PART I

MPLS Introduction 95

CHAPTER 1

MPLS Transport Profile 1

Reference the Chapter Map here 1

Restrictions for MPLS Transport Profile 1

Information About MPLS-TP 2

How MPLS Transport Profile Works 2

MPLS-TP Path Protection 3

Bidirectional LSPs 3

Support for MPLS Transport Profile OAM 3

MPLS Transport Profile Static and Dynamic Multisegment Pseudowires 4

MPLS-TP OAM Status for Static and Dynamic Multisegment Pseudowires 4

MPLS Transport Profile Links and Physical Interfaces 5

Tunnel Midpoints 5

How to Configure MPLS Transport Profile 6
Configuring the MPLS Label Range 6
Configuring the Router ID and Global ID 7
Configuring Bidirectional Forwarding Detection Templates 8
Configuring Pseudowire OAM Attributes 9
Configuring the Pseudowire Class 10
Configuring the Pseudowire 11
Configuring the MPLS-TP Tunnel 13
Configuring MPLS-TP LSPs at Midpoints 16
Configuring MPLS-TP Links and Physical Interfaces 17
Configuring Static-to-Static Multisegment Pseudowires for MPLS-TP 19
Configuring a Template with Pseudowire Type-Length-Value Parameters 21
Configuring Static-to-Dynamic Multisegment Pseudowires for MPLS-TP 22
Verifying the MPLS-TP Configuration 25
Configuration Examples for MPLS Transport Profile 25
Example: Configuring Static-to-dynamic Multisegment Pseudowires for MPLS-TP 25
Additional References for MPLS Transport Profile 26
Feature Information for MPLS Transport Profile 26

CHAPTER 2 **Multiprotocol Label Switching (MPLS) on Cisco Routers 27**
Information About MPLS 27
MPLS Overview 27
Functional Description of MPLS 28
Label Switching Functions 28
Distribution of Label Bindings 28
Benefits of MPLS 29
How to Configure MPLS 30
Configuring a Router for MPLS Switching 30
Verifying Configuration of MPLS Switching 30
Configuring a Router for MPLS Forwarding 31
Verifying Configuration of MPLS Forwarding 32
Additional References 33
Feature Information for MPLS on Cisco Routers 34
Glossary 34

CHAPTER 3 **MPLS Infrastructure Changes Introduction of MFI and Removal of MPLS LSC and LC-ATM Features** 37

Information About MPLS Infrastructure Changes 37

Introduction of the MPLS Forwarding Infrastructure 37

Introduction of IP Rewrite Manager 37

MPLS LSC and LC-ATM Configurations 38

Additional References 38

Feature Information for MPLS Infrastructure Changes 39

CHAPTER 4 **MPLS Static Labels** 41

Restrictions for MPLS Static Labels 41

Prerequisites for MPLS Static Labels 41

Information About MPLS Static Labels 42

MPLS Static Labels Overview 42

Benefits of MPLS Static Labels 42

How to Configure MPLS Static Labels 42

Configuring MPLS Static Prefix Label Bindings 42

Verifying MPLS Static Prefix Label Bindings 43

Configuring MPLS Static Crossconnects 44

Verifying MPLS Static Crossconnect Configuration 45

Monitoring and Maintaining MPLS Static Labels 46

Configuration Examples for MPLS Static Labels 47

Example Configuring MPLS Static Prefixes Labels 47

Example Configuring MPLS Static Crossconnects 48

Additional References 48

Feature Information for MPLS Static Labels 49

Glossary 50

CHAPTER 5 **MPLS Multilink PPP Support** 51

Prerequisites for MPLS Multilink PPP Support 51

Information About MPLS Multilink PPP Support 51

MPLS Layer 3 Virtual Private Network Features Supported for Multilink PPP 51

MPLS Quality of Service Features Supported for Multilink PPP 52

MPLS Multilink PPP Support and PE-to-CE Links 53
MPLS Multilink PPP Support and Core Links 54
MPLS Multilink PPP Support in a CSC Network 54
MPLS Multilink PPP Support in an Interautonomous System 55
How to Configure MPLS Multilink PPP Support 56
Enabling Cisco Express Forwarding 56
Creating a Multilink Bundle 57
Assigning an Interface to a Multilink Bundle 59
Disabling PPP Multilink Fragmentation 61
Verifying the Multilink PPP Configuration 62
Configuration Examples for MPLS Multilink PPP Support 65
Example: Configuring Multilink PPP on an MPLS CSC PE Device 65
Example: Enabling Cisco Express Forwarding 66
Example: Creating a Multilink Bundle 67
Example: Assigning an Interface to a Multilink Bundle 67
Additional References for MPLS Multilink PPP Support 68
Feature Information for MPLS Multilink PPP Support 68
Glossary 69

CHAPTER 6 **6PE Multipath 71**
Information About 6PE Multipath 71
6PE Multipath 71
How to Configure 6PE Multipath 71
Configuring IBGP Multipath Load Sharing 71
Configuration Examples for 6PE Multipath 72
Example: Configuring 6PE Multipath 72
Additional References 73
Feature Information for 6PE Multipath 73

CHAPTER 7 **IPv6 Switching: Provider Edge Router over MPLS 75**
Prerequisites for IPv6 Switching: Provider Edge Router over MPLS 75
Information About IPv6 Switching: Provider Edge Router over MPLS 75
Benefits of Deploying IPv6 over MPLS Backbones 75
IPv6 on the Provider Edge Devices 76

How to Deploy IPv6 Switching: Provider Edge Router over MPLS 77
Deploying IPv6 on the Provider Edge Devices (6PE) 77
Specifying the Source Address Interface on a 6PE Device 77
Binding and Advertising the 6PE Label to Advertise Prefixes 78
Configuring IBGP Multipath Load Sharing 80
Configuration Examples for IPv6 Switching: Provider Edge Router over MPLS 81
Example: Provider Edge Device 81
Example: Core Device 82
Example: Monitoring 6PE 82
Additional References for IPv6 Switching: Provider Edge Router over MPLS 84
Feature Information for IPv6 Switching: Provider Edge Router over MPLS 85

PART II MPLS Embedded Management 87

CHAPTER 8 MPLS Enhancements to Interfaces MIB 89
Prerequisites for MPLS Enhancements to Interfaces MIB 89
Restrictions for MPLS Enhancements to Interfaces MIB 89
Information About MPLS Enhancements to Interfaces MIB 90
Feature Design of the MPLS Enhancements to Interfaces MIB 90
ifStackTable Objects 91
ifRcvAddressTable Objects 91
Interfaces MIB Scalar Objects 92
Stacking Relationships for MPLS Layer Interfaces 92
Stacking Relationships for Traffic Engineering Tunnels 94
MPLS Label Switching Router MIB Enhancements 94
Benefits of the MPLS Enhancements to Interfaces MIB 95
How to Configure MPLS Enhancements to Interfaces MIB 95
Enabling the SNMP Agent 95
Configuration Examples for the MPLS Enhancements to Interfaces MIB 97
MPLS Enhancements to Interfaces MIB: Examples 97
Additional References 97
Feature Information for MPLS Enhancements to Interfaces MIB 99
Glossary 99

CHAPTER 9 **MPLS Label Switching Router MIB** 101

Information About MPLS Label Switching Router MIB 101

MPLS-LSR-MIB Elements 102

MPLS-LSR-MIB Tables 103

Information from Scalar Objects 106

Linking Table Elements 107

Interface Configuration Table and Interface MIB Links 108

Using the MPLS-LSR-MIB 110

MPLS-LSR-MIB Structure 110

CLI Commands and the MPLS-LSR-MIB 111

Benefits 112

How to Configure the MPLS LSR MIB 113

Prerequisites 113

Enabling the SNMP Agent 113

Verifying That the SNMP Agent Has Been Enabled 114

Configuration Examples for the MPLS LSR MIB 115

Additional References 116

Feature Information for MPLS Label Switching Router MIB 117

Glossary 119

CHAPTER 10 **MPLS LSP Ping Traceroute for LDP TE and LSP Ping for VCCV** 121

Prerequisites for MPLS LSP Ping Traceroute for LDP TE and LSP Ping for VCCV 121

Restrictions for MPLS LSP Ping Traceroute for LDP TE and LSP Ping for VCCV 122

Information About MPLS LSP Ping Traceroute for LDP TE and LSP Ping for VCCV 123

MPLS LSP Ping Traceroute for LDP TE and LSP Ping for VCCV Functionality 123

MPLS LSP Ping Operation 123

MPLS LSP Traceroute Operation 124

MPLS Network Management with MPLS LSP Ping and MPLS LSP Traceroute 126

Any Transport over MPLS Virtual Circuit Connection 127

AToM VCCV Signaling 127

Selection of AToM VCCV Switching Types 127

Information Provided by the Router Processing LSP Ping or LSP Traceroute 128

IP Does Not Forward MPLS Echo Request Packets 129

Compatibility Between the MPLS LSP and Ping or Traceroute Implementations 130
CiscoVendorExtensions 131
DSCP Option to Request a Specific Class of Service in an Echo Reply 131
Reply Modes for an MPLS LSP Ping and LSP Traceroute Echo Request Response 131
IPv4 Reply Mode 132
Router-Alert Reply Mode 132
LSP Breaks 132
How to Configure MPLS LSP Ping Traceroute for LDP TE and LSP Ping for VCCV 133
Enabling Compatibility Between the MPLS LSP and Ping or Traceroute Implementation 133
Validating an LDP IPv4 FEC by Using MPLS LSP Ping and MPLS LSP Traceroute 134
Validating a Layer 2 FEC by Using MPLS LSP Ping and MPLS LSP Traceroute 135
Using DSCP to Request a Specific Class of Service in an Echo Reply 136
Controlling How a Responding Router Replies to an MPLS Echo Request 137
Using MPLS LSP Ping to Discover Possible Loops 138
Using MPLS LSP Traceroute to Discover Possible Loops 139
Tracking Packets Tagged as Implicit Null 140
Tracking Untagged Packets 140
Determining Why a Packet Could Not Be Sent 141
Detecting LSP Breaks when Load Balancing Is Enabled for IPv4 LDP LSPs 142
Specifying the Interface Through Which Echo Packets Leave a Router 143
Pacing the Transmission of Packets 144
Interrogating the Transit Router for Its Downstream Information by Using Echo Request request-dsmap 145
Interrogating a Router for Its DSMAP 146
Requesting that a Transit Router Validate the Target FEC Stack 147
Enabling LSP Ping to Detect LSP Breakages Caused by Untagged Interfaces 148
Viewing the AToM VCCV Capabilities Advertised to and Received from the Peer 150
Configuration Examples for MPLS LSP Ping Traceroute for LDP TE and LSP Ping for VCCV 150
Enabling Compatibility Between the MPLS LSP and Ping or Traceroute Implementation Example 151
Validating a Layer 2 FEC by Using MPLS LSP Ping Example 151
Validating an LDP IPv4 FEC by Using MPLS LSP Ping and MPLS LSP Traceroute Example 151
Using DSCP to Request a Specific Class of Service in an Echo Reply Example 152
Controlling How a Responding Router Replies to an MPLS Echo Request Example 152
Preventing Possible Loops with MPLS LSP Ping Example 152

Preventing Possible Loops with MPLS LSP Traceroute Example 153
Troubleshooting with LSP Ping or Traceroute Example 155
Configuration for Sample Topology 156
Verification That the LSP Is Configured Correctly 162
Discovery of LSP Breaks 163
MTU Discovery in an LSP Example 165
Tracking Packets Tagged as Implicit Null Example 166
Tracking Untagged Packets Example 167
Determining Why a Packet Could Not Be Sent Example 168
Detecting LSP Breaks when Load Balancing Is Enabled for IPv4 LSPs Example 169
Specifying the Interface Through Which Echo Packets Leave a Router Example 170
Pacing the Transmission of Packets Example 171
Interrogating the Transit Router for Its Downstream Information Example 172
Interrogating a Router for Its DSMAP Example 173
Requesting that a Transit Router Validate the Target FEC Stack Example 174
Enabling LSP Ping to Detect LSP Breakages Caused by Untagged Interfaces Example 175
Viewing the AToM VCCV Capabilities Advertised to and Received from the Peer Example 175
Additional References 176
Feature Information for MPLS LSP Ping Traceroute for LDP TE and LSP Ping for VCCV 176
Glossary 177

CHAPTER 11 **MPLS LSP Ping, Traceroute, and AToM VCCV 179**
Prerequisites for MPLS LSP Ping, Traceroute, and AToM VCCV 179
Restrictions for MPLS LSP Ping, Traceroute, and AToM VCCV 180
Information About MPLS LSP Ping, Traceroute, and AToM VCCV 180
MPLS LSP Ping Operation 180
MPLS LSP Traceroute Operation 181
Any Transport over MPLS Virtual Circuit Connection Verification 184
AToM VCCV Signaling 184
Selection of AToM VCCV Switching Types 185
Command Options for ping mpls and trace mpls 186
Selection of FECs for Validation 186
Reply Mode Options for MPLS LSP Ping and Traceroute 186
Other MPLS LSP Ping and Traceroute Command Options 188

Option Interactions and Loops 190
MPLS Echo Request Packets Not Forwarded by IP 193
Information Provided by the Device Processing LSP Ping or LSP Traceroute 194
MTU Discovery in an LSP 194
LSP Network Management 196
ICMP ping and trace Commands and Troubleshooting 196
MPLS LSP Ping and Traceroute Discovers LSP Breakage 197
MPLS LSP Traceroute Tracks Untagged Cases 205
MPLS LSP Ping and Traceroute Returns a Q 207
Load Balancing for IPv4 LDP LSPs 207
Additional References 209
Feature Information for MPLS LSP Ping, Traceroute, and AToM VCCV 210
Glossary 211

CHAPTER 12 **MPLS EM - MPLS LSP Multipath Tree Trace 213**
Prerequisites for MPLS EMMPLS EM - MPLS LSP Multipath Tree Trace MPLS LSP Multipath Tree Trace 213
Restrictions for MPLS EM - MPLS LSP Multipath Tree Trace 214
Information About MPLS EM - MPLS LSP Multipath Tree Trace 214
Overview of MPLS LSP Multipath Tree Trace 214
Discovery of IPv4 Load Balancing Paths by MPLS LSP Multipath Tree Trace 215
Echo Reply Return Codes Sent by the Router Processing Multipath LSP Tree Trace 215
MPLS Embedded Management Configuration 216
How to Configure MPLS EM - MPLS LSP Multipath Tree Trace 217
Customizing the Default Behavior of MPLS Echo Packets 217
Configuring MPLS LSP Multipath Tree Trace 218
Discovering IPv4 Load Balancing Paths Using MPLS LSP Multipath Tree Trace 220
Monitoring LSP Paths Discovered by MPLS LSP Multipath Tree Trace Using MPLS LSP Traceroute 222
Using DSCP to Request a Specific Class of Service in an Echo Reply 225
Controlling How a Responding Router Replies to an MPLS Echo Request 226
Reply Modes for an MPLS LSP Multipath Tree Trace Echo Request Response 226
Specifying the Output Interface for Echo Packets Leaving a Router for MPLS LSP Multipath Tree Trace 228

Setting the Pace of MPLS Echo Request Packet Transmission for MPLS LSP Multipath Tree Trace 229
Enabling MPLS LSP Multipath Tree Trace to Detect LSP Breakages 230
Requesting That a Transit Router Validate the Target FEC Stack for MPLS LSP Multipath Tree Trace 232
Setting the Number of Timeout Attempts for MPLS LSP Multipath Tree Trace 233
Configuration Examples for MPLS EM - MPLS LSP Multipath Tree Trace 234
Customizing the Default Behavior of MPLS Echo Packets Example 234
Configuring MPLS LSP Multipath Tree Trace Example 234
Discovering IPv4 Load Balancing Paths Using MPLS LSP Multipath Tree Trace Example 235
Using DSCP to Request a Specific Class of Service in an Echo Reply Example 236
Controlling How a Responding Router Replies to an MPLS Echo Request Example 237
Specifying the Output Interface for Echo Packets Leaving a Router for MPLS LSP Multipath Tree Trace Example 237
Setting the Pace of MPLS Echo Request Packet Transmission for MPLS LSP Multipath Tree Trace Example 238
Enabling MPLS LSP Multipath Tree Trace to Detect LSP Breakages Example 238
Requesting That a Transit Router Validate the Target FEC Stack for MPLS LSP Multipath Tree Trace Example 240
Setting the Number of Timeout Attempts for MPLS LSP Multipath Tree Trace Example 241
Additional References 242

Standards 243
MIBs 244
RFCs 244
Technical Assistance 244
Feature Information for MPLS EM - MPLS LSP Multipath Tree Trace 244
Glossary 245

CHAPTER 13 **MPLS Label Distribution Protocol MIB** 247
Restrictions for MPLS LDP MIB 247
Information About MPLS LDP MIB 247
MPLS LDP Overview 247
MPLS LDP MIB Overview 248
Benefits of Using MPLS LDP MIB 249

Description of MPLS LDP MIB Elements 249
LDP Entities 250
LDP Peers 250
LDP Sessions 251
LDP Hello Adjacencies 251
MPLS LDP MIB Object Categories 251
Events Generating MPLS LDP MIB Notifications 252
How to Configure MPLS LDP MIB 253
Enabling the SNMP Agent for the MPLS LDP MIB 253
Configuring the Router to Send SNMP Traps 254
Verifying the Status of the SNMP Agent 257
Configuration Examples for MPLS LDP MIB 258
Enabling the SNMP Agent Examples 258
Additional References 258
Feature Information for MPLS LDP MIB 259

CHAPTER 14 **MPLS Label Distribution Protocol MIB Version 8 Upgrade 261**
Prerequisites for MPLS LDP MIB Version 8 Upgrade 261
Restrictions for MPLS LDP MIB Version 8 Upgrade 261
Information About MPLS LDP MIB Version 8 Upgrade 262
Feature Design of MPLS LDP MIB Version 8 Upgrade 262
Enhancements in Version 8 of the MPLS LDP MIB 263
Benefits of MPLS LDP MIB Version 8 Upgrade 264
Description of MPLS LDP MIB Elements for MPLS LDP MIB Version 8 Upgrade 264
LDP Entities 265
LDP Sessions and Peers 266
LDP Hello Adjacencies 267
Events Generating MPLS LDP MIB Notifications in MPLS LDP MIB Version 8 Upgrade 268
MIB Tables in MPLS LDP MIB Version 8 Upgrade 269
mplsLdpEntityTable 270
mplsLdpEntityConfGenLRTable 273
mplsLdpEntityAtmParmsTable 273
mplsLdpEntityConfAtmLRTable 274
mplsLdpEntityStatsTable 274

mplsLdpPeerTable 275
mplsLdpHelloAdjacencyTable 276
mplsLdpSessionTable 277
mplsLdpAtmSesTable 277
mplsLdpSesStatsTable 278
VPN Contexts in MPLS LDP MIB Version 8 Upgrade 278
SNMP Context 278
VPN Aware LDP MIB Sessions 279
VPN Aware LDP MIB Notifications 280
How to Configure MPLS LDP MIB Version 8 Upgrade 282
Enabling the SNMP Agent 282
Enabling Distributed Cisco Express Forwarding 283
Enabling MPLS Globally 284
Enabling LDP Globally 285
Enabling MPLS on an Interface 286
Enabling LDP on an Interface 287
Configuring a VPN Aware LDP MIB 288
Configuring SNMP Support for a VPN 288
Configuring an SNMP Context for a VPN 289
Associating an SNMP VPN Context with SNMPv1 or SNMPv2 291
Verifying MPLS LDP MIB Version 8 Upgrade 293
Configuration Examples for MPLS LDP MIB Version 8 Upgrade 293
MPLS LDP MIB Version 8 Upgrade Examples 293
Configuring a VPN Aware SNMP Context for SNMPv1 or SNMPv2 Example 294
Additional References 295
Feature Information for MPLS LDP MIB Version 8 Upgrade 296
Glossary 298

CHAPTER 15 **MPLS VPN--MIB Support** 301
Prerequisites for MPLS VPN--MIB Support 301
Restrictions for MPLS VPN--MIB Support 301
Information About MPLS VPN--MIB Support 302
MPLS VPN Overview 302
MPLS VPN MIB Overview 302

MPLS VPN MIB and the IETF 302
Capabilities Supported by PPVPN-MPLS-VPN MIB 303
Functional Structure of the PPVPN-MPLS-VPN MIB 303
Supported Objects in PPVPN-MPLS-VPN MIB 304
Scalar Objects 304
MIB Tables 305
PPVPN-MPLS-VPN MIB Notifications 314
Unsupported Objects in PPVPN-MPLS-VPN MIB 317
How to Configure MPLS VPN--MIB Support 318
Configuring the SNMP Community 318
Configuring the Router to Send SNMP Traps 319
Configuring Threshold Values for MPLS VPN--SNMP Notifications 322
Configuration Examples for MPLS VPN--MIB Support 324
Example Configuring the SNMP Community 324
Example Configuring the Router to Send SNMP Traps 324
Example Configuring Threshold Values for MPLS VPN--SNMP Notifications 324
Additional References 325
Feature Information for MPLS VPN--MIB Support 326
Glossary 326

CHAPTER 16 **MPLS VPN SNMP Notifications** 329
Prerequisites for MPLS VPN SNMP Notifications 329
Restrictions for MPLS VPN SNMP Notifications 330
Information About MPLS VPN SNMP Notifications 330
Cisco Implementation of MPLS VPN MIB 330
Capabilities Supported by MPLS VPN SNMP Notifications 330
Notification Generation Events for the MPLS VPN MIB 331
Notification Specification for MPLS-VPN-MIB 332
Monitoring the MPLS VPN SNMP Notifications 333
How to Configure the MPLS VPN SNMP Notifications 333
Configuring an SNMP Community 333
Configuring the Device to Send SNMP Traps 334
Configuring Threshold Values for MPLS VPN SNMP Notifications 337
Configuration Examples for MPLS VPN SNMP Notifications 338

Example: Configuring the Community 338
Example: Configuring the Device to Send SNMP Traps 339
Example: Configuring Threshold Values for MPLS VPN SNMP Notifications 339
Additional References 339
Feature Information for MPLS VPN SNMP Notifications 340
Glossary 341

CHAPTER 17 **Pseudowire Emulation Edge-to-Edge MIBs 345**
Prerequisites for Pseudowire Emulation Edge-to-Edge MIBs 345
Restrictions for Pseudowire Emulation Edge-to-Edge MIBs 346
Information About Pseudowire Emulation Edge-to-Edge MIBs 346
The Function of a Pseudowire in the PWE3 MIBs 346
PWE3 MIBs Architecture 347
Components and Functions of the PWE3 MIBs 348
Tables in the PW-MIB 349
cpwVcTable 349
cpwVcPerfTotalTable 353
cpwVcIdMappingTable 353
cpwVcPeerMappingTable 354
Tables in the PW-MPLS-MIB 354
cpwVcMplsTable 355
cpwVcMplsOutboundTable 356
cpwVcMplsInboundTable 356
cpwVcMplsNonTeMappingTable 357
cpwVcMplsTeMappingTable 358
Tables in the PW-ENET-MIB 358
cpwVcEnetTable 358
Tables in the PW-FR-MIB 359
cpwVcFrTable 359
Tables in the PW-ATM-MIB 360
cpwVcAtmTable 360
cpwVcAtmPerfTable 361
Objects in the PWE3 MIBs 361
Scalar Objects in the PWE3 MIBs 362

Notifications in the PWE3 MIBs 362
Benefits of the PWE3 MIBs 362
How to Configure Pseudowire Emulation Edge-to-Edge MIBs 363
Enabling the SNMP Agent for the PWE3 MIBs 363
Configuring the Pseudowire Class 364
What to Do Next 366
Configuration Examples for the Pseudowire Emulation Edge-to-Edge MIBs 366
PWE3 MIBs Example 366
Additional References 367
Feature Information for Pseudowire Emulation Edge-to-Edge MIBs 368
Glossary 369

CHAPTER 18 **MPLS Traffic Engineering--Fast Reroute MIB** 371
Prerequisites for the MPLS Traffic Engineering--Fast Reroute MIB 371
Restrictions for the MPLS Traffic Engineering--Fast Reroute MIB 372
Information About the MPLS Traffic Engineering--Fast Reroute MIB 372
Feature Design of the MPLS Traffic Engineering--Fast Reroute MIB 372
Functional Structure of the MPLS Traffic Engineering--Fast Reroute MIB 373
System Flow of SNMP Protocol Requests and Response Messages 373
FRR MIB Scalar Objects 373
FRR MIB Notification Generation Events 374
FRR MIB Notification Specification 374
FRR MIB Notification Monitoring 375
MIB Tables in the MPLS Traffic Engineering--Fast Reroute MIB 375
cmplsFrrConstTable 375
cmplsFrrLogTable 376
cmplsFrrFacRouteDBTable 376
How to Configure the MPLS Traffic Engineering--Fast Reroute MIB 378
Enabling the SNMP Agent for FRR MIB Notifications 378
Enabling Cisco Express Forwarding 379
Enabling TE Tunnels 380
Enabling MPLS FRR on Each TE Tunnel 381
Enabling a Backup Tunnel on an Interface 382
Configuration Examples for the MPLS Traffic Engineering--Fast Reroute MIB 383

Example Enabling an SNMP Agent on a Host NMS 383
Example Enabling Cisco Express Forwarding 383
Example Enabling TE Tunnels 383
Example Enabling MPLS FRR on Each TE Tunnel 384
Example Enabling a Backup Tunnel on an Interface 384
Additional References 384
Feature Information for MPLS Traffic Engineering--Fast Reroute MIB 385
Glossary 385

CHAPTER 19 **MPLS Traffic Engineering MIB** 387
Restrictions for the MPLS Traffic Engineering MIB 387
Information About the MPLS Traffic Engineering MIB 387
MPLS Traffic Engineering MIB Cisco Implementation 387
MPLS Traffic Engineering Overview 388
Capabilities Supported by the MPLS Traffic Engineering MIB 388
Notification Generation Events 388
Notification Implementation 389
Benefits of the MPLS Traffic Engineering MIB 389
MPLS Traffic Engineering MIB Layer Structure 390
Features and Technologies Related to the MPLS Traffic Engineering MIB 390
Supported Objects in the MPLS Traffic Engineering MIB 390
CLI Access to MPLS Traffic Engineering MIB Information 394
Retrieving Information from the MPLS Traffic Engineering MIB 394
How to Configure the MPLS Traffic Engineering MIB 395
Enabling the SNMP Agent to Help Manage Various MPLS TE Tunnel Characteristics of Tunnels on the Local Router 395
Verifying the Status of the SNMP Agent 396
Examples 397
Configuration Examples for the MPLS Traffic Engineering MIB 397
Example Enabling the SNMP Agent to Help Manage MPLS TE Characteristics of Tunnels on the Local Router 397
Additional References 398
Feature Information for the MPLS Traffic Engineering MIB 399
Glossary 399

CHAPTER 20 **Point-to-Multipoint MPLS-TE MIB** 403

Restrictions for Point-to-Multipoint MPLS-TE MIB 403

Information About the Point-to-Multipoint MPLS-TE MIB 404

Point-to-Multipoint MPLS-TE MIB Cisco Implementation 404

Functionality Supported by the Point-to-Multipoint MPLS-TE MIB 404

Notification Generation Events for the Point-to-Multipoint MPLS-TE MIB 404

Supported Objects in the Point-to-Multipoint MPLS-TE MIB 405

How to Configure the Point-to-Multipoint MPLS-TE MIB 410

Configuring the Router to Send SNMP Notifications to a Host for Monitoring Point-to-Multipoint MPLS-TE 410

Additional References 411

Feature Information for Point-to-Multipoint MPLS-TE MIB 413

CHAPTER 21 **MPLS-TP MIB** 415

Prerequisites for MPLS-TP MIB 415

Restrictions for MPLS-TP MIB 415

Information about MPLS-TP MIB 416

Overview of MPLS-TP MIB 416

CISCO-MPLS-TC-EXT-STD-MIB 416

CISCO-MPLS-ID-EXT-STD-MIB 417

MPLS LSR STD MIB 417

CISCO-MPLS-LSR-EXT-STD-MIB 421

MPLS-TE-STD-MIB and MPLS Draft TE MIB 422

CISCO-MPLS-TE-EXT-STD-MIB 424

How to Configure MPLS-TP MIB 426

Configuring MPLS-TP MIB 426

Enabling the SNMP Agent 426

Verifying the Status of the SNMP Agent 428

Configuration Examples for MPLS-TP MIB 428

Example Enabling the SNMP Agent 428

Example Verifying the Status of the SNMP Agent 429

Additional References 429

Feature Information for MPLS-TP MIB 430

PART III MPLS High Availability 431

CHAPTER 22 MPLS LDP Graceful Restart 433

Prerequisites for MPLS LDP Graceful Restart 433

Restrictions for MPLS LDP Graceful Restart 433

Information About MPLS LDP Graceful Restart 434

How MPLS LDP Graceful Restart Works 434

How a Route Processor Advertises That It Supports MPLS LDP Graceful Restart 435

What Happens If a Route Processor Does Not Have MPLS LDP Graceful Restart 435

How to Configure MPLS LDP Graceful Restart 435

Configuring MPLS LDP Graceful Restart 435

Verifying the MPLS LDP Graceful Restart Configuration 437

Configuration Examples for MPLS LDP Graceful Restart 438

Configuring MPLS LDP Graceful Restart Example 438

Additional References 441

Feature Information for MPLS LDP Graceful Restart 442

CHAPTER 23 Configuring NSF SSO--MPLS VPN 445

Restrictions for NSF SSO--MPLS VPN 445

Information About NSF SSO--MPLS VPN 445

Elements That Enable NSF SSO--MPLS VPN 445

How VPN Prefix Information Is Checkpointed to the Backup Route Processor 446

How BGP Graceful Restart Preserves Prefix Information During a Restart 446

How to Configure NSF SSO--MPLS VPN 446

Configuring NSF Support for Basic VPNs 446

Verifying the Configuration 448

Configuration Examples for NSF SSO--MPLS VPN 449

Example NSF SSO--MPLS VPN for a Basic MPLS VPN 449

Additional References 452

Feature Information for NSF SSO--MPLS VPN 454

CHAPTER 24 ISSU MPLS Clients 455

Prerequisites for ISSU MPLS Clients 455

Information About ISSU MPLS Clients 456
ISSU-Capable Protocols and Applications Clients 456
ISSU-Capable MPLS Feature Sets 457
How to Verify that an MPLS Client Can Support an In Service Software Upgrade 457
Verifying the ISSU Process for an MPLS Client 457
Configuration Examples for ISSU MPLS Clients 459
Verifying the ISSU Process for an MPLS LDP Client Example 460
Verifying the ISSU Process for an MPLS VPN Client Example 461
Verifying the ISSU Process for an MPLS VRF ("Table ID") Client Example 462
Verifying the ISSU Process for an MPLS LSD Label Manager HA Client Example 463
Verifying the ISSU Process for an MPLS MFI Pull Client Example 464
Verifying the ISSU Process for an MPLS MFI Push Client Example 464
Verifying the ISSU Process for an MPLS LSPV Push Client Example 465
Verifying the ISSU Process for an MPLS TE Client Example 466
Additional References 467
Feature Information for ISSU MPLS Clients 468
Glossary 469

