[How does the installer choose a port number for the Default Cache db \(Postgres\)?](#)

Introduction

This document describes installation of the Default Cache database (db).

How does the installer choose a port number for the Default Cache db (Postgres)?

When you introduce a Service Pack or hotfix that brings your install into v7.0.2.00.00 or above for the first time, it installs an additional Postgres instance db to serve as the Default Cache db. This is a new feature introduced by SP-2.

During the installation, reply on InstallBuilder to use regex to determine the port to assign to the new cache db.

Regex scans through our `/conf/server/server_values.xml` file to detect the base http port in use and add +4 to that number.
