Protected Management Frames (Management Frame Protection)

By default, 802.11 management frames are unauthenticated and hence not protected against spoofing. Infrastructure management frame protection (MFP) and 802.11w protected management frames (PMF) provide protection against such attacks.

Infrastructure MFP

Infrastructure MFP protects management frames by detecting adversaries that are invoking denial-of-service attacks, flooding the network with associations and probes, interjecting as rogue APs, and affecting network performance by attacking the QoS and radio measurement frames. Infrastructure MFP is a global setting that provides a quick and effective means to detect and report phishing incidents.

Specifically, infrastructure MFP protects 802.11 session management functions by adding message integrity check information elements (MIC IEs) to the management frames emitted by APs (and not those emitted by clients), which are then validated by other APs in the network. Infrastructure MFP is passive, can detect and report intrusions but has no means to stop them.

Infrastructure MFP consists of three main components:

- **Management frame protection**: The AP protects the management frames it transmits by adding a MIC IE to each frame. Any attempt to copy, alter, or replay the frame invalidates the MIC, causing any receiving AP configured to detect MFP frames to report the discrepancy. MFP is supported for use with Cisco Aironet lightweight APs.

- **Management frame validation**: In infrastructure MFP, the AP validates every management frame that it receives from other APs in the network. It ensures that the MIC IE is present (when the originator is configured to transmit MFP frames) and matches the content of the management frame. If it receives any frame that does not contain a valid MIC IE from a BSSID belonging to an AP that is configured to
transmit MFP frames, it reports the discrepancy to the network management system. In order for the
timestamps to operate properly, all controllers must be Network Time Protocol (NTP) synchronized.

• **Event reporting:** The AP notifies the controller when it detects an anomaly, and the controller aggregates
the received anomaly events and can report the results through SNMP traps to the network management
system.

Infrastructure MFP is disabled by default, and you can enable it globally. When you upgrade from a previous
software release, infrastructure MFP is disabled globally if you have enabled AP authentication because the
two features are mutually exclusive. When you enable infrastructure MFP globally, signature generation
(adding MICs to outbound frames) can be disabled for selected WLANs, and validation can be disabled for
selected APs.

---

**Note**

CCXv5 client MFP is no longer supported. Client MFP is enabled as optional by default on WLANs that are
configured for WPA2. However, client MFP is not supported on Wave 2 APs or 802.11ax Wi-Fi6 APs, and
there exist no clients that support CCXv5.

---

**802.11w PMF**

802.11w standard protects the transmission of control and management frames, between APs and clients,
against forgery and replay attacks. The frame types protected include Disassociation, Deauthentication, and
Robust Action frames such as:

- Spectrum Management
- Quality of Service (QoS)
- Block Ack
- Radio measurement
- Fast Basic Service Set (BSS) Transition

For information about 802.11w PMF, see the **802.11w** section.

This section contains the following subsections:

---

### Configuring Infrastructure MFP (GUI)

**Procedure**

**Step 1** Choose **Security > Wireless Protection Policies > AP Authentication/MFP** to open the AP Authentication
Policy page.

**Step 2** Enable infrastructure MFP globally for the controller by choosing **Management Frame Protection** from the
**Protection Type** drop-down list.

**Step 3** Click **Apply** to commit your changes.
If more than one controller is included in the mobility group, you must configure an NTP/SNTP server on all controllers in the mobility group that are configured for infrastructure MFP.

**Note**

Configure client MFP for a particular WLAN after infrastructure MFP has been enabled globally for the controller as follows:

a) Choose **WLANs**.
b) Click the profile name of the desired **WLAN**. The **WLANs > Edit** page appears.
c) Choose **Advanced**. The **WLANs > Edit (Advanced)** page is displayed.
d) From the **MFP Client Protection** drop-down list, choose **Disabled**, **Optional**, or **Required**. The default value is **Optional**. If you choose **Required**, clients are allowed to associate only if MFP is negotiated (that is, if WPA2 is configured on the controller and the client supports CCXv5 MFP and is also configured for WPA2).
e) Click **Apply** to commit your changes.

**Step 5**

Save the configuration.

**Viewing the Management Frame Protection Settings (GUI)**

To see the controller’s current global MFP settings, choose **Security > Wireless Protection Policies > Management Frame Protection**. The Management Frame Protection Settings page appears.

On this page, you can see the following MFP settings:

- The **Management Frame Protection** field shows if infrastructure MFP is enabled globally for the controller.

- The **Controller Time Source Valid** field indicates whether the controller time is set locally (by manually entering the time) or through an external source (such as the NTP/SNTP server). If the time is set by an external source, the value of this field is “True.” If the time is set locally, the value is “False.” The time source is used for validating the timestamp on management frames between access points of different controllers within a mobility group.

- The **Client Protection** field shows if client MFP is enabled for individual WLANs and whether it is optional or required.

---

**Configuring Infrastructure MFP (CLI)**

**Procedure**

- Enable or disable infrastructure MFP globally for the controller by entering this command:

  ```
  config wps mfp infrastructure {enable | disable}
  ```

- Enable or disable client MFP on a specific WLAN by entering this command:

  ```
  config wlan mfp client {enable | disable} wlan_id [required ]
  ```

  If you enable client MFP and use the optional **required** parameter, clients are allowed to associate only if MFP is negotiated.

Configuring 802.11w (CLI)

Viewing the Management Frame Protection Settings (CLI)

Procedure

• See the controller’s current MFP settings by entering this command:
  
  `show wps mfp summary`

• See the current MFP configuration for a particular WLAN by entering this command:
  
  `show wlan wlan_id`

• See whether client MFP is enabled for a specific client by entering this command:
  
  `show client detail client_mac`

• See MFP statistics for the controller by entering this command:
  
  `show wps mfp statistics`

Note

This report contains no data unless an active attack is in progress. This table is cleared every 5 minutes when the data is forwarded to any network management stations.

Debugging Management Frame Protection Issues (CLI)

Procedure

• Use this command if you experience any problems with MFP:
  
  `debug wps mfp ? {enable | disable}`

where ? is one of the following:

  - `client`—Configures debugging for client MFP messages.
  - `capwap`—Configures debugging for MFP messages between the controller and access points.
  - `detail`—Configures detailed debugging for MFP messages.
  - `report`—Configures debugging for MFP reporting.
  - `mm`—Configures debugging for MFP mobility (inter-controller) messages.

Client Exclusion Policies

This section contains the following subsections:
Configuring Client Exclusion Policies (GUI)

Procedure

**Step 1** Choose Security > Wireless Protection Policies > Client Exclusion Policies to open the Client Exclusion Policies page.

**Step 2** Select any of these check boxes if you want the controller to exclude clients for the condition specified. The default value for each exclusion policy is enabled.

- **Excessive 802.11 Association Failures**—Clients are excluded on the sixth 802.11 association attempt, after five consecutive failures.
- **Excessive 802.11 Authentication Failures**—Clients are excluded on the sixth 802.11 authentication attempt, after five consecutive failures.
- **Excessive 802.1X Authentication Failures**—Clients are excluded on the fourth 802.1X authentication attempt, after three consecutive failures.
- **IP Theft or IP Reuse**—Clients are excluded if the IP address is already assigned to another device.
- **Excessive Web Authentication Failures**—Clients are excluded on the fourth web authentication attempt, after three consecutive failures.

**Step 3** Save your configuration.

Configuring Client Exclusion Policies (CLI)

Procedure

**Step 1** Enable or disable the controller to exclude clients on the sixth 802.11 association attempt, after five consecutive failures by entering this command:

```
config wps client-exclusion 802.11-assoc {enable | disable}
```

**Step 2** Enable or disable the controller to exclude clients on the sixth 802.11 authentication attempt, after five consecutive failures by entering this command:

```
config wps client-exclusion 802.11-auth {enable | disable}
```

**Step 3** Enable or disable the controller to exclude clients on the fourth 802.1X authentication attempt, after three consecutive failures by entering this command:

```
config wps client-exclusion 802.1x-auth {enable | disable}
```

**Step 4** Configure the controller to exclude clients that reaches the maximum failure 802.1X authentication attempt with the RADIUS server by entering this command:

```
config wps client-exclusion 802.1x-auth max-1x-aaa-fail-attempts
```

You can configure the maximum failure 802.1X authentication attempt from 1 to 3 and the default value is 3.

**Step 5** Enable or disable the controller to exclude clients if the IP address is already assigned to another device by entering this command:

```
```
config wps client-exclusion ip-theft {enable | disable}

**Step 6**
Enable or disable the controller to exclude clients on the fourth web authentication attempt, after three consecutive failures by entering this command:

```
config wps client-exclusion web-auth {enable | disable}
```

**Step 7**
Enable or disable the controller to exclude clients for all of the above reasons by entering this command:

```
config wps client-exclusion all {enable | disable}
```

**Step 8**
Use the following command to add or delete client exclusion entries.

```
config exclusionlist {add mac-addr description | delete mac-addr | description mac-addr description}
```

**Step 9**
Save your changes by entering this command:

```
save config
```

**Step 10**
See a list of clients that have been dynamically excluded, by entering this command:

```
show exclusionlist
```

Information similar to the following appears:

```
Dynamically Disabled Clients
--------------------------------
 MAC Address  Exclusion Reason Time Remaining (in secs)  
--------------  ----------------- ------------------------
00:40:96:b4:82:55  802.1X Failure  51
```

**Step 11**
See the client exclusion policy configuration settings by entering this command:

```
show wps summary
```

Information similar to the following appears:

```
Auto-Immune
 Auto-Immune............................ Disabled

Client Exclusion Policy
 Excessive 802.11-association failures.......... Enabled
 Excessive 802.11-authentication failures....... Enabled
 Excessive 802.1x-authentication................ Enabled
 IP-theft.................................. Enabled
 Excessive Web authentication failure.......... Enabled
 Maximum 802.1x-AAA failure attempts.......... 3

Signature Policy
 Signature Processing......................... Enabled
```

**Rogue Devices**

Rogue access points can disrupt wireless LAN operations by hijacking legitimate clients and using plain-text or other denial-of-service or man-in-the-middle attacks. That is, a hacker can use a rogue access point to capture sensitive information, such as usernames and passwords. The hacker can then transmit a series of Clear to Send (CTS) frames. This action mimics an access point, informing a particular client to transmit, and instructing all the other clients to wait, which results in legitimate clients being unable to access network...
resources. Wireless LAN service providers have a strong interest in banning rogue access points from the air space.

Because rogue access points are inexpensive and readily available, employees sometimes plug unauthorized rogue access points into existing LANs and build ad hoc wireless networks without their IT department's knowledge or consent. These rogue access points can be a serious breach of network security because they can be plugged into a network port behind the corporate firewall. Because employees generally do not enable any security settings on the rogue access point, it is easy for unauthorized users to use the access point to intercept network traffic and hijack client sessions. There is an increased chance of enterprise security breach when wireless users connect to access points in the enterprise network.

The following are some guidelines to manage rogue devices:

• The containment frames are sent immediately after the authorization and associations are detected. The enhanced containment algorithm provides more effective containment of ad hoc clients.

• In a dense RF environment, where maximum rogue access points are suspected, the chances of detecting rogue access points by a local mode access point and FlexConnect mode access point in channel 157 or channel 161 are less when compared to other channels. To mitigate this problem, we recommend that you use dedicated monitor mode access points.

• The local and FlexConnect mode access points are designed to serve associated clients. These access points spend relatively less time performing off-channel scanning: about 50 milliseconds on each channel. If you want to perform high rogue detection, a monitor mode access point must be used. Alternatively, you can reduce the scan intervals from 180 seconds to a lesser value, for example, 120 or 60 seconds, ensuring that the radio goes off-channel more frequently, which improves the chances of rogue detection. However, the access point continues to spend about 50 milliseconds on each channel.

• Rogue detection is disabled by default for OfficeExtend access points because these access points, which are deployed in a home environment, are likely to detect many rogue devices.

• Client card implementations might mitigate the effectiveness of ad hoc containment.

• It is possible to classify and report rogue access points by using rogue states and user-defined classification rules that enable rogues to automatically move between states.

• Each controller limits the number of rogue containments to three per radio (or six per radio for access points in the monitor mode).

• Rogue Location Discovery Protocol (RLDP) detects rogue access points that are configured for open authentication.

• RLDP detects rogue access points that use a broadcast Basic Service Set Identifier (BSSID), that is, the access point broadcasts its Service Set Identifier in beacons.

• RLDP detects only those rogue access points that are on the same network. If an access list in the network prevents the sending of RLDP traffic from the rogue access point to the controller, RLDP does not work.

• RLDP does not work on 5-GHz Dynamic Frequency Selection (DFS) channels. However, RLDP works when the managed access point is in the monitor mode on a DFS channel.

• If RLDP is enabled on mesh APs, and the APs perform RLDP tasks, the mesh APs are dissociated from the controller. The workaround is to disable RLDP on mesh APs.

• If RLDP is enabled on non-monitor APs, client connectivity outages occur when RLDP is in process.

• If the rogue is manually contained, the rogue entry is retained even after the rogue expires.
• If the rogue is contained by any other means, such as auto, rule, and AwIPS prevention, the rogue entry is deleted when it expires.

