Introduction

L'implémentation de Microsoft du rappel n'est pas conforme avec [RFC 1570](#) . [Cependant, en raison de la grande part de marché du client réseau commuté de Microsoft, Cisco a mis en application le Control Protocol du rappel de service Microsoft \(MSCB\) dans la version de logiciel 11.3\(2\)T et ultérieures de Cisco IOS®.](#)

Conditions préalables

Conditions requises

Assurez-vous de répondre à ces exigences avant d'essayer cette configuration :

- Configurez le serveur d'accès à distance (NAS) pour recevoir des appels analogiques du client. Le rappel est une fonctionnalité supplémentaire d'accès distant de modem. , Vérifiez par conséquent si cet aspect fonctionne correctement. Ceci peut vous aider à dépanner.
- Le circuit T1/E1 doit être capable du dialout. Contactez votre opérateur téléphonique (compagnie de téléphone) pour vérifier ceci.

Composants utilisés

Les informations dans ce document sont basées sur le Logiciel Cisco IOS version 11.3(2)T et les versions ultérieures.

Ce scénario a été testé sur un PC avec le réseau de connexion à distance de Windows.

Les informations présentées dans ce document ont été créées à partir de périphériques dans un environnement de laboratoire spécifique. Tous les périphériques utilisés dans ce document ont démarré avec une configuration effacée (par défaut). Si vous travaillez dans un réseau opérationnel, assurez-vous de bien comprendre l'impact potentiel de toute commande avant de l'utiliser.

Conventions

Pour plus d'informations sur les conventions des documents, référez-vous aux [Conventions utilisées pour les conseils techniques de Cisco](#).

Théorie générale

Le rappel exécute dans cette commande :

1. Un utilisateur sur PC (client) se connecte au serveur d'accès Cisco.
2. Le processus de rappel est négocié pendant la phase du Link Control Protocol de Protocole point à point (PPP) (LCP).
3. L'authentification de PPP est exécutée.
4. Le logiciel de Cisco IOS valide des règles de rappel pour ce utilisateur ou ligne et déconnecte l'appelant pour le rappel.
5. Le serveur d'accès Cisco compose le client.

Il y a quatre types de MSCB :

1. Aucun rappel.
2. Numéro de rappel personnalisé par l'utilisateur.
3. numéro de rappel (préconfiguré) Serveur-spécifié.
4. Liste de numéro de rappel préconfiguré.

La configuration par défaut n'est aucun rappel (option 1). Des Option 2 ou 3 peuvent être configurés :

- Localement (si aucun serveur d'AAA n'est utilisé).
- Dans le profil TACACS+ ou d'utilisateur RADIUS (si l'AAA est utilisé).

Si l'option 2 est configurée, l'utilisateur est incité à introduire son numéro de rappel. Si l'option 3 est configurée, la demande offre seulement un choix, qui est le nombre administrateur-défini.

Cisco implémente seulement la fonctionnalité de serveur de rappel de MSCB et pas de la fonctionnalité de client de rappel. Ceci signifie qu'un routeur de Cisco peut être utilisé seulement en tant que serveur MSCB et pas en tant que client MSCB. En outre, l'implémentation de Cisco de MSCB exige de l'authentification d'être exécutée sur le client.

Configurez

Cette section vous fournit des informations pour configurer les fonctionnalités décrites dans ce document.

Résumé de configuration

Pour activer MSCB, vous devez activer le **rappel de ppp recevez la** commande sous l'interface de réception (par exemple, group-async). En outre, parce que l'authentification est exigée, vous devez activer l'authentification de Password Authentication Protocol (PAP) ou de protocole d'authentification CHAP (Challenge Handshake Authentication Protocol) :

```
ppp authentication chap pap
```

Deux chats-script sont créés automatiquement. Ce sont les chats-script d'**offhook** et de **rappel** :

```
ppp authentication chap pap
```

Les chats-script sont également automatiquement appliqués aux lignes en service :

```
ppp authentication chap pap
```

Un utilisateur doit **être autorisé** à s'appeler de retour. Vous pouvez configurer ceci localement sur le NAS ou sur le serveur externe d'AAA (RAYON ou TACACS+), basé sur où les informations de nom d'utilisateur et mot de passe sont stockées.