CHAPTER 25 **MPLS Traffic Engineering--RSVP Graceful Restart 471**
Prerequisites for MPLS TE--RSVP Graceful Restart 471
Restrictions for MPLS TE--RSVP Graceful Restart 472
Information About MPLS TE--RSVP Graceful Restart 472
Graceful Restart 472
Graceful Restart Benefits 474
How to Configure MPLS TE--RSVP Graceful Restart 474
Enabling Graceful Restart 474
Setting a DSCP Value on a Router for MPLS TE Graceful Restart 475
Setting a Hello Refresh Interval for MPLS TE Graceful Restart 476
Setting a Missed Refresh Limit for MPLS TE Graceful Restart 477
Verifying Graceful Restart Configuration 477
Configuration Examples for MPLS TE--RSVP Graceful Restart 478
Example MPLS TE--RSVP Graceful Restart 478
Additional References 479
Feature Information for MPLS Traffic Engineering--RSVP Graceful Restart 480

Glossary 481

CHAPTER 26 NSF SSO--MPLS TE and RSVP Graceful Restart 483

Prerequisites for NSF SSO--MPLS TE and RSVP Graceful Restart 483

Restrictions for NSF SSO--MPLS TE and RSVP Graceful Restart 484

Information About NSF SSO--MPLS TE and RSVP Graceful Restart 484

Overview of MPLS TE and RSVP Graceful Restart 484

Benefits of MPLS TE and RSVP Graceful Restart 485

How to Configure NSF SSO--MPLS TE and RSVP Graceful Restart 486

Enabling RSVP Graceful Restart Globally 486

Enabling RSVP Graceful Restart on an Interface 487

Setting a DSCP Value for RSVP Graceful Restart 488

Setting a Value to Control the Refresh Interval for RSVP Hello Messages 489

Setting a Value to Control the Missed Refresh Limit for RSVP Graceful Restart Hello Acknowledgements 490

Verifying the RSVP Graceful Restart Configuration 491

Configuration Examples for NSF SSO--MPLS TE and RSVP Graceful Restart 491

Example Configuring NSF SSO--MPLS TE and RSVP Graceful Restart 491

Example Verifying the NSF SSO--MPLS TE and RSVP Graceful Restart Configuration 492

Additional References 492

Feature Information for NSF SSO--MPLS TE and RSVP Graceful Restart 493

Glossary 494

CHAPTER 27 AToM Graceful Restart 497

Prerequisites for AToM Graceful Restart 497

Restrictions for AToM Graceful Restart 497

Information About AToM Graceful Restart 498

How AToM Graceful Restart Works 498

How to Configure AToM Graceful Restart 498

Configuring AToM Graceful Restart 498

Configuration Examples for AToM Graceful Restart 499

Example: Configuring AToM Graceful Restart 499

Examples: Verifying AToM Graceful Restart Recovery from an LDP Session Disruption 500

Additional References 502

Feature Information for AToM Graceful Restart 503

CHAPTER 28 NSF SSO--Any Transport over MPLS and AToM Graceful Restart 505

Prerequisites for AToM NSF 505

Restrictions for AToM NSF 506

Information About AToM NSF 506

How AToM NSF Works 506

AToM Information Checkpointing 506

Checkpointing Troubleshooting Tips for AToM NSF 507

NSF SSO Support for Ethernet to Ethernet VLAN Interworking 507

ISSU Support for AToM NSF 507

How to Configure AToM NSF 507

Configuring MPLS LDP Graceful Restart 508

Configuration Examples for AToM NSF 509

Example Ethernet to VLAN Interworking with AToM NSF 509

Additional References 511

Feature Information for AToM NSF 512

CHAPTER 29 Prerequisites for NSF SSO--MPLS VPN 515

Restrictions for NSF SSO--MPLS VPN 515

Information About NSF SSO--MPLS VPN 516

Elements That Enable NSF SSO--MPLS VPN 516

How VPN Prefix Information Is Checkpointed to the Backup Route Processor 516

How BGP Graceful Restart Preserves Prefix Information During a Restart 516

How to Configure NSF SSO--MPLS VPN 517

Configuring NSF Support for Basic VPNs 517

Verifying the Configuration 518

Configuration Examples for NSF SSO--MPLS VPN 520

Example NSF SSO--MPLS VPN for a Basic MPLS VPN 520

Additional References 523

Feature Information for NSF SSO--MPLS VPN 524

CHAPTER 30 SSO and ISSU--MPLS VPN 6VPE and 6PE Support 525

Prerequisites for SSO and ISSU--MPLS VPN 6VPE and 6PE Support 525

Restrictions for SSO and ISSU--MPLS VPN 6VPE and 6PE Support 526
Information About SSO and ISSU--MPLS VPN 6VPE and 6PE Support 526
Elements Supporting SSO and ISSU--MPLS VPN 6VPE and 6PE Support Features 526
How BGP Graceful Restart Works for MPLS VPN 6vPE and 6PE 526
How BGP Graceful Restart Preserves Prefix Information During a Restart 527
ISSU Support for MPLS VPN 6vPE and 6PE 527
SSO Support for MPLS VPN 6VPE and 6PE 527
BGP Graceful Restart Support for MPLS VPN Configurations 528
Graceful Restart Support for a Basic 6VPE Setup 528
Graceful Restart for 6VPE in Carrier Supporting Carrier and Interautonomous System Setups 528
How to Configure SSO and ISSU--MPLS VPN 6VPE and 6PE Support 529
Configuring SSO for a Basic MPLS 6VPE and 6PE Setup 529
Verifying SSO and ISSU Support for 6VPE and 6PE 531
Configuration Examples for Configuring SSO and ISSU--MPLS VPN 6VPE and 6PE Support 534
Example Configuring SSO for a Basic 6VPE Setup 535
Example Configuring SSO for a Basic 6PE Setup 536
Additional References 537
Feature Information for SSO and ISSU--MPLS VPN 6VPE and 6PE Support 539
Glossary 539

CHAPTER 31 **SSO Support for MPLS TE Autotunnel and Automesh 541**
Prerequisites for SSO Support for MPLS TE Autotunnel and Automesh 541
Restrictions for SSO Support for MPLS TE Autotunnel and Automesh 542
Information About SSO Support for MPLS TE Autotunnel and Automesh 542
Overview of SSO Support for MPLS TE Autotunnel and Automesh 542
Additional References 543
Feature Information for SSO Support for MPLS TE Autotunnel and Automesh 543
Glossary 544

CHAPTER 32 **MPLS Traffic Engineering Nonstop Routing Support 547**
Prerequisites for MPLS Traffic Engineering Nonstop Routing Support 547
Restrictions for MPLS Traffic Engineering Nonstop Routing Support 548
How to Configure MPLS Traffic Engineering Nonstop Routing Support 548
MPLS Traffic Engineering Nonstop Routing Support Overview 548

How to Configure MPLS Traffic Engineering Nonstop Routing Support 548
Configuring MPLS Traffic Engineering Nonstop Routing Support 548
Verifying MPLS Traffic Engineering Nonstop Routing Support 549
Configuration Examples for MPLS Traffic Engineering Nonstop Routing Support 551
Example: Configuring MPLS Traffic Engineering Nonstop Routing Support 551
Example: Verifying MPLS Traffic Engineering Nonstop Routing Support 551
Additional References for MPLS Traffic Engineering Nonstop Routing Support 558
Feature Information for MPLS Traffic Engineering Nonstop Routing Support 559

CHAPTER 33 **NSR LDP Support 561**
Prerequisites for NSR LDP Support 561
Information About NSR LDP Support 561
Roles of the Standby Route Processor and Standby LDP 561
LDP Operating States 562
Initial State 563
Steady State 563
Post Switchover 563
Supported NSR Scenarios 563
How to Configure NSR LDP Support 564
Enabling NSR LDP Support 564
Troubleshooting Tips for NSR LDP Support 565
Configuration Examples for NSR LDP Support 565
Example: NSR LDP Configuration 565
Additional References for NSR LDP Support 565

PART IV **MPLS LDP 567**

CHAPTER 34 **MPLS Label Distribution Protocol 569**
Prerequisites for MPLS Label Distribution Protocol 569
Information About MPLS Label Distribution Protocol 569
Introduction to MPLS Label Distribution Protocol 569
MPLS Label Distribution Protocol Functional Overview 570
Introduction to LDP Sessions 570
Directly Connected MPLS LDP Sessions 570

Nondirectly Connected MPLS LDP Sessions 570
Introduction to LDP Label Bindings Label Spaces and LDP Identifiers 571
How to Configure MPLS Label Distribution Protocol 572
Enabling Directly Connected LDP Sessions 572
Establishing Nondirectly Connected MPLS LDP Sessions 575
Saving Configurations MPLS Tag Switching Commands 578
Specifying the LDP Router ID 578
Preserving QoS Settings with MPLS LDP Explicit Null 581
Protecting Data Between LDP Peers with MD5 Authentication 585
Configuration Examples for MPLS Label Distribution Protocol 587
Example: Configuring Directly Connected MPLS LDP Sessions 587
Example: Establishing Nondirectly Connected MPLS LDP Sessions 589
Additional References 591

CHAPTER 35 **MPLS LDP Session Protection** 593
Prerequisites for MPLS LDP Session Protection 593
Restrictions for MPLS LDP Session Protection 593
Information About MPLS LDP Session Protection 594
How MPLS LDP Session Protection Works 594
MPLS LDP Session Protection Customization 594
How Long an LDP Targeted Hello Adjacency Should Be Retained 594
Which Devices Should Have MPLS LDP Session Protection 594
How to Configure MPLS LDP Session Protection 595
Enabling MPLS LDP Session Protection 595
Troubleshooting Tips 597
Verifying MPLS LDP Session Protection 597
Configuration Examples for MPLS LDP Session Protection 599
Example: Configuring MPLS LDP Session Protection 599
Additional References 602
Feature Information for MPLS LDP Session Protection 603

CHAPTER 36 **MPLS LDP Autoconfiguration** 605
Restrictions for MPLS LDP Autoconfiguration 605
Information About MPLS LDP Autoconfiguration 606

MPLS LDP Autoconfiguration on OSPF and IS-IS Interfaces 606
How to Configure MPLS LDP Autoconfiguration 606
Configuring MPLS LDP Autoconfiguration with OSPF Interfaces 606
Disabling MPLS LDP Autoconfiguration from Selected OSPF Interfaces 608
Verifying MPLS LDP Autoconfiguration with OSPF 609
Configuring MPLS LDP Autoconfiguration with IS-IS Interfaces 610
Disabling MPLS LDP Autoconfiguration from Selected IS-IS Interfaces 612
Verifying MPLS LDP Autoconfiguration with IS-IS 613
Troubleshooting Tips 613
Configuration Examples for MPLS LDP Autoconfiguration 614
Example: MPLS LDP Autoconfiguration with OSPF 614
Example: MPLS LDP Autoconfiguration with IS-IS 614
Additional References 615
Feature Information for MPLS LDP Autoconfiguration 616

CHAPTER 37 **MPLS LDP IGP Synchronization 617**
Prerequisites for MPLS LDP IGP Synchronization 617
Restrictions for MPLS LDP IGP Synchronization 617
Information About MPLS LDP IGP Synchronization 618
How MPLS LDP IGP Synchronization Works 618
MPLS LDP IGP Synchronization with Peers 618
MPLS LDP IGP Synchronization Delay Timer 619
MPLS LDP IGP Synchronization Incompatibility with IGP Nonstop Forwarding 619
MPLS LDP IGP Synchronization Compatibility with LDP Graceful Restart 619
How to Configure MPLS LDP IGP Synchronization 620
Configuring MPLS LDP IGP Synchronization with OSPF Interfaces 620
Disabling MPLS LDP IGP Synchronization from Some OSPF Interfaces 621
Verifying MPLS LDP IGP Synchronization with OSPF 623
Configuring MPLS LDP IGP Synchronization with IS-IS Interfaces 624
Configuring MPLS LDP IGP Synchronization on All IS-IS Interfaces 624
Configuring MPLS LDP IGP Synchronization on an IS-IS Interface 626
Disabling MPLS LDP IGP Synchronization from Some IS-IS Interfaces 627
Troubleshooting Tips 628
Configuration Examples for MPLS LDP IGP Synchronization 628

Example: MPLS LDP IGP Synchronization with OSPF 628
Example: MPLS LDP IGP Synchronization with IS-IS 629
Additional References 629
Feature Information for MPLS LDP IGP Synchronization 630

CHAPTER 38 MPLS LDP Inbound Label Binding Filtering 631
Restrictions for MPLS LDP Inbound Label Binding Filtering 631
Information about MPLS LDP Inbound Label Binding Filtering 631
Overview of MPLS LDP Inbound Label Binding Filtering 631
How to Configure MPLS LDP Inbound Label Binding Filtering 632
Configuring MPLS LDP Inbound Label Binding Filtering 632
Verifying that MPLS LDP Inbound Label Bindings are Filtered 633
Configuration Examples for MPLS LDP Inbound Label Binding Filtering 635
Examples: MPLS LDP Inbound Label Binding Filtering Configuration 635
Additional References 635
Feature Information for MPLS LDP Inbound Label Binding Filtering 636
Glossary 636

CHAPTER 39 MPLS LDP Local Label Allocation Filtering 639
Prerequisites for MPLS LDP Local Label Allocation Filtering 639
Restrictions for MPLS LDP Local Label Allocation Filtering 639
Information About MPLS LDP Local Label Allocation Filtering 640
MPLS LDP Local Label Allocation Filtering Overview 640
Prefix Lists for MPLS LDP Local Label Allocation Filtering Benefits and Description 641
Local Label Allocation Changes and LDP Actions 641
LDP Local Label Filtering and BGP Routes 642
How to Configure MPLS LDP Local Label Allocation Filtering 643
Creating a Prefix List for MPLS LDP Local Label Allocation Filtering 643
Configuring MPLS LDP Local Label Allocation Filtering 644
Verifying MPLS LDP Local Label Allocation Filtering Configuration 646
Configuration Examples for MPLS LDP Local Label Allocation Filtering 648
Examples: Creating a Prefix List for MPLS LDP Local Label Allocation Filtering 648
Examples: Configuring MPLS LDP Local Label Allocation Filtering 648
Examples: Sample MPLS LDP Local Label Allocation Filtering Configuration 649

Routing Table on Device R1 650
Local Label Bindings on Devices R1, R2, and R3 650
Local Label Allocation Filtering Configuration on Device R1 652
Local Label Allocation Filtering Changes Label Bindings on Devices R1, R2, and R3 652
Command to Display the Local Label Allocation Filter 654
Additional References 655
Feature Information for MPLS LDP Local Label Allocation Filtering 655
Glossary 656

CHAPTER 40 **MPLS LDP MD5 Global Configuration** 657
Prerequisites for MPLS LDP MD5 Global Configuration 657
Restrictions for MPLS LDP MD5 Global Configuration 658
Information About MPLS LDP MD5 Global Configuration 658
Enhancements to LDP MD5 Protection for LDP Messages Between Peers 658
LDP MD5 Password Configuration Information 658
LDP MD5 Password Configuration for Routing Tables 660
How LDP Tears Down Sessions 660
How to Configure MPLS LDP MD5 Global Configuration 660
Identifying LDP Neighbors for LDP MD5 Password Protection 660
Configuring an LDP MD5 Password for LDP Sessions 662
Configuring an LDP MD5 Password for a Specified Neighbor 662
Configuring an LDP MD5 Password for LDP Sessions with Peers from a Specified VRF 665
Configuring an LDP MD5 Password for LDP Sessions with a Selected Group of Peers 666
Verifying the LDP MD5 Configuration 668
Configuration Examples for MPLS LDP MD5 Global Configuration 671
Example: Configuring an LDP MD5 Password for LDP Sessions for a Specified Neighbor 671
Examples: Configuring an LDP MD5 Password for LDP Sessions with Peers from a Specified VRF 671
Example: Configuring an LDP MD5 Password for LDP Sessions with a Selected Group of Peers 672
Additional References 672
Feature Information for MPLS LDP MD5 Global Configuration 673
Glossary 673

CHAPTER 41 **MPLS LDP Lossless MD5 Session Authentication** 675

Prerequisites for MPLS LDP Lossless MD5 Session Authentication 675
Restrictions for MPLS LDP Lossless MD5 Session Authentication 676
Information About MPLS LDP Lossless MD5 Session Authentication 676
How MPLS LDP Messages in MPLS LDP Lossless MD5 Session Authentication are Exchanged 676
The Evolution of MPLS LDP MD5 Password Features 676
Keychains Use with MPLS LDP Lossless MD5 Session Authentication 677
Application of Rules to Overlapping Passwords 678
Password Rollover Period Guidelines 678
Resolving LDP Password Problems 679
How to Configure MPLS LDP Lossless MD5 Session Authentication 679
Configuring MPLS LDP Lossless MD5 Session Authentication Using a Keychain 679
Enabling the Display of MPLS LDP Password Rollover Changes and Events 683
Changing MPLS LDP Lossless MD5 Session Authentication Passwords 685
Configuration Examples for MPLS LDP Lossless MD5 Session Authentication 687
Example: Configuring MPLS LDP Lossless MD5 Session Authentication Using a Keychain (Symmetrical) 687
Example: Configuring MPLS LDP Lossless MD5 Session Authentication Using a Keychain (Asymmetrical) 688
Examples: Changing MPLS LDP Lossless MD5 Session Authentication Password 689
Examples: Changing MPLS LDP Lossless MD5 Session Authentication Password Using a Rollover Without Keychain 690
Example: Changing MPLS LDP Lossless MD5 Session Authentication Password Using a Rollover with a Keychain 691
Examples: Changing MPLS LDP Lossless MD5 Session Authentication Password Using a Fallback Password with a Keychain 693
Examples: Changing MPLS LDP Lossless MD5 Session Authentication Common Misconfiguration 695
Examples: Incorrect Keychain LDP Password Configuration 695
Avoiding Access List Configuration Problems 697
Examples: Changing MPLS LDP Lossless MD5 Session Authentication Using a Second Key to Avoid LDP Session Failure 697
Example: TCP Authentication and LDP Sessions Can Fail When a Second Rollover Period Is Missing 697
Examples: Reconfigure a Keychain to Prevent TCP Authentication and LDP Session Failures 698
Additional References 699

Feature Information for MPLS LDP Lossless MD5 Session Authentication 699

CHAPTER 42 **MPLS LDP VRF-Aware Static Labels 701**

Information About MPLS LDP VRF-Aware Static Labels 701

Overview of MPLS Static Labels and MPLS LDP VRF-Aware Static Labels 701

Labels Reserved for Static Assignment 702

How to Configure MPLS LDP VRF-Aware Static Labels 702

Reserving Labels to Use for MPLS Static Labels and MPLS LDP VRF-Aware Static Labels 702

Configuring MPLS Static Labels in the MPLS VPN Provider Core 703

Configuring MPLS Static Cross Connects 704

Configuring MPLS LDP VRF-Aware Static Labels at the Edge of the VPN 706

Troubleshooting Tips 707

Configuration Examples for MPLS LDP VRF-Aware Static Labels 707

Example: Reserving Labels to Use for MPLS Static Labels and MPLS LDP VRF-Aware Static Labels 707

Example: Configuring MPLS Static Labels in the MPLS VPN Provider Core 708

Example: Configuring MPLS LDP VRF-Aware Static Labels at the VPN Edge 708

Additional References 709

Feature Information for MPLS LDP VRF-Aware Static Labels 709

CHAPTER 43 **MPLS LDP Entropy Label Support 711**

Information About MPLS LDP Entropy Label Support 711

Overview of MPLS LDP Entropy Label 711

Benefits of MPLS LDP Entropy Label Support 711

LDP Entropy Label Capability Signaling 712

How to Configure MPLS LDP Entropy Label Support 712

Enabling MPLS LDP Entropy Label Support 712

Verifying MPLS LDP Entropy Label Support 713

Additional References for MPLS LDP Entropy Label Support 717

Feature Information for MPLS LDP Entropy Label Support 718

PART V **MPLS Layer 2 VPNs 719**

CHAPTER 44 **L2VPN Protocol-Based CLIs 721**

Information About L2VPN Protocol-Based CLIs 721
Overview of L2VPN Protocol-Based CLIs 721
Benefits of L2VPN Protocol-Based CLIs 721
L2VPN Protocol-Based CLI Changes 722
MPLS L2VPN Protocol-Based CLI: Examples 726
Additional References 729
Feature Information for L2VPN Protocol-Based CLIs 730

CHAPTER 45 **Any Transport over MPLS 731**
Prerequisites for Any Transport over MPLS 731
Restrictions for Any Transport over MPLS 732
General Restrictions 732
ATM AAL5 over MPLS Restrictions 733
ATM Cell Relay over MPLS Restrictions 733
Ethernet over MPLS (EoMPLS) Restrictions 733
Per-Subinterface MTU for Ethernet over MPLS Restrictions 733
Frame Relay over MPLS Restrictions 734
HDLC over MPLS Restrictions 734
PPP over MPLS Restrictions 734
Tunnel Selection Restrictions 734
Experimental Bits with AToM Restrictions 735
Remote Ethernet Port Shutdown Restrictions 735
Information About Any Transport over MPLS 735
How AToM Transports Layer 2 Packets 735
How AToM Transports Layer 2 Packets Using Commands Associated with L2VPN Protocol-Based Feature 736
Benefits of AToM 737
MPLS Traffic Engineering Fast Reroute 738
Maximum Transmission Unit Guidelines for Estimating Packet Size 738
Estimating Packet Size Example 739
Per-Subinterface MTU for Ethernet over MPLS 739
Per-Subinterface MTU for Ethernet over MPLS using the commands associated with the L2VPN Protocol-Based CLIs feature 740
Frame Relay over MPLS and DTE DCE and NNI Connections 740

Local Management Interface and Frame Relay over MPLS 741
QoS Features Supported with AToM 742
OAM Cell Emulation for ATM AAL5 over MPLS 745
OAM Cell Emulation for ATM AAL5 over MPLS in VC Class Configuration Mode 745
Any Transport over MPLS (AToM) Remote Ethernet Port Shutdown 746
Any Transport over MPLS (AToM) Remote Ethernet Port Shutdown Using Commands Associated with L2VPN Protocol-Based Feature 747
AToM Load Balancing with Single PW 748
Flow-Aware Transport (FAT) Load Balancing 748
Information About EoMPLS over IPv6 GRE Tunnel 748
Additional Information on EoMPLS over IPv6 GRE Tunnel 749
How to Configure Any Transport over MPLS 749
Configuring the Pseudowire Class 749
Configuring the Pseudowire Class Using Commands Associated with L2VPN Protocol-Based Feature 750
Changing the Encapsulation Type and Removing a Pseudowire 751
Changing the Encapsulation Type and Removing a Pseudowire Using Commands Associated with the L2VPN Protocol-Based Feature 751
Configuring ATM AAL5 over MPLS 752
Configuring ATM AAL5 over MPLS on PVCs 752
Configuring ATM AAL5 over MPLS on PVCs using the commands associated with the L2VPN Protocol-Based CLIs feature 753
Configuring ATM AAL5 over MPLS in VC Class Configuration Mode 756
Configuring ATM AAL5 over MPLS in VC Class Configuration Mode using the commands associated with the L2VPN Protocol-Based CLIs feature 758
Configuring OAM Cell Emulation for ATM AAL5 over MPLS 761
Configuring OAM Cell Emulation for ATM AAL5 over MPLS on PVCs 761
Configuring OAM Cell Emulation for ATM AAL5 over MPLS on PVCs using the commands associated with the L2VPN Protocol-Based CLIs feature 763
Configuring OAM Cell Emulation for ATM AAL5 over MPLS in VC Class Configuration Mode 766
Configuring OAM Cell Emulation for ATM AAL5 over MPLS in VC Class Configuration Mode using the commands associated with the L2VPN Protocol-Based CLIs feature 768
Configuring ATM Cell Relay over MPLS 771
Configuring ATM Cell Relay over MPLS in VC Mode 771

Configuring ATM Cell Relay over MPLS in VC Mode using the commands associated with the L2VPN Protocol-Based CLIs feature 772

Configuring ATM Cell Relay over MPLS in VC Mode Using VC Class Configuration Mode 775

Configuring ATM Cell Relay over MPLS in VC Mode Using VC Class Configuration Mode using the commands associated with the L2VPN Protocol-Based CLIs feature 776

Configuring ATM Cell Relay over MPLS in PVP Mode 778

Configuring ATM Cell Relay over MPLS in PVP Mode using the commands associated with the L2VPN Protocol-Based CLIs feature 780

Configuring Ethernet over MPLS 782

Configuring Ethernet over MPLS in VLAN Mode to Connect Two VLAN Networks That Are in Different Locations. 782

Configuring Ethernet over MPLS in VLAN Mode to Connect Two VLAN Networks That Are in Different Locations using the commands associated with the L2VPN Protocol-Based CLIs feature 783

Configuring Ethernet over MPLS in Port Mode 785

Configuring Ethernet over MPLS in Port Mode Using Commands Associated with the L2VPN Protocol-Based Feature 786

Configuring Ethernet over MPLS with VLAN ID Rewrite 788

Configuring Ethernet over MPLS with VLAN ID Rewrite Using Commands Associated with the L2VPN Protocol-Based Feature 789

Configuring per-Subinterface MTU for Ethernet over MPLS 791

Configuring per-Subinterface MTU for Ethernet over MPLS using the commands associated with the L2VPN Protocol-Based CLIs feature 793

Configuring Frame Relay over MPLS 796

Configuring Frame Relay over MPLS with DLCI-to-DLCI Connections 796

Configuring Frame Relay over MPLS with DLCI-to-DLCI Connections using the commands associated with the L2VPN Protocol-Based CLIs feature 797

Configuring Frame Relay over MPLS with Port-to-Port Connections 800

Configuring Frame Relay over MPLS with Port-to-Port Connections using the commands associated with the L2VPN Protocol-Based CLIs feature 801

Configuring HDLC or PPP over MPLS 803

Configuring HDLC or PPP over MPLS using the commands associated with the L2VPN Protocol-Based CLIs feature 804

Configuring Tunnel Selection 806

Troubleshooting Tips 808

Configuring Tunnel Selection Using Commands Associated with L2VPN Protocol-Based Feature 809

Troubleshooting Tips using the commands associated with the L2VPN Protocol-Based CLIs feature 811

Setting Experimental Bits with AToM 811

Enabling the Control Word 813

Enabling the Control Word using the commands associated with the L2VPN Protocol-Based CLIs feature 814

Configuring MPLS AToM Remote Ethernet Port Shutdown 816

Configuring MPLS AToM Remote Ethernet Port Shutdown using the commands associated with the L2VPN Protocol-Based CLIs feature 817

Configuring AToM Load Balancing with Single PW 819

Configuring AToM Load Balancing with Single PW using the commands associated with the L2VPN Protocol-Based CLIs feature 820

Configuring Flow-Aware Transport (FAT) Load Balancing 822

Configuring Flow-Aware Transport (FAT) Load Balancing using a template 825

Configuration Examples for Any Transport over MPLS 830

Example: ATM over MPLS 830

Example: ATM over MPLS Using Commands Associated with L2VPN Protocol-Based Feature 831

Example: Configuring ATM AAL5 over MPLS in VC Class Configuration Mode 834

Example: Configuring ATM AAL5 over MPLS in VC Class Configuration Mode Using Commands Associated with L2VPN Protocol-Based Feature 834

Example: Ethernet over MPLS with MPLS Traffic Engineering Fast Reroute 835

Example: Ethernet over MPLS with MPLS Traffic Engineering Fast Reroute Using Commands Associated with L2VPN Protocol-Based Feature 837

Example: Configuring OAM Cell Emulation 841

Example: Configuring OAM Cell Emulation using the commands associated with the L2VPN Protocol-Based CLIs feature 842

Example: Configuring ATM Cell Relay over MPLS 843

Example: Configuring ATM Cell Relay over MPLS using the commands associated with the L2VPN Protocol-Based CLIs feature 844