• The controller requests to the AAA server for rogue client validation only once. As a result, if rogue client validation fails on the first attempt then the rogue client will not be detected as a threat any more. To avoid this, add the valid client entries in the authentication server before enabling Validate Rogue Clients Against AAA.

• The controller has to be added to the AAA server as a AAA client with authentication as RADIUS(CISCO IOS/PIX 6.0). Add the rogue AP in question to the user database with relevant delimiter, username, and password being the MAC address with relevant delimiter. You must define the [009:001] cisco-av-pair for this user with the following keywords:
  * rogue-ap-state=contain—Where, rogue-ap-state can be the following: alert/contain/internal/external/threat
  * rogue-ap-class=malicious—Where, rogue-ap-class can be following keywords: unclassified/malicious/friendly

The allowed combinations of class/state are:
  * unclassified—alert/contain/threat
  * malicious—alert/contain/threat
  * friendly—alert/internal/external

• All the valid client MAC details should be registered in the AAA authentication server with the same MAC delimiter options as set in the RADIUS configuration on the controller. For more information about configuring MAC delimiter options, see the Configuring RADIUS (GUI) section.

• In the 7.4 and earlier releases, if a rogue that was already classified by a rule was not reclassified. In the 7.5 release, this behavior is enhanced to allow reclassification of rogues based on the priority of the rogue rule. The priority is determined by using the rogue report that is received by the controller.

• All rogues that are marked as friendly or contained state (due to auto or rule or manual) are stored in the flash memory of the controller. When you reboot the controller loaded with Release 7.4, these rogues are shown as manually changed. If you wish to reboot the controller, you need to clear all rogue APs and rogue adhoc from the controller, save the configuration, and then reboot the controller.

• All rogues that are marked as friendly or contained state (only due to manual) are stored in the flash memory of the controller. If you upgrade the controller from the Release 7.4 to 7.6 or later versions, then all rogues stored in the Release 7.4 are shown as manually classified (if friendly classified) or manually contained. Hence after upgrading the controller from the Release 7.4 to 7.6 or later versions, you need to delete all rogue APs and rogue adhoc from the controller and then start configuring rogue detection.

• A FlexConnect AP (with rogue detection enabled) in the connected mode takes the containment list from the controller. If auto-contain SSID and auto contain adhoc are set in the controller, then these configurations are set to all FlexConnect APs in the connected mode and the AP stores it in its memory. When the FlexConnect AP moves to a standalone mode, the following tasks are performed:
  * The containment set by the controller continues.
• If the FlexConnect AP detects any rogue AP that has same SSID as that of infra SSID (SSID configured in the controller that the FlexConnect AP is connected to), then containment gets started if auto contain SSID was enabled from the controller before moving to the standalone mode.

• If the FlexConnect AP detects any adhoc rogue, containment gets started if auto-contain adhoc was enabled from the controller when it was in the connected mode.

When the standalone FlexConnect AP moves back to the connected mode, then the following tasks are performed:

• All containment gets cleared.

• Containment initiated from the controller will take over.

• The rogue detector AP fails to co-relate and contain the wired rogue AP on a 5Mhz channel because the MAC address of the rogue AP for WLAN, LAN, 11a radio and 11bg radio are configured with a difference of +/-1 of the rogue BSSID. In the 8.0 release, this behavior is enhanced by increasing the range of MAC address, that the rogue detector AP co-relates the wired ARP MAC and rogue BSSID, by +/-3.

• The rogue access points with open authentication can be detected on wire. The NAT wired or rogue wired detection is not supported in by WLC (both RLDP and rogue detector AP). The non-adjacent MAC address is supported by rogue detector mode of AP and not by RLDP.

• In a High Availability scenario, if the rogue detection security level is set to either High or Critical, the rogue timer on the standby controller starts only after the rogue detection pending stabilization time, which is 300 seconds. Therefore, the active configurations on the standby controller are reflected only after 300 seconds.

• After an AP is moved from rogue detection mode to any other mode or after an AP is moved from sniffer mode to local or monitor mode, the rogue detection functionality is not retained on the AP. To enable rogue detection functionality on the AP, you have to explicitly move the AP to the rogue detection mode.

• Some rogue devices exhibit RSSI value of –128 dBm although the minimum RSSI has seen configured to a higher value. In some scenarios, APs show the RSSI value of 0 for some rogue devices. If the controller receives the RSSI value as 0, the controller invalidates the value and replaces it with –128 dBm so that rogue rules or policies are not applied to the rogue device.

• Even though rogue events are reported to Cisco DNA Center instantly, due to a big number of rogue events, the rogue sync occurs only on detection, on moving to contained state, and every half hour. The rogue sync does not occur for any other rogue event.

---

**Note**
A rogue AP or client or adhoc containment configuration is not saved after the reload. You have to configure all the rogues again after the reload.

**Note**
No separate command exists for controlling rogue client traps. However, you can enable or disable rogue client traps using the `config trapflags rogueap {enable | disable}` command, which is also used for rouge APs. In GUI configuration also, you should use the rogue AP flag under Management > SNMP > TrapControl > Security > Rogue AP to control rogue clients.
Restrictions on Rogue Detection

- Rogue containment is not supported on DFS channels.

Rogue Location Discovery Protocol

Rogue Location Discovery Protocol (RLDP) is an active approach, which is used when rogue AP has no authentication (Open Authentication) configured. This mode, which is disabled by default, instructs an active AP to move to the rogue channel and connect to the rogue as a client. During this time, the active AP sends de-authentication messages to all connected clients and then shuts down the radio interface. Then, it associates to the rogue AP as a client. The AP then tries to obtain an IP address from the rogue AP and forwards a User Datagram Protocol (UDP) packet (port 6352) that contains the local AP and rogue connection information to the controller through the rogue AP. If the controller receives this packet, the alarm is set to notify the network administrator that a rogue AP was discovered on the wired network with the RLDP feature.

RLDP has 100% accuracy in rogue AP detection. It detects Open APs and NAT APs.

Note

Use the `debug dot11 rldp enable` command in order to check if the Lightweight AP associates and receives a DHCP address from the rogue AP. This command also displays the UDP packet sent by the Lightweight AP to the controller.

A sample of a UDP (destination port 6352) packet sent by the Lightweight AP is shown here:

```
0020 0a 01 01 0d 0a 01 .......(*)...... 0030 01 1e 00 07 85 92 78 01 00 00 00 00 00 00 00 .......x......... 0040 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00
```

The first 5 bytes of the data contain the DHCP address given to the local mode AP by the rogue AP. The next 5 bytes are the IP address of the controller, followed by 6 bytes that represent the rogue AP MAC address. Then, there are 18 bytes of zeroes.

The following steps describe the functioning of RLDP:

1. Identify the closest Unified AP to the rogue using signal strength values.
2. The AP then connects to the rogue as a WLAN client, attempting three associations before timing out.
3. If association is successful, the AP then uses DHCP to obtain an IP address.
4. If an IP address was obtained, the AP (acting as a WLAN client) sends a UDP packet to each of the controller’s IP addresses.
5. If the controller receives even one of the RLDP packets from the client, that rogue is marked as on-wire.

Note

The RLDP packets are unable to reach the controller if filtering rules are placed between the controller’s network and the network where the rogue device is located.

Restrictions for RLDP:

- RLDP only works with open rogue APs broadcasting their SSID with authentication and encryption disabled.
- RLDP requires that the Managed AP acting as a client is able to obtain an IP address via DHCP on the rogue network.
• Manual RLDP can be used to attempt an RLDP trace on a rogue multiple number of times.

• During RLDP process, the AP is unable to serve clients. This negatively impacts performance and connectivity for local mode APs. To avoid this case, RLDP can be selectively enabled for Monitor Mode AP only.

• RLDP does not attempt to connect to a rogue AP operating in a 5GHz DFS channel.

• RLDP is not supported for use with Cisco autonomous rogue access points. These access points drop the DHCP Discover request sent by the RLDP client. Also, RLDP is not supported if the rogue access point channel requires dynamic frequency selection (DFS). If the automatic RLDP attempt does not detect the rogue (due to a noisy RF environment, for example), the controller does not retry. However, you can initiate RLDP manually on a rogue device.

Detecting Rogue Devices
The controller continuously monitors all the nearby access points and automatically discovers and collects information on rogue access points and clients. When the controller discovers a rogue access point, it uses the Rogue Location Discovery Protocol (RLDP) and the rogue detector mode access point is connected to determine if the rogue is attached to your network.

Controller initiates RLDP on rogue devices that have open authenticated and configured. If RLDP uses FlexConnect or local mode access points, then clients are disconnected for that moment. After the RLDP cycle, the clients are reconnected to the access points. As and when rogue access points are seen (auto-configuration), the RLDP process is initiated.

You can configure the controller to use RLDP on all the access points or only on the access points configured for the monitor (listen-only) mode. The latter option facilitates automated rogue access point detection in a crowded radio frequency (RF) space, allowing monitoring without creating unnecessary interference and without affecting the regular data access point functionality. If you configure the controller to use RLDP on all the access points, the controller always chooses the monitor access point for RLDP operation if a monitor access point and a local (data) access point are both nearby. If RLDP determines that the rogue is on your network, you can choose to contain the detected rogue either manually or automatically.

RLDP detects on wire presence of the rogue access points that are configured with open authentication only once, which is the default retry configuration. Retries can be configured using the `config rogue ap rldp retries` command.

You can initiate or trigger RLDP from controller in three ways:

1. Enter the RLDP initiation command manually from the controller CLI. The equivalent GUI option for initiating RLDP is not supported.

   `config rogue ap rldp initiate mac-address`

2. Schedule RLDP from the controller CLI. The equivalent GUI option for scheduling RLDP is not supported.

   `config rogue ap rldp schedule`

3. Auto RLDP. You can configure auto RLDP on controller either from controller CLI or GUI but keep in mind the following guidelines:

   • The auto RLDP option can be configured only when the rogue detection security level is set to custom.

   • Either auto RLDP or schedule of RLDP can be enabled at a time.
A rogue access point is moved to a contained state either automatically or manually. The controller selects the best available access point for containment and pushes the information to the access point. The access point stores the list of containments per radio. For auto containment, you can configure the controller to use only the monitor mode access point. The containment operation occurs in the following two ways:

- The container access point goes through the list of containments periodically and sends unicast containment frames. For rogue access point containment, the frames are sent only if a rogue client is associated.
- Whenever a contained rogue activity is detected, containment frames are transmitted.

Individual rogue containment involves sending a sequence of unicast disassociation and deauthentication frames.

**Cisco Prime Infrastructure Interaction and Rogue Detection**

Cisco Prime Infrastructure supports rule-based classification and uses the classification rules configured on the controller. The controller sends traps to Cisco Prime Infrastructure after the following events:

- If an unknown access point moves to the Friendly state for the first time, the controller sends a trap to Cisco Prime Infrastructure only if the rogue state is Alert. It does not send a trap if the rogue state is Internal or External.
- If a rogue entry is removed after the timeout expires, the controller sends a trap to Cisco Prime Infrastructure for rogue access points that are categorized as Malicious (Alert, Threat) or Unclassified (Alert). The controller does not remove rogue entries with the following rogue states: Contained, Contained Pending, Internal, and External.

This section contains the following subsections:

**Configuring Rogue Detection (GUI)**

**Procedure**

**Step 1**  
Make sure that rogue detection is enabled on the corresponding access points. Rogue detection is enabled by default for all access points joined to the controller (except for OfficeExtend access points). However, you can enable or disable rogue detection for individual access points by selecting or unselecting the Rogue Detection check box on the All APs > Details for (Advanced) page.

**Step 2**  
The Rogue Policies page is displayed.

**Step 3**  
Choose the Rogue Detection Security Level from the following options:

- **Low**—Basic rogue detection for small-scale deployments.
- **High**—Basic rogue detection with auto containment for medium-scale deployments.
- **Critical**—Basic rogue detection with auto containment and RLDP for highly sensitive deployments.
- **Custom**

**Note**  
For auto RLDP, set the security level to Custom mode. Do not enable scheduling for RLDP even in the Custom mode.

**Step 4**  
Choose one of the following options from the Rogue Location Discovery Protocol drop-down list:
• **Disable**—Disables RLDP on all the access points. This is the default value.
• **All APs**—Enables RLDP on all the access points.
• **Monitor Mode APs**—Enables RLDP only on the access points in the monitor mode.

**Step 5**

In the **Expiration Timeout for Rogue AP and Rogue Client Entries** text box, enter the number of seconds after which the rogue access point and client entries expire and are removed from the list. The valid range is 240 to 3600 seconds, and the default value is 1200 seconds.

**Note**  If a rogue access point or client entry times out, it is removed from the controller only if its rogue state is Alert or Threat for any classification type.

**Step 6**

To use the AAA server or local database to validate if rogue clients are valid clients, select the **Validate Rogue Clients Against AAA** check box. By default, the check box is unselected.

**Note**  To validate a rogue client against AAA, the format of the Cisco AVP pair is mandatory. The free RADIUS format is:

- e09d3166fb2c Cleartext-Password := "e09d3166fb2c"
- Cisco-AVPair := "rogue-ap-state=threat"

**Step 7**

To use the Cisco Mobility Services Engine (MSE) that has the rogue client details to validate the clients, select the **Validate Rogue Clients Against MSE** check box.

MSE responds with information about whether the rogue client is a valid learned client or not. The controller can contain or consider the rogue client as a threat.

