[Información Relacionada](#)

[Introducción](#)

Este consejo técnico explica cómo implementar tiempos de espera por usuario en los servidores de acceso de Cisco. Para que los tiempos de espera por usuario funcionen correctamente, ejecute Cisco IOS versión 11.3(8)T o posterior. Si ejecuta una versión anterior de Cisco IOS, los temporizadores quizás sólo funcionen en algunas configuraciones básicas, como sólo asíncrona sin perfiles virtuales.

Este documento abarca la configuración del servidor de acceso a la red (NAS) y del servidor del Authentication, Authorization, and Accounting (AAA). También proporciona salida de los comandos show y debug para que pueda confirmar si sus dispositivos funcionan correctamente y así pueda depurar cualquier problema.

[prerrequisitos](#)

Requisitos

No hay requisitos específicos para este documento.

Componentes Utilizados

La información que contiene este documento se basa en las siguientes versiones de software y hardware.

- Versión de Cisco IOS 11.3(8)T o más adelante

La información que contiene este documento se creó a partir de los dispositivos en un ambiente de laboratorio específico. Todos los dispositivos que se utilizan en este documento se pusieron en funcionamiento con una configuración verificada (predeterminada). Si la red está funcionando, asegúrese de haber comprendido el impacto que puede tener cualquier comando.

Convenciones

Para obtener más información sobre las convenciones del documento, consulte [Convenciones de Consejos Técnicos de Cisco](#).

Detalles técnicos

Antes de tratar los tiempos de espera por usuario, que incorporan otras variables como la configuración AAA y los servidores RADIUS/TACACS+, examinaremos cómo configurar un servidor de acceso para tiempos de espera fijos, que son aquéllos que se aplican de manera global y a todas las personas que realizan la marcación de entrada.

Los principales comandos de Cisco IOS son dialer idle-timeout y timeout absolute. Estos son dos comandos de configuración de interfaces. También veremos un tercer comando, ppp timeout idle, utilizado en las interfaces de acceso virtual.

dialer idle-timeout <x>

Este comando se puede configurar en cualquier interfaz habilitada para dialer y control cuánto tiempo la conexión puede estar ociosa (en los segundos) antes de que se termine. A continuación se enumeran cuatro puntos que se deben tener en cuenta acerca de este comando:

1. Este comando sólo puede aplicarse a interfaces que sean capaces de utilizar el marcador. Por abandono todas las interfaces de ISDN (BRI y PRI) son dialer capaz, así que agregar este comando no son un problema. Las interfaces asíncronas (incluidas las interfaces asíncronas de grupo) no tienen capacidad de marcador de manera predeterminada. Para que así sea, debe ingresar el comando dialer in-band. Sólo luego de haber ingresado el comando dialer in-band en la interfaz asíncrona puede configurar el dialer idle-timeout. **NotaNota:** El vtemplate (y por lo tanto las interfaces de acceso v) no son dialer capaz (son de punto a punto solamente) y no pueden utilizar así este comando.
2. En una interfaz habilitada para dialer (es decir, ISDN o async con el dialer dentro de la banda), el valor por defecto es el ocioso-**descanso 120** (segundos) del **marcador**. Este tiempo es generalmente muy corto en un entorno ISP, por lo tanto, deberá aumentarlo casi siempre.

3. El valor predeterminado del tiempo de espera inactiva del marcador sólo se restablece en el tráfico saliente (tráfico hacia el usuario) que coincide con la lista del marcador (es decir, que se considera interesante). Es posible reajustarlo para el tráfico interesante entrante también agregando la **cualquier** palabra clave en el final del comando (es decir, **ocioso-descanso 600 del marcador cualquiera**).
4. El tráfico considerado “interesante” es definido por el **comando dialer-list <n>**, donde el **<n>** hace juego el número en su declaración de **comando dialer-group <n>**.

timeout absolute <x> <y>

Este comando se puede configurar en cualquier interfaz de WAN, incluyendo las interfaces asincrónicas, las interfaces de ISDN, las interfaces del dialer, y las interfaces de Vtemplate. Controlan el tiempo de actividad de la conexión antes de finalizarla. Observe que la sintaxis es **<x> <y>** en donde **<x>** está en minutos e **<y>** está en segundos.