Example: Configuring per-Subinterface MTU for Ethernet over MPLS 845

Example: Configuring per-Subinterface MTU for Ethernet over MPLS using the commands associated with the L2VPN Protocol-Based CLIs feature 847

Example: Configuring Tunnel Selection 849

Example: Configuring Tunnel Selection Using Commands Associated with L2VPN Protocol-Based Feature 851
Example: Configuring MTU Values in xconnect Configuration Mode for L2VPN Interworking 853
Example: Configuring MTU Values in xconnect Configuration Mode for L2VPN Interworking Using Commands Associated with L2VPN Protocol-Based Feature 856
Examples: Configuring Any Transport over MPLS (AToM) Remote Ethernet Port Shutdown 858
Examples: Configuring Any Transport over MPLS (AToM) Remote Ethernet Port Shutdown Using Commands Associated with L2VPN Protocol-Based Feature 859
Additional References for Any Transport over MPLS 860
Feature Information for Any Transport over MPLS 860

CHAPTER 46 L2VPN Interworking 865
Prerequisites for L2VPN Interworking 865
Restrictions for L2VPN Interworking 866
General Restrictions for L2VPN Interworking 866
Restrictions for Routed Interworking 867
Restrictions for PPP Interworking 867
Restrictions for Ethernet/VLAN-to-ATM AAL5 Interworking 868
Restrictions for Ethernet/VLAN-to-Frame Relay Interworking 869
Restrictions for HDLC-to-Ethernet Interworking 869
Information About L2VPN Interworking 870
Overview of L2VPN Interworking 870
L2VPN Interworking Modes 870
Ethernet or Bridged Interworking 870
IP or Routed Interworking 871
Ethernet VLAN-to-ATM AAL5 Interworking 872
ATM AAL5-to-Ethernet Port AToM--Bridged Interworking 872
ATM AAL5-to-Ethernet VLAN 802.1Q AToM--Bridged Interworking 873
ATM-to-Ethernet--Routed Interworking 874
Ethernet VLAN-to-Frame Relay Interworking 875
Frame Relay DLCI-to-Ethernet Port AToM--Bridged Interworking 875
Frame Relay DLCI-to-Ethernet VLAN 802.1Q AToM--Bridged Interworking 876
Frame Relay DLCI-to-Ethernet VLAN Qot1Q QinQ AToM - Bridged Interworking 877
HDLC-to-Ethernet Interworking 878

HDLC-to-Ethernet — Ethernet or Bridged Interworking 878
HDLC-to-Ethernet — IP or Routed Interworking 879
ATM Local Switching 880
VC-to-VC Local Switching 880
VP-to-VP Local Switching 881
PPP-to-Ethernet AToM-Routed Interworking 882
PPP-to-Ethernet AToM-Routed Interworking using the commands associated with the L2VPN Protocol-Based CLIs feature 882
Static IP Addresses for L2VPN Interworking for PPP 883
Static IP Addresses for L2VPN Interworking for PPP using the commands associated with the L2VPN Protocol-Based CLIs feature 883
How to Configure L2VPN Interworking 884
Configuring L2VPN Interworking 884
Verifying the L2VPN Configuration 885
Configuring L2VPN Interworking using the commands associated with the L2VPN Protocol-Based CLIs feature 885
Verifying the L2VPN Configuration using the commands associated with the L2VPN Protocol-Based CLIs feature 887
Configuring Ethernet VLAN-to-ATM AAL5 Interworking 887
ATM AAL5-to-Ethernet Port 887
ATM AAL5-to-Ethernet Port using the commands associated with the L2VPN Protocol-Based CLIs feature 889
ATM AAL5-to-Ethernet Port on a PE2 Router 892
ATM AAL5-to-Ethernet Port on a PE2 Router using the commands associated with the L2VPN Protocol-Based CLIs feature 894
ATM AAL5-to-Ethernet VLAN 802.1Q on a PE1 Router 897
ATM AAL5-to-Ethernet VLAN 802.1Q on a PE1 Router using the commands associated with the L2VPN Protocol-Based CLIs feature 899
ATM AAL5-to-Ethernet VLAN 802.1Q on a PE2 router 902
ATM AAL5-to-Ethernet VLAN 802.1Q on a PE2 router using the commands associated with the L2VPN Protocol-Based CLIs feature 904
Configuring Ethernet VLAN-to-Frame Relay Interworking 907
Frame Relay DLCI-to-Ethernet Port on a PE1 Router 907
Frame Relay DLCI-to-Ethernet Port on a PE1 Router using the commands associated with the L2VPN Protocol-Based CLIs feature 909
Frame Relay DLCI-to-Ethernet Port on a PE2 router 912

Frame Relay DLCI-to-Ethernet Port on a PE2 router using the commands associated with the L2VPN Protocol-Based CLIs feature **914**

Frame Relay DLCI-to-Ethernet VLAN 802.1Q on a PE1 Router **917**

Frame Relay DLCI-to-Ethernet VLAN 802.1Q on a PE1 Router using the commands associated with the L2VPN Protocol-Based CLIs feature **919**

Frame Relay DLCI-to-Ethernet VLAN 802.1Q on a PE2 Router **923**

Frame Relay DLCI-to-Ethernet VLAN 802.1Q on a PE2 Router using the commands associated with the L2VPN Protocol-Based CLIs feature **925**

Configuring HDLC-to-Ethernet Interworking **928**

HDLC-to-Ethernet Bridged Interworking on a HDLC PE Device **928**

HDLC-to-Ethernet Bridged Interworking on a HDLC PE Device Using the Commands Associated with the L2VPN Protocol-Based CLIs Feature **929**

HDLC-to-Ethernet Bridged Interworking (Port Mode) on an Ethernet PE Device **932**

HDLC-to-Ethernet Bridged Interworking (Port Mode) on an Ethernet PE Device Using the Commands Associated with the L2VPN Protocol-Based CLIs Feature **933**

HDLC-to-Ethernet Bridged Interworking (dot1q and QinQ Modes) on an Ethernet PE Device **936**

HDLC-to-Ethernet Bridged Interworking (dot1q and QinQ Modes) on an Ethernet PE Device Using the Commands Associated with the L2VPN Protocol-Based CLIs Feature **937**

HDLC-to-Ethernet Routed Interworking on a HDLC PE Device **940**

HDLC-to-Ethernet Routed Interworking on a HDLC PE Device Using the Commands Associated with the L2VPN Protocol-Based CLIs Feature **942**

HDLC-to-Ethernet Routed Interworking (Port Mode) on an Ethernet PE Device **944**

HDLC-to-Ethernet Routed Interworking (Port Mode) on an Ethernet PE Device Using the Commands Associated with the L2VPN Protocol-Based CLIs Feature **946**

HDLC-to-Ethernet Routed Interworking (dot1q and QinQ Modes) on an Ethernet PE Device **949**

HDLC-to-Ethernet Routed Interworking (dot1q and QinQ Modes) on an Ethernet PE Device Using the Commands Associated with the L2VPN Protocol-Based CLIs Feature **950**

Verifying HDLC-to-Ethernet Interworking (Port Mode) Configuration on a HDLC PE Device **953**

Verifying HDLC-to-Ethernet Interworking (Port Mode) Configuration on an Ethernet PE Device **956**

Verifying HDLC-to-Ethernet Interworking (dot1q Mode) Configuration on a HDLC PE Device **958**

Verifying HDLC-to-Ethernet Interworking (dot1q Mode) Configuration on an Ethernet PE Device **960**

Verifying HDLC-to-Ethernet Interworking (QinQ Mode) Configuration on a HDLC PE Device **963**

Verifying HDLC-to-Ethernet Interworking (QinQ Mode) Configuration on an Ethernet PE Device **965**

Verifying L2VPN Interworking 968

Verifying L2VPN Interworking using the commands associated with the L2VPN Protocol-Based CLIs feature 968

Configuration Examples for L2VPN Interworking 969

Frame Relay DLCI-to-Ethernet VLAN 802.1Q Using Bridged Internetworking Example 969

Frame Relay DLCI-to-Ethernet VLAN 802.1Q Using Bridged Internetworking Example using the commands associated with the L2VPN Protocol-Based CLIs feature 969

ATM AAL5-to-Ethernet VLAN 802.1Q Using Bridged Internetworking Example 970

ATM AAL5-to-Ethernet VLAN 802.1Q Using Bridged Internetworking Example using the commands associated with the L2VPN Protocol-Based CLIs feature 970

ATM AAL5-to-Ethernet Port Using Routed Interworking Example 971

Frame Relay DLCI-to-Ethernet Port Using Routed Interworking Example 971

Frame Relay DLCI-to-Ethernet Port Using Routed Interworking Example using the commands associated with the L2VPN Protocol-Based CLIs feature 972

Ethernet-to-VLAN over AToM--Bridged Example 972

Ethernet to VLAN over AToM (Bridged) Example using the commands associated with the L2VPN Protocol-Based CLIs feature 973

VLAN-to-ATM AAL5 over AToM (Bridged) Example 974

VLAN-to-ATM AAL5 over AToM (Bridged) Example using the commands associated with the L2VPN Protocol-Based CLIs feature 978

Ethernet VLAN-to-PPP over AToM (Routed) Example 981

Ethernet VLAN to PPP over AToM (Routed) Example using the commands associated with the L2VPN Protocol-Based CLIs feature 983

ATM VC-to-VC Local Switching (Different Port) Example 986

ATM VP-to-VP Local Switching (Different Port) Example 988

Example: Configuring HDLC-to-Ethernet Interworking: Controller Slot on HDLC Devices 989

Example: Configuring HDLC-to-Ethernet Bridged Interworking on HDLC Devices 989

Example: Configuring HDLC-to-Ethernet Bridged Interworking on HDLC Devices Using the Commands Associated with the L2VPN Protocol-Based CLIs Feature 989

Example: Configuring HDLC-to-Ethernet Bridged Interworking on Ethernet Devices 990

Example: Configuring HDLC-to-Ethernet Bridged Interworking on Ethernet Devices Using the Commands Associated with the L2VPN Protocol-Based CLIs Feature 990

Example: Configuring HDLC-to-VLAN Bridged Interworking (Port Mode) on Ethernet Devices 991

Example: Configuring HDLC-to-VLAN Bridged Interworking on Ethernet Devices Using the Commands Associated with the L2VPN Protocol-Based CLIs Feature 991

Example: Configuring HDLC-to-VLAN Bridged Interworking (dot1q Mode) Using the Commands Associated with the L2VPN Protocol-Based CLIs Feature 992
Example: Configuring HDLC-to-VLAN Bridged Interworking (QinQ Mode) on Ethernet Devices 993
Example: Configuring HDLC-to-VLAN Bridged Interworking (QinQ Mode) on Ethernet Devices Using the Commands Associated with the L2VPN Protocol-Based CLIs Feature 994
Additional References for L2VPN Interworking 994
Feature Information for L2VPN Interworking 996

CHAPTER 47 **L2VPN Pseudowire Preferential Forwarding 997**
Prerequisites for L2VPN—Pseudowire Preferential Forwarding 997
Guidelines and Limitations for L2VPN--Pseudowire Preferential Forwarding 998
Information About L2VPN--Pseudowire Preferential Forwarding 998
Overview of L2VPN--Pseudowire Preferential Forwarding 998
Overview of L2VPN—Pseudowire Preferential Forwarding using the commands associated with the L2VPN Protocol-Based CLIs feature 998
How to Configure L2VPN--Pseudowire Preferential Forwarding 999
Configuring the Pseudowire Connection Between PE Routers 999
Configuring the Pseudowire Connection Between PE Routers 1000
Configuration Examples for L2VPN--Pseudowire Preferential Forwarding 1002
Example: L2VPN--Pseudowire Preferential Forwarding Configuration 1002
Example: L2VPN--Pseudowire Preferential Forwarding Configuration using the commands associated with the L2VPN Protocol-Based CLIs feature 1003
Example: Displaying the Status of the Pseudowires 1003
Additional References 1005
Feature Information for L2VPN--Pseudowire Preferential Forwarding 1006

CHAPTER 48 **L2VPN Multisegment Pseudowires 1007**
Prerequisites for L2VPN Multisegment Pseudowires 1007
Restrictions for L2VPN Multisegment Pseudowires 1007
Information About L2VPN Multisegment Pseudowires 1008
L2VPN Pseudowire Defined 1008
L2VPN Multisegment Pseudowire Defined 1008
How to Configure L2VPN Multisegment Pseudowires 1009
Configuring L2VPN Multisegment Pseudowires 1009

Configuring L2VPN Multisegment Pseudowires using the commands associated with the L2VPN Protocol-Based CLIs feature 1011
Displaying Information About the L2VPN Multisegment Pseudowires 1013
Displaying Information About the L2VPN Multisegment Pseudowires using the commands associated with the L2VPN Protocol-Based CLIs feature 1014
Performing ping mpls and trace mpls Operations on the L2VPN Multisegment Pseudowires 1015
Additional References 1017
Feature Information for L2VPN Multisegment Pseudowires 1018

CHAPTER 49 **MPLS Quality of Service** 1021
Prerequisites for MPLS Quality of Service 1021
Information About MPLS Quality of Service 1022
MPLS Quality of Service Overview 1022
Tag Switching and MPLS Terminology 1023
LSRs Used at the Edge of an MPLS Network 1024
LSRs Used at the Core of an MPLS Network 1025
Benefits of MPLS CoS in IP Backbones 1025
How to Configure MPLS Quality of Service 1026
Configuring WRED 1026
Verifying WRED 1027
Configuring CAR 1027
Verifying the CAR Configuration 1028
Configuring CBWFQ 1029
Verifying the CBWFQ Configuration 1030
Configuration Examples for MPLS Quality of Service 1032
Example: Configuring Cisco Express Forwarding 1033
Example: Running IP on Device 1 1033
Example: Running MPLS on Device 2 1034
Example: Running MPLS on Device 3 1034
Example: Running MPLS on Device 4 1035
Example: Running MPLS on Device 5 1036
Example: Running IP on Device 6 1037
Additional References for MPLS Quality of Service 1038
Feature Information for MPLS Quality of Service 1039

CHAPTER 50 QoS Policy Support on L2VPN ATM PVPs 1041

Prerequisites for QoS Policy Support on L2VPN ATM PVPs 1041

Restrictions for QoS Policy Support on L2VPN ATM PVPs 1041

Information About QoS Policy Support on L2VPN ATM PVPs 1042

The MQC Structure 1042

Elements of a Traffic Class 1042

Elements of a Traffic Policy 1042

How to Configure QoS Policy Support on L2VPN ATM PVPs 1043

Enabling a Service Policy in ATM PVP Mode 1043

Enabling a Service Policy in ATM PVP Mode using the commands associated with the L2VPN Protocol-Based CLIs feature 1044

Enabling Traffic Shaping in ATM PVP Mode 1047

Enabling Traffic Shaping in ATM PVP Mode using the commands associated with the L2VPN Protocol-Based CLIs feature 1048

Enabling Traffic Shaping in ATM PVP Mode Example using the commands associated with the L2VPN Protocol-Based CLIs feature 1051

Enabling Matching of ATM VCIs 1051

Configuration Examples for QoS Policy Support on L2VPN ATM PVPs 1052

Example Enabling Traffic Shaping in ATM PVP Mode 1052

Example Enabling Traffic Shaping in ATM PVP Mode using the commands associated with the L2VPN Protocol-Based CLIs feature 1053

Additional References 1053

Feature Information for QoS Policy Support on L2VPN ATM PVPs 1054

CHAPTER 51 MPLS Pseudowire Status Signaling 1057

Prerequisites for MPLS Pseudowire Status Signaling 1057

Restrictions for MPLS Pseudowire Status Signaling 1057

Information About MPLS Pseudowire Status Signaling 1058

How MPLS Pseudowire Status Switching Works 1058

How MPLS Pseudowire Status Switching Works using the commands associated with the L2VPN Protocol-Based CLIs feature 1058

When One Router Does Not Support MPLS Pseudowire Status Signaling 1058

When One Router Does Not Support MPLS Pseudowire Status Signaling using the commands associated with the L2VPN Protocol-Based CLIs feature 1059

Status Messages Indicating That the Attachment Circuit Is Down 1060
Status Messages Indicating That the Attachment Circuit Is Down using the commands associated with the L2VPN Protocol-Based CLIs feature 1060
Message Codes in the Pseudowire Status Messages 1061
Message Codes in the Pseudowire Status Messages using the commands associated with the L2VPN Protocol-Based CLIs feature 1061
How to Configure MPLS Pseudowire Status Signaling 1062
Enabling MPLS Pseudowire Status Signaling 1062
Enabling MPLS Pseudowire Status Signaling using the commands associated with the L2VPN Protocol-Based CLIs feature 1063
Configuration Examples for MPLS Pseudowire Status Signaling 1065
Example MPLS Pseudowire Status Signaling 1065
Example MPLS Pseudowire Status Signaling using the commands associated with the L2VPN Protocol-Based CLIs feature 1066
Example Verifying That Both Routers Support Pseudowire Status Messages 1066
Example Verifying That Both Routers Support Pseudowire Status Messages using the commands associated with the L2VPN Protocol-Based CLIs feature 1067
Additional References 1067
Feature Information for MPLS Pseudowire Status Signaling 1068

CHAPTER 52 **L2VPN VPLS Inter-AS Option B 1069**
Prerequisites for L2VPN VPLS Inter-AS Option B 1069
Restrictions for L2VPN VPLS Inter-AS Option B 1069
Information About L2VPN VPLS Inter-AS Option B 1070
VPLS Functionality and L2VPN VPLS Inter-AS Option B 1070
L2VPN VPLS Inter-AS Option B Description 1070
L2VPN VPLS Inter-AS Option B Sample Topology 1070
Active and Passive PEs in an L2VPN VPLS Inter-AS Option B Configuration 1071
Benefits of L2VPN VPLS Inter-AS Option B 1071
Private IP Addresses 1071
One Targeted LDP Session 1071
How to Configure L2VPN VPLS Inter-AS Option B 1072
Modifying the VPLS Autodiscovery Settings for Use with L2VPN VPLS Inter-AS Option B 1072
What to Do Next 1073

Modifying the VPLS Autodiscovery Settings for Use with L2VPN VPLS Inter-AS Option B using the commands associated with the L2VPN Protocol-Based CLIs feature 1074

What to Do Next 1075

Enabling L2VPN VPLS Inter-AS Option B on the ASBR 1076

What to Do Next 1078

Enabling L2VPN VPLS Inter-AS Option B on the ASBR using the commands associated with the L2VPN Protocol-Based CLIs feature 1078

What to Do Next 1080

Enabling L2VPN VPLS Inter-AS Option B on the Provider Edge (PE) Router 1081

What to Do Next 1082

Enabling L2VPN VPLS Inter-AS Option B on the Provider Edge (PE) Router using the commands associated with the L2VPN Protocol-Based CLIs feature 1082

What to Do Next 1083

Verifying the L2VPN VPLS Inter-AS Option B Configuration 1083

Verifying the L2VPN VPLS Inter-AS Option B Configuration using the commands associated with the L2VPN Protocol-Based CLIs feature 1084

Configuration Examples for L2VPN VPLS Inter-AS Option B 1085

Example Modifying the VPLS Autodiscovery Settings for Use with L2VPN VPLS Inter-AS Option B 1085

Example: Modifying the VPLS Autodiscovery Settings for Use with L2VPN VPLS Inter-AS Option B using the commands associated with the L2VPN Protocol-Based CLIs feature 1086

Example Enabling L2VPN VPLS Inter-AS Option B on the ASBR 1086

Example Enabling L2VPN VPLS Inter-AS Option B on the PE Router 1087

Example Enabling L2VPN VPLS Inter-AS Option B on the PE Device using the commands associated with the L2VPN Protocol-Based CLIs feature 1087

Example Verifying the L2VPN VPLS Inter-AS Option B Configuration 1087

Example Verifying the L2VPN VPLS Inter-AS Option B Configuration using the commands associated with the L2VPN Protocol-Based CLIs feature 1088

Example Sample L2VPN VPLS Inter-AS Option B Configuration 1089

Example Sample L2VPN VPLS Inter-AS Option B Configuration using the commands associated with the L2VPN Protocol-Based CLIs feature 1094

Additional References for L2VPN VPLS Inter-AS Option B 1099

Feature Information for L2VPN VPLS Inter-AS Option B 1100

Glossary 1101

CHAPTER 53 **IEEE 802.1Q Tunneling (QinQ) for AToM** 1103

Prerequisites for IEEE 802.1Q Tunneling (QinQ) for AToM 1103

Restrictions for IEEE 802.1Q Tunneling (QinQ) for AToM 1103

Information About IEEE 802.1Q Tunneling (QinQ) for AToM 1104

Ethernet VLAN QinQ AToM 1104

QinQ Tunneling Based on Inner and Outer VLAN Tags 1104

Rewritten Inner and Outer VLAN Tags on QinQ Frames 1105

How to Configure IEEE 802.1Q Tunneling (QinQ) for AToM 1105

Configuring Unambiguous IEEE 802.1Q Tunneling (QinQ) for AToM 1105

Configuring Unambiguous IEEE 802.1Q Tunneling (QinQ) for AToM using the commands associated with the L2VPN Protocol-Based CLIs feature 1106

Configuring Ambiguous IEEE 802.1Q Tunneling (QinQ) for AToM 1108

Configuring Ambiguous IEEE 802.1Q Tunneling (QinQ) for AToM using the commands associated with the L2VPN Protocol-Based CLIs feature 1110

Verifying the IEEE 802.1Q Tunneling (QinQ) for ATM Configuration 1113

Verifying the IEEE 802.1Q Tunneling (QinQ) for ATM Configuration using the commands associated with the L2VPN Protocol-Based CLIs feature 1113

Configuration Examples for IEEE 801.2 Tunneling (QinQ) for ATM 1114

Example Configuring Unambiguous IEEE 802.1Q Tunneling (QinQ) for ATM 1114

Example Configuring Unambiguous IEEE 802.1Q Tunneling (QinQ) for ATM using the commands associated with the L2VPN Protocol-Based CLIs feature 1114

Example Configuring Ambiguous IEEE 802.1Q Tunneling (QinQ) for ATM 1114

Example Configuring Ambiguous IEEE 802.1Q Tunneling (QinQ) for ATM using the commands associated with the L2VPN Protocol-Based CLIs feature 1114

Example Verifying the IEEE 802.1Q Tunneling (QinQ) for ATM Configuration 1115

Example Verifying the IEEE 802.1Q Tunneling (QinQ) for ATM Configuration using the commands associated with the L2VPN Protocol-Based CLIs feature 1115

Additional References 1115

Feature Information for IEEE 802.1Q Tunneling (QinQ) for AToM 1116

CHAPTER 54 **Configuring the Managed IPv6 Layer 2 Tunnel Protocol Network Server** 1119

Prerequisites for Configuring the Managed IPv6 LNS 1119

Information About Configuring the Managed IPv6 LNS 1119

L2TP Network Server 1119

Tunnel Accounting 1120
How to Configure the Managed LNS 1121
Configuring a VRF on the LNS 1121
Configuring a Virtual Template Interface 1123
Assigning a VRF via the RADIUS Server 1125
Configuring the LNS to Initiate and Receive L2TP Traffic 1127
Limiting the Number of Sessions per Tunnel 1128
Configuring RADIUS Attribute Accept or Reject Lists 1130
Configuring AAA Accounting Using Named Method Lists 1132
Configuring RADIUS Tunnel Authentication Method Lists on the LNS 1134
Configuring the LNS for RADIUS Tunnel Authentication 1135
Configuring RADIUS Tunnel Authentication Method Lists on the LNS 1136
Configuring AAA Authentication Methods 1138
Configuration Examples for the Managed IPv6 Layer 2 Tunnel Protocol Network Server 1139
Example Managed IPv6 LNS Configuration 1139
Example LNS Tunnel Accounting Configuration 1142
Example Verifying the User Profile on the RADIUS Server 1144
Additional References 1144
Feature Information for Configuring Managed IPv6 Layer 2 Tunnel Protocol Network Server 1146

CHAPTER 55 **L2VPN Pseudowire Redundancy** 1147
Prerequisites for L2VPN Pseudowire Redundancy 1147
Restrictions for L2VPN Pseudowire Redundancy 1148
Information About L2VPN Pseudowire Redundancy 1148
Introduction to L2VPN Pseudowire Redundancy 1148
How to Configure L2VPN Pseudowire Redundancy 1150
Configuring the Pseudowire 1150
Configuring the Pseudowire using the commands associated with the L2VPN Protocol-Based CLIs feature 1151
Configuring L2VPN Pseudowire Redundancy 1153
Configuring L2VPN Pseudowire Redundancy using the commands associated with the L2VPN Protocol-Based CLIs feature 1154
Forcing a Manual Switchover to the Backup Pseudowire VC 1156
Verifying the L2VPN Pseudowire Redundancy Configuration 1157

Verifying the L2VPN Pseudowire Redundancy Configuration using the commands associated with the L2VPN Protocol-Based CLIs feature 1159
Configuration Examples for L2VPN Pseudowire Redundancy 1161
Example L2VPN Pseudowire Redundancy and AToM (Like to Like) 1161
Example L2VPN Pseudowire Redundancy and L2VPN Interworking 1161
Example L2VPN Pseudowire Redundancy with Layer 2 Local Switching 1162
Example L2VPN Pseudowire Redundancy and Layer 2 Tunneling Protocol Version 3 1162
Configuration Examples for L2VPN Pseudowire Redundancy using the commands associated with the L2VPN Protocol-Based CLIs feature 1163
Example L2VPN Pseudowire Redundancy and AToM (Like to Like) using the commands associated with the L2VPN Protocol-Based CLIs feature 1164
Example L2VPN Pseudowire Redundancy and L2VPN Interworking using the commands associated with the L2VPN Protocol-Based CLIs feature 1164
Example L2VPN Pseudowire Redundancy and Layer 2 Tunneling Protocol Version 3 using the commands associated with the L2VPN Protocol-Based CLIs feature 1165
Additional References 1167
Feature Information for L2VPN Pseudowire Redundancy 1168

CHAPTER 56 **Pseudowire Group Switchover** 1171
Prerequisites for Pseudowire Group Switchover 1171
Restrictions for Pseudowire Group Switchover 1171
Information About Pseudowire Group Switchover 1172
Introduction to Pseudowire Group Switchover 1172
How to Configure Predictive Switchover 1172
Configuring Predictive Switchover (Global Configuration Mode) 1173
Configuring Predictive Switchover (Xconnect Configuration Mode) 1173
Verifying a Pseudowire Group Switchover Configuration 1174
Troubleshooting a Pseudowire Group Switchover Configuration 1176
Configuration Examples for Predictive Switchover 1176
Example: Configuring Predictive Switchover (Global Configuration Mode) 1176
Example: Configuring Predictive Switchover (Xconnect Configuration Mode) 1176
Additional References 1177
Feature Information for Pseudowire Group Switchover 1177

CHAPTER 57 **L2VPN Pseudowire Switching** 1179

Restrictions for L2VPN Pseudowire Switching 1179
Information About L2VPN Pseudowire Switching 1180
How L2VPN Pseudowire Switching Works 1180
How Packets Are Manipulated at the Aggregation Point 1180
How to Configure L2VPN Pseudowire Switching 1181
Configuring 1181
How to Configure L2VPN Pseudowire Switching using the commands associated with the L2VPN Protocol-Based CLIs feature 1183
Configuring 1186
Configuration Examples for L2VPN Pseudowire Switching 1189
L2VPN Pseudowire Switching in an Inter-AS Configuration Example 1189
Additional References 1192
Feature Information for L2VPN Pseudowire Switching 1193

CHAPTER 58 **Xconnect as a Client of BFD** 1195
Information About Xconnect as a Client of BFD 1195
Xconnect as a Client of BFD 1195
How to Configure Xconnect as a Client of BFD 1195
Configuring Xconnect as a Client of BFD 1195
Configuration Examples for Xconnect as a Client of BFD 1197
Example: Xconnect as a Client of BFD 1197
Additional References 1197
Feature Information for Xconnect as a Client of BFD 1198

CHAPTER 59 **H-VPLS N-PE Redundancy for QinQ Access** 1201
Prerequisites for H-VPLS N-PE Redundancy for QinQ Access 1201
Restrictions for H-VPLS N-PE Redundancy for QinQ Access 1202
Information About H-VPLS N-PE Redundancy for QinQ Access 1202
How H-VPLS N-PE Redundancy for QinQ Access Works 1202
H-VPLS N-PE Redundancy with QinQ Access Based on MSTP 1202
How to Configure H-VPLS N-PE Redundancy for QinQ Access 1203
Configuring the VPLS Pseudowire Between the N-PE Devices using the commands associated with the L2VPN Protocol-Based CLIs feature 1203

Configuring the VPLS Pseudowire Between the N-PE Devices using the commands associated with the L2VPN Protocol-Based CLIs feature 1205
Binding the Service Instance to the Bridge-Domain 1207
Configuration Examples for H-VPLS N-PE Redundancy for QinQ Access 1208
Example: H-VPLS N-PE Redundancy for QinQ Access 1208
Example: H-VPLS N-PE Redundancy for MPLS Access using the commands associated with the L2VPN Protocol-Based CLIs feature 1209
Additional References for L2VPN VPLS Inter-AS Option B 1211
Feature Information for H-VPLS N-PE Redundancy for QinQ Access 1212
Glossary 1213