**Step 8**

If necessary, select the **Detect and Report Ad-Hoc Networks** check box to enable ad hoc rogue detection and reporting. By default, the check box is selected.

**Step 9**

In the **Rogue Detection Report Interval** text box, enter the time interval, in seconds, at which APs send the rogue detection report to the Cisco WLC. The valid range is 10 to 300 seconds, and the default value is 10 seconds.

**Note**  The minimum value of 10 seconds is applicable only to APs in monitor mode. For the APs in Local mode, the minimum interval value that you can set is 30 seconds.

**Step 10**

In the **Rogue Detection Minimum RSSI** text box, enter the minimum Received Signal Strength Indicator (RSSI) value for APs to detect the rogue and for a rogue entry to be created in the controller. The valid range is −128 dBm to −0 dBm, and the default value is 0 dBm.

**Note**  This feature is applicable to all the AP modes. There can be many rogues with weak RSSI values that do not provide any valuable information in rogue analysis. Therefore, you can use this option to filter rogues by specifying the minimum RSSI value at which APs detect rogues.

**Step 11**

In the **Rogue Detection Transient Interval** text box, enter the time interval at which a rogue should be scanned for by the AP after the first time the rogue is scanned. After the rogue is scanned for consistently, updates are sent periodically to the controller. Thus, the APs filter the transient rogues, which are active for a short period and are then silent. The valid range is between 120 to 1800 seconds, and the default value is 0.

The rogue detection transient interval is applicable to the monitor mode APs only.

This feature has the following advantages:

- Rogue reports from APs to the controller are shorter.
• Transient rogue entries are avoided in the controller.
• Unnecessary memory allocation for transient rogues is avoided.

**Step 12**
In the **Rogue Client Threshold** text box, enter the threshold value. A value of 0 disables the rogue client threshold parameter.

**Step 13**
Enable or disable the **Rogue Containment Automatic Rate Selection** check box.

Using this option, you can optimize the rate to use the best rate for the target rogue. The AP selects the best rate based on rogue RSSI.

**Step 14**
If you want the controller to automatically contain certain rogue devices, enable the following parameters. By default, these parameters are in disabled state.

**Caution**
When you select any of the Auto Contain parameters and click **Apply**, the following message is displayed: “Using this feature may have legal consequences. Do you want to continue?” The 2.4-GHz and 5-GHz frequencies in the Industrial, Scientific, and Medical (ISM) band are open to the public and can be used without a license. As such, containing devices on another party’s network could have legal consequences.

• **Auto Containment Level**—Set the auto containment level. By default, the auto containment level is set to 1.

  If you choose **Auto**, the controller dynamically chooses the number of APs required for effective containment.

• **Auto Containment only for Monitor mode APs**—Configure the monitor mode access points for auto-containment.

• **Auto Containment on FlexConnect Standalone**—Configure the FlexConnect Standalone mode access points for auto containment.

  **Note**
  The auto-containment is continued if it was configured when the AP was in connected FlexConnect mode. After the standalone AP reassociates with the controller, auto containment is stopped. The configuration on the controller the AP is associated with determines the future course of action. You can also configure auto containment on the ad hoc SSIDs and managed SSIDs on FlexConnect APs.

• **Rogue on Wire**—Configure the auto containment of rogues that are detected on the wired network.

• **Using Our SSID**—Configure the auto containment of rogues that are advertising your network’s SSID.

  If you leave this parameter unselected, the controller only generates an alarm when such a rogue is detected.

• **Valid Client on Rogue AP**—Configure the auto containment of a rogue access point to which trusted clients are associated. If you leave this parameter unselected, the controller only generates an alarm when such a rogue is detected.

• **AdHoc Rogue AP**—Configure the auto containment of ad hoc networks detected by the controller. If you leave this parameter unselected, the controller only generates an alarm when such a network is detected.

**Step 15**
Click **Apply**.

**Step 16**
Click **Save Configuration**.
Configuring Rogue Detection (CLI)

Procedure

Step 1
Ensure that rogue detection is enabled on the desired access points. Rogue detection is enabled by default for all the access points that are associated with the controller. You can enable or disable rogue detection for individual access points by entering this command:

```
config rogue detection {enable | disable} cisco-ap command.
```

Note To see the current rogue detection configuration for a specific access point, enter the `show ap config general Cisco_AP` command.

Note Rogue detection is disabled by default for OfficeExtend access points because these access points, which are deployed in a home environment, are likely to detect a large number of rogue devices.

Step 2
Configure the rogue detection security level by entering this command:

```
config rogue detection security-level {critical | custom | high | low}
```

- **critical**—Basic rogue detection with auto containment and RLDP for highly sensitive deployments.
- **high**—Basic rogue detection with auto containment for medium-scale deployments.
- **low**—Basic rogue detection for small-scale deployments.

Step 3
Enable, disable, or initiate RLDP by entering these commands:

- `config rogue ap rldp enable alarm-only`—Enables RLDP on all the access points.
- `config rogue ap rldp enable alarm-only monitor_ap_only`—Enables RLDP only on the access points in the monitor mode.
- `config rogue ap rldp initiate rogue_mac_address`—Initiates RLDP on a specific rogue access point.
- `config rogue ap rldp disable`—Disables RLDP on all the access points.
- `config rogue ap rldp retries`—Specifies the number of times RLDP to be tried per rogue access point. The range is from 1 to 5 and default is 1.

Step 4
Specify the number of seconds after which the rogue access point and client entries expire and are removed from the list by entering this command:

```
config rogue ap timeout seconds
```

The valid range for the `seconds` parameter is 240 to 3600 seconds (inclusive). The default value is 1200 seconds.

Note If a rogue access point or client entry times out, it is removed from the controller only if its rogue state is Alert or Threat for a classification type.

Step 5
Enable or disable ad hoc rogue detection and reporting by entering this command:

```
config rogue adhoc {enable | disable}
```

Step 6
Enable or disable the AAA server or local database to validate if rogue clients are valid clients by entering this command:
config rogue client aaa {enable | disable}

**Step 7**
Enable or disable the use of MSE that has the rogue client details to validate the clients by entering this command:

config rogue client mse {enable | disable}

**Step 8**
Specify the time interval, in seconds, at which APs should send the rogue detection report to the controller by entering this command:

config rogue detection monitor-ap report-interval time in sec

The valid range for the *time in sec* parameter is 10 seconds to 300 seconds. The default value is 10 seconds.

**Note**
This feature is applicable only to the monitor mode APs.

**Step 9**
Specify the minimum RSSI value that rogues should have for APs to detect them and for the rogue entries to be created in the controller by entering this command:

config rogue detection min-rssi rssi in dBm

The valid range for the *rssi in dBm* parameter is –128 dBm to 0 dBm. The default value is 0 dBm.

**Note**
This feature is applicable to all the AP modes. There can be many rogues with very weak RSSI values that do not provide any valuable information in rogue analysis. Therefore, you can use this option to filter rogues by specifying the minimum RSSI value at which APs should detect rogues.

**Step 10**
Specify the time interval at which rogues have to be consistently scanned for by APs after the first time the rogues are scanned for by entering this command:

config rogue detection monitor-ap transient-rogue-interval time in sec

The valid range for the *time in sec* parameter is 120 seconds to 1800 seconds. The default value is 0.

**Note**
This feature is applicable only to the monitor mode APs.

Using the transient interval values, you can control the time interval at which APs should scan for rogues. APs can also filter rogues based on their transient interval values.

This feature has the following advantages:

- Rogue reports from APs to the controller are shorter.
- Transient rogue entries are avoided in the controller.
- Unnecessary memory allocation for transient rogues are avoided.

**Step 11**
If you want the controller to automatically contain certain rogue devices, enter these commands.

**Caution**
When you enter any of these commands, the following message is displayed: Using this feature may have legal consequences. Do you want to continue? The 2.4-GHz and 5-GHz frequencies in the Industrial, Scientific, and Medical (ISM) band are open to the public and can be used without a license. As such, containing devices on another party's network could have legal consequences.

- **config rogue ap rldp enable auto-contain**—Automatically contains the rogues that are detected on the wired network.
• **config rogue ap ssid auto-contain**—Automatically contains the rogues that are advertising your network’s SSID.

**Note** If you want the controller to only generate an alarm when such a rogue is detected, enter the **config rogue ap ssid alarm** command.

• **config rogue ap valid-client auto-contain**—Automatically contains a rogue access point to which trusted clients are associated.

**Note** If you want the controller to only generate an alarm when such a rogue is detected, enter the **config rogue ap valid-client alarm** command.

• **config rogue adhoc auto-contain**—Automatically contains ad hoc networks detected by the controller.

**Note** If you want the controller to only generate an alarm when such a network is detected, enter the **config rogue adhoc alert** command.

• **config rogue auto-contain level** level **monitor_mode_ap_only**—Sets the auto containment level for the monitor mode access points. The default value is 1. If you enter the level as 0, then the controller dynamically chooses the number of APs required for effective containment.

• **config rogue containment flexconnect** {enable | disable}—Sets the auto containment options for standalone FlexConnect access points.

**Note** The auto containment is continued if the auto containment was configured when the AP was in the connected FlexConnect mode. After the standalone AP is reassociated with the controller, auto containment is stopped and the future course of action is determined by the configuration on the controller the AP is associated with. You can also configure auto containment on ad hoc SSIDs and managed SSIDs on FlexConnect APs.

• **config rogue containment auto-rate** {enable | disable}—Sets the auto rate for containment of rogues.

**Step 12** Configure ad hoc rogue classification by entering these commands:

- **config rogue adhoc classify friendly state** {internal | external} mac-addr
- **config rogue adhoc classify malicious state** {alert | contain} mac-addr
- **config rogue adhoc classify unclassified state** {alert | contain} mac-addr

The following is a brief description of the parameters:

- **internal**—Trusts a foreign ad hoc rogue.
- **external**—Acknowledges the presence of an ad hoc rogue.
- **alert**—Generates a trap when an ad hoc rogue is detected.
- **contain**—Starts containing a rogue ad hoc.

**Step 13** Configure RLDP scheduling by entering this command:

**config rogue ap rldp schedule** { add | delete | disable | enable }

- **add**—Enables you to schedule RLDP on a particular day of the week. You must enter the day of the week (for example, **mon**, **tue**, **wed**, and so on) on which you want to schedule RLDP and the start time and end time in HH:MM:SS format. For example: **config rogue ap rldp schedule add mon 22:00:00 23:00:00**.
• **delete**—Enables you to delete the RLDP schedule. You must enter the number of days.

• **disable**—Configure to disable RLDP scheduling.

• **enable**—Configure to enable RLDP scheduling.

**Note** When you configure RLDP scheduling, it is assumed that the scheduling will occur in the future, that is, after the configuration is saved.

**Step 14**

Save your changes by entering this command:

```
save config
```

**Note** Rogue client detection on non monitor AP on serving channel was not done until 8.1 Release. From Release 8.1 onwards, serving channel rogue client detection will happen only if WIPS submode is turned on non monitor AP's.

---

**Rogue Access Point Classification**

The controller software enables you to create rules that can organize and display rogue access points as Friendly, Malicious, Custom, or Unclassified. For the Custom type, you must specify a severity score and a classification name.

**Note** Manual classification and classification that is the result of auto-containment or rogue-on-wire overrides the rogue rule. If you have manually changed the class and/or the state of a rogue AP, then to apply rogue rules to the AP, you must change it to unclassified and alert condition.

**Note** If you manually move any rogue device to contained state (any class) or friendly state, this information is stored in the standby Cisco WLC flash memory; however, the database is not updated. When HA switchover occurs, the rogue list from the previously standby Cisco WLC flash memory is loaded.

By default, none of the classification rules are enabled. Therefore, all unknown access points are categorized as Unclassified. When you create a rule, configure conditions for it, and enable the rule, the unclassified access points are reclassified. Whenever you change a rule, it is applied to all access points (friendly, malicious, custom, and unclassified) in the Alert state only.

You can configure up to 64 rogue classification rules per controller.

You can also apply rogue rules to ad hoc rogues except for client count condition.

The number of rogue clients that can be stored in the database table of a rogue access point is 256.

If a rogue AP or an ad hoc rogue is classified because of an RSSI rogue rule condition, the RSSI value that caused the trigger is displayed on the controller GUI/CLI. The controller includes the classified RSSI, the classified AP MAC address, and rule name in the trap. A new trap is generated for every new classification or change of state due to rogue rule but is rate limited to every half hour for every rogue AP or ad hoc rogue. However, if there is a change of state in containment by rogue rule, the trap is sent immediately. The ‘classified
by,' ‘classified at,’ and ‘classified by rule name’ are valid for the non-default classification types, which are Friendly, Malicious, and Custom classifications. For the unclassified types, these fields are not displayed.

Note
For the RSSI condition of rogue rule, reclassification occurs only if the RSSI change is more than 2 dBm of the configured RSSI value.

The rogue rule may not work properly if friendly rogue rule is configured with RSSI as a condition. Then, you need to modify the rules with the expectation that friendly rule is using maximum RSSI and modify rules accordingly.

When the controller receives a rogue report from one of its managed access points, it responds as follows:

1. The controller verifies that the unknown access point is in the friendly MAC address list. If it is, the controller classifies the access point as Friendly.

2. If the unknown access point is not in the friendly MAC address list, the controller starts applying rogue classification rules.

