Cisco AP Identifier          : 55

Displaying TCP MSS Settings: Example

This example shows how to display the current TCP MSS setting for all the access points that are associated with the controller:

```
Controller# show ap tcp-adjust-mss
```

AP Name	TCP State	MSS Size
AP01	Disabled	6146
AP02	Disabled	536
AP03	Disabled	6146
AP04	Disabled	6146
AP05	Disabled	6146