CHAPTER 60 **H-VPLS N-PE Redundancy for MPLS Access** 1215
Prerequisites for H-VPLS N-PE Redundancy for MPLS Access 1215
Restrictions for H-VPLS N-PE Redundancy for MPLS Access 1215
Information About H-VPLS N-PE Redundancy for MPLS Access 1216
How H-VPLS N-PE Redundancy for MPLS Access 1216
H-VPLS N-PE Redundancy with MPLS Access Based on Pseudowire Redundancy 1216
How to Configure H-VPLS N-PE Redundancy for MPLS Access 1216
Specifying the Devices in the Layer 2 VPN VFI 1216
Specifying the N-PE Devices That Form the Layer 2 VPN Cross Connection With the U-PE 1218
Configuration Examples for H-VPLS N-PE Redundancy for MPLS Access 1220
Example: H-VPLS N-PE Redundancy for MPLS Access 1220
Additional References for L2VPN VPLS Inter-AS Option B 1222
Feature Information for H-VPLS N-PE Redundancy for MPLS Access 1223
Glossary 1224

CHAPTER 61 **VPLS MAC Address Withdrawal** 1227
Information About VPLS MAC Address Withdrawal 1227
VPLS MAC Address Withdrawal 1227
VPLS MAC Address Withdrawal Using Commands Associated with L2VPN Protocol-Based Feature 1228
How MAC Address Withdrawal Works with H-VPLS N-PE Redundancy with MPLS Access 1229
How MAC Address Withdrawal Works with H-VPLS N-PE Redundancy with QinQ Access 1229
Additional References for Any Transport over MPLS 1229

Feature Information for VPLS MAC Address Withdrawal 1230

CHAPTER 62 **Configuring Virtual Private LAN Services** 1231

Prerequisites for Virtual Private LAN Services 1231

Restrictions for Virtual Private LAN Services 1231

Information About Virtual Private LAN Services 1232

VPLS Overview 1232

Full-Mesh Configuration 1232

Static VPLS Configuration 1233

H-VPLS 1233

Supported Features 1233

Multipoint-to-Multipoint Support 1233

Non-Transparent Operation 1234

Circuit Multiplexing 1234

MAC-Address Learning, Forwarding, and Aging 1234

Jumbo Frame Support 1234

Q-in-Q Support and Q-in-Q to EoMPLS Support 1234

VPLS Services 1234

VPLS Integrated Routing and Bridging 1235

VPLS and Type 4 dummy VLAN Tag 1235

How to Configure Virtual Private LAN Services 1236

Configuring PE Layer 2 Interfaces on CE Devices 1236

Configuring 802.1Q Access Ports for Tagged Traffic from a CE Device 1236

Configuring 802.1Q Access Ports for Tagged Traffic from a CE Device: Alternate Configuration 1238

Configuring Access Ports for Untagged Traffic from a CE Device 1240

Configuring 802.1Q Access Ports for Tagged Traffic from a CE Device: Alternate Configuration 1241

Configuring Q-in-Q EFP 1243

Configuring Q-in-Q EFP: Alternate Configuration 1245

Configuring MPLS on a PE Device 1247

Configuring a VFI on a PE Device 1248

Configuring a VFI on a PE Device: Alternate Configuration 1250

Configuring Static Virtual Private LAN Services 1251

Configuring a Pseudowire for Static VPLS 1251
Configuring VFI for Static VPLS 1254
Configuring a VFI for Static VPLS: Alternate Configuration 1256
Configuring an Attachment Circuit for Static VPLS 1259
Configuring an Attachment Circuit for Static VPLS: Alternate Configuration 1260
Configuring an MPLS-TP Tunnel for Static VPLS with TP 1262
Configuration Examples for Virtual Private LAN Services 1265
Example: Configuring 802.1Q Access Ports for Tagged Traffic from a CE Device 1265
Example: Configuring 802.1Q Access Ports for Tagged Traffic from a CE Device: Alternate Configuration 1265
Example: Configuring Access Ports for Untagged Traffic from a CE Device 1265
Example: Configuring Access Ports for Untagged Traffic from a CE Device: Alternate Configuration 1267
Example: Configuring Q-in-Q EFP 1267
Example: Configuring Q-in-Q in EFP: Alternate Configuration 1267
Example: Configuring MPLS on a PE Device 1268
Example: VFI on a PE Device 1268
Example: VFI on a PE Device: Alternate Configuration 1269
Example: Full-Mesh VPLS Configuration 1270
Example: Full-Mesh Configuration : Alternate Configuration 1272
Example: MAC ACL with Dummy VLAN ID 1275
Feature Information for Configuring Virtual Private LAN Services 1276

CHAPTER 63 **Routed Pseudo-Wire and Routed VPLS 1277**
Configuring Routed Pseudo-Wire and Routed VPLS 1277
Verifying Routed Pseudo-Wire and Routed VPLS Configuration 1278
Feature Information for Routed Pseudo-Wire and Routed VPLS 1279

CHAPTER 64 **VPLS Autodiscovery BGP Based 1281**
Restrictions for VPLS Autodiscovery BGP Based 1281
Information About VPLS Autodiscovery BGP Based 1282
How VPLS Works 1282
How the VPLS Autodiscovery BGP Based Feature Works 1282
How Enabling VPLS Autodiscovery Differs from Manually Configuring VPLS 1283

How Enabling VPLS Autodiscovery Differs from Manually Configuring VPLS using the commands associated with the L2VPN Protocol-Based CLIs feature 1283
show Commands Affected by VPLS Autodiscovery BGP Based 1284
BGP VPLS Autodiscovery Support on a Route Reflector 1284
N-PE Access to VPLS Using MST 1285
How to Configure VPLS Autodiscovery BGP Based 1285
Enabling VPLS Autodiscovery BGP Based 1285
Enabling VPLS Autodiscovery BGP Based using the commands associated with the L2VPN Protocol-Based CLIs feature 1286
Configuring VPLS BGP Signaling 1287
Configuring BGP to Enable VPLS Autodiscovery 1290
Customizing the VPLS Autodiscovery Settings 1293
Configuring BGP to Enable VPLS Autodiscovery using the commands associated with the L2VPN Protocol-Based CLIs feature 1295
Customizing the VPLS Autodiscovery Settings using the commands associated with the L2VPN Protocol-Based CLIs feature 1298
Configuring MST on VPLS N-PE Devices 1300
Configuring MST on VPLS N-PE Devices using the commands associated with the L2VPN Protocol-Based CLIs feature 1302
Configuration Examples for VPLS Autodiscovery BGP Based 1304
Example: Enabling VPLS Autodiscovery BGP Based 1304
Example: Enabling VPLS Autodiscovery BGP Based Using Commands Associated with L2VPN Protocol-Based Feature 1305
Example: Configuring BGP to Enable VPLS Autodiscovery 1305
Example: Configuring BGP to Enable VPLS Autodiscovery Using Commands Associated with L2VPN Protocol-Based Feature 1307
Example: Customizing VPLS Autodiscovery Settings 1309
Example: Customizing VPLS Autodiscovery Settings using the commands associated with the L2VPN Protocol-Based CLIs feature 1309
Example: Configuring MST on VPLS N-PE Devices 1310
Example: Configuring MST on VPLS N-PE Devices using the commands associated with the L2VPN Protocol-Based CLIs feature 1311
Example: BGP VPLS Autodiscovery Support on Route Reflector 1311
Additional References for VPLS Autodiscovery BGP Based 1312
Feature Information for VPLS Autodiscovery BGP Based 1313

CHAPTER 65 N:1 PVC Mapping to PWE with Nonunique VPIs 1315

Restrictions for N:1 PVC Mapping to PWE with Nonunique VPIs 1315

Information About N:1 PVC Mapping to PWE with Nonunique VPIs 1316

N:1 PVC Mapping to PWE with Nonunique VPIs Feature Description 1316

How to Configure N:1 PVC Mapping to PWE with Nonunique VPIs 1316

Configuring N:1 PVC Mapping to PWE with Nonunique VPIs 1316

Configuring N:1 PVC Mapping to PWE with Nonunique VPIs using the commands associated with the L2VPN Protocol-Based CLIs feature 1318

Configuration Examples for N:1 PVC Mapping to PWE with Nonunique VPIs 1321

Example: Configuring N:1 PVC Mapping to PWE with Nonunique VPIs 1321

Example: Configuring N:1 PVC Mapping to PWE with Nonunique VPIs using the commands associated with the L2VPN Protocol-Based CLIs feature 1322

Additional References 1322

Feature Information for N:1 PVC Mapping to PWE with Nonunique VPIs 1323

CHAPTER 66 QoS Policies for VFI Pseudowires 1325

Restrictions for QoS Policies for VFI Pseudowires 1325

Information About QoS Policies for VFI Pseudowires 1325

QoS Policies for VFI Pseudowires 1325

How to Configure QoS Policies for VFI Pseudowires 1326

Configuring QoS Policies for Pseudowires 1326

Creating a Hierarchical Policy for VFI Pseudowires 1332

Attaching a Policy Map to a VFI Pseudowire 1336

Configuring VFI with Two Pseudowire Members with Different QoS Policies 1338

Configuring VFI with Two Pseudowire Members with the Same QoS Policy 1340

Configuring VFI with Auto Discovered Pseudowires 1343

Configuration Examples for QoS Policies for VFI Pseudowires 1345

Example: Configuring QoS Policies for Pseudowires 1345

Example: Configuring VFI with Two Pseudowire Members with Different QoS Policies 1346

Example: Configuring VFI with Two Pseudowire Members with the Same QoS Policy 1347

Example: Configuring VFI with Auto Discovered Pseudowires 1347

Example: Displaying Pseudowire Policy Map Information 1348

Additional References for QoS Policies for VFI Pseudowires 1349

Feature Information For QoS Policies for VFI Pseudowires 1350

CHAPTER 67 VPLS BGP Signaling L2VPN Inter-AS Option A 1351

Prerequisites for VPLS BGP Signaling L2VPN Inter-AS Option A 1351

Information About VPLS BGP Signaling L2VPN Inter-AS Option A 1351

BGP Auto-discovery and Signaling for VPLS 1351

BGP L2VPN Signaling with NLRI 1352

How to Configure VPLS BGP Signaling L2VPN Inter-AS Option A 1353

Enabling BGP Auto-discovery and BGP Signaling 1353

Configuring BGP Signaling for VPLS Autodiscovery 1355

VPLS BGP Signaling L2VPN Inter-AS Option A: Example 1358

Additional References for VPLS Autodiscovery BGP Based 1359

Feature Information for VPLS BGP Signaling L2VPN Inter-AS Option A 1360

CHAPTER 68 VPLS BGP Signaling L2VPN Inter-AS Option B 1363

Prerequisites for VPLS BGP Signaling L2VPN Inter-AS Option B 1363

Information About VPLS BGP Signaling L2VPN Inter-AS Option B 1364

BGP Auto-discovery and Signaling for VPLS 1364

BGP L2VPN Signaling with NLRI 1364

How to Configure VPLS BGP Signaling L2VPN Inter-AS Option B 1365

Enabling BGP Auto-discovery and BGP Signaling 1365

Configuring BGP Signaling for VPLS Autodiscovery 1367

Configuration Examples for L2VPN VPLS Inter-AS Option B 1370

Example: VPLS BGP Signaling L2VPN Inter-AS Option B 1370

Additional References for VPLS BGP Signaling L2VPN Inter-AS Option B 1375

Feature Information for VPLS BGP Signaling L2VPN Inter-AS Option B 1376

CHAPTER 69 Frame Relay over L2TPv3 1377

Prerequisites for Configuring Frame Relay over L2TPv3 1377

Restrictions for Configuring Frame Relay over L2TPv3 1377

Information About Configuring Frame Relay over L2TPv3 1378

Frame Relay over L2TPv3 Overview 1378

How to Configure Frame Relay over L2TPv3 1378

Configuring Frame Relay over L2TPv3 without LMI 1378

On CE1 1379
On PE1 1380
Configuring Frame Relay over L2TPv3 with LMI 1383
On CE1 1383
On PE1 1384
Configuring Frame Relay L2TPv3 Tunnel Marking 1386
Verifying Frame Relay over L2TPv3 Configuration 1389
Configuration Examples for Frame Relay over L2TPv3 1391
Example: Frame Relay over L2TPv3 with LMI 1391
Examples: Frame Relay over L2TPv3 without LMI 1391
Additional References for Frame Relay over L2TPv3 1392
Feature Information for Frame Relay over L2TPv3 1393

CHAPTER 70 **Loop-Free Alternate Fast Reroute with L2VPN** 1395
Restrictions for Loop-Free Alternate Fast Reroute with L2VPN 1395
Information About Loop-Free Alternate Fast Reroute with L2VPN 1395
L2VPN Over Loop-Free Alternate Fast Reroute 1395
How to Configure Loop-Free Alternate Fast Reroute with L2VPN 1396
Verifying Loop-Free Alternate Fast Reroute with L2VPN 1396
Configuration Examples for Loop-Free Alternate Fast Reroute with L2VPN 1397
Example: Verifying LFA FRR with L2VPN 1397
Example: Configuring Remote LFA FRR with VPLS 1399
Example: Verifying Remote LFA FRR with VPLS 1400
Additional References 1403
Feature Information for Loop-Free Alternate Fast Reroute with L2VPN 1404

CHAPTER 71 **EVPN Single-Homing** 1405
Information about EVPN Single-Homing 1405
Ethernet Multipoint Connectivity 1405
EVPN Multipoint Solution 1405
EVPN Building Blocks 1405
Service Interfaces 1406
Route Types 1407
Prerequisites for EVPN Single-Homing 1409

Restrictions for EVPN Single-Homing 1409
How to Configure EVPN Single Homing 1410
Configuring EVPN 1410
Configuring EVPN Single-Homing 1411
Verification Examples for EVPN Single-Homing 1413
Additional References for EVPN Single-Homing 1418
Feature Information for EVPN Single-Homing 1418

CHAPTER 72 **EVPN Multihoming** 1419
Information about EVPN Multihoming 1419
BGP MPLS-based EVPN 1419
EVPN Multihoming Topology 1420
All-Active Multihoming 1421
Route Types 1421
Core Isolation 1425
Prerequisites for EVPN Multihoming 1425
Restrictions for EVPN Multihoming 1426
How to Configure EVPN Multioming 1426
Configuring EVPN Multihoming 1426
Configuration Examples for EVPN Mulltihoming 1429
Verifying EVPN Multihoming 1429
Additional References for EVPN Multihoming 1435
Feature Information for EVPN Multihoming 1436

CHAPTER 73 **EVPN Over MPLS with Integrated Routing and Bridging** 1437
Information about EVPN Over MPLS with Distributed Anycast Gatways 1438
Distributed Anycast Gateway with Bridge Domains 1438
Symmetric IRB with MPLS on Distributed Gateways 1439
IP Prefix Route on Distributed Gateways 1439
IP Prefix Route on Border Gateways 1440
Host MAC-IP Binding on a Single-Homed DAG 1440
Host MAC-IP Binding on Multi-Homing All-Active DAGs 1441
Host MAC-IP Mobility 1442
Host MAC-IP Synchronization 1442

ARP and ND Flooding Suppression 1443
MAC-IP Proxy Route for Multi-Homing All-Active Hosts with Symmetric IRB 1444
Prerequisites for EVPN Over MPLS 1445
Restrictions EVPN over MPLS 1445
How to Configure EVPN over MPLS 1446
Configure Basic EVPN over MPLS 1446
Configure Basic EVPN over MPLS with IRB 1447
EVPN over MPLS with Multi-VRF Hand-off 1448
EVPN over MPLS L3VPN Hand-offf 1449
Layer 2 Multihoming Configuration for EVPN over MPLS 1449
Verification Examples for EVPN over MPLS 1450
Advertising Proxy MAC-IP Route 1456
Suppressing Unknown Unicast Flooding 1456
Configuring Bridge Domain MAC Age Timer 1457
Configuring ARP and ND Timers 1457
Configuring IP Local Learning, Limits, and Timers 1457
Configuring ARP and ND Flooding Suppression 1457
Additional References for EVPN Single-Homing 1458
Feature Information for EVPN MPLS IRB with Distributed Anycast Gateways 1458

CHAPTER 74 **Unknown Unicast Flooding Supperssion** 1459
About Unknown Unicast Flooding on Bridge Domain 1459
Limitations for Unknown Unicast Suppression 1459
Enabling Unknown Unicast Flooding on Bridge Domain 1459
Verifying the Unknown Unicast Flooding Suppression 1460
Feature Information for Unknown Unicast Flooding Suppression 1461

CHAPTER 75 **BGP EVPN over MultiProtocol Label Switching** 1463
Feature Information for BGP EVPN Over MPLS 1463
Information about BGP EVPN over MultiProtocol Label Switching 1463
BGP MPLS based Ethernet VPN (EVPN) Overview 1463
EVPN Building Blocks 1464
Service Interfaces 1464
BGP EVPN over MPLS Inter-AS and Prefix SID 1465

Importing IP Routes to EVPN 1466
Route Reoriginate 1467
EVPN Encapsulation 1468
How to Configure BGP EVPN over MultiProtocol Label Switching 1468
Configuring BGP over MPLS 1468
Configuring BGP EVPN over MPLS (Inter AS) 1469
Configuring BGP EVPN over MPLS (InterAS L3VPN) 1470
Configuration Examples for BGP EVPN over MPLS 1471
Verifying EVPN Neighbor 1471
Additional References for BGP EVPN over MultiProtocol Label Switching 1471

PART VI MPLS Layer 3 VPNs 1473

CHAPTER 76 MPLS VPN Inter-AS with ASBRs Exchanging VPN-IPv4 Addresses 1475
Prerequisites for MPLS VPN Inter-AS with ASBRs Exchanging VPN-IPv4 Addresses 1475
Restrictions for MPLS VPN Inter-AS with ASBRs Exchanging VPN-IPv4 Addresses 1476
Information About MPLS VPN Inter-AS with ASBRs Exchanging VPN-IPv4 Addresses 1476
MPLS VPN Inter-AS Introduction 1476
Benefits of MPLS VPN Inter-AS 1476
Use of Inter-AS with ASBRs Exchanging VPN-IPv4 Addresses 1477
Information Exchange in an MPLS VPN Inter-AS with ASBRs Exchanging VPN-IPv4 Addresses 1477
Transmission of Information in an MPLS VPN Inter-AS with ASBRs Exchanging VPN-IPv4 Addresses 1477
Exchange of VPN Routing Information in an MPLS VPN Inter-AS with ASBRs Exchanging VPN-IPv4 Addresses 1479
Packet Forwarding Between MPLS VPN Inter-AS Systems with ASBRs Exchanging VPN-IPv4 Addresses 1481
Use of a Confederation for MPLS VPN Inter-AS with ASBRs Exchanging VPN-IPv4 Addresses 1482
How to Configure MPLS VPN Inter-AS with ASBRs Exchanging VPN-IPv4 Addresses 1484
Configuring the ASBRs to Exchange VPN-IPv4 Addresses 1484
Configuring EBGP Routing to Exchange VPN Routes Between Subautonomous Systems in a Confederation 1485
Verifying Inter-AS with ASBRs Exchanging VPN-IPv4 Addresses 1488
Configuration Examples for MPLS VPN Inter-AS with ASBRs Exchanging VPN-IPv4 Addresses 1489

Example: Configuring MPLS VPN Inter-AS with ASBRs Exchanging VPN-IPv4 Addresses 1489
Example: Configuration for Autonomous System 1 CE1 1489
Example: Configuration for Autonomous System 1 PE1 1490
Example: Configuration for Autonomous System 1 P1 1491
Example: Configuration for Autonomous System 1 EBGP1 1491
Example: Configuration for Autonomous System 2 EBGP2 1492
Example: Configuration for Autonomous System 2 P2 1493
Example: Configuration for Autonomous System 2 PE2 1494
Example: Configuration for Autonomous System 2 CE2 1495
Example: Configuring MPLS VPN Inter-AS with ASBRs Exchanging VPN-IPv4 Addresses in a Confederation 1496
Example: Configuration for Autonomous System 1 CE1 1496
Example: Configuration for Autonomous System 1 PE1 1497
Example: Configuration for Autonomous System 1 P1 1497
Example: Configuration for Autonomous System 1 ASBR1 1498
Example: Configuration for Autonomous System 2 ASBR2 1499
Example: Configuration for Autonomous System 2 P2 1500
Example: Configuration for Autonomous System 2 PE2 1501
Example: Configuration for Autonomous System 2 CE2 1502

CHAPTER 77 **MPLS VPN Inter-AS with ASBRs Exchanging IPv4 Routes and MPLS Labels** 1503
Prerequisites for MPLS VPN Inter-AS with ASBRs Exchanging IPv4 Routes and MPLS Labels 1503
Restrictions for MPLS VPN Inter-AS with ASBRs Exchanging IPv4 Routes and MPLS Labels 1505
Information About MPLS VPN Inter-AS with ASBRs Exchanging IPv4 Routes and MPLS Labels 1505
MPLS VPN Inter-AS Introduction 1505
Benefits of MPLS VPN Inter-AS 1505
Information About Using MPLS VPN Inter-AS with ASBRs Exchanging IPv4 Routes and MPLS Labels 1506
Benefits of MPLS VPN Inter-AS with ASBRs Exchanging IPv4 Routes and MPLS Labels 1506
How the Inter-AS Works When ASBRs Exchange IPv4 Routes with MPLS Labels 1506
BGP Routing Information 1507
Types of BGP Messages and MPLS Labels 1507
How BGP Sends MPLS Labels with Routes 1508
How to Configure MPLS VPN Inter-AS with ASBRs Exchanging IPv4 Routes and MPLS Labels 1508

Configuring the ASBRs to Exchange IPv4 Routes and MPLS Labels 1508
Configuring the Route Reflectors to Exchange VPN-IPv4 Routes 1510
Configuring the Route Reflector to Reflect Remote Routes in Its Autonomous System 1512
Verifying the MPLS VPN Inter-AS with ASBRs Exchanging IPv4 Routes and MPLS Labels Configuration 1515
Verifying the Route Reflector Configuration 1515
Verifying that CE1 Can Communicate with CE2 1516
Verifying that PE1 Can Communicate with CE2 1517
Verifying that PE2 Can Communicate with CE2 1519
Verifying the ASBR Configuration 1520
Configuration Examples for MPLS VPN Inter-AS with ASBRs Exchanging IPv4 Routes and MPLS Labels 1522
Configuring MPLS VPN Inter-AS with ASBRs Exchanging IPv4 Routes and MPLS Labels over an MPLS VPN Service Provider Examples 1522
Route Reflector 1 Configuration Example (MPLS VPN Service Provider) 1522
ASBR1 Configuration Example (MPLS VPN Service Provider) 1523
Route Reflector 2 Configuration Example (MPLS VPN Service Provider) 1525
ASBR2 Configuration Example (MPLS VPN Service Provider) 1526
Configuring MPLS VPN Inter-AS with ASBRs Exchanging IPv4 Routes and MPLS Labels over a Non-MPLS VPN Service Provider Examples 1527
Route Reflector 1 Configuration Example (Non-MPLS VPN Service Provider) 1527
ASBR1 Configuration Example (Non-MPLS VPN Service Provider) 1529
Route Reflector 2 Configuration Example (Non-MPLS VPN Service Provider) 1530
ASBR2 Configuration Example (Non-MPLS VPN Service Provider) 1531
ASBR3 Configuration Example (Non-MPLS VPN Service Provider) 1532
Route Reflector 3 Configuration Example (Non-MPLS VPN Service Provider) 1533
ASBR4 Configuration Example (Non-MPLS VPN Service Provider) 1534
Additional References 1535
Feature Information for MPLS VPN Inter-AS with ASBRs Exchanging IPv4 Routes and MPLS Labels 1537

CHAPTER 78 **MPLS VPN--Inter-AS Option AB 1539**
Prerequisites for MPLS VPN--Inter-AS Option AB 1539
Restrictions for MPLS VPN--Inter-AS Option AB 1540
Information About MPLS VPN--Inter-AS Option AB 1540

MPLS VPN--Inter-AS Option AB Introduction 1540
Benefits of MPLS VPN--Inter-AS Option AB 1540
Option B Style Peering with Shared Link Forwarding 1541
Route Distribution and Packet Forwarding in Non-CSC Networks 1541
Route Distribution for VPN 1 1542
Packet Forwarding for VPN 1 1543
Route Distribution for VPN 2 1543
Route Distribution and Packet Forwarding for CSC 1544
Route Distribution for VPN 1 1545
Packet Forwarding for VPN 1 1546
Shared Link Forwarding in Non-CSC Networks 1546
Route Distribution for VPN 1 1547
Packet Forwarding for VPN1 1547
How to Configure Inter-AS Option AB 1548
Configuring an Inter-AS Option AB Connection 1548
Configuring the VRFs on the ASBR Interface for Each VPN Customer 1548
Configuring the MP-BGP Session Between ASBR Peers 1549
Configuring the Routing Policy for VPNs that Need Inter-AS Connections 1551
Changing an Inter-AS Option A Deployment to an Option AB Deployment 1554
Configuration Examples for MPLS VPN--Inter-AS Option AB 1556
Examples Inter-AS AB Network Configuration 1556
Example CE1 1556
Example CE2 1557
Example PE1 1557
Example Route Reflector 1 1559
Example ASBR1 1559
Example ASBR 3 1561
Example PE2 1562
Example CE3 1564
Example CE4 1564
Examples Inter-AS AB CSC Configuration 1565
Example CE1 1565
Example CE2 1565
Example CE3 1566

Example CE4 1566
Example PE1 1567
Example CSC-CE1 1568
Example CSC-PE1 1569
Example PE 2 1570
Example CSC-CE2 1571
Example ASBR1 1572
Example CSC-PE 3 1575
Example CSC-CE3 1576
Example CSC-CE 4 1577
Example PE 3 1578
Example PE 4 1579
Additional References 1580
Feature Information for MPLS VPN--Inter-AS Option AB 1581
Glossary 1582

CHAPTER 79 **MPLS VPN Carrier Supporting Carrier Using LDP and an IGP** 1585
Prerequisites for MPLS VPN CSC with LDP and IGP 1585
Restrictions for MPLS VPN CSC with LDP and IGP 1585
Information About MPLS VPN CSC with LDP and IGP 1587
MPLS VPN CSC Introduction 1587
Benefits of Implementing MPLS VPN CSC 1587
Configuration Options for MPLS VPN CSC with LDP and IGP 1588
Customer Carrier Is an ISP 1588
Customer Carrier Is a BGP MPLS VPN Service Provider 1590
How to Configure MPLS VPN CSC with LDP and IGP 1592
Configuring the Backbone Carrier Core 1592
Prerequisites 1592
Verifying IP Connectivity and LDP Configuration in the CSC Core 1592
Configuring VRFs for CSC-PE Routers 1594
Configuring Multiprotocol BGP for VPN Connectivity in the Backbone Carrier 1596
Configuring the CSC-PE and CSC-CE Routers 1598
Prerequisites 1598
Configuring LDP on the CSC-PE and CSC-CE Routers 1599

Enabling MPLS Encapsulation on the CSC-PE and CSC-CE Routers 1600
Verifying the Carrier Supporting Carrier Configuration 1601
Configuration Examples for MPLS VPN CSC with LDP and IGP 1602
MPLS VPN CSC Network with a Customer Who Is an ISP Example 1602
CSC-CE1 Configuration 1603
CSC-PE1 Configuration 1603
CSC-PE2 Configuration 1605
CSC-CE2 Configuration 1606
MPLS VPN CSC Network with a Customer Who Is an MPLS VPN Provider Example 1607
CE1 Configuration 1608
PE1 Configuration 1608
CSC-CE1 Configuration 1609
CSC-PE1 Configuration 1610
CSC-PE2 Configuration 1612
CSC-CE2 Configuration 1613
PE2 Configuration 1614
CE2 Configuration 1615
MPLS VPN CSC Network That Contains Route Reflectors Example 1616
Backbone Carrier Configuration 1617
Customer Carrier Site 1 Configuration 1623
Customer Carrier Site 2 Configuration 1628
MPLS VPN CSC Network with a Customer Who Has VPNs at the Network Edge Example 1632
Backbone Carrier Configuration 1633
Customer Carrier Site 1 Configuration 1640
Customer Carrier Site 2 Configuration 1643
Additional References for MPLS VPN Carrier Supporting Carrier Using LDP and an IGP 1647
Feature Information for MPLS VPN CSC with LDP and IGP 1648
Glossary 1648

CHAPTER 80 **MPLS VPN Carrier Supporting Carrier with BGP 1651**
Prerequisites for MPLS VPN CSC with BGP 1651
Restrictions for MPLS VPN CSC with BGP 1651
Information About MPLS VPN CSC with BGP 1652
MPLS VPN CSC Introduction 1652

Benefits of Implementing MPLS VPN CSC 1652
Benefits of Implementing MPLS VPN CSC with BGP 1653
Configuration Options for MPLS VPN CSC with BGP 1653
Customer Carrier Is an ISP with an IP Core 1653
Customer Carrier Is an MPLS Service Provider With or Without VPN Services 1654
How to Configure MPLS VPN CSC with BGP 1654
Identifying the Carrier Supporting Carrier Topology 1654
What to Do Next 1655
Configuring the Backbone Carrier Core 1656
Prerequisites 1656
Verifying IP Connectivity and LDP Configuration in the CSC Core 1656
Configuring VRFs for CSC-PE Routers 1658
Configuring Multiprotocol BGP for VPN Connectivity in the Backbone Carrier 1660
Configuring the CSC-PE and CSC-CE Routers 1662
Configuring CSC-PE Routers 1662
Configuring CSC-CE Routers 1664
Verifying Labels in the CSC-PE Routers 1667
Verifying Labels in the CSC-CE Routers 1669
Configuring the Customer Carrier Network 1671
Prerequisites 1671
Verifying IP Connectivity in the Customer Carrier 1671
Configuring a Customer Carrier Core Router as a Route Reflector 1672
Troubleshooting Tips 1674
Configuring the Customer Site for Hierarchical VPNs 1674
Defining VPNs on PE Routers for Hierarchical VPNs 1675
Configuring BGP Routing Sessions on the PE Routers for Hierarchical VPNs 1676
Verifying Labels in Each PE Router for Hierarchical VPNs 1678
Configuring CE Routers for Hierarchical VPNs 1679
Verifying IP Connectivity in the Customer Site 1681
Configuration Examples for MPLS VPN CSC with BGP 1683
Configuring the Backbone Carrier Core Examples 1684
Verifying IP Connectivity and LDP Configuration in the CSC Core Example 1684
Configuring VRFs for CSC-PE Routers Example 1685
Configuring Multiprotocol BGP for VPN Connectivity in the Backbone Carrier Example 1685