<x> de la marcha lenta del descanso ppp

Este comando se puede configurar solamente en las interfaces de Vtemplate (e incluso se oculta en el analizador de sintaxis), y los controles cuánto tiempo la conexión puede estar ociosa (en los segundos) antes de que se termine. Su función es muy similar a la del comando dialer idle-timeout en las interfaces del marcador, sólo que ppp timeout idle es para las interfaces vtemplate/vaccess. Porque se utiliza específicamente en el vtemplate/las interfaces de accesov, este comando es apropiado para las configuraciones del perfil virtual (donde una interfaz de accesov se crea siempre para un usuario), y los gateways de inicio del Virtual Private Dialup Network (VPDN) (donde las interfaces proyectadas se terminan siempre en una interfaz de accesov). A diferencia del comando dialer idle-timeout, no existe el concepto de tráfico interesante y, por lo tanto, todo el tráfico de los usuarios reiniciará el temporizador ocioso. El tráfico que no es de usuarios, tal como el de las señales de mantenimiento del protocolo de control de link (LCP) y el de los paquetes de negociación del protocolo de control de red (NCP), no restaura el temporizador.

[Configurar](#)

En esta sección encontrará la información para configurar las funciones descritas en este documento.

Nota: Para obtener información adicional sobre los comandos que se utilizan en este documento, use la Command Lookup Tool (solo para clientes [registrados](#)).

En este documento, se utilizan estas configuraciones:

- [Configuración baja \(perfiles virtuales no habilitados\)](#)
- [Tiempos de espera agotados globales](#)
- [Tiempos de espera por usuario – configuración del servidor AAA](#)
- [Tiempos de espera por usuario – configuración de NAS'](#)

[Configuración baja \(perfiles virtuales no habilitados\)](#)

Para fines de aprendizaje, supongamos que se trata de una configuración base como la que se muestra a continuación. No está activada la función de perfiles virtuales.

```

Tiempos de espera agotados globales

Para el próximo ejemplo, impondremos un tiempo de inactividad de 30 minutos (1800 segundos) y un tiempo de espera absoluto de tres horas (de 180 minutos) para los usuarios. El cambio de configuración del delta que habilitará los **tiempos de espera PPP globales** será como sigue:

```
interface Serial0:23
 dialer idle-timeout 1800
 timeout absolute 180
!
<output omitted> ! interface Group=Async1 dialer in-band dialer idle-timeout 1800 dialer-group 1
 timeout absolute 180
```

Si usted no tiene un dialer-list 1, usted necesitará definir uno. El más simple sería dialer-list 1 protocol ip permit.

Si usa perfiles virtuales, su configuración puede ser más sencilla, ya que puede colocar el tiempo de espera en la interfaz de plantilla virtual, tal como se muestra a continuación:

```
interface Virtual-Template1
 ppp timeout idle 1800
 timeout absolute 180
```

Tiempos de espera por usuario – configuración del servidor AAA

Ahora que hemos trabajado con tiempos de espera agotados globales, ampliaremos este conocimiento a tiempos de espera por usuario. Sus valores de temporizador por usuario comenzarán a bajar durante la autorización de la red, entonces, debe tener configurado un comando de red de autorización aaa para cualquier método que esté utilizando, que sea RADIUS o TACACS+. También observe que los temporizadores por usuario reemplazarán siempre cualquier valor global que se preconfigure en el NAS. La manera el trabajo de los temporizadores por usuario es que cuando el servidor de acceso recibe los atributos de tiempo de espera durante la fase de la Autorización de red, traducirá estos atributos a un conjunto de los comandos configuration que serán ingresados en la interfaz con la cual el usuario será conectado. Estos comandos configuration que son ingresados en la interfaz por un proceso de origen son temporales; se eliminan cuando el usuario se desconecta.

Se enumeran abajo varios perfiles del usuario de la muestra en el servidor:

Perfiles de RADIUS