3. If the rogue is already classified as Malicious, Alert or Friendly, Internal or External, the controller does not reclassify it automatically. If the rogue is classified differently, the controller reclassifies it automatically only if the rogue is in the Alert state.

4. The controller applies the first rule based on priority. If the rogue access point matches the criteria specified by the rule, the controller classifies the rogue according to the classification type configured for the rule.

5. If the rogue access point does not match any of the configured rules, the controller classifies the rogue as Unclassified.

6. The controller repeats the previous steps for all rogue access points.

7. If RLDP determines that the rogue access point is on the network, the controller marks the rogue state as Threat and classifies it as Malicious automatically, even if no rules are configured. You can then manually contain the rogue (unless you have configured RLDP to automatically contain the rogue), which would change the rogue state to Contained. If the rogue access point is not on the network, the controller marks the rogue state as Alert, and you can manually contain the rogue.

8. If desired, you can manually move the access point to a different classification type and rogue state.

Table 1: Classification Mapping

<table>
<thead>
<tr>
<th>Rule-Based Classification Type</th>
<th>Rogue States</th>
</tr>
</thead>
</table>
| Friendly                      | • Internal—If the unknown access point is inside the network and poses no threat to WLAN security, you would manually configure it as Friendly, Internal. An example is the access points in your lab network.  
  • External—If the unknown access point is outside the network and poses no threat to WLAN security, you would manually configure it as Friendly, External. An example is an access point that belongs to a neighboring coffee shop.  
  • Alert—The unknown access point is moved to Alert if it is not in the neighbor list or in the user-configured friendly MAC list. |
### Rule-Based Classification Type

<table>
<thead>
<tr>
<th>Rogue States</th>
<th>Rule-Based Classification Type</th>
</tr>
</thead>
</table>
| Malicious    | • Alert—The unknown access point is moved to Alert if it is not in the neighbor list or in the user-configured friendly MAC list.  
|              | • Contained—The unknown access point is contained. |
| Custom       | • Alert—The unknown access point is moved to Alert if it is not in the neighbor list or in the user-configured friendly MAC list.  
|              | • Contained—The unknown access point is contained. |
| Unclassified | • Pending—On first detection, the unknown access point is put in the Pending state for 3 minutes. During this time, the managed access points determine if the unknown access point is a neighbor access point.  
|              | • Alert—The unknown access point is moved to Alert if it is not in the neighbor list or in the user-configured friendly MAC list.  
|              | • Contained—The unknown access point is contained.  
|              | • Contained Pending—The unknown access point is marked Contained, but the action is delayed due to unavailable resources. |

The classification and state of the rogue access points are configured as follows:

- From Known to Friendly, Internal
- From Acknowledged to Friendly, External
- From Contained to Malicious, Contained

If the rogue state is Contained, you have to uncontain the rogue access point before you can change the classification type. If you want to move a rogue access point from Malicious to Unclassified, you must delete the access point and allow the controller to reclassify it.

This section contains the following subsections:

### Guidelines and Restrictions for Classifying Rogue Access Points

- Classifying Custom type rogues is tied to rogue rules. Therefore, it is not possible to manually classify a rogue as Custom. Custom class change can occur only when rogue rules are used.

- Some are sent for containment by rule and every 30 minutes for rogue classification change. For custom classification, the first trap does not contain the severity score because the trap has existed before the custom classification. The severity score is obtained from the subsequent trap that is generated after 30 minutes if the rogue is classified.

- Rogue rules are applied on every incoming new rogue report in the controller in the order of their priority.

- After a rogue satisfies a higher priority rule and is classified, it does not move down the priority list for the same report.

- Previously classified rogue gets re-classified on every new rogue report with the following restrictions:
• Rogues which are classified as friendly by rule and whose state is set to ALERT, go through re-classification on receiving the new rogue report.

• If a rogue is classified as friendly by the administrator manually, then the state is INTERNAL and it does not get re-classified on successive rogue reports.

• If rogue is classified as malicious, irrespective of the state it does not get re-classified on subsequent rogue reports.

• Transition of the rogue's state from friendly to malicious is possible by multiple rogue rules if some attribute is missing in new rogue report.

• Transition of the rogue's state from malicious to any other classification is not possible by any rogue rule.

• The status change of a rogue device to contain or alert does not work when you move it between different class types until you move the class type of the rogue to unclassified.

• If a rogue AP is classified as friendly, it means that the rogue AP exists in the vicinity, is a known AP, and need not be tracked. Therefore, all the rogue clients are either deleted or not tracked if they are associated with the friendly rogue AP.

• Until the controller discovers all the APs through neighbor reports from APs, the rogue APs are kept in unconfigured state for three minutes after they are detected. After 3 minutes, the rogue policy is applied on the rogue APs and the APs are moved to unclassified, friendly, malicious, or custom class. Rogue APs kept in unconfigured state means that no rogue policy has yet been applied on them.

---

**Configuring Rogue Classification Rules (GUI)**

**Procedure**

**Step 1**

Any rules that have already been created are listed in priority order. The name, type, and status of each rule is provided.

**Note** To delete a rule, hover your cursor over the blue drop-down arrow for that rule and click Remove.

**Step 2**
Create a new rule as follows:

a) Click Add Rule. An Add Rule section appears at the top of the page.

b) In the Rule Name text box, enter a name for the new rule. Ensure that the name does not contain any spaces.

c) From the Rule Type drop-down list, choose from the following options to classify rogue access points matching this rule as friendly or malicious:

   • Friendly
   • Malicious
   • Custom
d) Configure the notification when the rule is matched from the Notify drop-down list to All, Global, Local, or None.

Rule description:
- **All**—Notifies the Cisco WLC and a trap receiver such as Cisco Prime Infrastructure.
- **Global**—Notifies only a trap receiver such as Cisco Prime Infrastructure.
- **Local**—Notifies only Cisco WLC.
- **None**—No notifications are sent.

**Note** Rogue Rule Notification options **All, Global, Local, and None** can control only the following rogue traps mentioned:

- Rogue AP contained (Rogue AP: Rogue with MAC Address: XX:XX:XX:XX:XX:XX has been contained due to rule with containment Level : 1)

- Rogue AP clear contained (Rogue AP: Rogue with MAC Address: XX:XX:XX:XX:XX:XX is no longer contained due to rule)

e) Configure the state of the rogue AP when the rule is matched from the State drop-down list.

f) If you choose the Rule Type as Custom, enter the Severity Score and the Classification Name.

g) Click Add to add this rule to the list of existing rules, or click Cancel to discard this new rule.

**Step 3** Edit a rule as follows:

a) Click the name of the rule that you want to edit. The Rogue Rule > Edit page appears.

b) From the Type drop-down list, choose from the following options to classify rogue access points matching this rule:

- **Friendly**
- **Malicious**
- **Custom**

c) Configure the notification when the rule is matched from the Notify drop-down list to All, Global, Local, or None.

d) Configure the state of the rogue AP when the rule is matched from the State drop-down list.

e) From the Match Operation text box, choose one of the following:

**Match All**—If this rule is enabled, a detected rogue access point must meet all of the conditions specified by the rule in order for the rule to be matched and the rogue to adopt the classification type of the rule.
**Match Any**—If this rule is enabled, a detected rogue access point must meet any of the conditions specified by the rule in order for the rule to be matched and the rogue to adopt the classification type of the rule. This is the default value.

f) To enable this rule, select the **Enable Rule** check box. The default value is unselected.

g) If you choose the Rule Type as Custom, enter the Severity Score and the Classification Name.

h) From the Add Condition drop-down list, choose one or more of the following conditions that the rogue access point must meet and click **Add Condition**.

   - **SSID**—Requires that the rogue access point have a specific user-configured SSID. If you choose this option, enter the SSID in the **User Configured SSID** text box, and click **Add SSID**.
     
     **Note** To delete an SSID, highlight the SSID and click **Remove**.

   - **RSSI**—Requires that the rogue access point have a minimum received signal strength indication (RSSI) value. For example, if the rogue access point has an RSSI that is greater than the configured value, then the access point could be classified as malicious. If you choose this option, enter the minimum RSSI value in the **Minimum RSSI** text box. The valid range is 0 to –128 dBm (inclusive).

   - **Duration**—Requires that the rogue access point be detected for a minimum period of time. If you choose this option, enter a value for the minimum detection period in the **Time Duration** text box. The valid range is 0 to 3600 seconds (inclusive), and the default value is 0 seconds.

   - **Client Count**—Requires that a minimum number of clients be associated to the rogue access point. For example, if the number of clients associated to the rogue access point is greater than or equal to the configured value, then the access point could be classified as malicious. If you choose this option, enter the minimum number of clients to be associated to the rogue access point in the **Minimum Number of Rogue Clients** text box. The valid range is 1 to 10 (inclusive), and the default value is 0.

   - **No Encryption**—Requires that the rogue access point’s advertised WLAN does not have encryption enabled. If a rogue access point has encryption disabled, it is likely that more clients will try to associate to it. No further configuration is required for this option.
     
     **Note** Cisco Prime Infrastructure refers to this option as “Open Authentication.”

   - **Managed SSID**—Requires that the rogue access point’s managed SSID (the SSID configured for the WLAN) be known to the controller. No further configuration is required for this option.
     
     **Note** The SSID and Managed SSID conditions cannot be used with the Match All operation because these two SSID lists are mutually exclusive. If you define a rule with Match All and have these two conditions configured, the rogue access points are never classified as friendly or malicious because one of the conditions can never be met.

     You can add up to six conditions per rule. When you add a condition, it appears under the **Conditions** section.

     **Note** To delete a condition from this rule, hover your cursor over the blue drop-down arrow for that condition and click **Remove**.

   - **SSID Wildcard**—Requires that the rogue access point have a substring of the specific user-configured SSID. The controller searches the substring in the same occurrence pattern and returns a match if the substring is found in the whole string of an SSID.

i) Click **Apply**.
Step 4  Click **Save Configuration**.

Step 5  If you want to change the order in which rogue classification rules are applied, follow these steps:

   a.  Click **Back** to return to the Rogue Rules page.

   b.  Click **Change Priority** to access the Rogue Rules > Priority page.

       The rogue rules are listed in priority order in the Change Rules Priority text box.

   c.  Highlight the rule for which you want to change the priority, and click **Up** to raise its priority in the list or **Down** to lower its priority in the list.

   d.  Continue to move the rules up or down until the rules are in the desired order.

   e.  Click **Apply**.

Step 6  Classify any rogue access points as friendly and add them to the friendly MAC address list as follows:

   - Choose **Security > Wireless Protection Policies > Rogue Policies > Friendly Rogue** to open the Friendly Rogue > Create page.
   - In the MAC Address text box, enter the MAC address of the friendly rogue access point.
   - Click **Apply**.
   - Click **Save Configuration**. This access point is added to the controller’s list of friendly access points and should now appear on the Friendly Rogue APs page.

# Viewing and Classifying Rogue Devices (GUI)

## Before you begin

### Caution

When you choose to **contain a rogue device**, the following warning appears: “There may be legal issues following this containment. Are you sure you want to continue?” The 2.4- and 5-GHz frequencies in the Industrial, Scientific, and Medical (ISM) band are open to the public and can be used without a license. As such, containing devices on another party’s network could have legal consequences.

## Procedure

**Step 1**  Choose **Monitor > Rogues**.

**Step 2**  Choose the following options to view the different types of rogue access points detected by the controller:

   - **Friendly APs**
   - **Malicious APs**
   - **Unclassified APs**
   - **Custom APs**
The respective rogue APs pages provide the following information: the MAC address and SSID of the rogue access point, channel number, the number of radios that detected the rogue access point, the number of clients connected to the rogue access point, and the current status of the rogue access point.

**Note** To remove acknowledged rogues from the database, change the rogue state to Alert. If the rogue is no longer present, the rogue data is deleted from the database in 20 minutes.

**Note** To delete a rogue access point from one of these pages, hover your cursor over the blue drop-down arrow and click **Remove**. To delete multiple rogue access points, select the check box corresponding to the row you want to delete and click **Remove**.

**Note** You can move the Malicious or Unclassified rogue APs that are being contained or were contained back to Alert state by clicking the **Move to Alert** button on the respective pages.

**Step 3** Get more details about a rogue access point by clicking the MAC address of the access point. The Rogue AP Detail page appears.

This page provides the following information: the MAC address of the rogue device, the type of rogue device (such as an access point), whether the rogue device is on the wired network, the dates and times when the rogue device was first and last reported, and the current status of the device.

The Class Type text box shows the current classification for this rogue access point:

- **Friendly**—An unknown access point that matches the user-defined friendly rules or an existing known and acknowledged rogue access point. Friendly access points cannot be contained.

- **Malicious**—An unknown access point that matches the user-defined malicious rules or is moved manually by the user from the Friendly or Unclassified classification type.

  **Note** Once an access point is classified as Malicious, you cannot apply rules to it in the future, and it cannot be moved to another classification type. If you want to move a malicious access point to the Unclassified classification type, you must delete the access point and allow the controller to reclassify it.

- **Unclassified**—An unknown access point that does not match the user-defined friendly or malicious rules. An unclassified access point can be contained. It can also be moved to the Friendly or Malicious classification type automatically in accordance with user-defined rules or manually by the user.

