[Introdução](#)

Esta configuração de exemplo ilustra como configurar uma interface T1 ou E1 para chamadas analógicas de saída com o comando `modem dialout controller`

[Antes de Começar](#)

[Convenções](#)

Para obter mais informações sobre convenções de documento, consulte as [Convenções de dicas técnicas Cisco](#).

[Pré-requisitos](#)

Não existem requisitos específicos para este documento.

[Componentes Utilizados](#)

As informações neste documento são baseadas nas versões de software e hardware abaixo.

- Software Cisco IOS® Release 12.1(5)T
- Cisco AS5300 com duas PRIs E1

Nota: O comando **modem dialout controller** foi introduzido no software Cisco IOS Release 12.1(T). Recomendamos o software Cisco IOS Release 12.1(3)T ou mais novo para esta implementação. O comando **modem dialout controller** dá suporte a várias interfaces, a partir do software IOS Release 12.1(5)T. Por exemplo:

```
AS5300-3(config)#line 1 60 AS5300-3(config-line)#modem dialout controller t1 ? <0-7> List of controllers to dial out AS5300-3(config-line)#modem dialout controller t1 0,1,3
```

As informações neste documento foram criadas a partir de dispositivos em um ambiente de laboratório específico. Todos os dispositivos utilizados neste documento foram iniciados com uma configuração (padrão) inicial. Se você estiver trabalhando em uma rede ativa, certifique-se de que entende o impacto potencial de qualquer comando antes de utilizá-lo.

[Visão geral](#)

Para que as chamadas analógicas de saída usem determinada linha T1/E1, use o comando **modem dialout controller**. Esse comando é configurado no modo de configuração de linha; assim, os modems ficam limitados à interface T1/E1 especificada para qualquer chamada analógica de saída. Você poderá então configurar os comandos necessários de roteamento de discagem por demanda (DDR, dial on demand routing) na interface assíncrona (ou group-async) correspondente aos modems.

Nesta configuração de exemplo, um servidor de acesso à rede (NAS, network access server) Cisco AS5300 tem duas Interfaces de acesso básico (PRIs, Primary Rate Interfaces), cada uma mapeada para um Serviço de identificação de número discado (DNIS, Dialed Number Identification Service) diferente. Se um cliente discar 8210, a telco comuta a chamada para E1 0, e uma chamada para 8211 é comutada para E1 1. Essa configuração também usa pooling de modem para alocar modems com base nas mensagens do número chamado (DNIS) entregues pelo switch telco durante a configuração de chamada. Dessa forma, as chamadas para determinado número serão "respondidas" apenas por um modem que seja membro de um conjunto de modems específico. Como cada T1/E1 também está limitada a determinado número chamado, correlacionamos efetivamente um conjunto de modems a uma T1/E1 específica para chamadas recebidas.

Para demonstrar o cenário de discagem, o cliente solicita um retorno do servidor de acesso. O retorno é configurado localmente no servidor de acesso, mas os atributos do retorno também podem ser obtidos de um servidor de autenticação, autorização e auditoria (AAA, authentication, authorization, and accounting) RADIUS/TACACS+. Para uma chamada recebida em um número específico, a chamada é comutada para a T1 apropriada e respondida por um membro do conjunto de modems. Depois que o retorno é negociado, o servidor de acesso desconecta a chamada e um retorno é iniciado no mesmo modem. A discagem então é feita usando a interface T1 ou E1 especificada no comando **modem dialout controller**. Neste exemplo, a discagem é configurada para estar na mesma T1/E1 que a chamada recebida.

[Configurar](#)

Nesta seção, você encontrará informações para configurar os recursos descritos neste documento.

Nota: Para encontrar a informação adicional nos comandos usados neste documento, use a

[ferramenta de pesquisa do comando IOS \(clientes registrados somente\)](#).

Diagrama de Rede

Este documento utiliza a instalação de rede mostrada no diagrama abaixo.

Verificar

No momento, não há procedimento de verificação disponível para esta configuração.

Troubleshooting

Esta seção fornece informações que podem ser usadas para o troubleshooting da sua configuração.

Comandos para Troubleshooting

Os determinados comandos de exibição são apoiados pela [ferramenta Output Interpreter](#) ([clientes registrados somente](#)), que permite que você ver uma análise do emissor de comando de execução.

Nota: Antes de emitir **comandos debug**, consulte [Informações importantes sobre comandos debug](#).

- **debug isdn q931** - Mostra as configurações de chamada e o desligamento da conexão de rede ISDN (camada 3) entre o roteador e o Switch ISDN.
- **debug ppp negotiation** - Mostra informações sobre trocas e sobre o tráfego Point-to-Point Protocol (PPP) durante a negociação dos componentes PPP, incluindo o Link Control Protocol (LCP), a autenticação e o Network Control Protocol (NCP). Uma negociação PPP bem-sucedida abre primeiramente o estado LCP; em seguida, efetua a autenticação e,

- finalmente, negocia o NCP (geralmente o IP Control Protocol - IPCP).
- debug ppp authentication – Exibe mensagens de protocolo de autenticação PPP, incluindo intercâmbios de pacote de Protocolo de Autenticação de Desafio (CHAP) e intercâmbios de Protocolo de Autenticação de Senha (PAP).
 - **debug chat** - Para monitorar a execução do script de bate-papo quando a discagem do serviço telefônico comum (POTS, plain old telephone service)/assíncrono é iniciada. Um script de bate-papo é um conjunto de pares de strings expect-send que definem o reconhecimento entre os dispositivos do equipamento de terminal de dados (DTE, data terminal equipment) e do equipamento de comunicação de dados (DCE, data communications equipment).
 - **debug callback** - Mostra eventos de retorno quando o roteador está usando um modem e um script de bate-papo a ser retornado por uma linha do terminal.
 - **debug dialer** - Mostra informações de depuração dos pacotes recebidos na interface do discador.
 - **debug modem csm** (não mostrado aqui) - Mostra informações de depuração na máquina de estado de chamada usada para conectar chamadas no modem. Mostra como a chamada do modem é tratada pelo processo de gerenciamento do modem interno.

Exemplo de debug

Abaixo está a saída obtida com os comandos **debug** mostrados acima.

A saída mostra o cliente efetuando uma chamada para 8210. A chamada é comutada para E1 0 e atendida pelo modem 14 (Async 14), que é membro do conjunto ModemPool8210. A chamada estabelece a conexão, o PPP (e o retorno) é negociado, o cliente é autenticado e o AS5300 desconecta a chamada preparando o retorno. O roteador inicia então o retorno usando o mesmo modem (Async 14). Com o comando **modem dialout controller**, a chamada usa E1 0 e a discagem é efetuada.

Nota: Algumas das linhas mais longas de depuração foram quebradas para impressão adequada. As linhas que começam sem carimbo de hora/data são do final da linha anterior.