C'est une configuration locale pour un utilisateur qui s'appelle de retour à 5551212 :

```
ppp authentication chap pap
```

Cette configuration locale s'applique aux utilisateurs qui sont permis pour spécifier leur propre numéro de rappel :

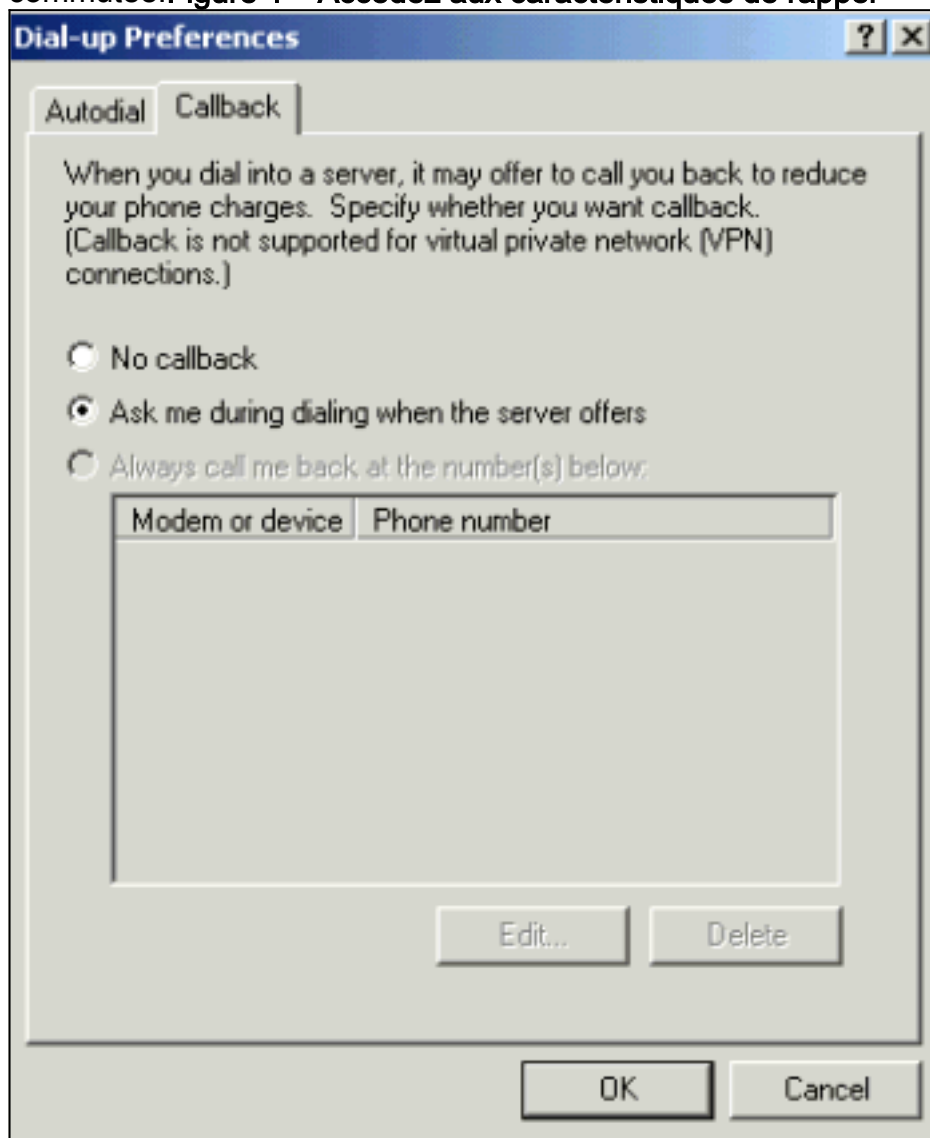

```
ppp authentication chap pap
```