Configuring the Links Between CSC-PE and CSC-CE Routers Examples 1686
Configuring the CSC-PE Routers Examples 1686
Configuring the CSC-CE Routers Examples 1687
Verifying Labels in the CSC-PE Routers Examples 1688
Verifying Labels in the CSC-CE Routers Examples 1690
Configuring the Customer Carrier Network Examples 1693
Verifying IP Connectivity in the Customer Carrier Example 1693
Configuring a Customer Carrier Core Router as a Route Reflector Example 1693
Configuring the Customer Site for Hierarchical VPNs Examples 1694
Configuring PE Routers for Hierarchical VPNs Examples 1694
Verifying Labels in Each PE Router for Hierarchical VPNs Examples 1695
Configuring CE Routers for Hierarchical VPNs Examples 1696
Verifying IP Connectivity in the Customer Site Examples 1696
Additional References 1697
Feature Information for MPLS VPN CSC with BGP 1698
Glossary 1699

CHAPTER 81 **MPLS VPN Load Balancing Support for Inter-AS and CSC VPNs 1701**
Prerequisites for MPLS VPN Load Balancing Support for Inter-AS and CSC VPNs 1701
Restrictions for MPLS VPN Load Balancing Support for Inter-AS and CSC VPNs 1701
Information About MPLS VPN Load Balancing Support for Inter-AS and CSC VPNs 1704
Load Sharing Using Directly Connected Loopback Peering 1704
How to Configure MPLS VPN Load Balancing Support for Inter-AS and CSC VPN 1704
Configuring Directly Connected Loopback Peering for MPLS VPN Inter-AS using ASBRs to Exchange VPN-IPv4 Addresses 1704
Configuring Loopback Interface Addresses for Directly Connected ASBRs 1705
Configuring /32 Static Routes to the eBGP Neighbor Loopback 1706
Configuring Forwarding on Connecting Loopback Interfaces 1707
Configuring an eBGP Session Between the Loopbacks 1708
Verifying That Load Sharing Occurs Between Loopbacks 1711
Configuring Directly Connected Loopback Peering for MPLS VPN Inter-AS Using ASBRs to Exchange IPv4 Routes and Labels 1712
Configuring Loopback Interface Addresses for Directly Connected ASBRs 1712
Configuring /32 Static Routes to the eBGP Neighbor Loopback 1714

Configuring Forwarding on Connecting Loopback Interfaces 1715
Configuring an eBGP Session Between the Loopbacks 1716
Verifying That Load Sharing Occurs Between Loopbacks 1719
Configuring Directly Connected Loopback Peering on MPLS VPN Carrier Supporting Carrier 1720
Configuring Loopback Interface Addresses on CSC-PE Devices 1720
Configuring Loopback Interface Addresses for CSC-CE Routers 1722
Configuring /32 Static Routes to the eBGP Neighbor Loopback on the CSC-PE Device 1723
Configuring /32 Static Routes to the eBGP Neighbor Loopback on the CSC-CE Device 1724
Configuring Forwarding on CSC-PE Interfaces That Connect to the CSC-CE Loopback 1725
Configuring Forwarding on CSC-CE Interfaces That Connect to the CSC-PE Loopback 1727
Configuring an eBGP Session Between the CSC-PE Device and the CSC-CE Loopback 1728
Configuring an eBGP Session Between the CSC-CE Device and the CSC-PE Loopback 1730
Verifying That Load Sharing Occurs Between Loopbacks 1733
Configuration Examples for MPLS VPN Load Balancing Support for Inter-AS and CSC VPN 1734
Examples: Configuring a 32 Static Route from an ASBR to the Loopback Address of Another ASBR 1734
Example: Configuring BGP MPLS Forwarding on the Interfaces Connecting ASBRs 1734
Example: Configuring VPNv4 Sessions on an ASBR 1734
Additional References 1735
Feature Information for MPLS VPN Load Balancing Support for Inter-AS and CSC VPN 1736

CHAPTER 82 **MPLS VPN eBGP Multipath Support for CSC and Inter-AS MPLS VPNs 1737**
Prerequisites for MPLS VPN eBGP Multipath Support for CSC and Inter-AS MPLS VPNs 1737
Restrictions for MPLS VPN eBGP Multipath Support for CSC and Inter-AS MPLS VPNs 1738
Information About MPLS VPN eBGP Multipath Support for CSC and Inter-AS MPLS VPNs 1740
Overview of MPLS VPN eBGP Multipath Support for CSC and Inter-AS MPLS VPNs 1740
How to Configure MPLS VPN eBGP Multipath Support for CSC and Inter-AS MPLS VPNs 1740
Configuring MPLS VPN eBGP Multipath Load Sharing with Inter-AS MPLS VPNs 1740
Configuring MPLS VPN eBGP Multipath Load Sharing with Carrier Supporting Carrier on the CSC-PE Devices 1742
Configuring MPLS VPN eBGP Multipath Load Sharing with Carrier Supporting Carrier on the CSC-CE Devices 1745
Configuration Examples for MPLS VPN eBGP Multipath Support for CSC and Inter-AS MPLS VPNs 1747
Example: Configuring MPLS VPN eBGP Multipath Load Sharing with MPLS VPN Inter-AS 1747

Example: Configuring MPLS VPN eBGP Multipath Load Sharing with MPLS VPN Carrier Supporting Carrier on the CSC-PE Devices 1748
Example: Configuring MPLS VPN eBGP Multipath Load Sharing with MPLS VPN Carrier Supporting Carrier on the CSC-CE Devices 1748
Additional References 1749
Feature Information for MPLS VPN eBGP Multipath Support for CSC and Inter-AS MPLS VPNs 1750

CHAPTER 83 **MPLS VPN Explicit Null Label Support with BGP IPv4 Label Session** 1751
Prerequisites for MPLS VPN Explicit Null Label Support with BGP IPv4 Label Session 1751
Restrictions for MPLS VPN Explicit Null Label Support with BGP IPv4 Label Session 1751
Information About MPLS VPN Explicit Null Label Support with BGP IPv4 Label Session 1752
Feature Design of MPLS VPN Explicit Null Label Support with BGP IPv4 Label Session 1752
Benefits of MPLS VPN Explicit Null Label Support BGP IPv4 Label Session 1752
How to Configure MPLS VPN Explicit Null Label Support with BGP IPv4 Label Session 1752
Configuring CSC with BGP 1752
Verifying the Explicit Null Configuration 1753
Configuration Examples for MPLS VPN Explicit Null Label Support with BGP IPv4 Label Session 1755
Example: Configuring CSC-CE with BGP 1755
Example: Verifying the Explicit Null Configuration 1755
Additional References for MPLS VPN Explicit Null Label with BGP IPv4 Label Session 1756
Feature Information for MPLS VPN Explicit Null Label Support with BGP IPv4 Label Session 1757
Glossary 1758

PART VII **MPLS Traffic Engineering** 1761

CHAPTER 84 **MPLS Traffic Engineering - DiffServ Aware (DS-TE)** 1763
Information About MPLS Traffic Engineering - DiffServ Aware (DS-TE) 1763
MPLS TE and Constraint-Based Routing (CBR) 1763
From Traditional to IETF-Standard Commands 1765
Transitioning a Network to the IETF Standard 1767
Guaranteed Bandwidth Service Configuration 1767
Providing Strict QoS Guarantees Using DS-TE Sub-pool Tunnels 1767
Providing Differentiated Service Using DS-TE Global Pool Tunnels 1768
Providing Strict Guarantees and Differentiated Service in the Same Network 1768

Prerequisites for MPLS Traffic Engineering - DiffServ Aware (DS-TE) 1769
How to Configure MPLS Traffic Engineering - DiffServ Aware (DS-TE) 1769
Configuring DS-TE Tunnels 1769
Level 1 Configuring the Device 1769
Level 2 Configuring the Physical Interface 1771
Level 3 Configuring the Tunnel Interface 1772
Verifying the Configuration 1773
MPLS Traffic Engineering - DiffServ Aware (DS-TE): Examples 1775
Tunnel Head: Example 1775
Midpoint Devices: Example 1776
Tail-End Device: Example 1778
Guaranteed Bandwidth Service: Examples 1779
Single Destination Prefix: Example 1779
Many Destination Prefixes: Example 1790
Additional References 1803
Glossary 1804
Feature Information for MPLS Traffic Engineering - DiffServ Aware (DS-TE) 1806

CHAPTER 85 **MPLS DiffServ Tunneling Modes** 1811
Prerequisites for MPLS DiffServ Tunneling Modes 1812
Restrictions for MPLS DiffServ Tunneling Modes 1812
Information About MPLS DiffServ Tunneling Modes 1813
QoS and Its Use in MPLS Tunneling 1813
What is QoS 1813
Services Supported by MPLS QoS 1813
Providing QoS to an IP Packet 1814
Providing QoS to an MPLS Packet 1814
DiffServ as a Standardization of QoS 1814
Tunneling Modes for MPLS DiffServ 1815
MPLS PHB Layer Management 1816
Tunneling Modes Operation 1816
Pipe Mode with an Explicit NULL LSP 1817
Short Pipe Mode 1820
Uniform Mode 1823

How to Configure MPLS DiffServ Tunneling Modes 1825
Determining Which Tunneling Mode is Appropriate 1825
Setting the MPLS EXP field 1825
Configuring Pipe Mode with an Explicit NULL LSP 1825
Ingress CE Router--Customer Facing Interface 1826
Ingress CE Router--PE Facing Interface 1827
Ingress PE Router--P Facing Interface 1829
P Router--P Facing Interface 1830
Egress PE Router--P Facing Interface 1831
Egress PE Router--Customer Facing Interface 1833
Configuring Short Pipe Mode 1834
Ingress PE Router--Customer Facing Interface 1835
Ingress PE Router--P Facing Interface 1836
P Router--P Facing Interface 1837
Egress PE Router--Customer Facing Interface 1839
Configuring Uniform Mode 1840
Ingress PE Router--Customer Facing Interface 1840
Ingress PE Router--P Facing Interface 1841
P Router--Upstream P Facing Interface 1843
P Router--Downstream P Facing Interface 1844
Egress PE Router--P Facing Interface 1845
Egress PE Router--Customer Facing Interface 1847
Verifying MPLS DiffServ Tunneling Mode Support 1848
Troubleshooting Tips 1848
Configuration Examples for MPLS DiffServ Tunneling Modes 1848
Pipe Mode with an Explicit NULL LSP Configuration Example 1849
Short Pipe Mode Configuration Example 1850
Uniform Mode Configuration Example 1852
Additional References 1853
Feature Information for MPLS DiffServ Tunneling Modes 1854
Glossary 1855

CHAPTER 86 **MPLS Traffic Engineering and Enhancements** 1859
Prerequisites for MPLS Traffic Engineering and Enhancements 1859

Restrictions for MPLS Traffic Engineering and Enhancements 1859
Information About MPLS Traffic Engineering and Enhancements 1860
Introduction to MPLS Traffic Engineering and Enhancements 1860
Benefits of MPLS Traffic Engineering 1860
How MPLS Traffic Engineering Works 1861
Mapping Traffic into Tunnels 1862
Enhancement to the SPF Computation 1862
Special Cases and Exceptions for SPF Calculations 1863
Additional Enhancements to SPF Computation Using Configured Tunnel Metrics 1864
Transition of an IS-IS Network to a New Technology 1865
Extensions for the IS-IS Routing Protocol 1865
Problems with Old and New TLVs in Theory and in Practice 1866
First Solution for Transitioning an IS-IS Network to a New Technology 1866
Transition Actions During the First Solution 1867
Second Solution for Transitioning an IS-IS Network to a New Technology 1867
Transition Actions During the Second Solution 1868
TLV Configuration Commands 1868
Implementation in Cisco IOS XE Software 1868
How to Configure MPLS Traffic Engineering and Enhancements 1868
Configuring a Device to Support Tunnels 1868
Configuring an Interface to Support RSVP-Based Tunnel Signaling and IGP Flooding 1869
Configuring IS-IS for MPLS Traffic Engineering 1871
Configuring OSPF for MPLS Traffic Engineering 1871
Configuring an MPLS Traffic Engineering Tunnel 1873
DEFAULT STEPS 1875
Configuring an MPLS Traffic Engineering Tunnel that an IGP Can Use 1877
DEFAULT STEPS 1877
Configuration Examples for MPLS Traffic Engineering and Enhancements 1878
Example Configuring MPLS Traffic Engineering Using IS-IS 1878
Router 1--MPLS Traffic Engineering Configuration 1878
Router 1--IS-IS Configuration 1879
Example Configuring MPLS Traffic Engineering Using OSPF 1879
Router 1--MPLS Traffic Engineering Configuration 1879
Router 1--OSPF Configuration 1879

Example Configuring an MPLS Traffic Engineering Tunnel 1879
Router 1--Dynamic Path Tunnel Configuration 1880
Router 1--Dynamic Path Tunnel Verification 1880
Router 1--Explicit Path Configuration 1880
Router 1--Explicit Path Tunnel Configuration 1880
Router 1--Explicit Path Tunnel Verification 1880
Example Configuring Enhanced SPF Routing over a Tunnel 1880
Router 1--IGP Enhanced SPF Consideration Configuration 1881
Router 1--Route and Traffic Verification 1881
Additional References 1881
Feature Information for MPLS Traffic Engineering and Enhancements 1882
Glossary 1883

CHAPTER 87 **MPLS Traffic Engineering Configurable Path Calculation Metric for Tunnels** 1885
Prerequisites for MPLS Traffic Engineering - Configurable Path Calculation Metric for Tunnels 1885
Restrictions for MPLS Traffic Engineering - Configurable Path Calculation Metric for Tunnels 1886
Information About MPLS Traffic Engineering - Configurable Path Calculation Metric for Tunnels 1886
Overview 1886
Benefits 1886
How to Configure MPLS Traffic Engineering - Configurable Path Calculation Metric for Tunnels 1887
Configuring a Platform to Support Traffic Engineering Tunnels 1887
Configuring IS-IS for MPLS Traffic Engineering 1888
Configuring OSPF for MPLS Traffic Engineering 1888
Configuring Traffic Engineering Link Metrics 1890
Configuring an MPLS Traffic Engineering Tunnel 1891
Configuring the Metric Type for Tunnel Path Calculation 1894
Verifying the Tunnel Path Metric Configuration 1895
Configuration Examples for Configuring a Path Calculation Metric for Tunnels 1897
Example Configuring Link Type and Metrics for Tunnel Path Selection 1897
Additional References 1899
Feature Information for MPLS Traffic Engineering - Configurable Path Calculation Metric for Tunnels 1900

CHAPTER 88 **MPLS Traffic Engineering--Scalability Enhancements** 1903

Prerequisites for MPLS Traffic Engineering--Scalability Enhancements 1903
Restrictions for MPLS Traffic Engineering--Scalability Enhancements 1904
Information About MPLS Traffic Engineering--Scalability Enhancements 1904
Scalability Enhancements for Traffic Engineering Tunnels 1904
RSVP Rate Limiting 1904
Improved Recovery Response for Signaling and Management of MPLS Traffic Engineering Tunnels 1904
IS-IS and MPLS Traffic Engineering Topology Database Interactions 1905
Improved Counter Capabilities for MPLS TE Tunnels Events and RSVP Signaling 1905
Benefits of MPLS Traffic Engineering--Scalability Enhancements 1905
How to Configure MPLS Traffic Engineering--Scalability Enhancements 1906
Enabling RSVP Rate Limiting for MPLS Traffic Engineering Scalability Enhancements 1906
Managing Link Failure Timeouts for MPLS Traffic Engineering Tunnels 1907
Controlling IS-IS Communication with the MPLS Traffic Engineering Topology Database 1908
Monitoring and Maintaining MPLS TE Scalability Enhancements 1910
Configuration Examples for MPLS Traffic Engineering--Scalability Enhancements 1913
Example Enabling RSVP Rate Limiting for MPLS Traffic Engineering Scalability Enhancements 1913
Example Managing Link Failure Timeouts for MPLS Traffic Engineering Tunnels 1913
Example Controlling IS-IS Communication with the MPLS Traffic Engineering Topology Database 1913
Additional References 1914
Feature Information for MPLS Traffic Engineering Scalability Enhancements 1915
Glossary 1915

CHAPTER 89 **MPLS Traffic Engineering--LSP Attributes** 1919
Prerequisites for MPLS Traffic Engineering--LSP Attributes 1919
Restrictions for MPLS Traffic Engineering--LSP Attributes 1919
Information About MPLS Traffic Engineering - Configurable Path Calculation Metric for Tunnels 1920
MPLS Traffic Engineering--LSP Attributes Benefits 1920
Traffic Engineering Bandwidth and Bandwidth Pools 1920
Tunnel Attributes and LSP Attributes 1920
LSP Attributes and the LSP Attribute List 1921
LSP Attribute Lists Management 1921
Constraint-Based Routing and Path Option Selection 1921

Tunnel Reoptimization and Path Option Selection 1922
Path Option Selection with Bandwidth Override 1922
Default Path Option Attributes for TE Tunnels Using LSP Attribute Lists 1923
How to Configure MPLS Traffic Engineering--LSP Attributes 1924
Configuring an LSP Attribute List 1924
Adding Attributes to an LSP Attribute List 1927
Removing an Attribute from an LSP Attribute List 1929
Modifying an Attribute in an LSP Attribute List 1930
Deleting an LSP Attribute List 1932
Verifying Attributes Within an LSP Attribute List 1933
Verifying All LSP Attribute Lists 1934
Associating an LSP Attribute List with a Path Option for an MPLS TE Tunnel 1935
Modifying a Path Option to Use a Different LSP Attribute List 1938
Removing a Path Option for an LSP for an MPLS TE Tunnel 1940
Verifying that LSP Is Signaled Using the Correct Attributes 1942
Configuring a Path Option for Bandwidth Override 1943
Configuring Fallback Bandwidth Path Options for TE Tunnels 1944
Modifying the Bandwidth on a Path Option for Bandwidth Override 1946
Removing a Path Option for Bandwidth Override 1948
Verifying that LSP Is Signaled Using the Correct Bandwidth 1950
Configuration Examples for MPLS Traffic Engineering--RSVP Hello State Timer 1952
Configuring LSP Attribute List Examples 1952
Configuring an LSP Attribute List: Example 1952
Adding Attributes to an LSP Attribute List: Example 1952
Removing an Attribute from an LSP Attribute List: Example 1952
Modifying an Attribute in an LSP Attribute List: Example 1952
Deleting an LSP Attribute List: Example 1953
Associating an LSP Attribute List with a Path Option for a TE Tunnel: Example 1953
Modifying a Path Option to Use a Different LSP Attribute List: Example 1953
Removing a Path Option for an LSP for an MPLS TE Tunnel: Example 1954
Configuring a Path Option for Bandwidth Override Examples 1954
Configuring a Path Option to Override the Bandwidth: Example 1954
Configuring Fallback Bandwidth Path Options for TE Tunnels: Example 1955
Modifying the Bandwidth on a Path Option for Bandwidth Override: Example 1955

Removing the Path Option Bandwidth Value for an LSP for an MPLS TE Tunnel: Example 1956
Additional References 1956
Feature Information for MPLS Traffic Engineering LSP Attributes 1957
Glossary 1958

CHAPTER 90 MPLS Traffic Engineering AutoTunnel Mesh Groups 1959
Prerequisites for MPLS Traffic Engineering--AutoTunnel Mesh Groups 1959
Restrictions for MPLS Traffic Engineering--AutoTunnel Mesh Groups 1959
Information About MPLS Traffic Engineering--AutoTunnel Mesh Groups 1960
AutoTunnel Mesh Groups Description and Benefits 1960
Access Lists for Mesh Tunnel Interfaces 1960
AutoTunnel Template Interfaces 1961
OSPF Flooding of Mesh Group Information 1961
How to Configure MPLS Traffic Engineering--AutoTunnel Mesh Groups 1961
Configuring a Mesh of TE Tunnel LSPs 1961
Enabling Autotunnel Mesh Groups Globally 1961
Creating an Access List Using a Name 1962
Creating an Autotunnel Template Interface 1964
Specifying the Range of Mesh Tunnel Interface Numbers 1966
Displaying Configuration Information About Tunnels 1967
Monitoring the Autotunnel Mesh Network 1968
Troubleshooting Tips 1970
Configuring IGP Flooding for Autotunnel Mesh Groups 1970
Configuration Examples for MPLS Traffic Engineering--Autotunnel Mesh Groups 1972
Examples: Configuring a Mesh of TE Tunnel LSPs 1972
Example: Enabling Autotunnel Mesh Groups Globally 1972
Example: Creating an Access List Using a Name 1972
Example: Creating an AutoTunnel Template Interface 1972
Example: Specifying the Range of Mesh Tunnel Interface Numbers 1973
Example: Configuring IGP Flooding for Autotunnel Mesh Groups 1973
Additional References 1973
Feature Information for MPLS Traffic Engineering--Autotunnel Mesh Groups 1974
Glossary 1975

CHAPTER 91 **MPLS Traffic Engineering Verbatim Path Support** 1977

Prerequisites for MPLS Traffic Engineering--Verbatim Path Support 1977

Restrictions for MPLS Traffic Engineering Verbatim Path Support 1977

Information About MPLS Traffic Engineering - Configurable Path Calculation Metric for Tunnels 1978

MPLS TE Verbatim Path Support Overview 1978

How to Configure MPLS Traffic Engineering - Configurable Path Calculation Metric for Tunnels 1978

Configuring MPLS Traffic Engineering--Verbatim Path Support 1978

Verifying Verbatim LSPs for MPLS TE Tunnels 1981

Configuration Examples for MPLS Traffic Engineering Verbatim Path Support 1982

Configuring MPLS Traffic Engineering Verbatim Path Support Example 1982

Additional References 1982

Feature Information for MPLS Traffic Engineering Verbatim Path Support 1983

Glossary 1984

CHAPTER 92 **MPLS Traffic Engineering--RSVP Hello State Timer** 1985

Prerequisites for MPLS Traffic Engineering--RSVP Hello State Timer 1985

Restrictions for MPLS Traffic Engineering--RSVP Hello State Timer 1986

Information About MPLS Traffic Engineering - Configurable Path Calculation Metric for Tunnels 1986

Hellos for State Timeout 1986

Hello Instance 1986

Hellos for Nonfast-Reroutable TE LSP 1986

Hellos for Fast-Reroutable TE LSP with Backup Tunnel 1987

Hellos for Fast-Reroutable TE LSP Without Backup Tunnel 1988

How to Configure MPLS Traffic Engineering--RSVP Hello State Timer 1989

Enabling the Hello State Timer Globally 1989

Enabling the Hello State Timer on an Interface 1990

Setting a DSCP Value on an Interface 1990

Setting a Hello Request Interval on an Interface 1991

Setting the Number of Hello Messages that can be Missed on an Interface 1992

Verifying Hello for State Timer Configuration 1993

Configuration Examples for MPLS Traffic Engineering--RSVP Hello State Timer 1994

Example 1994

Additional References 1995

Feature Information for MPLS Traffic Engineering--RSVP Hello State Timer 1996
Glossary 1996

CHAPTER 93 MPLS Traffic Engineering Forwarding Adjacency 1999
Prerequisites for MPLS Traffic Engineering Forwarding Adjacency 1999
Restrictions for MPLS Traffic Engineering Forwarding Adjacency 1999
Information About MPLS Traffic Engineering Forwarding Adjacency 2000
MPLS Traffic Engineering Forwarding Adjacency Functionality 2000
MPLS Traffic Engineering Forwarding Adjacency Benefits 2000
How to Configure MPLS Traffic Engineering Forwarding Adjacency 2001
Configuring a Tunnel Interface for MPLS TE Forwarding Adjacency 2001
Configuring MPLS TE Forwarding Adjacency on Tunnels 2002
Verifying MPLS TE Forwarding Adjacency 2003
Configuration Examples for MPLS Traffic Engineering Forwarding Adjacency 2004
Example MPLS TE Forwarding Adjacency 2004
Usage Tips 2005
Additional References 2006
Glossary 2007
Feature Information for MPLS Traffic Engineering Forwarding Adjacency 2008

CHAPTER 94 MPLS Traffic Engineering Class-based Tunnel Selection 2011
Prerequisites for MPLS Traffic Engineering Class-based Tunnel Selection 2011
Restrictions for MPLS Traffic Engineering Class-based Tunnel Selection 2012
Information About MPLS Traffic Engineering Class-based Tunnel Selection 2012
Incoming Traffic Supported by MPLS TE Class-based Tunnel Selection 2012
CoS Attributes for MPLS TE Class-based Tunnel Selection 2012
Routing Protocols and MPLS TE Class-based Tunnel Selection 2013
Tunnel Selection with MPLS TE Class-based Tunnel Selection 2013
EXP Mapping Configuration 2013
Tunnel Selection for EXP Values 2014
Tunnel Failure Handling 2016
Misordering of Packets 2018
Fast Reroute and MPLS TE Class-based Tunnel Selection 2018
DS-TE Tunnels and MPLS TE Class-based Tunnel Selection 2019

Reoptimization and MPLS TE Class-based Tunnel Selection 2019
Interarea and Inter-AS and MPLS TE Class-based Tunnel Selection 2019
ATM PVCs and MPLS TE Class-based Tunnel Selection 2019
How to Configure MPLS Traffic Engineering Class-based Tunnel Selection 2019
Creating Multiple MPLS TE or DS-TE Tunnels from the Same Headend to the Same Tailend 2019
Configuring EXP Values to Be Carried by Each MPLS TE or DS-TE Tunnel 2021
Verifying That the MPLS TE or DS-TE Tunnels Are Operating and Announced to the IGP 2023
Configuring a Primary Tunnel 2025
Configuration Examples for MPLS Traffic Engineering Class-based Tunnel Selection 2027
Example: Creating Multiple MPLS TE or DS-TE Tunnels from the Same Headend to the Same Tailend 2027
Example: Configuring EXP Values to Be Carried by Each MPLS TE or DS-TE Tunnel 2027
Example: Verifying That the MPLS TE or DS-TE Tunnels Are Operating and Announced to the IGP 2028
Example: Configuring a Primary Tunnel 2034
Additional References 2034
Feature Information for MPLS Traffic Engineering Class-based Tunnel Selection 2035
Glossary 2035

CHAPTER 95 **MPLS Traffic Engineering Interarea Tunnels** 2037
Prerequisites for MPLS Traffic Engineering Interarea Tunnels 2037
Restrictions for MPLS Traffic Engineering Interarea Tunnels 2037
Information About MPLS Traffic Engineering Interarea Tunnels 2038
Interarea Tunnels Functionality 2038
Autoroute Destination Functionality 2039
CBTS Interaction with Autoroute Destination 2039
Manually Configured Static Routes Interaction with Autoroute Destination 2039
Autoroute Announce Interaction with Autoroute Destination 2040
Forwarding Adjacency Interaction with Autoroute Destination 2040
MPLS Traffic Engineering Interarea Tunnels Benefits 2040
How to Configure MPLS Traffic Engineering Interarea Tunnels 2040
Configuring OSPF for Interarea Tunnels 2040
Configuring OSPF for ABR Routers 2040
Configuring OSPF for Non-ABR Routers 2042

Configuring IS-IS for Interarea Tunnels 2043
Configuring IS-IS for Backbone Routers 2043
Configuring IS-IS for Nonbackbone Routers 2045
Configuring IS-IS for Interfaces 2047
Configuring MPLS and RSVP to Support Traffic Engineering 2048
Configuring an MPLS Traffic Engineering Interarea Tunnel 2050
Configuring an MPLS Traffic Engineering Interarea Tunnel to Use Explicit Paths 2050
Configuring Explicit Paths 2051
Configuring an MPLS Traffic Engineering Tunnel with Autoroute Destination 2052
Configuration Examples for MPLS Traffic Engineering Interarea Tunnels 2054
Configuring OSPF for Interarea Tunnels Example 2054
Configuring IS-IS for Interarea Tunnels Example 2056
Configuring MPLS and RSVP to Support Traffic Engineering Example 2057
Configuring an MPLS Traffic Engineering Interarea Tunnel Example 2058
Configuring an MPLS Traffic Engineering Tunnel with Autoroute Destination Example 2058
Additional References 2059
Feature Information for MPLS Traffic Engineering Interarea Tunnels 2060
Glossary 2061

CHAPTER 96 **MPLS Traffic Engineering Static IPv6 Routes over MPLS TE IPv4 Tunnels** 2065
Prerequisites for MPLS Traffic Engineering Static IPv6 Routes over MPLS TE IPv4 Tunnels 2065
Restrictions for MPLS Traffic Engineering Static IPv6 Routes over MPLS TE IPv4 Tunnels 2066
Information About MPLS Traffic Engineering Static IPv6 Routes over MPLS TE IPv4 Tunnels 2066
Overview of Static IPv6 Routes over MPLS TE IPv4 Tunnels 2066
How to Configure MPLS Traffic Engineering Static IPv6 Routes over MPLS TE IPv4 Tunnels 2067
Assigning an IPv6 Address to an MPLS TE IPv4 Tunnel 2067
Configuring a Static IPv6 Route by Specifying an MPLS TE IPv4 Tunnel as the Egress Interface 2068
Verifying IPv6 Routing over a TE IPv4 Tunnel 2069
Displaying IPv6 Statistics over a TE IPv4 Tunnel 2070
Troubleshooting IPv6 Routing over a TE IPv4 Tunnel 2071
Configuration Examples for MPLS Traffic Engineering Static IPv6 Routes over MPLS TE IPv4 Tunnels 2072
Example: Assigning an IPv6 Address to an MPLS TE IPv4 Tunnel 2072

Example: Configuring a Static IPv6 Route by Specifying an MPLS TE IPv4 Tunnel as an Egress Interface 2072
Additional References for MPLS TE - Bundled Interface Support 2072
Feature Information for MPLS Traffic Engineering Static IPv6 Routes over MPLS TE IPv4 Tunnels 2073

CHAPTER 97 MPLS Traffic Engineering Automatic Bandwidth Adjustment for TE Tunnels 2075
Prerequisites for MPLS TE Automatic Bandwidth Adjustment for TE Tunnels 2075

Preface

This preface describes the audience, organization, and conventions of this document. It also provides information on how to obtain other documentation.