- **Custom**—A user-defined classification type that is tied to rogue rules. It is not possible to manually classify a rogue as Custom. Custom class change can occur only using rogue rules.

**Step 4** If you want to change the classification of this device, choose a different classification from the Class Type drop-down list.

**Note** A rogue access point cannot be moved to another class if its current state is Contain.

**Step 5** From the Update Status drop-down list, choose one of the following options to specify how the controller should respond to this rogue access point:

- **Internal**—The controller trusts this rogue access point. This option is available if the Class Type is set to Friendly.

- **External**—The controller acknowledges the presence of this rogue access point. This option is available if the Class Type is set to Friendly.
• **Contain**—The controller contains the offending device so that its signals no longer interfere with authorized clients. This option is available if the Class Type is set to Malicious or Unclassified.

• **Alert**—The controller forwards an immediate alert to the system administrator for further action. This option is available if the Class Type is set to Malicious or Unclassified.

The bottom of the page provides information on both the access points that detected this rogue access point and any clients that are associated to it. To see more details for any of the clients, click **Edit** to open the Rogue Client Detail page.

**Step 6**  
Click **Apply**.

**Step 7**  
Click **Save Configuration**.

**Step 8**  
View any rogue clients that are connected to the controller by choosing **Rogue Clients**. The Rogue Clients page appears. This page shows the following information: the MAC address of the rogue client, the MAC address of the access point to which the rogue client is associated, the SSID of the rogue client, the number of radios that detected the rogue client, the date and time when the rogue client was last reported, and the current status of the rogue client.

**Step 9**  
Obtain more details about a rogue client by clicking the MAC address of the client. The Rogue Client Detail page appears.

This page provides the following information: the MAC address of the rogue client, the MAC address of the rogue access point to which this client is associated, the SSID and IP address of the rogue client, the dates and times when the rogue client was first and last reported, and the current status of the rogue client.

**Step 10**  
From the Update Status drop-down list, choose one of the following options to specify how the controller should respond to this rogue client:

- **Contain**—The controller contains the offending device so that its signals no longer interfere with authorized clients.

- **Alert**—The controller forwards an immediate alert to the system administrator for further action.

The bottom of the page provides information on the access points that detected this rogue client.

**Step 11**  
Click **Apply**.

**Step 12**  
If desired, you can test the controller’s connection to this client by clicking **Ping**.

**Step 13**  
Click **Save Configuration**.

**Step 14**  
See any ad-hoc rogues detected by the controller by choosing **Adhoc Rogues**. The Adhoc Rogues page appears.

This page shows the following information: the MAC address, BSSID, and SSID of the ad-hoc rogue, the number of radios that detected the ad-hoc rogue, and the current status of the ad-hoc rogue.

**Step 15**  
Obtain more details about an ad-hoc rogue by clicking the MAC address of the rogue. The Adhoc Rogue Detail page appears.

This page provides the following information: the MAC address and BSSID of the ad-hoc rogue, the dates and times when the rogue was first and last reported, and the current status of the rogue.

**Step 16**  
From the Update Status drop-down list, choose one of the following options to specify how the controller should respond to this ad-hoc rogue:

- **Contain**—The controller contains the offending device so that its signals no longer interfere with authorized clients.

- **Alert**—The controller forwards an immediate alert to the system administrator for further action.
• **Internal**—The controller trusts this rogue access point.

• **External**—The controller acknowledges the presence of this rogue access point.

**Step 17**

From the Maximum number of APs to contain the rogue drop-down list, choose one of the following options to specify the maximum number of access points used to contain this ad-hoc rogue: **1, 2, 3, or 4**.

The bottom of the page provides information on the access points that detected this ad-hoc rogue.

- **1**—Specifies targeted rogue access point is contained by one access point. This is the lowest containment level.
- **2**—Specifies targeted rogue access point is contained by two access points.
- **3**—Specifies targeted rogue access point is contained by three access points.
- **4**—Specifies targeted rogue access point is contained by four access points. This is the highest containment level.

**Step 18**

Click **Apply**.

**Step 19**

Click **Save Configuration**.

**Step 20**

View any access points that have been configured to be ignored by choosing **Rogue AP Ignore-List**. The Rogue AP Ignore-List page appears.

This page shows the MAC addresses of any access points that are configured to be ignored. The rogue-ignore list contains a list of any autonomous access points that have been manually added to Cisco Prime Infrastructure maps by the users. The controller regards these autonomous access points as rogues even though the Prime Infrastructure is managing them. The rogue-ignore list allows the controller to ignore these access points. The list is updated as follows:

- When the controller receives a rogue report, it checks to see if the unknown access point is in the rogue-ignore access point list.
- If the unknown access point is in the rogue-ignore list, the controller ignores this access point and continues to process other rogue access points.
- If the unknown access point is not in the rogue-ignore list, the controller sends a trap to the Prime Infrastructure. If the Prime Infrastructure finds this access point in its autonomous access point list, the Prime Infrastructure sends a command to the controller to add this access point to the rogue-ignore list. This access point is then ignored in future rogue reports.
- If a user removes an autonomous access point from the Prime Infrastructure, the Prime Infrastructure sends a command to the controller to remove this access point from the rogue-ignore list.

---

**Configuring Rogue Classification Rules (CLI)**

**Procedure**

**Step 1**

Create a rule by entering this command:

```
config rogue rule add ap priority priority classify {friendly | malicious} rule-name
```
If you later want to change the priority of this rule and shift others in the list accordingly, enter the `config rogue rule priority` command.

If you later want to change the classification of this rule, enter the `config rogue rule classify` command.

If you ever want to delete all of the rogue classification rules or a specific rule, enter the `config rogue rule delete` command.

**Step 2**

Create a rule by entering these commands:

- Configure a rule for friendly rogues by entering this command:
  
  ```
  config rogue rule add ap priority classify friendly notify {all | global | local | none} state {alert | internal | external | delete} rule-name
  ```

- Configure a rule for malicious rogues by entering this command:
  
  ```
  config rogue rule add ap priority classify malicious notify {all | global | local | none} state {alert | contain | delete} rule-name
  ```

- Configure a rule for custom rogues by entering this command:
  
  ```
  config rogue rule add ap priority classify custom severity-score classification-name notify {all | global | local | none} state {alert | contain | delete} rule-name
  ```

If you later want to change the priority of this rule and shift others in the list accordingly, enter the `config rogue rule priority` command.

If you later want to change the classification of this rule, enter the `config rogue rule classify` command.

If you ever want to delete all of the rogue classification rules or a specific rule, enter the `config rogue rule delete` command.

**Step 3**

Configure the state on the rogue AP upon rule match by entering this command:

```
config rogue rule state {alert | contain | internal | external | delete} rule-name
```

**Step 4**

Configure the notification upon rule match by entering this command:

```
config rogue rule notify {all | global | local | none} rule-name
```

**Step 5**

Disable all rules or a specific rule by entering this command:

```
config rogue rule disable {all | rule-name}
```

**Note** A rule must be disabled before you can modify its attributes.

**Step 6**

Add conditions to a rule that the rogue access point must meet by entering this command:

```
config rogue rule condition ap set condition_type condition_value rule-name
```

The following condition types are available:

- **ssid**—Requires that the rogue access point have a specific SSID. You should add SSIDs that are not managed by the controller. If you choose this option, enter the SSID for the `condition_value` parameter. The SSID is added to the user-configured SSID list.

  **Note** If you ever want to delete all of the SSIDs or a specific SSID from the user-configured SSID list, enter the `config rogue rule condition ap delete ssid {all | ssid} rule-name` command.
**Note**  The sub-string should be specified in full or part of SSID (without any asterisks). This sub-string is matched in the same sequence to its occurrence in the rogue AP SSID. Once the condition is met, the rogue AP is classified (depending on OR or AND match condition).

- **rssi**—Requires that the rogue access point have a minimum RSSI value. For example, if the rogue access point has an RSSI that is greater than the configured value, then the access point could be classified as malicious. If you choose this option, enter the minimum RSSI value for the `condition_value` parameter.

  In Release 8.0 and later releases, for friendly rogue rules, you are required to set a maximum RSSI value. The RSSI value of the rogue AP must be less than the RSSI value set, for the rogue AP to be classified as a friendly rogue. For malicious and custom rogue rules, there is no change in functionality.

  For example, for a friendly rogue rule, the RSSI value is set at –80 dBm. All the rogue APs that are detected and have RSSI value that is less than –80 dBm are classified as friendly rogues. For malicious and custom rogue rules, the RSSI value is set at –80 dBm. All the rogue APs that are detected and have RSSI value that is more than –80 dBm are classified as malicious or custom rogue APs.

- **duration**—Requires that the rogue access point be detected for a minimum period of time. If you choose this option, enter a value for the minimum detection period for the `condition_value` parameter. The valid range is 0 to 3600 seconds (inclusive), and the default value is 0 seconds.

- **client-count**—Requires that a minimum number of clients be associated to the rogue access point. For example, if the number of clients associated to the rogue access point is greater than or equal to the configured value, then the access point could be classified as malicious. If you choose this option, enter the minimum number of clients to be associated to the rogue access point for the `condition_value` parameter. The valid range is 1 to 10 (inclusive), and the default value is 0.

- **managed-ssid**—Requires that the rogue access point’s SSID be known to the controller. A `condition_value` parameter is not required for this option.

**Note**  You can add up to six conditions per rule. If you ever want to delete all of the conditions or a specific condition from a rule, enter the `config rogue rule condition ap delete all condition_type condition_value rule_name` command.

- **wildcard-ssid**—Requires that the rogue access point have a wildcard of the specific user-configured SSID. The controller searches the wildcard in the same occurrence pattern and returns a match if the substring is found in the whole string of an SSID.

**Step 7**  Specify whether a detected rogue access point must meet all or any of the conditions specified by the rule in order for the rule to be matched and the rogue access point to adopt the classification type of the rule by entering this command:

```
config rogue rule match {all | any} rule_name
```

**Step 8**  Enable all rules or a specific rule by entering this command:

```
config rogue rule enable {all | rule_name}
```

**Note**  For your changes to become effective, you must enable the rule.

**Step 9**  Add a new friendly access point entry to the friendly MAC address list or delete an existing friendly access point entry from the list by entering this command:

```
config rogue ap friendly {add | delete} ap_mac_address
```

**Step 10**  Save your changes by entering this command:
save config

**Step 11** View the rogue classification rules that are configured on the controller by entering this command:

```
show rogue rule summary
```

**Step 12** View detailed information for a specific rogue classification rule by entering this command:

```
show rogue rule detailed rule_name
```

---

**Viewing and Classifying Rogue Devices (CLI)**

**Procedure**

- View a list of all rogue access points detected by the controller by entering this command:

  ```
  show rogue ap summary
  ```

- See a list of the friendly rogue access points detected by the controller by entering this command:

  ```
  show rogue ap friendly summary
  ```

- See a list of the malicious rogue access points detected by the controller by entering this command:

  ```
  show rogue ap malicious summary
  ```

- See a list of the unclassified rogue access points detected by the controller by entering this command:

  ```
  show rogue ap unclassified summary
  ```

- See detailed information for a specific rogue access point by entering this command:

  ```
  show rogue ap detailed ap_mac_address
  ```

- See the rogue report (which shows the number of rogue devices detected on different channel widths) for a specific 802.11a/n/ac radio by entering this command:

  ```
  show ap auto-rf 802.11a Cisco_AP
  ```

- See a list of all rogue clients that are associated to a rogue access point by entering this command:

  ```
  show rogue ap clients ap_mac_address
  ```

- See a list of all rogue clients detected by the controller by entering this command:

  ```
  show rogue client summary
  ```

- See detailed information for a specific rogue client by entering this command:

  ```
  show rogue client detailed Rogue_AP client_mac_address
  ```

- See a list of all ad-hoc rogues detected by the controller by entering this command:

  ```
  show rogue adhoc summary
  ```

- See detailed information for a specific ad-hoc rogue by entering this command:

  ```
  show rogue adhoc detailed rogue_mac_address
  ```

- See a summary of ad hoc rogues based on their classification by entering this command:
show rogue adhoc {friendly | malicious | unclassified} summary

- See a list of rogue access points that are configured to be ignore by entering this command:

  show rogue ignore-list

- Classify a rogue access point as friendly by entering this command:

  config rogue ap classify friendly state {internal | external} ap_mac_address

  where

  internal means that the controller trusts this rogue access point.

  external means that the controller acknowledges the presence of this rogue access point.

**Note**

A rogue access point cannot be moved to the Friendly class if its current state is Contain.

- Mark a rogue access point as malicious by entering this command:

  config rogue ap classify malicious state {alert | contain} ap_mac_address

  where

  alert means that the controller forwards an immediate alert to the system administrator for further action.

  contain means that the controller contains the offending device so that its signals no longer interfere with authorized clients.

**Note**

A rogue access point cannot be moved to the Malicious class if its current state is Contain.

- Mark a rogue access point as unclassified by entering this command:

  config rogue ap classify unclassified state {alert | contain} ap_mac_address

**Note**

A rogue access point cannot be moved to the Unclassified class if its current state is Contain.

alert means that the controller forwards an immediate alert to the system administrator for further action.

contain means that the controller contains the offending device so that its signals no longer interfere with authorized clients.