```
timeout-absolute-ppp Password = "cisco"  
    Service-Type = Framed,  
    Framed-Protocol = PPP,  
    Framed-IP-Address = 255.255.255.254,  
    Session-Timeout = 600
```

```
timeout-idle-ppp Password = "cisco"  
    Service-Type = Framed,  
    Framed-Protocol = PPP  
    Framed-IP-Address = 255.255.255.254,  
    Idle-Timeout = 300
```

```
timeout-both-ppp Password = "cisco"  
    Service-Type = Framed,  
    Framed-Protocol = PPP,  
    Framed-IP-Address = 255.255.255.254,  
    Session-Timeout = 600,  
    Idle-Timeout = 300
```

Nota: Su sintaxis puede variar dependiendo de cómo se configura su diccionario.

Perfiles TACACS+

```
user = timeout-absolute-ppp {  
    chap = cleartext cisco  
    service = ppp protocol = lcp {  
        timeout = 10  
    }  
    service = ppp protocol = ip {  
        addr-pool = "default"  
    }  
}
```

```
user = timeout-idle-ppp {  
    chap = cleartext cisco  
    service = ppp protocol = lcp {  
        idletime = 5  
    }  
    service = ppp protocol = ip {  
        addr-pool = "default"  
    }  
}
```

```
user = timeout-both-ppp {  
    chap = cleartext cisco  
    service = ppp protocol = lcp {  
        timeout = 10  
        idletime = 5  
    }  
    service = ppp protocol = multilink { }  
    service = ppp protocol = ip {  
        addr-pool = "default"  
    }  
}
```

[‘Tiempos de espera por usuario – configuración de NAS’](#)

Si sólo utiliza la asincrónica (no ISDN) y no utiliza perfiles virtuales, siempre que tenga dialer in-band configurado en las interfaces asincrónicas (o asincrónicas de grupo), los temporizadores por usuario deberían funcionar. El proceso de origen insertará los temporizadores en la interfaz

asincrónica, usando los **comandos dialer idle-timeout y timeout absolute** con los valores pasajeros adentro del RADIUS/TACACS+, y los saca cuando las desconexiones del usuario.

Si sólo está haciendo asincrónico (sin ISDN) y está utilizando perfiles virtuales, no necesita un marcador configurado en banda en la interfaz asincrónica (o grupo asincrónico). Debería funcionar. El proceso de segundo plano insertará temporizadores en las interfaces de acceso virtual utilizando los comandos `ppp timeout idle` y `timeout absolute` con los valores transferidos por RADIUS/TACACS+, y los extrae cuando el usuario se desconecta.

Si usted tiene los usuarios ISDN y le necesidad de hacer los temporizadores por usuario, usted puede necesitar utilizar los Perfiles virtuales. La razón es porque el proceso de origen que tenemos discutido previamente no trabaja para las interfaces de ISDN; es decir, usted no puede configurar el Canal B con el cual el usuario está conectado. La única cosa que usted puede configurar es el canal D que afecta todo el mundo. Sin embargo, si un usuario negocia links múltiples en una sesión, el servidor de acceso creará una interfaz de acceso virtual de forma automática, que actuará como la interfaz de agrupamiento para el usuario. El proceso en segundo plano trabaja con interfaces de acceso virtual, pero no trabaja con una llamada ISDN no multilink cuando no existe una interfaz de acceso virtual. Por lo tanto, si tendrá usuarios de canal B únicos que no negocien multilink y desea instalar tiempos de espera por usuario para ellos, deberá habilitar los perfiles virtuales. La habilitación de perfiles virtuales obliga a la creación de una interfaz `vaccess` para todos los usuarios (no sólo los usuarios de links múltiples) y el proceso de fondo puede insertar satisfactoriamente los comandos `ppp timeout idle` y `timeout absolute`. Si usted elige no habilitar los Perfiles virtuales, los usuarios asincrónicos y los usuarios ISDN del multilink podrán tener agotamientos del tiempo de espera por usuario aplicados a ellos. Pero, los usuarios ISDN sin links múltiples no podrán aplicar el tiempo de espera por usuario. Solamente los tiempos de espera global agotados configurados estáticamente en la interfaz (eventualmente) se aplicarán. Si trata de aplicar los tiempos de espera agotados por usuario a un usuario ISDN no multilink y que no tenga activados los perfiles virtuales, la conexión de usuario no superaría la autorización porque el servidor de acceso era incapaz de procesar los atributos obligatorios de tiempo de espera agotados por usuario.