This preface includes the following sections:

- Preface, on page xci
- Audience and Scope, on page xci
- Feature Compatibility, on page xcii
- Document Conventions, on page xcii
- Communications, Services, and Additional Information, on page xciii
- Documentation Feedback, on page xciv
- Troubleshooting, on page xciv

Preface

This preface describes the audience, organization, and conventions of this document. It also provides information on how to obtain other documentation.

This preface includes the following sections:

Audience and Scope

This document is designed for the person who is responsible for configuring your Cisco Enterprise router. This document is intended primarily for the following audiences:

- Customers with technical networking background and experience.
- System administrators familiar with the fundamentals of router-based internetworking but who might not be familiar with Cisco IOS software.
- System administrators who are responsible for installing and configuring internetworking equipment, and who are familiar with Cisco IOS software.

Feature Compatibility

For more information about the Cisco IOS XE software, including features available on your device as described in the configuration guides, see the respective router documentation set.

To verify support for specific features, use the Cisco Feature Navigator tool. This tool enables you to determine the Cisco IOS XE software images that support a specific software release, feature set, or a platform.

Document Conventions

This documentation uses the following conventions:

Convention	Description
^ or **Ctrl**	The ^ and **Ctrl** symbols represent the Control key. For example, the key combination **^D** or **Ctrl-D** means hold down the **Control** key while you press the **D** key. Keys are indicated in capital letters but are not case sensitive.
string	A string is a nonquoted set of characters shown in italics. For example, when setting an SNMP community string to public, do not use quotation marks around the string or the string will include the quotation marks.

The command syntax descriptions use the following conventions:

Convention	Description
bold	Bold text indicates commands and keywords that you enter exactly as shown.
italics	Italic text indicates arguments for which you supply values.
[x]	Square brackets enclose an optional element (keyword or argument).
|	A vertical line indicates a choice within an optional or required set of keywords or arguments.
[x | y]	Square brackets enclosing keywords or arguments separated by a vertical line indicate an optional choice.
{x | y}	Braces enclosing keywords or arguments separated by a vertical line indicate a required choice.

Nested sets of square brackets or braces indicate optional or required choices within optional or required elements. For example, see the following table.

Convention	Description
[x {y | z}]	Braces and a vertical line within square brackets indicate a required choice within an optional element.

Examples use the following conventions:

Convention	Description
`screen`	Examples of information displayed on the screen are set in Courier font.
`bold screen`	Examples of text that you must enter are set in Courier bold font.
< >	Angle brackets enclose text that is not printed to the screen, such as passwords.
!	An exclamation point at the beginning of a line indicates a comment line. Exclamation points are also displayed by the Cisco IOS XE software for certain processes.
[ ]	Square brackets enclose default responses to system prompts.

Caution Means *reader be careful*. In this situation, you might do something that could result in equipment damage or loss of data.

Note Means *reader take note*. Notes contain helpful suggestions or references to materials that may not be contained in this manual.

Communications, Services, and Additional Information

- To receive timely, relevant information from Cisco, sign up at Cisco Profile Manager.
- To get the business results you're looking for with the technologies that matter, visit Cisco Services.
- To submit a service request, visit Cisco Support.
- To discover and browse secure, validated enterprise-class apps, products, solutions and services, visit Cisco DevNet.
- To obtain general networking, training, and certification titles, visit Cisco Press.
- To find warranty information for a specific product or product family, access Cisco Warranty Finder.

Cisco Bug Search Tool

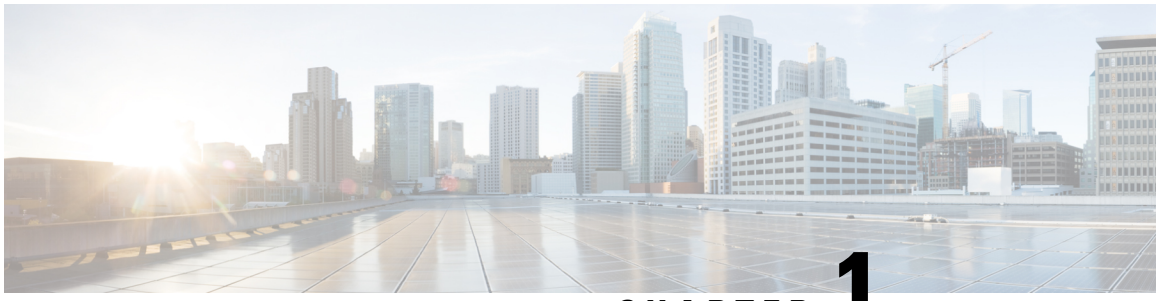
Cisco Bug Search Tool (BST) is a web-based tool that acts as a gateway to the Cisco bug tracking system that maintains a comprehensive list of defects and vulnerabilities in Cisco products and software. BST provides you with detailed defect information about your products and software.

Documentation Feedback

To provide feedback about Cisco technical documentation, use the feedback form available in the right pane of every online document.

Troubleshooting

For the most up-to-date, detailed troubleshooting information, see the Cisco TAC website at https://www.cisco.com/en/US/support/index.html.



Go to **Products by Category** and choose your product from the list, or enter the name of your product. Look under **Troubleshoot and Alerts** to find information for the issue that you are experiencing.

CHAPTER 1

MPLS Transport Profile

Multiprotocol Label Switching (MPLS) Transport Profile (TP) enables you to create tunnels that provide the transport network service layer over which IP and MPLS traffic traverses. MPLS-TP tunnels enable a transition from Synchronous Optical Networking (SONET) and Synchronous Digital Hierarchy (SDH) time-division multiplexing (TDM) technologies to packet switching to support services with high bandwidth requirements, such as video.

- Reference the Chapter Map here, on page 1
- Restrictions for MPLS Transport Profile, on page 1
- Information About MPLS-TP, on page 2
- How to Configure MPLS Transport Profile, on page 6
- Configuration Examples for MPLS Transport Profile, on page 25
- Additional References for MPLS Transport Profile, on page 26
- Feature Information for MPLS Transport Profile, on page 26

Reference the Chapter Map here

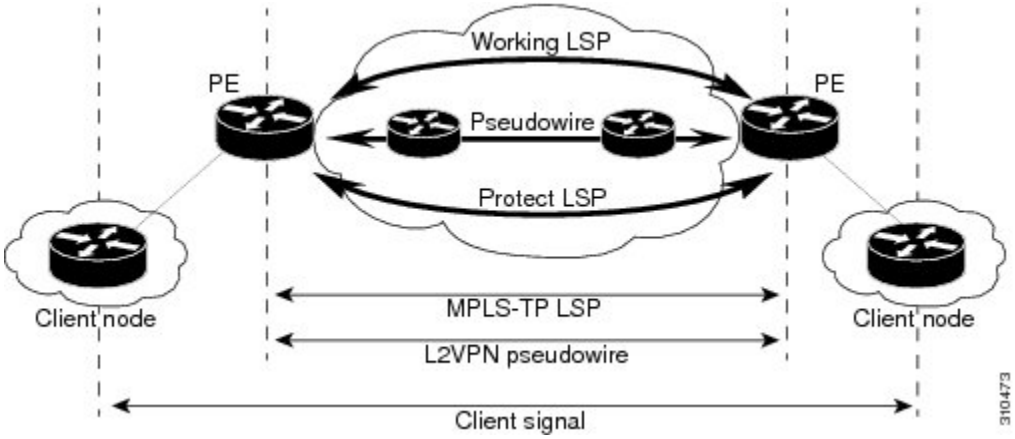
Restrictions for MPLS Transport Profile

- Multiprotocol Label Switching Transport Profile (MPLS-TP) penultimate hop popping is not supported. Only ultimate hop popping is supported, because label mappings are configured at the MPLS-TP endpoints.
- Ethernet subinterfaces are not supported.
- IPv6 addressing is not supported.

L2VPN Restrictions

- Layer 2 Virtual Private Network (L2VPN) interworking is not supported.
- Local switching with Any Transport over MPLS (AToM) pseudowire as a backup is not supported.
- L2VPN pseudowire redundancy to an AToM pseudowire by one or more attachment circuits is not supported.
- Pseudowire ID Forward Equivalence Class (FEC) type 128 is supported, but generalized ID FEC type 129 is not supported.

- Static pseudowire Operations, Administration, and Maintenance (OAM) protocol and BFD VCCV attachment circuit (AC) status signaling are mutually exclusive protocols. Bidirectional Forwarding Detection (BFD) and Virtual Circuit Connectivity Verification (VCCV) in failure detection mode can be used with Static Pseudowire OAM protocol.
- BFD VCCV AC status signaling cannot be used in pseudowire redundancy configurations. You can use Static Pseudowire OAM instead.



Ping and Trace Restrictions

- Ping for static pseudowires over MPLS-TP tunnels is not supported.
- Pseudowire ping and traceroute functionality for multisegment pseudowires that have one or more static pseudowire segments is not supported.
- The following packet format is supported:
  - A labeled packet with Generic Associated Channel Label (GAL) at the bottom of the label stack.
  - ACH channel is IP (0x21).
  - RFC-4379-based IP, UDP packet payload with valid source.
  - Destination IP address and UDP port 3503.
- Default reply mode for (1) is 4—Reply via application level control channel is supported. An echo reply consists of the following elements:
  - A labeled packet with a GAL label at the bottom of the label stack.
  - Associated Channel (ACh) is IP (0x21).
  - RFC-4379-based IP, UDP packet payload with valid source.
  - Destination IP address and UDP port 3503.
- The optional “do not reply” mode may be set.
- The following reply modes are not allowed and are disabled in CLI:
  - 2—Reply via an IPv4/IPv6 UDP packet
  - 3—Reply via an IPv4/IPv6 UDP packet with router alert
- Force-explicit-null is not supported with ping and trace.
- Optional Reverse Path Connectivity verification is not supported.

Information About MPLS-TP

How MPLS Transport Profile Works

Multiprotocol Label Switching Transport Profile (MPLS-TP) tunnels provide the transport network service layer over which IP and MPLS traffic traverses. MPLS-TP tunnels help transition from Synchronous Optical Network/Synchronous Digital Hierarchy (SONET/SDH) and Time Division Multiplexing (TDM) technologies to packet switching to support services with high bandwidth utilization and lower cost. Transport networks are connection-oriented, statically provisioned, and have long-lived connections. Transport networks usually avoid control protocols that change identifiers (like labels). MPLS-TP tunnels provide this functionality through statically provisioned bidirectional label switched paths (LSPs), as shown in the figure below.

MPLS-TP Path Protection

MPLS-TP label switched paths (LSPs) support 1-to-1 path protection. There are two types of LSPs: protect LSPs and working LSPs. You can configure the both types of LSPs when configuring the MPLS-TP tunnel. The working LSP is the primary LSP used to route traffic. The protect LSP acts as a backup for a working LSP. If the working LSP fails, traffic is switched to the protect LSP until the working LSP is restored, at which time forwarding reverts back to the working LSP.

Bidirectional LSPs

Multiprotocol Label Switching Transport Profile (MPLS-TP) label switched paths (LSPs) are bidirectional and co-routed. They comprise of two unidirectional LSPs that are supported by the MPLS forwarding infrastructure. A TP tunnel consists of a pair of unidirectional tunnels that provide a bidirectional LSP. Each unidirectional tunnel can be optionally protected with a protect LSP that activates automatically upon failure conditions.

Support for MPLS Transport Profile OAM

Several Operations, Administration, and Maintenance (OAM) protocols and messages support the provisioning and maintenance of Multiprotocol Label Switching Transport Profile (MPLS-TP) tunnels and bidirectional label switched paths (LSPs).

The following OAM messages are forwarded along the specified MPLS LSP:

- OAM Fault Management—Alarm Indication Signal (AIS), Link Down Indication (LDI), and Lock Report (LKR) messages (GAL with BFD messages).
- OAM Connection Verification—Ping and traceroute messages (GAL with IP channel by default).
- OAM Continuity Check—Bidirectional Forwarding Detection (BFD) messages—non-IP BFD and IP BFD (GAL with non-IP BFD channel or IP BFD channel depending on message format).
- The following messages are forwarded along the specified pseudowire:
    - Static pseudowire OAM messages
    - Pseudowire ping and traceroute messages
    - BFD messages

- MPLS-TP OAM Fault Management (LDI, AIS, and LKR messages)—LDI messages are AIS messages whose L-flags are set. The LDI messages are generated at midpoint nodes when a failure is detected. From the midpoint, an LDI message is sent to the endpoint that is reachable with the existing failure. Similarly, LKR messages are sent from a midpoint node to the reachable endpoint when an interface is administratively shut down. By default, the reception of LDI and LKR messages on the active LSP at an endpoint will cause a path protection switchover, whereas the reception of an AIS message will not.
- MPLS-TP OAM Fault Management with Emulated Protection Switching for LSP Lockout—Cisco implements a form of Emulated Protection Switching to support LSP Lockout using customized Fault messages. When a Lockout message is sent, it does not cause the LSP to be administratively down. The Cisco Lockout message causes a path protection switchover and prevents data traffic from using the LSP. The LSP remains administratively up so that BFD and other OAM messages can continue to traverse it and so that maintenance of the LSP can take place (such as reconfiguring or replacing a midpoint LSR). After OAM verifies the LSP connectivity, the Lockout is removed and the LSP is brought back to service. Lockout of the working LSP is not allowed if a protect LSP is not configured. Conversely, the Lockout of a protect LSP is allowed if a working LSP is not configured.
- LSP ping and trace—To verify MPLS-TP connectivity, use the **ping mpls tp** and **trace mpls tp** commands. You can specify that echo requests be sent along the working LSP, the protect LSP, or the active LSP. You can also specify that echo requests be sent on a locked-out MPLS-TP tunnel LSP (either working or protected) if the working or protected LSP is explicitly specified. You can also specify ping/trace messages with or without IP.
- MPLS-TP OAM Continuity Check (CC) via BFD and Remote Defect Indication (RDI)—RDI is communicated via the BFD diagnostic field in BFD CC messages. BFD sessions run on both the working LSP and the protect LSP. To perform a path protection switchover within 60 milliseconds on an MPLS-TP endpoint, use the BFD Hardware Offload feature, which enables the router hardware to construct and send BFD messages, removing the task from the software path. The BFD Hardware Offload feature is enabled automatically on supported platforms.

MPLS-TP OAM GACH—Generic Associated Channel (G-ACh) is the control channel mechanism associated with Multiprotocol Label Switching (MPLS) LSPs in addition to MPLS pseudowire. The G-ACh Label (GAL) (Label 13) is a generic alert label to identify the presence of the G-ACh in the label packet. It is taken from the reserved MPLS label space. G-ACh/GAL supports OAMs of LSPs and in-band OAMs of pseudowires (PWs). OAM messages are used for fault management, connection verification, continuity check, and so on.

MPLS Transport Profile Static and Dynamic Multisegment Pseudowires

Multiprotocol Label Switching Transport Profile (MPLS-TP) supports the following combinations of static and dynamic multisegment pseudowires:

- Dynamic-static
- Static-dynamic
- Static-static

MPLS-TP OAM Status for Static and Dynamic Multisegment Pseudowires

With static pseudowires, status notifications can be provided by BFD over VCCV or by the static pseudowire OAM protocol. However, BFD over VCCV sends only attachment circuit status code notifications. Hop-by-hop notifications of other pseudowire status codes are not supported. Therefore, the static pseudowire OAM

protocol is preferred. You can acquire per pseudowire OAM for attachment circuit/pseudowire notification over the VCCV channel with or without the control word.

MPLS Transport Profile Links and Physical Interfaces

Multiprotocol Label Switching Transport Profile (MPLS-TP) link numbers may be assigned to physical interfaces only. Bundled interfaces and virtual interfaces are not supported for MPLS-TP link numbers.

The MPLS-TP link creates a layer of indirection between the MPLS-TP tunnel and midpoint LSP configuration and the physical interface. The **mpls tp link** command is used to associate an MPLS-TP link number with a physical interface and next-hop node. On point-to-point interfaces or Ethernet interfaces designated as point-to-point using the **medium p2p** command, the next-hop can be implicit, so the **mpls tp link** command just associates a link number to the interface.

Multiple tunnels and LSPs may then refer to the MPLS-TP link to indicate that they are traversing that interface. You can move the MPLS-TP link from one interface to another without reconfiguring all the MPLS-TP tunnels and LSPs that refer to the link.

Link numbers must be unique on the router or node.

See the section Configuring MPLS-TP Links and Physical Interfaces, on page 17, for more information.

Tunnel Midpoints

Tunnel LSPs, whether endpoint or midpoint, use the same identifying information. However, it is entered differently.

- At the midpoint, all information for the LSP is specified with the **mpls tp lsp** command for configuring forward and reverse information for forwarding.
- At the midpoint, determining which end is source and which is destination is arbitrary. That is, if you are configuring a tunnel between your device and a coworker's device, then your device is the source. However, your coworker considers his or her device to be the source. At the midpoint, either device could be considered the source. At the midpoint, the forward direction is from source to destination, and the reverse direction is from destination to source.
- At the endpoint, the local information (source) either comes from the global device ID and global ID, or from the locally configured information using the **tp source** command.
- At the endpoint, the remote information (destination) is configured using the **tp destination** command after you enter the **interface tunnel-tp** *number* command. The **tp destination** command includes the destination node ID, and optionally the global ID and the destination tunnel number. If you do not specify the destination tunnel number, the source tunnel number is used.
- At the endpoint, the LSP number is configured in working-lsp or protect-lsp submode. The default is 0 for the working LSP and 1 for the protect LSP.
- When configuring LSPs at midpoint devices, ensure that the configuration does not deflect traffic back to the originating node.

How to Configure MPLS Transport Profile

Configuring the MPLS Label Range

You must specify a static range of Multiprotocol Label Switching (MPLS) labels using the **mpls label range** command with the **static** keyword.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls label range** *minimum-value maximum-value* **static** *minimum-static-value maximum-static-value*
4. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**mpls label range** *minimum-value maximum-value* **static** *minimum-static-value maximum-static-value* **Example:** `Device(config)# mpls label range 1001 1003 static 10000 25000`	Specifies a static range of MPLS labels.
Step 4	**end** **Example:** `Device(config)# end`	Exits global configuration mode and returns to privileged EXEC mode.

Configuring the Router ID and Global ID

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls tp**
4. **router-id** *node-id*
5. **global-id** *num*
6. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**mpls tp** **Example:** `Device(config)# mpls tp`	Enters MPLS-TP configuration mode, from which you can configure MPLS-TP parameters for the device.
Step 4	**router-id** *node-id* **Example:** `Device(config-mpls-tp)# router-id 10.10.10.10`	Specifies the default MPLS-TP router ID, which is used as the default source node ID for all MPLS-TP tunnels configured on the device.
Step 5	**global-id** *num* **Example:** `Device(config-mpls-tp)# global-id 1`	(Optional) Specifies the default global ID used for all endpoints and midpoints. • This command makes the router ID globally unique in a multiprovider tunnel. Otherwise, the router ID is only locally meaningful. • The global ID is an autonomous system number, which is a controlled number space by which providers can identify each other.

	Command or Action	Purpose
		• The router ID and global ID are also included in fault messages sent by devices from the tunnel midpoints to help isolate the location of faults.
Step 6	**end** **Example:** `Device(config-mpls-tp)# end`	Exits MPLS-TP configuration mode and returns to privileged EXEC mode.

Configuring Bidirectional Forwarding Detection Templates

The **bfd-template** command allows you to create a BFD template and enter BFD configuration mode. The template can be used to specify a set of BFD interval values. You invoke the template as part of the MPLS-TP tunnel. On platforms that support the BFD Hardware Offload feature and that can provide a 60-ms cutover for MPLS-TP tunnels, it is recommended to use the higher resolution timers in the BFD template.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **bfd-template single-hop** *template-name*
4. **interval** [**microseconds**] {**both** *time* | **min-tx** *time* **min-rx** *time*} [**multiplier** *multiplier-value*]
5. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**bfd-template single-hop** *template-name* **Example:** `Device(config)# bfd-template single-hop mpls-bfd-1`	Creates a BFD template and enter BFD configuration mode.

	Command or Action	Purpose
Step 4	**interval** [**microseconds**] {**both** *time* | **min-tx** *time* **min-rx** *time*} [**multiplier** *multiplier-value*] **Example:** `Device(config-bfd)# interval min-tx 99 min-rx 99 multiplier 3`	Specifies a set of BFD interval values.
Step 5	**end** **Example:** `Device(config-bfd)# exit`	Exits BFD configuration mode and returns to privileged EXEC mode.

Configuring Pseudowire OAM Attributes

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **pseudowire-static-oam class** *class-name*
4. **timeout refresh send** *seconds*
5. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**pseudowire-static-oam class** *class-name* **Example:** `Device(config)# pseudowire-static-oam class oam-class1`	Creates a pseudowire OAM class and enters pseudowire OAM class configuration mode.
Step 4	**timeout refresh send** *seconds* **Example:**	Specifies the OAM timeout refresh interval.

	Command or Action	Purpose
	`Device(config-st-pw-oam-class)# timeout refresh send 20`	
Step 5	**exit** **Example:** `Device(config-st-pw-oam-class)# exit`	Exits pseudowire OAM configuration mode and returns to privileged EXEC mode.

Configuring the Pseudowire Class

When you create a pseudowire class, you specify the parameters of the pseudowire, such as the use of the control word, preferred path, OAM class, and VCCV BFD template.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **pseudowire-class** *class-name*
4. **encapsulation mpls**
5. **control-word**
6. **protocol** {**l2tpv2** | **l2tpv3** | **none**} [*l2tp-class-name*]
7. **preferred-path** {**interface tunnel** *tunnel-number* | **peer** {*ip-address* | *host-name*}} [**disable-fallback**]
8. **status protocol notification static** *class-name*
9. **vccv bfd template** *name* [**udp** | **raw-bfd**]
10. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**pseudowire-class** *class-name* **Example:**	Creates a pseudowire class and enters pseudowire class configuration mode.

	Command or Action	Purpose
	`Device(config)# pseudowire-class mpls-tp-class1`	
Step 4	**encapsulation mpls** **Example:** `Device(config-pw-class)# encapsulation mpls`	Specifies the encapsulation type.
Step 5	**control-word** **Example:** `Device(config-pw-class)# control-word`	Enables the use of the control word.
Step 6	**protocol** {**l2tpv2** | **l2tpv3** | **none**} [*l2tp-class-name*] **Example:** `Device(config-pw-class)# protocol none`	Specifies the type of protocol.
Step 7	**preferred-path** {**interface tunnel** *tunnel-number* | **peer** {*ip-address* | *host-name*}} [**disable-fallback**] **Example:** `Device(config-pw-class)# preferred-path interface tunnel-tp2`	Specifies the tunnel to use as the preferred path.
Step 8	**status protocol notification static** *class-name* **Example:** `Device(config-pw-class)# status protocol notification static oam-class1`	Specifies the OAM class to use.
Step 9	**vccv bfd template** *name* [**udp** | **raw-bfd**] **Example:** `Device(config-pw-class)# vccv bfd template bfd-temp1 raw-bfd`	Specifies the VCCV BFD template to use.
Step 10	**end** **Example:** `Device(config-pw-class)# end`	Exits pseudowire class configuration mode and returns to privileged EXEC mode.

Configuring the Pseudowire

SUMMARY STEPS

1. **enable**
2. **configure terminal**

3. **interface** *type number*
4. **xconnect** *peer-ip-address vc-id* {**encapsulation** {**l2tpv3** [**manual**] | **mpls** [**manual**]} | **pw-class** *pw-class-name*} [**pw-class** *pw-class-name*] [**sequencing** {**transmit** | **receive** | **both**}]
5. **mpls label** *local-pseudowire-label remote-pseudowire-label*
6. **mpls control-word**
7. **backup delay** {*enable-delay-period* | **never**} {*disable-delay-period* | **never**}
8. **backup peer** *peer-router-ip-addr vcid* [**pw-class** *pw-class-name*] [**priority** *value*]
9. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**interface** *type number* **Example:** `Device(config)# interface Ethernet 1/0`	Specifies the interface and enters interface configuration mode.
Step 4	**xconnect** *peer-ip-address vc-id* {**encapsulation** {**l2tpv3** [**manual**] | **mpls** [**manual**]} | **pw-class** *pw-class-name*} [**pw-class** *pw-class-name*] [**sequencing** {**transmit** | **receive** | **both**}] **Example:** `Device(config-if)# xconnect 10.131.191.251 100 encapsulation mpls manual pw-class mpls-tp-class1`	Binds the attachment circuit to a pseudowire VC and enters xconnect interface configuration mode.
Step 5	**mpls label** *local-pseudowire-label remote-pseudowire-label* **Example:** `Device(config-if-xconn)# mpls label 100 150`	Configures the static pseudowire connection by defining local and remote circuit labels.
Step 6	**mpls control-word** **Example:** `Device(config-if-xconn)# no mpls control-word`	Specifies the control word.

	Command or Action	Purpose
Step 7	**backup delay** {*enable-delay-period* | **never**} {*disable-delay-period* | **never**} **Example:** `Device(config-if-xconn)# backup delay 0 never`	Specifies how long a backup pseudowire virtual circuit (VC) should wait before resuming operation after the primary pseudowire VC goes down.
Step 8	**backup peer** *peer-router-ip-addr vcid* [**pw-class** *pw-class-name*] [**priority** *value*] **Example:** `Device(config-if-xconn)# backup peer 10.0.0.2 50`	Specifies a redundant peer for a pseudowire virtual circuit (VC).
Step 9	**end** **Example:** `Device(config)# end`	Exits xconn interface connection mode and returns to privileged EXEC mode.

Configuring the MPLS-TP Tunnel

On the endpoint devices, create an MPLS TP tunnel and configure its parameters. See the **interface tunnel-tp** command for information on the parameters.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface tunnel-tp** *number*
4. **description** *tunnel-description*
5. **tp tunnel-name** *name*
6. **tp bandwidth** *num*
7. **tp source** *node-id* [*global-id num*]
8. **tp destination** *node-id* [**tunnel-tp** *num*[**global-id** *num*]]
9. **bfd** *bfd-template*
10. **working-lsp**
11. **in-label** *num*
12. **out-label** *num* **out-link** *num*
13. **exit**
14. **protect-lsp**
15. **in-label** *num*
16. **out-label** *num* **out-link** *num*
17. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**interface tunnel-tp** *number* **Example:** `Device(config)# interface tunnel-tp`	Enters tunnel interface configuration mode. Tunnel numbers from 0 to 999 are supported.
Step 4	**description** *tunnel-description* **Example:** `Device(config-if)# description headend tunnel`	(Optional) Specifies a tunnel description.
Step 5	**tp tunnel-name** *name* **Example:** `Device(config-if)# tp tunnel-name tunnel 122`	Specifies the name of the MPLS-TP tunnel.
Step 6	**tp bandwidth** *num* **Example:** `Device(config-if)# tp bandwidth 10000`	Specifies the tunnel bandwidth.
Step 7	**tp source** *node-id* [*global-id num*] **Example:** `Device(config-if)# tp source 10.11.11.11 global-id 10`	(Optional) Specifies the tunnel source and endpoint.
Step 8	**tp destination** *node-id* [**tunnel-tp** *num*[**global-id** *num*]] **Example:** `Device(config-if)# tp destination 10.10.10.10`	Specifies the destination node of the tunnel.
Step 9	**bfd** *bfd-template* **Example:**	Specifies the BFD template.

	Command or Action	Purpose
	`Device(config-if)# bfd mpls-tp-bfd-2`	
Step 10	**working-lsp** **Example:** `Device(config-if)# working-lsp`	Specifies a working LSP, also known as the primary LSP.
Step 11	**in-label** *num* **Example:** `Device(config-if-working)# in-label 111`	Specifies the in-label number.
Step 12	**out-label** *num* **out-link** *num* **Example:** `Device(config-if-working)# out-label 112 out-link`	Specifies the out-label number and out-link.
Step 13	**exit** **Example:** `Device(config-if-working)# exit`	Exits working LSP interface configuration mode and returns to interface configuration mode.
Step 14	**protect-lsp** **Example:** `Device(config-if)# protect-lsp`	Specifies a backup for a working LSP.
Step 15	**in-label** *num* **Example:** `Device(config-if-protect)# in-label 100`	Specifies the in label.
Step 16	**out-label** *num* **out-link** *num* **Example:** `Device(config-if-protect)# out-label 113 out-link`	Specifies the out label and out link.
Step 17	**end** **Example:** `Device(config-if-protect)# end`	Exits the interface configuration mode and returns to privileged EXEC mode.