- Choose the maximum number of access points used to contain the ad-hoc rogue by entering this command:

  config rogue ap classify unclassified state contain rogue_ap_mac_address 1, 2, 3, or 4

  • 1—Specifies targeted rogue access point will be contained by one access point. This is the lowest containment level.

  • 2—Specifies targeted rogue access point will be contained by two access points.

  • 3—Specifies targeted rogue access point will be contained by three access points.
• 4—Specifies targeted rogue access point will be contained by four access points. This is the highest containment level.

• Specify how the controller should respond to a rogue client by entering one of these commands:
  
  **config rogue client alert client_mac_address**—The controller forwards an immediate alert to the system administrator for further action.

  **config rogue client contain client_mac_address**—The controller contains the offending device so that its signals no longer interfere with authorized clients.

• Specify how the controller should respond to an ad-hoc rogue by entering one these commands:

  **config rogue adhoc alert rogue_mac_address**—The controller forwards an immediate alert to the system administrator for further action.

  **config rogue adhoc contain rogue_mac_address**—The controller contains the offending device so that its signals no longer interfere with authorized clients.

  **config rogue adhoc external rogue_mac_address**—The controller acknowledges the presence of this ad-hoc rogue.

• Configure the classification of ad hoc rogues by entering any one of these commands:

  • Friendly state—**config rogue adhoc classify friendly state** \{internal | external\} mac-addr

  • Malicious state—**config rogue adhoc classify malicious state** \{alert | contain\} mac-addr

  • Unclassified state—**config rogue adhoc classify unclassified state** \{alert | contain\} mac-addr

• View a summary of custom rogue AP information by entering this command:

  **show rogue ap custom summary**

• See custom ad hoc rogue information by entering this command:

  **show rogue adhoc custom summary**

• Delete the rogue APs by entering this command:

  **config rogue ap delete** \{class | all | mac-addr\}

• Delete the rogue clients by entering this command:

  **config rogue client delete** \{state | all | mac-addr\}

• Delete the ad hoc rogues by entering this command:

  **config rogue adhoc delete** \{class | all | mac-addr\}

• Save your changes by entering this command:

  **save config**

---

**Cisco Intrusion Detection System**

The Cisco Intrusion Detection System/Intrusion Prevention System (CIDS/CIPS) instructs controllers to block certain clients from accessing the wireless network when attacks involving these clients are detected at Layer 3 through Layer 7. This system offers significant network protection by helping to detect, classify, and stop
threats including worms, spyware/adware, network viruses, and application abuse. Two methods are available to detect potential attacks:

- IDS sensors
- IDS signatures

You can configure IDS sensors to detect various types of IP-level attacks in your network. When the sensors identify an attack, they can alert the controller to shun the offending client. When you add a new IDS sensor, you register the controller with that IDS sensor so that the controller can query the sensor to get the list of shunned clients.

This section contains the following subsections:

**Shunned Clients**

When an IDS sensor detects a suspicious client, it alerts the controller to shun this client. The shun entry is distributed to all controllers within the same mobility group. If the client to be shunned is currently joined to a controller in this mobility group, the anchor controller adds this client to the dynamic exclusion list, and the foreign controller removes the client. The next time that the client tries to connect to a controller, the anchor controller rejects the handoff and informs the foreign controller that the client is being excluded.

**Configuring IDS Sensors (GUI)**

**Procedure**

**Step 1**
Choose Security > Advanced > CIDS > Sensors to open the CIDSSensors List page.

**Note** If you want to delete an existing sensor, hover your cursor over the blue drop-down arrow for that sensor and choose Remove.

**Step 2**
Click New to add a new IDS sensor to the list. The CIDS Sensor Add page is displayed.

**Step 3**
From the Index drop-down list, choose a number (between 1 and 5) to determine the sequence in which the controller consults the IDS sensors. For example, if you choose 1, the controller consults this IDS sensor first. Cisco WLC supports up to five IDS sensors.

**Step 4**
In the Server Address text box, enter the IP address of your IDS server.

**Step 5**
In the Port text box, enter the number of the HTTPS port through which the controller has to communicate with the IDS sensor.

We recommend that you set this parameter to 443 because the sensor uses this value to communicate by default. The default value is 443 and the range is 1 to 65535.

**Step 6**
In the Username text box, enter the name that the controller uses to authenticate to the IDS sensor.

**Note** This username must be configured on the IDS sensor and have at least a read-only privilege.

**Step 7**
In the Password and Confirm Password text boxes, enter the password that the controller uses to authenticate to the IDS sensor.
Step 8  In the **Query Interval** text box, enter the time (in seconds) for how often the controller should query the IDS server for IDS events.

   The default is 60 seconds and the range is 10 to 3600 seconds.

Step 9  Check the **State** check box to register the controller with this IDS sensor or uncheck this check box to disable registration. The default value is disabled.

Step 10 Enter a 40-hexadecimal-character security key in the **Fingerprint** text box. This key is used to verify the validity of the sensor and is used to prevent security attacks.

   **Note**  Make sure you include colons that appear between every two bytes within the key. For example, enter AA:BB:CC:DD.

Step 11  Click **Apply**. Your new IDS sensor appears in the list of sensors on the CIDS Sensors List page.

Step 12  Click **Save Configuration**.

---

### Viewing Shunned Clients (GUI)

**Procedure**

Step 1  Choose **Security > Advanced > CIDS > Shunned Clients** to open the CIDS Shun List page.

   This page shows the IP address and MAC address of each shunned client, the length of time that the client’s data packets should be blocked by the controller as requested by the IDS sensor, and the IP address of the IDS sensor that discovered the client.

Step 2  Click **Re-sync** to purge and reset the list as desired.

   **Note**  The controller does not take any action on shun entries when the corresponding timers have expired. The shun entry timers are maintained only for the display purpose. The shun entries are cleaned up whenever the controller polls the IPS server. If the CIDS IPS server is not reachable, the shun entries are not removed even if they are timed out on the controller. The shun entries are cleaned up only when the CIDS IPS server is operational again and the controller polls the CIDS IPS server.

---

### Configuring IDS Sensors (CLI)

**Procedure**

Step 1  Add an IDS sensor by entering this command:

   ```
   config wps cids-sensor add index ids_ip_address username password.
   ```

   The index parameter determines the sequence in which the controller consults the IDS sensors. The controller supports up to five IDS sensors. Enter a number (between 1 and 5) to determine the priority of this sensor. For example, if you enter 1, the controller consults this IDS sensor first.
The username must be configured on the IDS sensor and have at least a read-only privilege.

**Step 2** (Optional) Specify the number of the HTTPS port through which the controller is to communicate with the IDS sensor by entering this command:

```
config wps cids-sensor port index port
```

For the port-number parameter, you can enter a value between 1 and 65535. The default value is 443. This step is optional because we recommend that you use the default value of 443. The sensor uses this value to communicate by default.

**Step 3** Specify how often the controller should query the IDS server for IDS events by entering this command:

```
config wps cids-sensor interval index interval
```

For the interval parameter, you can enter a value between 10 and 3600 seconds. The default value is 60 seconds.

**Step 4** Enter a 40-hexadecimal-character security key used to verify the validity of the sensor by entering this command:

```
config wps cids-sensor fingerprint index sha1 fingerprint
```

You can get the value of the fingerprint by entering `show tls fingerprint` on the sensor’s console.

**Note** Make sure to include the colons that appear between every two bytes within the key (for example, AA:BB:CC:DD).

**Step 5** Enable or disable this controller’s registration with an IDS sensor by entering this command:

```
config wps cids-sensor {enable | disable} index
```

**Step 6** Enable or disable protection from DoS attacks by entering this command:

```
config wps cids-sensor
```

The default value is disabled.

**Note** A potential attacker can use specially crafted packets to mislead the IDS into treating a legitimate client as an attacker. It causes the controller to wrongly disconnect this legitimate client and launches a DoS attack. The auto-immune feature, when enabled, is designed to protect against such attacks. However, conversations using Cisco 792x phones might be interrupted intermittently when the auto-immune feature is enabled. If you experience frequent disruptions when using 792x phones, you might want to disable this feature.

**Step 7** Save your settings by entering this command:

```
save config
```

**Step 8** See the IDS sensor configuration by entering one of these commands:

- `show wps cids-sensor summary`
- `show wps cids-sensor detail` index

**Step 9** The second command provides more information than the first.

**Step 10** See the auto-immune configuration setting by entering this command:

```
show wps summary
```

Information similar to the following appears:

```
Auto-Immune
Auto-Immune........................................ Disabled
```
Client Exclusion Policy
- Excessive 802.11-association failures.............. Enabled
- Excessive 802.11-authentication failures........... Enabled
- Excessive 802.1x-authentication..................... Enabled
- IP-theft........................................... Enabled
- Excessive Web authentication failure............... Enabled

Signature Policy
- Signature Processing.................................. Enabled

---

**Step 11**
Obtain debug information regarding IDS sensor configuration by entering this command:

```
debug wps cids enable
```

**Note**  
If you ever want to delete or change the configuration of a sensor, you must first disable it by entering the `config wps cids-sensor disable index` command. To delete the sensor, enter the `config wps cids-sensor delete index` command.

---

**Viewing Shunned Clients (CLI)**

**Procedure**

**Step 1**
View the list of clients to be shunned by entering this command:

```
show wps shun-list
```

**Step 2**
Force the controller to synchronize with other controllers in the mobility group for the shun list by entering this command:

```
config wps shun-list re-sync
```

**Note**  
The controller does not take any action on shun entries when the corresponding timers have expired. The shun entry timers are maintained only for the display purpose. The shun entries are cleaned up whenever the controller polls the IPS server. If the CIDS IPS server is not reachable, the shun entries are not removed even if they are timed out on the controller. The shun entries are cleaned up only when the CIDS IPS server is operational again and the controller polls the CIDS IPS server.

---

**Intrusion Detection System Signatures**

You can configure intrusion detection system (IDS) signatures, or bit-pattern matching rules used to identify various types of attacks in incoming 802.11 packets, on the controller. When the signatures are enabled, the access points joined to the controller perform signature analysis on the received 802.11 data or management frames and report any discrepancies to the controller. If an attack is detected, appropriate mitigation is initiated.

Cisco supports 17 standard signatures. These signatures are divided into six main groups. The first four groups contain management signatures, and the last two groups contain data signatures.

- **Broadcast deauthentication frame signatures**—During a broadcast deauthentication frame attack, a hacker sends an 802.11 deauthentication frame to the broadcast MAC destination address of another
client. This attack causes the destination client to disassociate from the access point and lose its connection. If this action is repeated, the client experiences a denial of service. When the broadcast deauthentication frame signature (precedence 1) is used to detect such an attack, the access point listens for clients transmitting broadcast deauthentication frames that match the characteristics of the signature. If the access point detects such an attack, it alerts the controller. Depending on how your system is configured, the offending device is contained so that its signals no longer interfere with authorized clients, or the controller forwards an immediate alert to the system administrator for further action, or both.

- **NULL probe response signatures**—During a NULL probe response attack, a hacker sends a NULL probe response to a wireless client adapter. As a result, the client adapter locks up. When a NULL probe response signature is used to detect such an attack, the access point identifies the wireless client and alerts the controller. The NULL probe response signatures are as follows:
  
  - NULL probe resp 1 (precedence 2)
  - NULL probe resp 2 (precedence 3)

  ![Note]

  Controller does not log historical NULL Probe IDS events within the Signature Events Summary output.

- **Management frame flood signatures**—During a management frame flood attack, a hacker floods an access point with 802.11 management frames. The result is a denial of service to all clients associated or attempting to associate to the access point. This attack can be implemented with different types of management frames: association requests, authentication requests, reassociation requests, probe requests, disassociation requests, deauthentication requests, and reserved management subtypes.

  When a management frame flood signature is used to detect such an attack, the access point identifies management frames matching the entire characteristic of the signature. If the frequency of these frames is greater than the value of the frequency set in the signature, an access point that hears these frames triggers an alarm. The controller generates a trap and forwards it to Cisco Prime Infrastructure.

  The management frame flood signatures are as follows:
  
  - Assoc flood (precedence 4)
  - Auth flood (precedence 5)
  - Reassoc flood (precedence 6)
  - Broadcast probe flood (precedence 7)
  - Disassoc flood (precedence 8)
  - Deauth flood (precedence 9)
  - Reserved mgmt 7 (precedence 10)
  - Reserved mgmt F (precedence 11)

  The reserved management frame signatures 7 and F are reserved for future use.

- **Wellenreiter signature**—Wellenreiter is a wireless LAN scanning and discovery utility that can reveal access point and client information. When the Wellenreiter signature (precedence 17) is used to detect such an attack, the access point identifies the offending device and alerts the controller.
• **EAPOL flood signature**—During an EAPOL flood attack, a hacker floods the air with EAPOL frames that contain 802.1X authentication requests. As a result, the 802.1X authentication server cannot respond to all of the requests and fails to send successful authentication responses to valid clients. The result is a denial of service to all affected clients. When the EAPOL flood signature (precedence 12) is used to detect such an attack, the access point waits until the maximum number of allowed EAPOL packets is exceeded. It then alerts the controller and proceeds with the appropriate mitigation.