Además, una característica se ha agregado a las versiones del Cisco IOS 11.3(8.1)T o posteriores que permite que los agotamientos del tiempo de espera por usuario sean aplicados a los usuarios ISDN del sin multilink. Básicamente, elude el modo de configuración de proceso en segundo plano utilizado por lo general y configura los temporizadores directamente en el canal B sin utilizar la interfaz de línea de comandos.

A continuación, se presentan dos reglas que puede seguir para resumir esta configuración complicada:

- Si no usando los Perfiles virtuales, configure al **dialer dentro de la banda** en las interfaces asincrónicas y ejecute el Cisco IOS 11.3(8.1)T o más adelante. Si ejecuta el IOS de Cisco 11.3(8)T, tenga en cuenta que no se puede aplicar el tiempo de espera por usuario a los usuarios ISDN sin links múltiples, ya que de lo contrario no podrían conectarse.
- Si utiliza perfiles virtuales, la versión 11.3(8)T o las versiones posteriores de Cisco IOS funcionarán bien.

Verificación

Actualmente, no hay un procedimiento de verificación disponible para esta configuración.

Troubleshooting

En esta sección encontrará información que puede utilizar para solucionar problemas de configuración. Con el propósito de hacer el debug de, seis ejemplos de resultado de la llamada son incluidos. Para saltar directamente a una sección determinada, seleccione uno de los links abajo:

La herramienta [Output Interpreter](#) (sólo para clientes [registrados](#)) permite utilizar algunos comandos "show" y ver un análisis del resultado de estos comandos.

Nota: [Antes de ejecutar un comando de depuración, consulte Información importante sobre comandos de depuración.](#)

- [Llamada asíncrona con perfiles virtuales: la conexión no se vuelve activa](#)
- ['Llamada asincrónica con perfiles virtuales - la conexión se interrumpe por inactividad'](#)
- [Llamada asíncrona sin perfiles virtuales](#)
- [Llamada ISDN con links múltiples de un solo canal sin perfiles virtuales](#)
- [Llamada ISDN sin links múltiples de un solo canal sin perfiles virtuales](#)
- [Llamada ISDN sin links múltiples de un solo canal con perfiles virtuales](#)

Nota: Para ver los mismos comandos y salida que se presentan abajo, usted debe ser la versión deL Cisco IOS corriente 11.3AA o versión 12.0T.

Llamada asíncrona con perfiles virtuales: la conexión no se vuelve activa

A continuación, hay una llamada asíncrona con perfiles virtuales. El perfil instala un tiempo de espera absoluto de 90 segundos y un tiempo de espera ocioso de 60 segundos. En este ejemplo, no dejaremos que la conexión se interrumpa por inactividad. Vea los comentarios en la salida abajo para más detalles. Los comentarios se resaltan y en el texto puesto en letra itálica.

Llamada asíncrona sin perfiles virtuales

A continuación, hay una llamada asíncrona sin perfiles virtuales activos. Observe que se usa el comando dialer idle-timeout en vez del comando ppp timeout idle, ya que no estamos usando perfiles virtuales y no hay interfaz de acceso virtual. Usted también nos verá crear el **comando per-user timeout** y, al mismo tiempo, la **ninguna** versión de los comandos. **Los comandos per-user timer** están instalados inmediatamente, mientras que no se envía a la cola la **ninguna** versión de los comandos a la interfaz que se procesará cuando las desconexiones del usuario.

[Llamada ISDN sin links múltiples de un solo canal sin perfiles virtuales](#)

A continuación, hay una llamada asíncrona sin perfiles virtuales activos. En este ejemplo, estamos ejecutando el Cisco IOS 11.3(8.2)AA así que estos temporizadores se pueden instalar correctamente. Sin embargo, observe que no se creó a ningunos comandos configuration de causar esto; los temporizadores fueron fijados internamente en el código.

```
