- 2. Habilitar encapsulación SRv6
- 3. R3 recibe la actualización BGP y la instala en la tabla de unidifusión IPv6 BGP
- 4. R3 instalar el RIB y FIB

Introducción

Este documento describe el flujo del plano de control cuando se aplica la encapsulación Segment Routing over IPv6 (SRv6) a la sesión de unidifusión BGP IPv6.

Antecedentes

Consulte la Guía de Configuración de Segment Routing para Cisco ASR 9000 Series Routers, IOS XR Release 24.1.x, 24.2.x, 24.3.x, 24.4.x para obtener información adicional.

Topología

La topología utilizada en este documento se muestra en la Figura 1. El dominio SRv6 consta de tres routers, todos los cuales funcionan en Cisco IOS-XR. La infraestructura subyacente SRv6 se implementa usando IS-IS con uSID SRv6. El peering unicast BGP IPv6 se establece entre los routers R1 y R3, mientras que el router R2 no participa en BGP y funciona como un router P en esta configuración. La interfaz Loopback 6 en R1 y R3 representa un prefijo IPv6 que se debe intercambiar entre los dos peers unidifusión BGP IPv6.

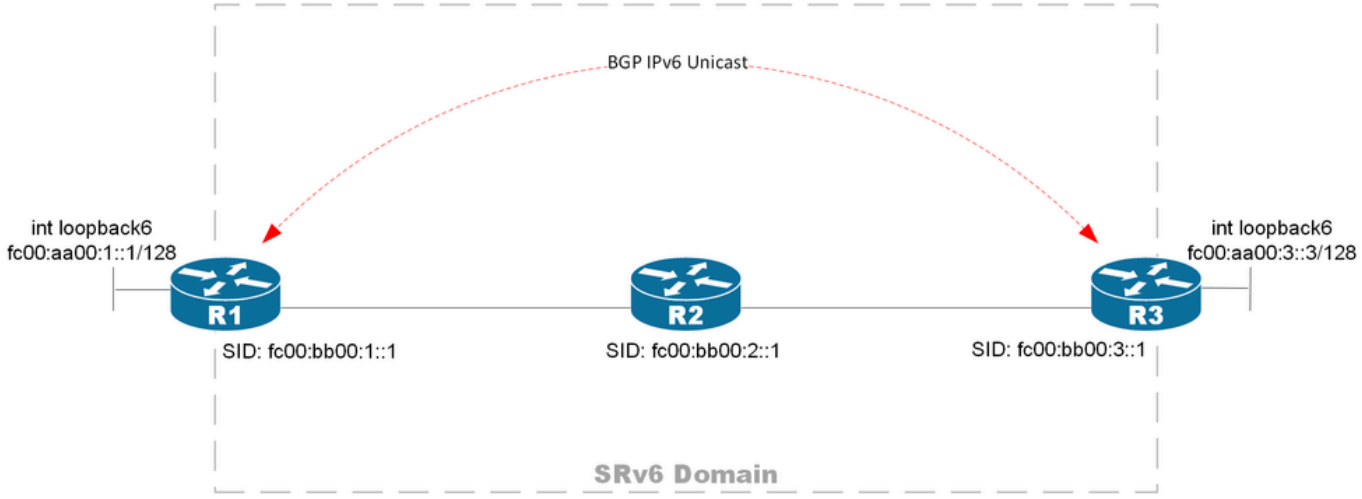

Figura 1. Diagrama de topología de unidifusión BGP ipv6 sobre SRv6

Configuración SRv6

Esta sección muestra la configuración de los tres routers SRv6. El router R2 incluye solamente la configuración SRv6, ya que no participa en BGP.

Configuración del Router R1

El router R1 forma parte del dominio SRv6 con un localizador de fc00:bb00:1::/48. También funciona como un router unicast BGP IPv6, originando el prefijo local fc00:aa00:1::1/128. Además, establece el peering unicast BGP IPv6 con el router R3 sobre la infraestructura SRv6. La configuración resaltada en negrita sirve como punto de partida para depurar el flujo de control descrito en este documento y es el único desencadenador utilizado en todo el proceso.

Flujo de señalización del SID SRv6

En la infraestructura SRv6 subyacente, cada router tiene información de estado de link en toda la topología, que cada uno anuncia su localizador SRv6 a través del protocolo ISIS de estado de link. La base de datos de ISIS en R1 muestra el localizador de todos los routers que participan en el dominio SRv6.

Esta implementación de SRv6 admite la superposición de tráfico de tabla de enrutamiento global (GRT). Cuando se habilita el servicio de superposición de unidifusión IPv6 BGP global en R1 y R3, cada router genera un nuevo SID de servicio. Este SID de servicio está asociado con el VRF predeterminado y utiliza el comportamiento de punto final uDT6 en este escenario. Este SID de servicio se debe intercambiar entre los peers unicast IPv6 BGP para habilitar el reenvío SRv6 entre los dos peers BGP. La siguiente sección describe los pasos del flujo de señalización BGP, empezando desde la ejecución del disparador (habilitando encapsulation-type srv6) hasta el punto en que el reenvío SRv6 está programado en el Router R3.

1. Estado anterior a habilitar la encapsulación de SRv6

Antes de habilitar la encapsulación SRv6 en el SAFI de unidifusión IPv6 para el par BGP, el router R1 debe tener prefijos BGP IPv6 con SID de servicio asignados. Esto ocurre cuando 'segment-routing srv6' está habilitado en el SAFI global de unidifusión IPv6 en R1. La salida muestra el SID local fc00:bb00:1:e002:: se asigna a todos los prefijos en unidifusión BGP ipv6.