Configuring MPLS-TP LSPs at Midpoints

Note When configuring LSPs at midpoint devices, ensure that the configuration does not deflect traffic back to the originating node.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls tp lsp source** *node-id* [**global-id** *num*] **tunnel-tp** *num* **lsp** {*lsp-num* | **protect** | **working**} **destination** *node-id* [**global-id** *num*] **tunnel-tp** *num*
4. **forward-lsp**
5. **bandwidth** *num*
6. **in-label** *num* **out-label** *num* **out-link** *num*
7. **exit**
8. **reverse-lsp**
9. **bandwidth** *num*
10. **in-label** *num* **out-label** *num* **out-link** *num*
11. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**mpls tp lsp source** *node-id* [**global-id** *num*] **tunnel-tp** *num* **lsp** {*lsp-num*	**protect**	**working**} **destination** *node-id* [**global-id** *num*] **tunnel-tp** *num* **Example:** `Device(config)# mpls tp lsp source 10.10.10.10 global-id 2 tunnel-tp 4 lsp protect destination 10.11.11.11 global-id 11 tunnel-tp 12`	Enables MPLS-TP midpoint connectivity and enters MPLS TP LSP configuration mode.

	Command or Action	Purpose
Step 4	**forward-lsp** **Example:** `Device(config-mpls-tp-lsp)# forward-lsp`	Enters MPLS-TP LSP forward LSP configuration mode.
Step 5	**bandwidth** *num* **Example:** `Device(config-mpls-tp-lsp-forw)# bandwidth 100`	Specifies the bandwidth.
Step 6	**in-label** *num* **out-label** *num* **out-link** *num* **Example:** `Device(config-mpls-tp-lsp-forw)# in-label 53 out-label 43 out-link 41`	Specifies the in label, out label, and out link numbers.
Step 7	**exit** **Example:** `Device(config-mpls-tp-lsp-forw)# exit`	Exits MPLS-TP LSP forward LSP configuration mode.
Step 8	**reverse-lsp** **Example:** `Device(config-mpls-tp-lsp)# reverse-lsp`	Enters MPLS-TP LSP reverse LSP configuration mode.
Step 9	**bandwidth** *num* **Example:** `Device(config-mpls-tp-lsp-rev)# bandwidth 100`	Specifies the bandwidth.
Step 10	**in-label** *num* **out-label** *num* **out-link** *num* **Example:** `Device(config-mpls-tp-lsp-rev)# in-label 33 out-label 23 out-link 44`	Specifies the in-label, out-label, and out-link numbers.
Step 11	**end** **Example:** `Device(config-mpls-tp-lsp-rev)# end`	Exits the MPLS TP LSP configuration mode and returns to privileged EXEC mode.

Configuring MPLS-TP Links and Physical Interfaces

MPLS-TP link numbers may be assigned to physical interfaces only. Bundled interfaces and virtual interfaces are not supported for MPLS-TP link numbers.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type number*
4. **ip address** *ip-address mask*
5. **mpls tp link** *link-num* {**ipv4** *ip-address* | **tx-mac** *mac-address*} **rx-mac** *mac-address*
6. **ip rsvp bandwidth** [**rdm** [**bc0** *interface-bandwidth*] [[*single-flow-bandwidth* [**bc1** *bandwidth* | **sub-pool** *bandwidth*]]] [*interface-bandwidth* [*single-flow-bandwidth* [**bc1** *bandwidth* | **sub-pool** *bandwidth*]] | **mam max-reservable-bw** [*interface-bandwidth* [*single-flow-bandwidth*] [**bc0** *interface-bandwidth* [**bc1** *bandwidth*]]] | **percent** *percent-bandwidth* [*single-flow-bandwidth*]]
7. **end**
8. **show mpls tp link-numbers**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**interface** *type number* **Example:** `Device(config)# interface ethernet 1/0`	Specifies the interface and enters interface configuration mode.
Step 4	**ip address** *ip-address mask* **Example:** `Device(config-if)# ip address 10.10.10.10 255.255.255.0`	Assigns an IP address to the interface.
Step 5	**mpls tp link** *link-num* {**ipv4** *ip-address*	**tx-mac** *mac-address*} **rx-mac** *mac-address* **Example:** `Device(config-if)# mpls tp link 1 ipv4 10.0.0.2`	Associates an MPLS-TP link number with a physical interface and next-hop node. On point-to-point interfaces or Ethernet interfaces designated as point-to-point using the **medium p2p** command, the next-hop can be implicit, so the **mpls tp link** command just associates a link number to the interface. Multiple tunnels and LSPs can refer to the MPLS-TP link to indicate they are traversing that interface. You can move

	Command or Action	Purpose
		the MPLS-TP link from one interface to another without reconfiguring all the MPLS-TP tunnels and LSPs that refer to the link. Link numbers must be unique on the device or node.
Step 6	**ip rsvp bandwidth** [**rdm** [**bc0** *interface-bandwidth*] [[*single-flow-bandwidth* [**bc1** *bandwidth* | **sub-pool** *bandwidth*]]] [*interface-bandwidth* [*single-flow-bandwidth* [**bc1** *bandwidth* | **sub-pool** *bandwidth*]] | **mam max-reservable-bw** [*interface-bandwidth* [*single-flow-bandwidth*] [**bc0** *interface-bandwidth* [**bc1** *bandwidth*]]] | **percent** *percent-bandwidth* [*single-flow-bandwidth*]] **Example:** `Device(config-if)# ip rsvp bandwidth 1158 100`	Enables Resource Reservation Protocol (RSVP) bandwidth for IP on an interface. For the Cisco 7600 platform, if you configure non-zero bandwidth for the TP tunnel or at a midpoint LSP, make sure that the interface to which the output link is attached has enough bandwidth available. For example, if three tunnel LSPs run over link 1 and each LSP was assigned 1000 with the **tp bandwidth** command, the interface associated with link 1 needs bandwidth of 3000 with the **ip rsvp bandwidth** command.
Step 7	**end** **Example:** `Device(config-if)# end`	Exits interface configuration mode and returns to privileged EXEC mode.
Step 8	**show mpls tp link-numbers** **Example:** `Device# show mpls tp link-numbers`	Displays the configured links.

Configuring Static-to-Static Multisegment Pseudowires for MPLS-TP

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **l2 vfi** *name* **point-to-point**
4. **neighbor** *ip-address vc-id* {**encapsulation mpls** | **pw-class** *pw-class-name*}
5. **mpls label** *local-pseudowire-label remote-pseudowire-label*
6. **mpls control-word**
7. **neighbor** *ip-address vc-id* {**encapsulation mpls** | **pw-class** *pw-class-name*}
8. **mpls label** *local-pseudowire-label remote-pseudowire-label*
9. **mpls control-word**
10. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**l2 vfi** *name* **point-to-point** **Example:** `Device(config)# l2 vfi atom point-to-point`	Creates a point-to-point Layer 2 virtual forwarding interface (VFI) and enters VFI configuration mode.
Step 4	**neighbor** *ip-address vc-id* {**encapsulation mpls** | **pw-class** *pw-class-name*} **Example:** `Device(config-vfi)# neighbor 10.111.111.111 123 pw-class atom`	Sets up an emulated VC. Specify the IP address, the VC ID of the remote device, and the pseudowire class to use for the emulated VC. **Note** Only two **neighbor** commands are allowed for each Layer 2 VFI point-to-point command.
Step 5	**mpls label** *local-pseudowire-label remote-pseudowire-label* **Example:** `Device(config-vfi)# mpls label 101 201`	Configures the static pseudowire connection by defining local and remote circuit labels.
Step 6	**mpls control-word** **Example:** `Device(config-vfi)# mpls control-word`	Specifies the control word.
Step 7	**neighbor** *ip-address vc-id* {**encapsulation mpls** | **pw-class** *pw-class-name*} **Example:** `Device(config-vfi)# neighbor 10.10.10.11 123 pw-class atom`	Sets up an emulated VC. Specify the IP address, the VC ID of the remote device, and the pseudowire class to use for the emulated VC.
Step 8	**mpls label** *local-pseudowire-label remote-pseudowire-label* **Example:**	Configures the static pseudowire connection by defining local and remote circuit labels.

	Command or Action	Purpose
	`Device(config-vfi)# mpls label 102 202`	
Step 9	**mpls control-word** **Example:** **Example:** `Device(config-vfi)# mpls control-word`	Specifies the control word.
Step 10	**end** **Example:** `Device(config)# end`	Exits VFI configuration mode and returns to privileged EXEC mode.

Configuring a Template with Pseudowire Type-Length-Value Parameters

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **pseudowire-tlv template** *template-name*
4. **tlv** [*type-name*] *type-value length* [**dec** | **hexstr** | **str**] *value*
5. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**pseudowire-tlv template** *template-name* **Example:** `Device(config)# pseudowire-tlv template statictemp`	Creates a template of pseudowire type-length-value (TLV) parameters and enters pseudowire TLV template configuration mode.

	Command or Action	Purpose
Step 4	**tlv** [*type-name*] *type-value length* [**dec** | **hexstr** | **str**] *value* **Example:** `Device(config-pw-tlv-template)# tlv statictemp 2 4 hexstr 1`	Specifies the TLV parameters.
Step 5	**end** **Example:** `Device(config-pw-tlv-template)# end`	Exits pseudowire TLV template configuration mode and returns to privileged EXEC mode.

Configuring Static-to-Dynamic Multisegment Pseudowires for MPLS-TP

When you configure static-to-dynamic pseudowires, you configure the static pseudowire class with the **protocol none** command, create a dynamic pseudowire class, and then invoke those pseudowire classes with the **neighbor** commands.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **pseudowire-class** *class-name*
4. **encapsulation mpls**
5. **control-word**
6. **protocol** {**l2tpv2** | **l2tpv3** | **none**} [*l2tp-class-name*]
7. **exit**
8. **pseudowire-class** *class-name*
9. **encapsulation mpls**
10. **exit**
11. **l2 vfi** *name* **point-to-point**
12. **neighbor** *ip-address vc-id* {**encapsulation mpls** | **pw-class** *pw-class-name*}
13. **neighbor** *ip-address vc-id* {**encapsulation mpls** | **pw-class** *pw-class-name*}
14. **mpls label** *local-pseudowire-label remote-pseudowire-label*
15. **mpls control-word**
16. **local interface** *pseudowire-type*
17. Do one of the following:
    - **tlv** [*type-name*] *type-value length* [**dec** | **hexstr** | **str**] *value*
    - **tlv template** *template-name*
18. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**pseudowire-class** *class-name* **Example:** `Device(config)# pseudowire-class mpls-tp-class1`	Creates a pseudowire class and enters pseudowire class configuration mode.
Step 4	**encapsulation mpls** **Example:** `Device(config-pw-class)# encapsulation mpls`	Specifies the encapsulation type.
Step 5	**control-word** **Example:** `Device(config-pw-class)# control-word`	Enables the use of the control word.
Step 6	**protocol** {**l2tpv2** | **l2tpv3** | **none**} [*l2tp-class-name*] **Example:** `Device(config-pw-class)# protocol none`	Specifies the type of protocol. Use the **protocol none** command to specify a static pseudowire.
Step 7	**exit** **Example:** `Device(config-pw-class)# exit`	Exits pseudowire class configuration mode and returns to global configuration mode.
Step 8	**pseudowire-class** *class-name* **Example:** `Device(config)# pseudowire-class mpls-tp-class1`	Creates a pseudowire class and enters pseudowire class configuration mode.
Step 9	**encapsulation mpls** **Example:**	Specifies the encapsulation type.

	Command or Action	Purpose
	`Device(config-pw-class)# encapsulation mpls`	
Step 10	**exit** **Example:** `Device(config-pw-class)# exit`	Exits pseudowire class configuration mode and returns to global configuration mode.
Step 11	**l2 vfi** *name* **point-to-point** **Example:** `Device(config)# l2 vfi atom point-to-point`	Creates a point-to-point Layer 2 virtual forwarding interface (VFI) and enters VFI configuration mode.
Step 12	**neighbor** *ip-address vc-id* {**encapsulation mpls** | **pw-class** *pw-class-name*} **Example:** `Device(config-vfi)# neighbor 10.111.111.111 123 pw-class atom`	Sets up an emulated VC and enters VFI neighbor configuration mode. **Note** Note: Only two **neighbor** commands are allowed for each **l2 vfi point-to-point** command.
Step 13	**neighbor** *ip-address vc-id* {**encapsulation mpls** | **pw-class** *pw-class-name*} **Example:** `Device(config-vfi-neighbor)# neighbor 10.111.111.111 123 pw-class atom`	Sets up an emulated VC. **Note** Only two **neighbor** commands are allowed for each **l2 vfi point-to-point** command.
Step 14	**mpls label** *local-pseudowire-label remote-pseudowire-label* **Example:** `Device(config-vfi-neighbor)# mpls label 101 201`	Configures the static pseudowire connection by defining local and remote circuit labels.
Step 15	**mpls control-word** **Example:** `Device(config-vfi-neighbor)# mpls control-word`	Specifies the control word.
Step 16	**local interface** *pseudowire-type* **Example:** `Device(config-vfi-neighbor)# local interface 4`	Specifies the pseudowire type.
Step 17	Do one of the following: • **tlv** [*type-name*] *type-value length* [**dec** | **hexstr** | **str**] *value* • **tlv template** *template-name* **Example:**	Specifies the TLV parameters or invokes a previously configured TLV template.

	Command or Action	Purpose
	`Device(config-vfi-neighbor)# tlv statictemp 2 4 hexstr 1`	
Step 18	**end** **Example:** `Device(config-vfi-neighbor)# end`	Ends the session.

Verifying the MPLS-TP Configuration

Use the following commands to verify and help troubleshoot your MPLS-TP configuration:

- **debug mpls tp**—Enables the logging of MPLS-TP error messages.
- **logging (MPLS-TP)**—Displays configuration or state change logging messages.
- **show bfd neighbors mpls-tp**—Displays the BFD state, which must be up in order for the endpoint LSPs to be up.
- **show mpls l2transport static-oam l2transport static-oam**—Displays MPLS-TP messages related to pseudowires.
- **show mpls tp tunnel-tp** *number* **detail**—Displays the number and details of the tunnels that are not functioning.
- **show mpls tp tunnel-tp lsps**—Displays the status of the LSPs, and helps you ensure that both LSPs are up and working from a tunnel endpoint.
- **traceroute mpls tp** and **ping mpls tp**—Helps you identify connectivity issues along the MPLS-TP tunnel path.

Configuration Examples for MPLS Transport Profile

Example: Configuring Static-to-dynamic Multisegment Pseudowires for MPLS-TP

The following example shows how to configure static-to-dynamic multisegment pseudowires for Layer 2 VFI.

```
l2 vfi atom point-to-point (static-dynamic MSPW)
 neighbor 10.116.116.116 4294967295 pw-class dypw (dynamic)
  neighbor 10.111.111.111 123 pw-class stpw (static)
  mpls label 101 201
  mpls control-word
  local interface 4
  tlv mtu 1 4 1500
  tlv description 3 6 str abcd
```

```
tlv descr C 4 hexstr 0505
```

CHAPTER 2

Multiprotocol Label Switching (MPLS) on Cisco Routers

This document describes commands for configuring and monitoring Multiprotocol Label Switching (MPLS) functionality on Cisco routers and switches. This document is a companion to other feature modules describing other MPLS applications.

Information About MPLS

MPLS Overview

Multiprotocol label switching (MPLS) combines the performance and capabilities of Layer 2 (data link layer) switching with the proven scalability of Layer 3 (network layer) routing. MPLS enables service providers to meet the challenges of explosive growth in network utilization while providing the opportunity to differentiate services without sacrificing the existing network infrastructure. The MPLS architecture is flexible and can be employed in any combination of Layer 2 technologies. MPLS support is offered for all Layer 3 protocols, and scaling is possible well beyond that typically offered in today's networks.

MPLS efficiently enables the delivery of IP services over an ATM switched network. MPLS supports the creation of different routes between a source and a destination on a purely router-based Internet backbone. By incorporating MPLS into their network architecture, service providers can save money, increase revenue and productivity, provide differentiated services, and gain competitive advantages.

Note In the Cisco IOS XE Release 16.x, the ASR 1000 routers only support fragmentation of the MPLS packets from the IP to MPLS direction.

Functional Description of MPLS

Label switching is a high-performance packet forwarding technology that integrates the performance and traffic management capabilities of data link layer (Layer 2) switching with the scalability, flexibility, and performance of network layer (Layer 3) routing.

Label Switching Functions

In conventional Layer 3 forwarding mechanisms, as a packet traverses the network, each router extracts all the information relevant to forwarding the packet from the Layer 3 header. This information is then used as an index for a routing table lookup to determine the next hop for the packet.

In the most common case, the only relevant field in the header is the destination address field, but in some cases, other header fields might also be relevant. As a result, the header analysis must be done independently at each router through which the packet passes. In addition, a complicated table lookup must also be done at each router.

In label switching, the analysis of the Layer 3 header is done only once. The Layer 3 header is then mapped into a fixed length, unstructured value called a *label* .

Many different headers can map to the same label, as long as those headers always result in the same choice of next hop. In effect, a label represents a *forwarding equivalence class* --that is, a set of packets which, however different they may be, are indistinguishable by the forwarding function.

The initial choice of a label need not be based exclusively on the contents of the Layer 3 packet header; for example, forwarding decisions at subsequent hops can also be based on routing policy.

Once a label is assigned, a short label header is added at the front of the Layer 3 packet. This header is carried across the network as part of the packet. At subsequent hops through each MPLS router in the network, labels are swapped and forwarding decisions are made by means of MPLS forwarding table lookup for the label carried in the packet header. Hence, the packet header does not need to be reevaluated during packet transit through the network. Because the label is of fixed length and unstructured, the MPLS forwarding table lookup process is both straightforward and fast.

Distribution of Label Bindings

Each label switching router (LSR) in the network makes an independent, local decision to determine a label value to represent a forwarding equivalence class. This association is known as a label binding. Each LSR informs its neighbors of the label bindings it has made.

When a labeled packet is being sent from LSR A to the neighboring LSR B, the label value carried by the IP packet is the label value that LSR B assigned to represent the forwarding equivalence class of the packet. Thus, the label value changes as the IP packet traverses the network.

The awareness of label bindings by neighbouring routers is facilitated using the following protocols:

- Label Distribution Protocol (LDP) - Enables peer LSRs in an MPLS network to exchange label binding information for supporting hop-by-hop forwarding in an MPLS network.
- Tag Distribution Protocol (TDP) - Supports MPLS forwarding along normally routed paths.
- Resource Reservation Protocol (RSVP) - Supports MPLS traffic engineering.
- Border Gateway Protocol (BGP) - Supports MPLS virtual private networks (VPNs) .

Benefits of MPLS

MPLS provides the following major benefits to service provider networks:

Scalable support for Virtual Private Networks (VPNs)--MPLS enables VPN services to be supported in service provider networks, thereby greatly accelerating Internet growth.

The use of MPLS for VPNs provides an attractive alternative to the building of VPNs by means of either ATM or Frame Relay permanent virtual circuits (PVCs) or various forms of tunneling to interconnect routers at customer sites.

Unlike the PVC VPN model, the MPLS VPN model is highly scalable and can accommodate increasing numbers of sites and customers. The MPLS VPN model also supports "any-to-any" communication among VPN sites without requiring a full mesh of PVCs or the backhauling (suboptimal routing) of traffic across the service provider network. For each MPLS VPN user, the service provider's network appears to function as a private IP backbone over which the user can reach other sites within the VPN organization, but not the sites of any other VPN organization.

From a user perspective, the MPLS VPN model enables network routing to be dramatically simplified. For example, rather than having to manage routing over a topologically complex virtual backbone composed of many PVCs, an MPLS VPN user can generally employ the service provider's backbone as the default route in communicating with all of the other VPN sites.

Explicit routing capabilities (also called constraint-based routing or traffic engineering)--Explicit routing employs "constraint-based routing," in which the path for a traffic flow is the shortest path that meets the resource requirements (constraints) of the traffic flow.

In MPLS traffic engineering, factors such as bandwidth requirements, media requirements, and the priority of one traffic flow versus another can be taken into account. These traffic engineering capabilities enable the administrator of a service provider network to

- Control traffic flow in the network
- Reduce congestion in the network
- Make best use of network resources

Thus, the network administrator can specify the amount of traffic expected to flow between various points in the network (thereby establishing a traffic matrix), while relying on the routing system to

- Calculate the best paths for network traffic
- Set up the explicit paths to carry the traffic

Support for IP routing on ATM switches (also called IP and ATM integration)--MPLS enables an ATM switch to perform virtually all of the functions of an IP router. This capability of an ATM switch stems from the fact that the MPLS forwarding paradigm, namely, label swapping, is exactly the same as the forwarding paradigm provided by ATM switch hardware.

The key difference between a conventional ATM switch and an ATM label switch is the control software used by the latter to establish its virtual channel identifier (VCI) table entries. An ATM label switch uses IP routing protocols and the Tag Distribution Protocol (TDP) to establish VCI table entries.

An ATM label switch can function as a conventional ATM switch. In this dual mode, the ATM switch resources (such as VCI space and bandwidth) are partitioned between the MPLS control plane and the ATM control plane. The MPLS control plane provides IP-based services, while the ATM control plane supports ATM-oriented functions, such as circuit emulation or PVC services.

How to Configure MPLS

This section explains how to perform the basic configuration required to prepare a router for MPLS switching and forwarding.

Configuration tasks for other MPLS applications are described in the feature module documentation for the application.

Configuring a Router for MPLS Switching

MPLS switching on Cisco routers requires that Cisco Express Forwarding be enabled.

For more information about Cisco Express Forwarding commands, see the Cisco IOS Switching Command Reference.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip cef distributed**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**ip cef distributed** **Example:** `Device(config)# ip cef distributed`	Enables Cisco Express Forwarding on the route processor card.

Verifying Configuration of MPLS Switching

To verify that Cisco Express Forwarding has been configured properly, issue the **show ip cef summary** command, which generates output similar to that shown below:

SUMMARY STEPS

1. **show ip cef summary**

DETAILED STEPS

Procedure

show ip cef summary

Example:

```
Router# show ip cef summary
IP CEF with switching (Table Version 49), flags=0x0
  43 routes, 0 resolve, 0 unresolved (0 old, 0 new)
  43 leaves, 49 nodes, 56756 bytes, 45 inserts, 2 invalidations
  2 load sharing elements, 672 bytes, 2 references
  1 CEF resets, 4 revisions of existing leaves
  4 in-place modifications
  refcounts:  7241 leaf, 7218 node
Adjacency Table has 18 adjacencies
Router#
```

Configuring a Router for MPLS Forwarding

MPLS forwarding on Cisco routers requires that forwarding of IPv4 packets be enabled.

For more information about MPLS forwarding commands, see the *Multiprotocol Label Switching Command Reference*.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type slot/subslot /port* [**.** *subinterface*]
4. **mpls ip**
5. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.

	Command or Action	Purpose
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**interface** *type slot/subslot /port* [**.** *subinterface*] **Example:** `Device(config)# interface gigabitethernet 4/0/0`	Specifies the Gigabit Ethernet interface and enters interface configuration mode.
Step 4	**mpls ip** **Example:** `Device(config-if)# mpls ip`	Enables MPLS forwarding of IPv4 packets along normally routed paths for the Gigabit Ethernet interface.
Step 5	**end** **Example:** `Device(config-if)# end`	Exits interface configuration mode and returns to privileged EXEC mode.

What to do next

Configure either of the following:

- MPLS Label Distribution Protocol (LDP). For information about configuring MPLS LDP, see the *MPLS Label Distribution Protocol Configuration Guid*e.
- Static labels. For information about configuring static labels, see *MPLS Static Labels*.

Verifying Configuration of MPLS Forwarding

To verify that MPLS forwarding has been configured properly, issue the **show mpls interfaces detail** command, which generates output similar to that shown below:

SUMMARY STEPS

1. **show mpls interfaces detail**

DETAILED STEPS

Procedure

show mpls interfaces detail

Example:

```
Device# show mpls interfaces detail

Interface GigabitEthernet1/0/0:
         IP labeling enabled (ldp)
         LSP Tunnel labeling not enabled
         MPLS operational
         MTU = 1500
Interface POS2/0/0:
         IP labeling enabled (ldp)
         LSP Tunnel labeling not enabled
         MPLS not operational
         MTU = 4470
```

Feature Information for MPLS on Cisco Routers

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Glossary

BGP --Border Gateway Protocol. The predominant interdomain routing protocol used in IP networks.

Border Gateway Protocol --See BGP.

FIB --Forwarding Information Base. A table that contains a copy of the forwarding information in the IP routing table.

Forwarding Information Base --See FIB.

label --A short, fixed-length identifier that tells switching nodes how the data (packets or cells) should be forwarded.

label binding --An association between a label and a set of packets, which can be advertised to neighbors so that a label switched path can be established.

Label Distribution Protocol --See LDP.

Label Forwarding Information Base --See LFIB.

label imposition --The act of putting the first label on a packet.

label switching router --See LSR.

LDP --Label Distribution Protocol. The protocol that supports MPLS hop-by-hop forwarding by distributing bindings between labels and network prefixes.

LFIB --Label Forwarding Information Base. A data structure in which destinations and incoming labels are associated with outgoing interfaces and labels.

LSR --label switching router. A Layer 3 router that forwards a packet based on the value of an identifier encapsulated in the packet.

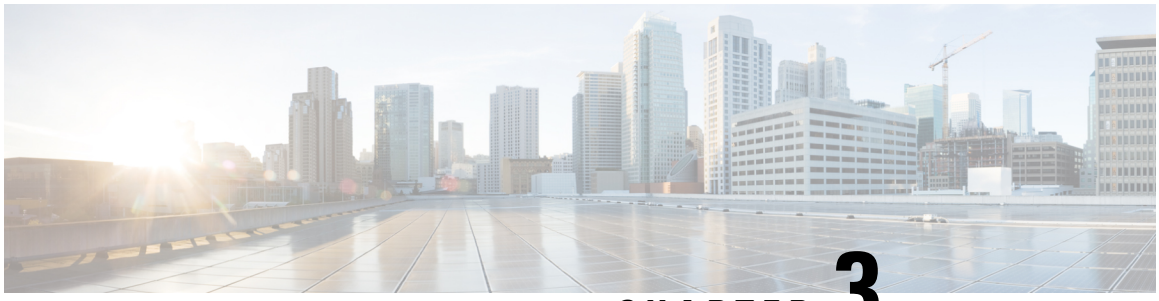
MPLS --Multiprotocol Label Switching. An industry standard on which label switching is based.

MPLS hop-by-hop forwarding --The forwarding of packets along normally routed paths using MPLS forwarding mechanisms.

Multiprotocol Label Switching --See MPLS.

Resource Reservation Protocol --See RSVP.

RIB --Routing Information Base. A common database containing all the routing protocols running on a router.



Routing Information Base --See RIB.

RSVP --Resource Reservation Protocol. A protocol for reserving network resources to provide quality of service guarantees to application flows.

traffic engineering --Techniques and processes used to cause routed traffic to travel through the network on a path other than the one that would have been chosen if standard routing methods were used.

Virtual Private Network --See VPN.

VPN --Virtual Private Network. A network that enables IP traffic to use tunneling to travel securely over a public TCP/IP network.

CHAPTER 3

MPLS Infrastructure Changes Introduction of MFI and Removal of MPLS LSC and LC-ATM Features

This document explains the new MPLS Forwarding Infrastructure (MFI) and removal of support for MPLS label switch controller (LSC) and label-controlled ATM (LC-ATM) features and commands.

- Information About MPLS Infrastructure Changes, on page 37
- Additional References, on page 38
- Feature Information for MPLS Infrastructure Changes, on page 39

Information About MPLS Infrastructure Changes

Introduction of the MPLS Forwarding Infrastructure

The MPLS control plane software is enhanced to make MPLS more scalable and flexible. The MFI, which manages MPLS data structures used for forwarding, replaces the Label Forwarding Information Base (LFIB).

Note The MFI and LFIB do not coexist in the same image. For a list of supported releases, see the "Feature Information for MPLS Forwarding Infrastructure."

Introduction of IP Rewrite Manager

Cisco software introduces a module called the MPLS IP Rewrite Manager (IPRM) that manages the interactions between Cisco Express Forwarding, the IP Label Distribution Modules (LDMs), and the MFI. MPLS IPRM is enabled by default. You need not configure or customize the IPRM. These commands are related to IPRM:

- **clear mpls ip iprm counters**
- **debug mpls ip iprm**
- **debug mpls ip iprm cef**
- **debug mpls ip iprm events**
- **debug mpls ip iprm ldm**

- **debug mpls ip iprm mfi**
- **show mpls ip iprm counters**
- **show mpls ip iprm ldm**

For information about these commands, see the *Cisco IOS Debug Command Reference* and the *Cisco IOS MPLS Command Reference*.

MPLS LSC and LC-ATM Configurations

Before upgrading to Cisco IOS Release 12.4(20)T, remove all the MPLS LSC and LC-ATM configurations from the routers in your network. If your core network has ATM links, you can use packet-based MPLS. See the MPLS Label Distribution Protocol Overview for more information. If you provide ATM access to customers, you can use the Any Transport over MPLS: ATM over MPLS feature. See Any Transport over MPLS for more information.