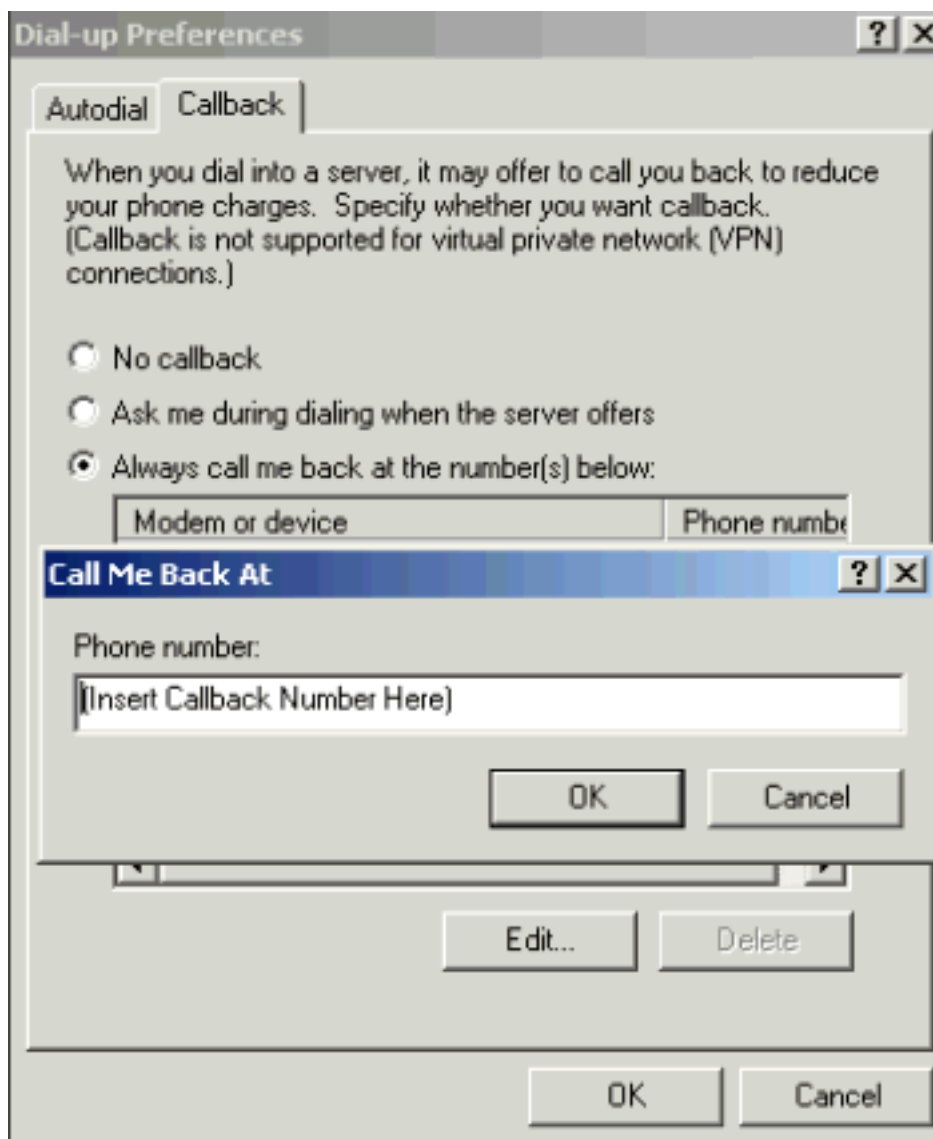

Diagramme du réseau

Ce document utilise la configuration réseau suivante :

périphérique et cliquer sur le bouton d'**éditer**. Introduisez le nombre dans le **champ Numéro de téléphone** suivant les indications de la figure 1, et puis cliquez sur OK-dans l'appel moi de retour à la zone de dialogue.