*> fc00:aa00:1::1/128 fc00:bb00:1:e002::                         per-vrf       MAIN
*>ifc00:aa00:3::3/128 NO SRv6 Sid                                -            -

Processed 2 prefixes, 2 paths
```

Este SID de servicio es programado localmente por el proceso sid_mgr en R1, que tiene un comportamiento de punto final como uDT6, que está asociado con el vrf predeterminado y es propiedad de bgp. Esto simplemente significa cuando el paquete de recepción R1 con la dirección de destino coincide con el servicio SID fc00:bb00:1:e002:: y es el último segmento, el R1 debe desencapsular el encabezado y enviar el paquete desencapsulado a la búsqueda FIB de la tabla vrf predeterminada IPv6. Esto es según RFC8986, que enumera todo el comportamiento de los terminales SRv6. Observe la salida donde muestra el sid_mgr para crear el servicio SID fc00:bb00:1:e002:: y pasar esta información a RIB y finalmente a FIB.

2. Habilitar encapsulación SRv6

La habilitación de la encapsulación SRv6 hace que R1 envíe un mensaje de actualización de BGP a su peer con el tipo de atributo 40, que se utiliza en Segment Routing para anunciar un prefijo BGP con un identificador de routing de segmento (SID) específico. El router R1 envía la ACTUALIZACIÓN a R3 para el prefijo IPv6 fc00:bb00:3::1 (Paso 1) con el SID asociado fc00:bb00:1:e002::. Al recibir la ACTUALIZACIÓN, el Router R3 actualiza su tabla unicast BGP IPv6 (Paso 2) y posteriormente actualiza sus tablas RIB y FIB (Paso 3). La figura 2 ilustra el flujo de señalización BGP junto con los pasos correspondientes.

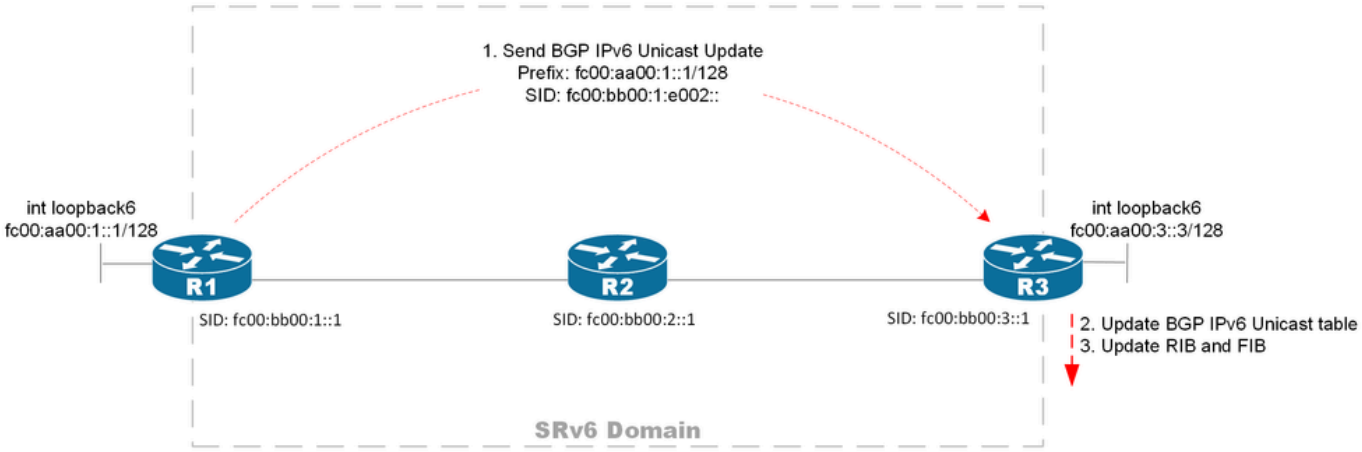

Figura 2. Flujo de señalización BGP después de habilitar la encapsulación srv6

El resultado muestra el registro de depuración de BGP inmediatamente después de habilitar la encapsulación SRv6 en el par R3, lo que muestra que R1 envía un mensaje de actualización de BGP a R3:

```
router bgp 1
 neighbor fc00:bb00:3::1
  address-family ipv6 unicast
   encapsulation-type srv6
  !

3. R3 recibe la actualización BGP y la instala en la tabla de unidifusión IPv6 BGP

El router R3 recibe una actualización de BGP de R1, que se puede observar habilitando la depuración de BGP en R3. El paquete de actualización de BGP recibido debe coincidir con el enviado por R1, como se muestra en la salida de depuración.

```

El router R3 genera un seguimiento BGP correspondiente al procesamiento de actualización de R1, lo que finalmente resulta en la actualización de R3 de su tabla unicast IPv6 BGP. Esta actualización, que contiene el atributo BGP tipo 40, implica la instalación de los SID recibidos junto con los prefijos unicast IPv6 BGP asociados de R1.

```

4. R3 instalar el RIB y FIB

Finalmente, R3 instala el RIB y el FIB para completar el proceso de señalización. R3 actuará como cabecera SRv6 con la lista de SID fc00:bb00:1:e002::. Esta entrada R1 actúa como cabecera SRv6 con encapsulación en una política SR, abreviada como H.Encaps (RFC 8986, sección 5.1). Este comportamiento encapsula el paquete en un encabezado IPv6, impone una lista de segmentos y agrega SRH si es necesario. En este caso, no es necesario agregar SRH ya que solo hay un segmento. El paquete se enviará con la dirección de destino fc00:bb00:1:e002::, que es el SID de servicio en R1 con comportamiento SRv6 Endpoint UDT6.