• **NetStumbler signatures**—NetStumbler is a wireless LAN scanning utility that reports access point broadcast information (such as operating channel, RSSI information, adapter manufacturer name, SSID, WEP status, and the latitude and longitude of the device running NetStumbler when a GPS is attached). If NetStumbler succeeds in authenticating and associating to an access point, it sends a data frame with the following strings, depending on the NetStumbler version:

<table>
<thead>
<tr>
<th>Version</th>
<th>String</th>
</tr>
</thead>
<tbody>
<tr>
<td>3.2.0</td>
<td>“Flurble gronk bloopit, bnip Frundletrune”</td>
</tr>
<tr>
<td>3.2.3</td>
<td>“All your 802.11b are belong to us”</td>
</tr>
<tr>
<td>3.3.0</td>
<td>Sends white spaces</td>
</tr>
</tbody>
</table>

When a NetStumbler signature is used to detect such an attack, the access point identifies the offending device and alerts the controller. The NetStumbler signatures are as follows:

- NetStumbler 3.2.0 (precedence 13)
- NetStumbler 3.2.3 (precedence 14)
- NetStumbler 3.3.0 (precedence 15)
- NetStumbler generic (precedence 16)

A standard signature file exists on the controller by default. You can upload this signature file from the controller, or you can create a custom signature file and download it to the controller or modify the standard signature file to create a custom signature.

### Uploading or Downloading IDS Signatures

#### Procedure

1. **Step 1** If desired, create your own custom signature file.

2. **Step 2** Make sure that you have a Trivial File Transfer Protocol (TFTP) server available. Follow these guidelines when setting up a TFTP server:
   - If you are downloading through the service port, the TFTP server must be on the same subnet as the service port because the service port is not routable, or you must create static routes on the controller.
   - If you are downloading through the distribution system network port, the TFTP server can be on the same or a different subnet because the distribution system port is routable.
A third-party TFTP server cannot run on the same computer as the Cisco Prime Infrastructure because the Prime Infrastructure built-in TFTP server and the third-party TFTP server require the same communication port.

**Step 3** If you are downloading a custom signature file (*.sig), copy it to the default directory on your TFTP server.

**Step 4** Choose Commands to open the Download File to Controller page.

**Step 5** Perform one of the following:

- If you want to download a custom signature file to the controller, choose Signature File from the File Type drop-down list on the Download File to Controller page.

- If you want to upload a standard signature file from the controller, choose Upload File and then Signature File from the File Type drop-down list on the Upload File from Controller page.

**Step 6** From the Transfer Mode drop-down list, choose TFTP, FTP, or SFTP.

The SFTP option was added in Release 7.4.

**Step 7** In the IP Address text box, enter the IP address of the TFTP, FTP, or SFTP server.

**Step 8** If you are downloading the signature file using a TFTP server, enter the maximum number of times that the controller should attempt to download the signature file in the Maximum retries text box.

The range is 1 to 254 and the default value is 10.

**Step 9** If you are downloading the signature file using a TFTP server, enter the amount of time in seconds before the controller times out while attempting to download the signature file in the Timeout text box.

The range is 1 to 254 seconds and the default is 6 seconds.

**Step 10** In the File Path text box, enter the path of the signature file to be downloaded or uploaded. The default value is “/.”

**Step 11** In the File Name text box, enter the name of the signature file to be downloaded or uploaded.

**Note** When uploading signatures, the controller uses the filename that you specify as a base name and then adds “_std.sig” and “_custom.sig” to it in order to upload both standard and custom signature files to the TFTP server. For example, if you upload a signature file called “ids1,” the controller automatically generates and uploads both ids1_std.sig and ids1_custom.sig to the TFTP server. If desired, you can then modify ids1_custom.sig on the TFTP server (making sure to set “Revision = custom”) and download it by itself.

**Step 12** If you are using an FTP or SFTP server, follow these steps:

a. In the Server Login Username text box, enter the username to log into the FTP or SFTP server.

b. In the Server Login Password text box, enter the password to log into the FTP or SFTP server.

c. In the Server Port Number text box, enter the port number on the FTP or SFTP server through which the download occurs. The default value is 21.

**Step 13** Choose Download to download the signature file to the controller or Upload to upload the signature file from the controller.
Enabling or Disabling IDS Signatures

Procedure

Step 1  Choose **Security > Wireless Protection Policies > Standard Signatures** or **Custom Signatures** to open the Standard Signatures page or the Custom Signatures page.

The Standard Signatures page shows the list of Cisco-supplied signatures that are currently on the controller. The Custom Signatures page shows the list of customer-supplied signatures that are currently on the controller. This page shows the following information for each signature:

- The order, or precedence, in which the controller performs the signature checks.
- The name of the signature, which specifies the type of attack that the signature is trying to detect.
- The frame type on which the signature is looking for a security attack. The possible frame types are data and management.
- The action that the controller is directed to take when the signature detects an attack. The possible actions are None and Report.
- The state of the signature, which indicates whether the signature is enabled to detect security attacks.
- A description of the type of attack that the signature is trying to detect.

Step 2  Perform one of the following:

- If you want to allow all signatures (both standard and custom) whose individual states are set to Enabled to remain enabled, select the **Enable Check for All Standard and Custom Signatures** check box at the top of either the Standard Signatures page or the Custom Signatures page. The default value is enabled (or selected). When the signatures are enabled, the access points joined to the controller perform signature analysis on the received 802.11 data or management frames and report any discrepancies to the controller.

- If you want to disable all signatures (both standard and custom) on the controller, unselect the **Enable Check for All Standard and Custom Signatures** check box. If you unselected this check box, all signatures are disabled, even the ones whose individual states are set to Enabled.

Step 3  Click **Apply** to commit your changes.

Step 4  Click the precedence number of the desired signature to enable or disable an individual signature. The **Standard Signature (or Custom Signature) > Detail** page appears.

This page shows much of the same information as the Standard Signatures and Custom Signatures pages but provides these additional details:

- The tracking method used by the access points to perform signature analysis and report the results to the controller. The possible values are as follows:
  
  - Per Signature—Signature analysis and pattern matching are tracked and reported on a per-signature and per-channel basis.
  
  - Per MAC—Signature analysis and pattern matching are tracked and reported separately for individual client MAC addresses on a per-channel basis.
  
  - Per Signature and MAC—Signature analysis and pattern matching are tracked and reported on a per-signature and per-channel basis as well as on a per-MAC-address and per-channel basis.
• The pattern that is being used to detect a security attack

Step 5  In the Measurement Interval text box, enter the number of seconds that must elapse before the signature frequency threshold is reached within the configured interval. The range is 1 to 3600 seconds, and the default value varies per signature.

Step 6  In the Signature Frequency text box, enter the number of matching packets per interval that must be identified at the individual access point level before an attack is detected. The range is 1 to 32,000 packets per interval, and the default value varies per signature.

Step 7  In the Signature MAC Frequency text box, enter the number of matching packets per interval that must be identified per client per access point level before an attack is detected. The range is 1 to 32,000 packets per interval, and the default value varies per signature.

Step 8  In the Quiet Time text box, enter the length of time (in seconds) after which no attacks have been detected at the individual access point level and the alarm can stop. The range is 60 to 32,000 seconds, and the default value varies per signature.

Step 9  Select the State check box to enable this signature to detect security attacks or unselect it to disable this signature. The default value is enabled (or selected).

Step 10 Click Apply to commit your changes. The Standard Signatures or Custom Signatures page reflects the signature’s updated state.

Step 11 Click Save Configuration to save your changes.

**Viewing IDS Signature Events (GUI)**

**Procedure**

**Step 1** Choose Security > Wireless Protection Policies > Signature Events Summary to open the Signature Events Summary page.

**Step 2** Click the Signature Type for the signature to see more information on the attacks detected by a particular signature. The Signature Events Detail page appears.

This page shows the following information:

- The MAC addresses of the clients identified as attackers
- The method used by the access point to track the attacks
- The number of matching packets per second that were identified before an attack was detected.
- The number of access points on the channel on which the attack was detected
- The day and time when the access point detected the attack

**Step 3** Click the Detail link for that attack to see more information for a particular attack. The Signature Events Track Detail page appears.

- The MAC address of the access point that detected the attack
- The name of the access point that detected the attack
- The type of radio (802.11a or 802.11b/g) used by the access point to detect the attack
• The radio channel on which the attack was detected
• The day and time when the access point reported the attack

Configuring IDS Signatures (CLI)

Procedure

Step 1  If desired, create your own custom signature file.
Step 2  Make sure that you have a TFTP server available.
Step 3  Copy the custom signature file (*.sig) to the default directory on your TFTP server.
Step 4  Specify the download or upload mode by entering the transfer {download | upload} mode tftp command.
Step 5  Specify the type of file to be downloaded or uploaded by entering the transfer {download | upload} datatype signature command.
Step 6  Specify the IP address of the TFTP server by entering the transfer {download | upload} serverip tftp-server-ip-address command.

Note   Some TFTP servers require only a forward slash (/) as the TFTP server IP address, and the TFTP server automatically determines the path to the correct directory.

Step 7  Specify the download or upload path by entering the transfer {download | upload} path absolute-tftp-server-path-to-file command.
Step 8  Specify the file to be downloaded or uploaded by entering the transfer {download | upload} filename filename.sig command.

Note   When uploading signatures, the controller uses the filename you specify as a base name and then adds “_std.sig” and “_custom.sig” to it in order to upload both standard and custom signature files to the TFTP server. For example, if you upload a signature file called “ids1,” the controller automatically generates and uploads both ids1_std.sig and ids1_custom.sig to the TFTP server. If desired, you can then modify ids1_custom.sig on the TFTP server (making sure to set “Revision = custom”) and download it by itself.

Step 9  Enter the transfer {download | upload} start command and answer y to the prompt to confirm the current settings and start the download or upload.
Step 10 Specify the number of seconds that must elapse before the signature frequency threshold is reached within the configured interval by entering this command:

```
config wps signature interval signature_id interval
```

where signature_id is a number used to uniquely identify a signature. The range is 1 to 3600 seconds, and the default value varies per signature.

Step 11 Specify the number of matching packets per interval that must be identified at the individual access point level before an attack is detected by entering this command:

```
config wps signature frequency signature_id frequency
```

The range is 1 to 32,000 packets per interval, and the default value varies per signature.
Step 12 Specify the number of matching packets per interval that must be identified per client per access point before an attack is detected by entering this command:

```
cfg-wps signature mac-frequency signature_id mac_frequency
```

The range is 1 to 32,000 packets per interval, and the default value varies per signature.

Step 13 Specify the length of time (in seconds) after which no attacks have been detected at the individual access point level and the alarm can stop by entering by entering this command:

```
cfg-wps signature quiet-time signature_id quiet_time
```

The range is 60 to 32,000 seconds, and the default value varies per signature.

Step 14 Perform one of the following:

- To enable or disable an individual IDS signature, enter this command:
  
  ```
  cfg-wps signature {standard | custom} state signature_id {enable | disable}
  ```

- To enable or disable IDS signature processing, which enables or disables the processing of all IDS signatures, enter this command:
  
  ```
  cfg-wps signature {enable | disable}
  ```

  **Note** If IDS signature processing is disabled, all signatures are disabled, regardless of the state configured for individual signatures.

Step 15 Save your changes by entering this command:

```
save config
```

Step 16 If desired, you can reset a specific signature or all signatures to default values. To do so, enter this command:

```
cfg-wps signature reset {signature_id | all}
```

**Note** You can reset signatures to default values only through the controller CLI.

---

**Viewing IDS Signature Events (CLI)**

**Procedure**

- See whether IDS signature processing is enabled or disabled on the controller by entering this command:
  
  ```
  show wps summary
  ```

  **Note** If IDS signature processing is disabled, all signatures are disabled, regardless of the state configured for individual signatures.

- See individual summaries of all of the standard and custom signatures installed on the controller by entering this command:
  
  ```
  show wps signature summary
  ```
• See the number of attacks detected by the enabled signatures by entering this command:

  show wps signature events summary

• See more information on the attacks detected by a particular standard or custom signature by entering this command:

  show wps signature events {standard | custom} precedence# summary

• See information on attacks that are tracked by access points on a per-signature and per-channel basis by entering this command:

  show wps signature events {standard | custom} precedence# detailed per-signature source_mac

• See information on attacks that are tracked by access points on an individual-client basis (by MAC address) by entering this command:

  show wps signature events {standard | custom} precedence# detailed per-mac source_mac

---

**Wireless Intrusion Prevention System**

The Cisco Adaptive Wireless Intrusion Prevention System (wIPS) uses an advanced approach to wireless threat detection and performance management. It combines network traffic analysis, network device and topology information, signature-based techniques, and anomaly detection to deliver highly accurate and complete wireless threat prevention. With a fully infrastructure-integrated solution, you can continually monitor wireless traffic on both the wired and wireless networks and use that network intelligence to analyze attacks from many sources to accurately pinpoint and proactively prevent attacks, rather than wait until damage or exposure has occurred.

Cisco Adaptive wIPS is a part of the Cisco 3300 Series Mobility Services Engine (MSE), which centralizes the processing of intelligence collected by the continuous monitoring of Cisco Aironet APs. With Cisco Adaptive wIPS functionalities and Cisco Prime Infrastructure integration into the Cisco MSE, the wIPS can configure and monitor wIPS policies and alarms and report threats.

---

**Note**

If your wIPS deployment consists of a controller, access point, and Cisco MSE, you must set all the three entities to the UTC time zone.