5. Cliquez sur le **champ Numéro de téléphone**, et introduisez le nombre dans l'appel je de retour à la boîte de dialogue (représentée sur le [schéma 1](#)). Cliquez sur **OK** quand vous avez terminé.
6. Quand vous êtes de finition, cliquez sur OK dans la boîte de dialogue Préférences commuté.**Figure 1 – Accédez aux caractéristiques de rappel**

Vérifiez

Cette section présente des informations que vous pouvez utiliser pour vous assurer que votre configuration fonctionne correctement.

Certaines commandes **show** sont prises en charge par l'[Output Interpreter Tool](#) ([clients enregistrés](#) uniquement), qui vous permet de voir une analyse de la sortie de la commande show.

- **active de show isdn** — affiche des informations au sujet des appels entrants et sortants en cours RNIS. Utilisez cette commande de vérifier si le rappel a été avec succès terminé. Si le rappel est réussi, l'**active de show isdn** affiche l'appel comme sortant sur le serveur de rappel.
- **utilisateurs d'exposition** — affiche des informations au sujet des lignes actives sur le routeur. Vous pouvez également utiliser l'ordre de **show caller** si votre version des supports logiciels de Cisco IOS il.
- **show dialer** — les informations générales de diagnostic d'expositions pour des interfaces configurées pour le Routage à établissement de connexion à la demande (DDR).

Dépannez

Cette section fournit des informations que vous pouvez utiliser pour dépanner votre configuration.

Dépannage des commandes

Note: Avant d'exécuter les commandes **debug**, référez-vous à la section **Informations importantes sur les commandes Debug**.

Pour plus d'informations sur des commandes de **débogage**, voyez la [référence de débogage des commandes de Cisco IOS version 12.0](#).

- **debug aaa authentication** — affiche des informations sur l'authentification d'AAA.
- **autorisation de debug aaa** — affiche des informations sur l'autorisation d'AAA.
- **debug callback** — événements de rappel d'affichages quand le routeur emploie un modem et un script de conversation pour faire appel de retour à une ligne de terminal.
- **debug modem** — te permet d'observer l'activité de ligne du modem sur un serveur d'accès.
- **debug ppp [paquet | négociation | erreur | authentification]** — affiche des informations sur le trafic et échanges d'un interréseau qui implémente le PPP.
paquet — paquets PPP d'affichages étant envoyés et reçus. (Cette commande affiche des vidages mémoire de paquet à bas niveau.)
négociation — paquets PPP d'affichages transmis pendant le startup de PPP, quand des options PPP sont négociées.
erreur — erreurs de protocole et statistiques sur les erreurs d'affichages associées avec la négociation et l'exécution de connexion PPP.
authentification — messages du protocole d'authentification d'affichages, qui incluent des échanges de CHAP et PAP.
- **mettez au point les talks-show** la prise de contact qui se produit entre le serveur d'accès et son modem interne tandis que le modem est chargé pour composer pour sortir. Un chat-script est un ensemble de paires de chaîne expect-send qui définissent la prise de contact entre l'équipement pour terminal de données (DTE) et les périphériques du Data Communications Equipment (DCI).
- **debug isdn q931** — affiche les messages d'établissement d'appel et de désinstallation RNIS Q.931 (canal D) et les met au point. Dans ce scénario, l'appel par modem est porté en tant que service de support vocal au-dessus du réseau téléphonique public commuté (PSTN).
- **debug modem csm** — te permet de dépanner des problèmes du module de commutation d'appel (CSM) sur des Routeurs avec des modems numériques internes. Avec cette commande, vous pouvez tracer la séquence complète d'appels entrant et sortants de commutation.