Cisco Adaptive wIPS is not configured on the controller. Instead, the Cisco Prime Infrastructure forwards the profile configuration to the wIPS service, which forwards the profile to the controller. The profile is stored in flash memory on the controller and sent to APs when they join the controller. When an access point disassociates and joins another controller, it receives the wIPS profile from the new controller.

Local-mode or FlexConnect mode APs with a subset of wIPS capabilities are referred to as Enhanced Local Mode access point or ELM AP. You can configure an access point to work in the wIPS mode if the AP is in any of the following modes:

• Monitor

• Local

• FlexConnect
The regular local mode or FlexConnect mode AP is extended with a subset of wIPS capabilities. This feature enables you to deploy your APs to provide protection without needing a separate overlay network.

wIPS ELM has the limited capability of detecting off-channel alarms. AN AP periodically goes off-channel, and monitors the nonserving channels for a short duration, and triggers alarms if any attack is detected on the channel. But off-channel alarm detection is best effort, and it takes a longer time to detect attacks and trigger alarms, which might cause the ELM AP to intermittently detect an alarm and clear it because it is not visible. APs in any of the above modes can periodically send alarms based on the policy profile to the wIPS service through the controller. The wIPS service stores and processes the alarms and generates SNMP traps. Cisco Prime Infrastructure configures its IP address as a trap destination to receive SNMP traps from the Cisco MSE.

This table lists all the SNMP trap controls and their respective traps. When a trap control is enabled, all the traps of that trap control are also enabled.

</table>
The following are the trap descriptions for the traps mentioned in the *SNMP Trap Controls and Their Respective Traps* table:

- **General Traps**
  - SNMP Authentication—The SNMPv2 entity has received a protocol message that is not properly authenticated.

  **Note** When a user who is configured in SNMP V3 mode tries to access the controller with an incorrect password, the authentication fails and a failure message is displayed. However, no trap logs are generated for the authentication failure.

- Link (Port) Up/Down—Link changes status from up or down.
- Link (Port) Up/Down—Link changes status from up or down.
- Multiple Users—Two users log in with the same ID.
- Rogue AP—Whenever a rogue access point is detected, this trap is sent with its MAC address; when a rogue access point that was detected earlier no longer exists, this trap is sent.
- Config Save—Notification that is sent when the controller configuration is modified.

- **Cisco AP Traps**
  - AP Register—Notification sent when an access point associates or disassociates with the controller.
  - AP Interface Up/Down—Notification sent when an access point interface (802.11X) status goes up or down.

- **Client-Related Traps**

</tbody>
</table>
• 802.11 Association—Associate notification that is sent when a client sends an association frame.

• 802.11 Disassociation—Disassociate notification that is sent when a client sends a disassociation frame.

• 802.11 Deauthentication—Deauthenticate notification that is sent when a client sends a deauthentication frame.

• 802.11 Failed Authentication—Authenticate failure notification that is sent when a client sends an authentication frame with a status code other than successful.

• 802.11 Failed Association—Associate failure notification that is sent when the client sends an association frame with a status code other than successful.

• Exclusion—Associate failure notification that is sent when a client is exclusion listed (in a blocked list).

---

**Note**

The maximum number of static blocked list entries that the APs can have is 340.

• Authentication—Authentication notification that is sent when a client is successfully authenticated.

• Max Clients Limit Reached—Notification that is sent when the maximum number of clients, defined in the Threshold field, are associated with the controller.

• NAC Alert—Alert that is sent when a client joins an SNMP NAC-enabled WLAN.

This notification is generated when a client on NAC-enabled SSIDs completes Layer2 authentication to inform the NAC appliance about the client's presence. clcClientWlanProfileName represents the profile name of the WLAN that the 802.11 wireless client is connected to, clcClientIPAddress represents the unique IP address of the client, clcApMacAddress represents the MAC address of the AP to which the client is associated, clcClientQuarantineVLAN represents the quarantine VLAN for the client, clcClientAccessVLAN represents the access VLAN for the client.

• Association with Stats—Associate notification that is sent with data statistics when a client is associated with the controller, or roams. Data statistics include transmitted and received bytes and packets.

• Disassociation with Stats—Disassociate notification that is sent with data statistics when a client disassociates from the controller. Data statistics include transmitted and received bytes and packets, SSID, and session ID.

---

**Note**

When you downgrade to Release 7.4 from a later release, if a trap that was not supported in Release 7.4 (for example, NAC Alert trap) is enabled before the downgrade, all traps are disabled. After the downgrade, you must enable all the traps that were enabled before the downgrade. We recommend that you disable the new traps before the downgrade so that all the other traps are not disabled.

• Security Traps

• User Auth Failure—This trap informs that a client RADIUS Authentication failure has occurred.
• RADIUS Server No Response—This trap is to indicate that no RADIUS servers are responding to authentication requests sent by the RADIUS client.

• WEP Decrypt Error—Notification sent when the controller detects a WEP decrypting error.

• Rogue AP—Whenever a rogue access point is detected, this trap is sent with its MAC address; when a rogue access point that was detected earlier no longer exists, this trap is sent.

• SNMP Authentication—The SNMPv2 entity has received a protocol message that is not properly authenticated.

Note When a user who is configured in SNMP V3 mode tries to access the controller with an incorrect password, authentication fails and a failure message is displayed. However, no trap logs are generated for the authentication failure.

• Multiple Users—Two users log in with the same ID.

• SNMP Authentication
  • Load Profile—Notification sent when the Load Profile state changes between PASS and FAIL.
  • Noise Profile—Notification sent when the Noise Profile state changes between PASS and FAIL.
  • Interference Profile—Notification sent when the Interference Profile state changes between PASS and FAIL.
  • Coverage Profile—Notification sent when the Coverage Profile state changes between PASS and FAIL.

• Auto RF Profile Traps
  • Load Profile—Notification sent when the Load Profile state changes between PASS and FAIL.
  • Noise Profile—Notification sent when the Noise Profile state changes between PASS and FAIL.
  • Interference Profile—Notification sent when the Interference Profile state changes between PASS and FAIL.
  • Coverage Profile—Notification sent when the Coverage Profile state changes between PASS and FAIL.

• Auto RF Update Traps
  • Channel Update—Notification sent when the access point dynamic channel algorithm is updated.
  • Tx Power Update—Notification sent when the access point dynamic transmit power algorithm is updated.

• Mesh Traps
  • Child Excluded Parent—Notification that is sent when a defined number of failed association to the controller occurs through a parent mesh node.
  • Notification sent when a child mesh node exceeds the threshold limit of the number of discovery response timeouts. The child mesh node does not try to associate an excluded parent mesh node for
the interval defined. The child mesh node remembers the excluded parent MAC address when it
joins the network, and informs the controller.

- **Parent Change**—Notification is sent by the agent when a child mesh node changes its parent. The
  child mesh node remembers previous parent and informs the controller about the change of parent
  when it rejoins the network.

- **Child Moved**—Notification sent when a parent mesh node loses connection with its child mesh
  node.

- **Excessive Parent Change**—Notification sent when the child mesh node changes its parent frequently.
  Each mesh node keeps a count of the number of parent changes in a fixed time. If it exceeds the
  defined threshold, the child mesh node informs the controller.

- **Excessive Children**—Notification sent when the child count exceeds for a RAP and a MAP.

- **Poor SNR**—Notification sent when the child mesh node detects a lower SNR on a backhaul link.
  For the other trap, a notification is sent to clear a notification when the child mesh node detects an
  SNR on a backhaul link that is higher than the object defined by 'clMeshSNRThresholdAbate'.

- **Console Login**—Notification is sent by the agent when a login on a MAP console is either successful
  or fail after three attempts.

- **Default Bridge Group Name**—Notification sent when the MAP mesh node joins its parent using
  the default bridge group name.

**Note**
The remaining traps do not have trap controls. These traps are not generated too frequently and do not require
any trap control. Any other trap that is generated by the controller cannot be turned off.

**Note**
In all of the above cases, the controller functions solely as a forwarding device.

**wIPS Support for 40 and 80 MHz**

Release 8.2 introduces wIPS support for 40 and 80 MHz range. This feature detects alarms in the 40 and 80
MHz range (if RRM channel scanning is selected) and provides information to the Cisco Prime Infrastructure.
The channel-width information is derived from the packet data rate and sent to the wIPS module that stores
the channel width per alarm. Using the `show capwap am alarm alarm-id` command, you can view the channel
width in which the attack has occurred.

The wIPS alarm report contains the *channel-width* of the attack and device capability (11a/b/g/n/ac). No wIPS
specific configuration is required to enable this feature. The only prerequisite is that RRM scanning should
be enabled for this feature to work properly.

**Restrictions for wIPS**

- wIPS ELM is not supported on the following APs:
  - 702i
• Request to Send (RTS) and Clear to Send (CTS) frames are not forwarded to driver if RTS and CTS are for the BSSID of the AP.

• WiPS and Rogue Detection must be disabled on the AP in IPv6 mode to prevent it from leaking traffic outside CAPWAP towards 32.x.x.x destination.

Configuring WiPS on an Access Point (GUI)

Procedure

Step 1  Choose Wireless > Access Points > All APs > ap-name.
Step 2  Set the AP Mode parameter. To configure an access point for WiPS, you must choose one of the following modes from the AP Mode drop-down list:
   • Local
   • FlexConnect
   • Monitor

Step 3  Choose WiPS from the AP Sub Mode drop-down list.
Step 4  Save the configuration.

Configuring WiPS on an Access Point (CLI)

Procedure

Step 1  Configure an access point for the monitor mode by entering this command:
config ap mode {monitor | local | flexconnect} Cisco_AP

Note  To configure an access point for WiPS, the access point must be in monitor, local, or flexconnect modes.

Step 2  Enter Y when you see the message that the access point will be rebooted if you want to continue.
Step 3  Save your changes by entering this command:
save config

Step 4  Disable the access point radio by entering this command:
config {802.11a | 802.11b} disable Cisco_AP

Step 5  Configure the WiPS submode on the access point by entering this command:
config ap mode ap_mode submode wips Cisco_AP

Note To disable wIPS on the access point, enter the config ap mode ap_mode submode none Cisco_AP command.

**Step 6** Enable wIPS-optimized channel scanning for the access point by entering this command:

```plaintext
config ap monitor-mode wips-optimized Cisco_AP
```

The access point scans each channel for 250 milliseconds. It derives the list of channels to be scanned from the monitor configuration. You can choose one of these options:

- **All**—All channels are supported by the access point’s radio
- **Country**—Only the channels supported by the access point’s country of operation
- **DCA**—Only the channel set used by the dynamic channel assignment (DCA) algorithm, which, by default, includes all of the nonoverlapping channels allowed in the access point’s country of operation

The 802.11a or 802.11b Monitor Channels information in the output of the `show advanced {802.11a | 802.11b} monitor` command shows the monitor configuration channel set:

```
Default 802.11b AP monitoring
802.11b Monitor Mode....................... enable
802.11b Monitor Channels.................. Country channels
802.11b AP Coverage Interval............. 180 seconds
802.11b AP Load Interval.................. 60 seconds
802.11b AP Noise Interval............... 180 seconds
802.11b AP Signal Strength Interval...... 60 seconds
```

**Step 7** Reenable the access point radio by entering this command:

```plaintext
config {802.11a | 802.11b} enable Cisco_AP
```

**Step 8** Save your changes by entering this command:

```plaintext
save config
```

---

**Viewing wIPS Information (CLI)**

**Note** You can also view the access point submode from the controller GUI. To do so, choose Wireless > Access Points > All APs > access point name > the Advanced tab. The AP Sub Mode field shows wIPS if the access point is in the monitor mode and the wIPS submode is configured on the access point, or None if the access point is not in the monitor mode or the access point is in the monitor mode, but the wIPS submode is not configured.

**Procedure**

- See the wIPS submode in the access point by entering this command:
  ```plaintext
  show ap config general Cisco_AP
  ```
- See the wIPS-optimized channel-scanning configuration in the access point by entering this command:
  ```plaintext
  show ap monitor-mode summary
  ```
• See the wIPS configuration forwarded by Cisco Prime Infrastructure to the controller by entering this command:
  `show wps wips summary`
• See the current state of the wIPS operation in the controller by entering this command:
  `show wps wips statistics`
• Clear the wIPS statistics in the controller by entering this command:
  `clear stats wps wips`

Cisco Adaptive wIPS Alarms

The controller supports five Cisco Adaptive wIPS alarms that serve as notifications for potential threats. You must enable these alarms based on your network topology using Cisco Prime Infrastructure. For more details on this, see the Cisco Prime Infrastructure User Guide.

• Device not protected by VPN—The controller generates an alarm when a wireless client and access point does not communicate over secure VPN, as all controller traffic must be routed through a VPN connection.
• WPA Dictionary Attack—The controller generates an alarm when a dictionary attack on the WPA security key occurs. The attack is detected before the initial handshake message between the client and the access point.
• WiFi Direct Session Detected—The controller generates an alarm when Wifi direct sessions of clients are detected with Wifi direct and prevents enterprise vulnerability.
• RSN Info Element Out-of-Bound Denial-of-Service—The controller generates an alarm when there are large values for RSN information element that results in an access point crash.
• DS Parameter Set DoS—The controller generates an alarm when confusion exists in the channel for the client while multiple channels overlap.