If you have MPLS LSC or LC-ATM features configured and you upgrade to Cisco IOS Release 12.4(20)T, the configuration is not accepted. The system displays “unrecognized command” errors for any commands that are no longer supported.

Restrictions for MPLS Static Labels

- The trouble shooting process for MPLS static labels is complex.
- On a provider edge (PE) router for MPLS VPNs, there is no mechanism for statically binding a label to a customer network prefix (VPN IPv4 prefix).
- MPLS static crossconnect labels remain in the LFIB even if the router to which the entry points goes down.
- MPLS static crossconnect mappings remain in effect even with topology changes.
- MPLS static labels are not supported for label-controlled Asynchronous Transfer Mode (lc-atm).
- MPLS static bindings are not supported for local prefixes.

Prerequisites for MPLS Static Labels

The network must support the following Cisco IOS features before you enable MPLS static labels:

- Multiprotocol Label Switching (MPLS)

- Cisco Express Forwarding

Information About MPLS Static Labels

MPLS Static Labels Overview

Generally, label switching routers (LSRs) dynamically learn the labels they should use to label-switch packets by means of label distribution protocols that include:

- Label Distribution Protocol (LDP), the Internet Engineering Task Force (IETF) standard, used to bind labels to network addresses
- Resource Reservation Protocol (RSVP) used to distribute labels for traffic engineering (TE)
- Border Gateway Protocol (BGP) used to distribute labels for Multiprotocol Label Switching (MPLS) Virtual Private Networks (VPNs)

To use a learned label to label-switch packets, an LSR installs the label into its Label Forwarding Information Base (LFIB).

The MPLS Static Labels feature provides the means to configure statically:

- The binding between a label and an IPv4 prefix
- The contents of an LFIB crossconnect entry

Benefits of MPLS Static Labels

Static Bindings Between Labels and IPv4 Prefixes

Static bindings between labels and IPv4 prefixes can be configured to support MPLS hop-by-hop forwarding through neighbor routers that do not implement LDP label distribution.

Static Crossconnects

Static crossconnects can be configured to support MPLS Label Switched Path (LSP) midpoints when neighbor routers do not implement either the LDP or RSVP label distribution, but do implement an MPLS forwarding path.

How to Configure MPLS Static Labels

Configuring MPLS Static Prefix Label Bindings

To configure MPLS static prefix/label bindings, use the following commands beginning in global configuration mode:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls label range** *min-label max-label* [**static** *min-static-label max-static-label*]
4. **mpls static binding ipv4** *prefix mask* [**input**| **output** *nexthop*] label

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**mpls label range** *min-label max-label* [**static** *min-static-label max-static-label*] **Example:** `Router(config)# mpls label range 200 100000 static 16 199`	Specifies a range of labels for use with MPLS Static Labels feature. (Default is no labels reserved for static assignment.)
Step 4	**mpls static binding ipv4** *prefix mask* [**input**| **output** *nexthop*] label **Example:** `Router(config)# mpls static binding ipv4 10.0.0.0 255.0.0.0 55`	Specifies static binding of labels to IPv4 prefixes. Bindings specified are installed automatically in the MPLS forwarding table as routing demands.

Verifying MPLS Static Prefix Label Bindings

To verify the configuration for MPLS static prefix/label bindings, use this procedure:

SUMMARY STEPS

1. Enter **show mpls label range** command. The output shows that the new label ranges do not take effect until a reload occurs:
2. Enter the **show mpls static binding ipv4** command to show the configured static prefix/label bindings:
3. Use the **show mpls forwarding-table** command to determine which static prefix/label bindings are currently in use for MPLS forwarding.

DETAILED STEPS

Procedure

Step 1 Enter **show mpls label range** command. The output shows that the new label ranges do not take effect until a reload occurs:

Example:

```
Router# show mpls label range

Downstream label pool: Min/Max label: 16/100000
   [Configured range for next reload: Min/Max label: 200/100000]
Range for static labels: Min/Max/Number: 16/199
```

The following output from the **show mpls label range** command, executed after a reload, indicates that the new label ranges are in effect:

Example:

```
Router# show mpls label range

Downstream label pool: Min/Max label: 200/100000
Range for static labels: Min/Max/Number: 16/199
```

Step 2 Enter the **show mpls static binding ipv4** command to show the configured static prefix/label bindings:

Example:

```
Router# show mpls static binding ipv4
10.17.17.17/32: Incoming label: 251 (in LIB)
  Outgoing labels:
     10.0.0.1                  18
10.18.18.18/32: Incoming label: 201 (in LIB)
  Outgoing labels:
10.0.0.1 implicit-null
```

Step 3 Use the **show mpls forwarding-table** command to determine which static prefix/label bindings are currently in use for MPLS forwarding.

Example:

```
Router# show mpls forwarding-table
Local  Outgoing    Prefix           Bytes tag  Outgoing   Next Hop
tag    tag or VC   or Tunnel Id     switched   interface
201    Pop tag     10.18.18.18/32   0          PO1/1/0    point2point
       2/35        10.18.18.18/32   0          AT4/1/0.1  point2point
251    18          10.17.17.17/32   0          PO1/1/0    point2point
```

Configuring MPLS Static Crossconnects

To configure MPLS static crossconnects, use the following command beginning in global configuration mode:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls label range** *min-label max-label* [**static** *min-static-label max-static-label*]
4. **mpls static binding ipv4** *prefix mask* [**input**| **output** *nexthop*] *label*

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**mpls label range** *min-label max-label* [**static** *min-static-label max-static-label*] **Example:** `Router(config)# mpls label range 200 100000 static 16 199`	Specifies a range of labels for use with MPLS Static Labels feature. (Default is no labels reserved for static assignment.)
Step 4	**mpls static binding ipv4** *prefix mask* [**input**| **output** *nexthop*] *label* **Example:** `Router(config)# Router(config)# mpls static binding ipv4 10.0.0.0 255.0.0.0 55`	Specifies static binding of labels to IPv4 prefixes. Bindings specified are installed automatically in the MPLS forwarding table as routing demands.

Verifying MPLS Static Crossconnect Configuration

To verify the configuration for MPLS static crossconnects, use this procedure:

SUMMARY STEPS

1. Use the **show mpls static crossconnect** command to display information about crossconnects that have been configured:

DETAILED STEPS

Procedure

Use the **show mpls static crossconnect** command to display information about crossconnects that have been configured:

Example:

```
Router# show mpls static crossconnect
Local  Outgoing    Outgoing   Next Hop
label  label       interface
34     22          pos3/0/0   point2point  (in LFIB)
```

Monitoring and Maintaining MPLS Static Labels

To monitor and maintain MPLS static labels, use one or more of the following commands:

SUMMARY STEPS

1. **enable**
2. **show mpls forwarding-table**
3. **show mpls label range**
4. **show mpls static binding ipv4**
5. **show mpls static crossconnect**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**show mpls forwarding-table** **Example:** `Router# show mpls forwarding-table`	Displays the contents of the MPLS LFIB.
Step 3	**show mpls label range** **Example:** `Router# show mpls label range`	Displays information about the static label range.

	Command or Action	Purpose
Step 4	**show mpls static binding ipv4** **Example:** `Router# show mpls static binding ipv4`	Displays information about the configured static prefix/label bindings.
Step 5	**show mpls static crossconnect** **Example:** `Router# show mpls static crossconnect`	Displays information about the configured crossconnects.

Configuration Examples for MPLS Static Labels

Example Configuring MPLS Static Prefixes Labels

In the following output, the **mpls label range** command reconfigures the range used for dynamically assigned labels from 16 to 100000 to 200 to 100000 and configures a static label range of 16 to 199.

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# mpls label range 200 100000 static 16 199
% Label range changes take effect at the next reload.
Router(config)# end
```

In the following output, the **show mpls label range** command indicates that the new label ranges do not take effect until a reload occurs:

```
Router# show mpls label range

Downstream label pool: Min/Max label: 16/100000
   [Configured range for next reload: Min/Max label: 200/100000]
Range for static labels: Min/Max/Number: 16/199
```

In the following output, the **show mpls label range** command, executed after a reload, indicates that the new label ranges are in effect:

```
Router# show mpls label range

Downstream label pool: Min/Max label: 200/100000
Range for static labels: Min/Max/Number: 16/199
```

In the following output, the **mpls static binding ipv4** commands configure static prefix/label bindings. They also configure input (local) and output (remote) labels for various prefixes:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# mpls static binding ipv4 10.0.0.0 255.0.0.0 55
Router(config)# mpls static binding ipv4 10.0.0.0 255.0.0.0 output 10.0.0.66 2607
Router(config)# mpls static binding ipv4 10.6.0.0 255.255.0.0 input 17
Router(config)# mpls static binding ipv4 10.0.0.0 255.0.0.0 output 10.13.0.8 explicit-null
Router(config)# end
```

In the following output, the **show mpls static binding ipv4** command displays the configured static prefix/label bindings:

```
Router# show mpls static binding ipv4

10.0.0.0/8: Incoming label: none;
  Outgoing labels:
10.13.0.8           explicit-null
10.0.0.0/8: Incoming label: 55 (in LIB)
  Outgoing labels:
     10.0.0.66              2607
10.66.0.0/16: Incoming label: 17 (in LIB)
  Outgoing labels:  None
```

Example Configuring MPLS Static Crossconnects

In the following output, the **mpls static crossconnect** command configures a crossconnect from incoming label 34 to outgoing label 22 out interface pos3/0/0:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# mpls static crossconnect 34 pos3/0/0 22
Router(config)# end
```

In the following output, the **show mpls static crossconnect** command displays the configured crossconnect:

```
Router# show mpls static crossconnect
Local  Outgoing    Outgoing   Next Hop
label  label       interface
34     22          pos3/0/0   point2point  (in LFIB)
```

Feature Information for MPLS Static Labels

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 1: Feature Information for MPLS Static Labels

Feature Name	Releases	Feature Information
MPLS Static Labels	Cisco IOS XE Amsterdam 17.3.2	The MPLS Static Labels feature provides the means to configure the following items statically: • The binding between a label and an IPv4 prefix • The contents of an LFIB crossconnect entry

Glossary

BGP --Border Gateway Protocol. The predominant interdomain routing protocol used in IP networks.

Border Gateway Protocol --See BGP.

FIB --Forwarding Information Base. A table that contains a copy of the forwarding information in the IP routing table.

Forwarding Information Base --See FIB.

label --A short, fixed-length identifier that tells switching nodes how the data (packets or cells) should be forwarded.

label binding --An association between a label and a set of packets, which can be advertised to neighbors so that a label switched path can be established.

Label Distribution Protocol --See LDP.

Label Forwarding Information Base --See LFIB.

label imposition --The act of putting the first label on a packet.

label switching router --See LSR.

LDP --Label Distribution Protocol. The protocol that supports MPLS hop-by-hop forwarding by distributing bindings between labels and network prefixes.

LFIB --Label Forwarding Information Base. A data structure in which destinations and incoming labels are associated with outgoing interfaces and labels.

LSR --label switching router. A Layer 3 router that forwards a packet based on the value of an identifier encapsulated in the packet.

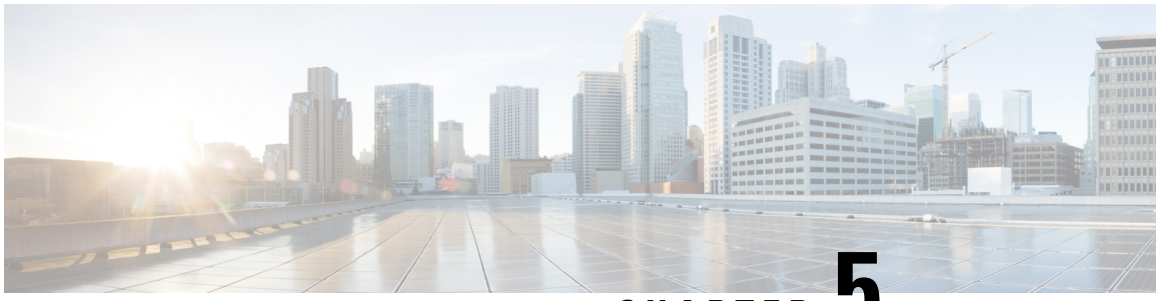
MPLS --Multiprotocol Label Switching. An industry standard on which label switching is based.

MPLS hop-by-hop forwarding --The forwarding of packets along normally routed paths using MPLS forwarding mechanisms.

Multiprotocol Label Switching --See MPLS.

Resource Reservation Protocol --See RSVP.

RIB --Routing Information Base. A common database containing all the routing protocols running on a router.



Routing Information Base --See RIB.

RSVP --Resource Reservation Protocol. A protocol for reserving network resources to provide quality of service guarantees to application flows.

traffic engineering --Techniques and processes used to cause routed traffic to travel through the network on a path other than the one that would have been chosen if standard routing methods were used.

Virtual Private Network --See VPN.

VPN --Virtual Private Network. A network that enables IP traffic to use tunneling to travel securely over a public TCP/IP network.

CHAPTER 5

MPLS Multilink PPP Support

The MPLS Multilink PPP Support feature ensures that MPLS Layer 3 Virtual Private Networks (VPNs) with quality of service (QoS) can be enabled for bundled links. This feature supports Multiprotocol Label Switching (MPLS) over Multilink PPP (MLP) links in the edge (provider edge [PE]-to-customer edge [CE]) or in the MPLS core (PE-to-PE and PE-to-provider [P] device).

Service providers that use relatively low-speed links can use MLP to spread traffic across them in their MPLS networks. Link fragmentation and interleaving (LFI) should be deployed in the CE-to-PE link for efficiency, where traffic uses a lower link bandwidth (less than 768 kbps). The MPLS Multilink PPP Support feature can reduce the number of Interior Gateway Protocol (IGP) adjacencies and facilitate load sharing of traffic.

- Prerequisites for MPLS Multilink PPP Support, on page 51
- Information About MPLS Multilink PPP Support, on page 51
- How to Configure MPLS Multilink PPP Support, on page 56
- Configuration Examples for MPLS Multilink PPP Support, on page 65

- Glossary, on page 69

Prerequisites for MPLS Multilink PPP Support

- Cisco Express Forwarding must be enabled.
- Multiprotocol Label Switching (MPLS) must be enabled on provider edge (PE) and provider (P) devices.
- Cisco Express Forwarding switching must be enabled on the interface by using the **ip route-cache cef** command.

Information About MPLS Multilink PPP Support

MPLS Layer 3 Virtual Private Network Features Supported for Multilink PPP

The table below lists Multiprotocol Label Switching (MPLS) Layer 3 Virtual Private Network (VPN) features supported for Multilink PPP (MLP) and indicates if the feature is supported on customer edge-to-provider edge (CE-to-PE) links, PE-to-provider (P) links, and Carrier Supporting Carrier (CSC) CE-to-PE links.

Table 2: MPLS Layer 3 VPN Features Supported for MLP

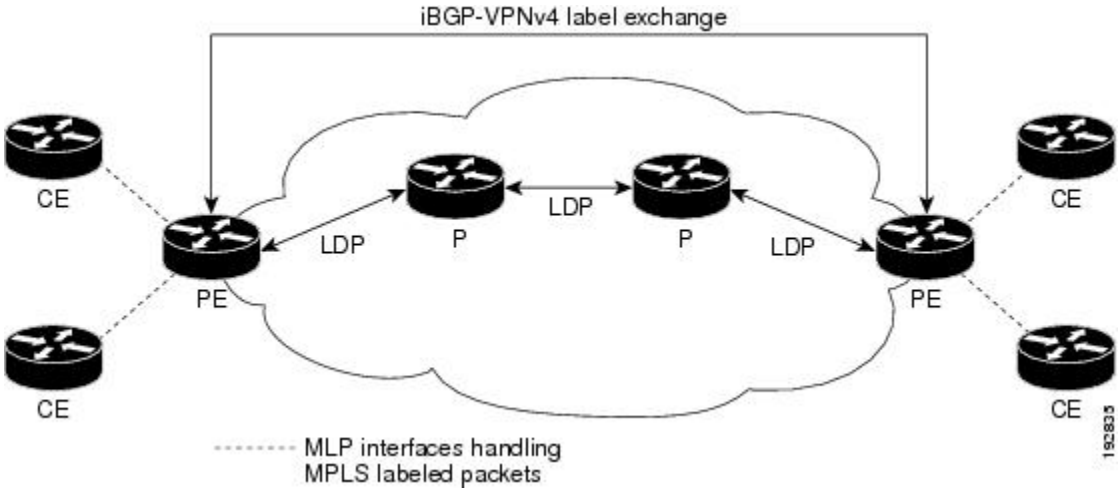
MPLS L3 VPN Feature	CE-to-PE Links	PE-to-P Links	CSC CE-to-PE Links
Static routes	Supported	Not supported	Not supported
External Border Gateway Protocol (eBGP)	Supported	Not applicable to this configuration	Supported
Intermediate System-to-Intermediate System (IS-IS)	Not supported	Supported	Not supported
Open Shortest Path First (OSPF)	Supported	Supported	Not supported
Enhanced Interior Gateway Routing Protocol (EIGRP)	Supported	Supported	Not supported
Interprovider interautonomous (Inter-AS) VPNs (with Label Distribution Protocol [LDP])	Not applicable to this configuration	Supported (MLP between Autonomous System Boundary Routers [ASBRs])	Not applicable to this configuration
Inter-AS VPNs with IPv4 Label Distribution	Not applicable to this configuration	Supported (MLP between ASBRs)	Not applicable to this configuration
CSC VPNs (with LDP)	Not supported	Not applicable to this configuration	Supported
CSC VPNs with IPv4 label distribution	Supported	Not applicable to this configuration	Supported
External and internal BGP (eiBGP) Multipath	Not supported	Not supported	Not applicable to this configuration
Internal BGP (iBGP) Multipath	Not applicable to this configuration	Not supported	Not applicable to this configuration
eBGP Multipath	Not supported	Not supported	Not supported

MPLS Quality of Service Features Supported for Multilink PPP

The table below lists the Multiprotocol Label Switching (MPLS) quality of service (QoS) features supported for Multilink PPP (MLP) and indicates if the feature is supported on customer edge-to-provider edge (CE-to-PE) links, PE-to-provider (P) links, and Carrier Supporting Carrier (CSC) CE-to-PE links.

Table 3: MPLS QoS Features Supported for MLP

MPLS QoS Feature	CE-to-PE Links	PE-to-P Links	CSC CE-to-PE Links
Default copy of IP Precedence to EXP bits and the reverse	Supported	Not supported	Not supported



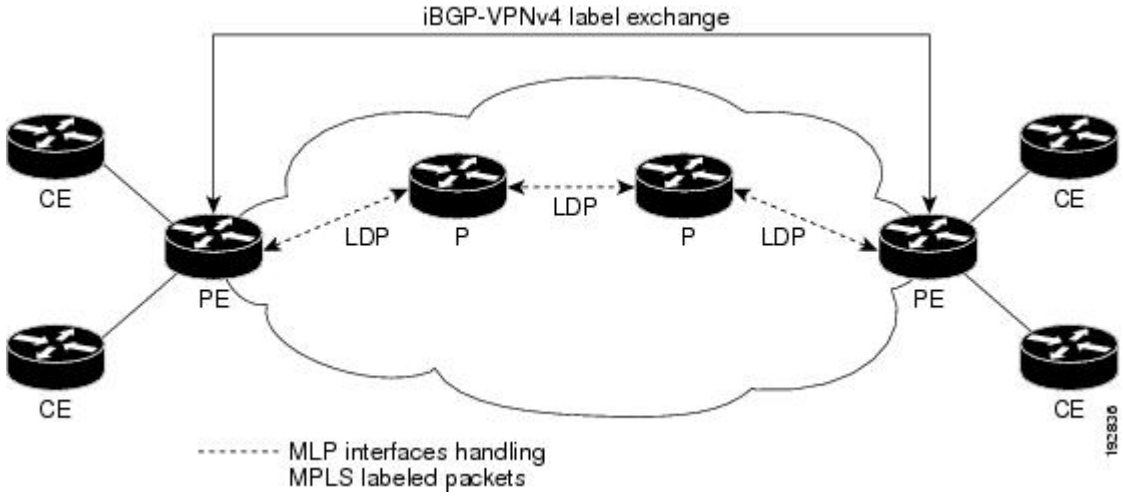
MPLS QoS Feature	CE-to-PE Links	PE-to-P Links	CSC CE-to-PE Links
Set MPLS EXP bits using the modular QoS Command-Line Interface (MQC)	Supported	Supported	Supported
Matching on MPLS EXP using MQC	Supported	Supported	Supported
Low Latency Queueing (LLQ)/Class-Based Weighted Fair Queueing (CBWFQ) support	Supported	Supported	Supported
Weighted Random Early Detection (WRED) based on EXP bits using MQC	Supported	Supported	Supported
Policer with EXP bit-marking using MQC-3 action	Supported	Supported	Supported
Support for EXP bits in MPLS accounting	Supported	Supported	Supported

MPLS Multilink PPP Support and PE-to-CE Links

The figure below shows a typical Multiprotocol Label Switching (MPLS) network in which the provider edge (PE) device is responsible for label imposition (at ingress) and disposition (at egress) of the MPLS traffic.

In this topology, Multilink PPP (MLP) is deployed on the PE-to-customer edge (CE) links. The Virtual Private Network (VPN) routing and forwarding instance (VRF) interface is in a multilink bundle. There is no MPLS interaction with MLP; all packets coming into the MLP bundle are IP packets.

Figure 1: MLP and Traditional PE-to-CE Links



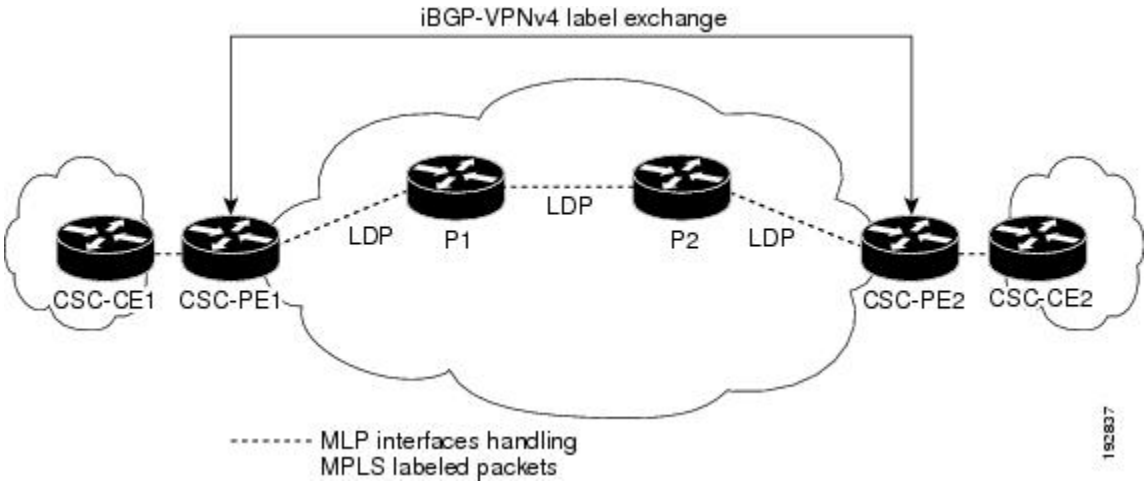
The PE-to-CE routing protocols that are supported for the MPLS Multilink PPP Support feature are external BGP (eBGP), Open Shortest Path First (OSPF), and Enhanced Interior Gateway Routing Protocol (EIGRP). Static routes are also supported between the CE and PE device.

Quality of service (QoS) features that are supported for the MPLS Multilink PPP Support feature on CE-to-PE links are link fragmentation and interleaving (LFI), header compression, policing, marking, and classification.

MPLS Multilink PPP Support and Core Links

The figure below shows a sample topology in which Multiprotocol Label Switching (MPLS) is deployed over Multilink PPP (MLP) on provider edge-to-provider (PE-to-P) and P-to-P links. Enabling MPLS on MLP for PE-to-P links is similar to enabling MPLS on MLP for P-to-P links.

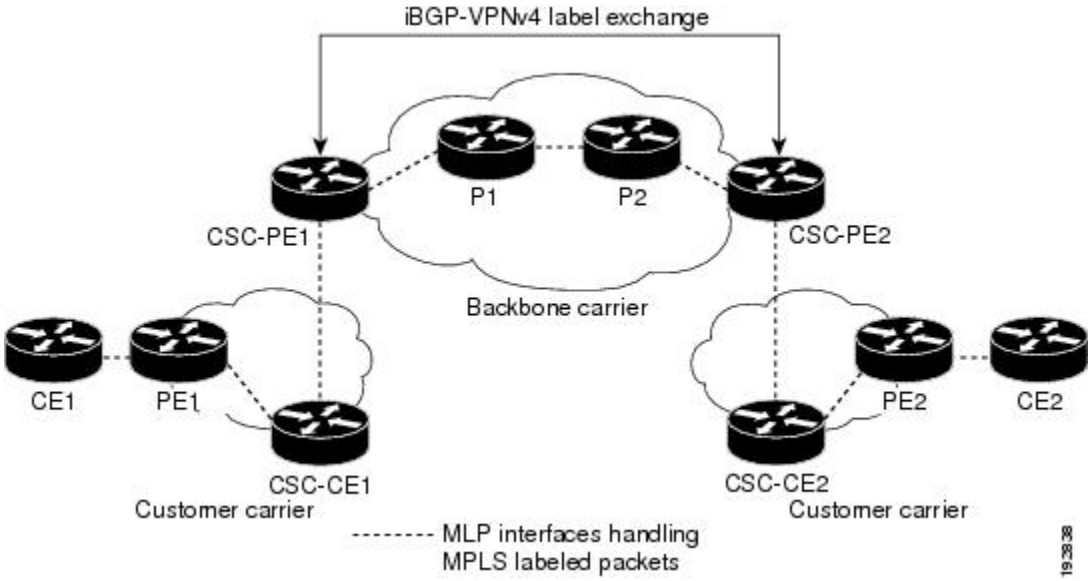
Figure 2: MLP on PE-to-P and P-to-P Links



You employ MLP in the PE-to-P or P-to-P links primarily so that you can reduce the number of Interior Gateway Protocol (IGP) adjacencies and facilitate the load sharing of traffic.

In addition to requiring MLP on the PE-to-P links, the MPLS Multilink PPP Support feature requires the configuration of an IGP routing protocol and the Label Distribution Protocol (LDP).

MPLS Multilink PPP Support in a CSC Network



The figure below shows a typical Multiprotocol Label Switching (MPLS) Virtual Private Network (VPN) Carrier Supporting Carrier (CSC) network where Multilink PPP (MLP) is configured on the CSC customer edge (CE)-to-provider edge (PE) links.

Figure 3: MLP on CSC CE-to-PE Links with MPLS VPN Carrier Supporting Carrier

The MPLS Multilink PPP Support feature supports MLP between CSC-CE and CSC-PE links with the Label Distribution Protocol (LDP) or with external Border Gateway Protocol (eBGP) IPv4 label distribution. This feature also supports link fragmentation and interleaving (LFI) for an MPLS VPN CSC configuration. The figure below shows all MLP links that this feature supports for CSC configurations.

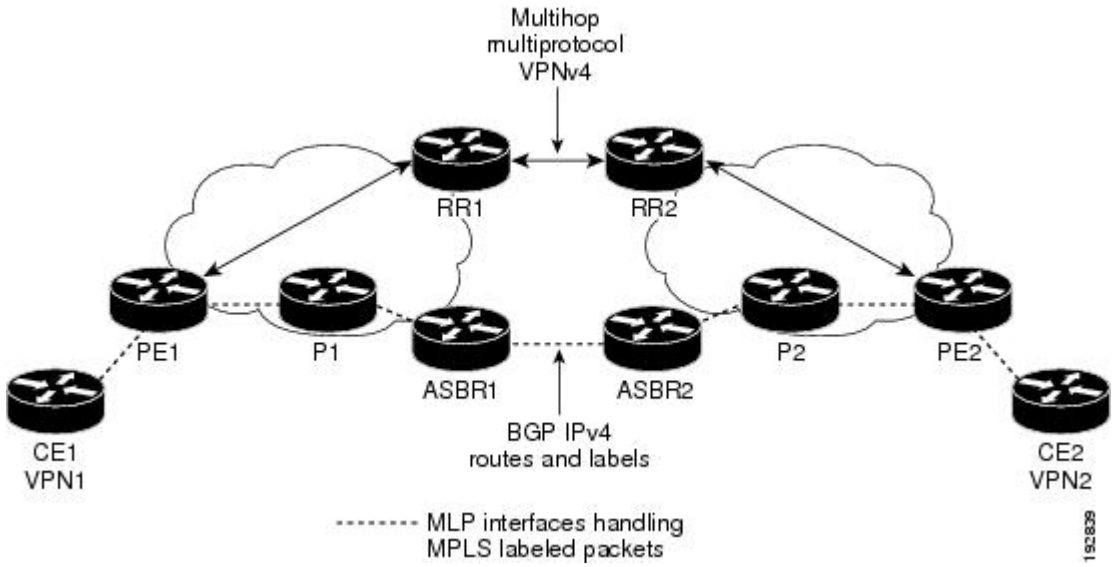


Figure 4: MLP Supported Links with MPLS VPN Carrier Supporting Carrier

MPLS Multilink PPP Support in an Interautonomous System

The figure below shows a typical Multiprotocol Label Switching (MPLS) Virtual Private Network (VPN) interautonomous system (Inter-AS) network where Multilink PPP (MLP) is configured on the provider edge-to-customer edge (PE-to-CE) links.

Figure 5: MLP on ASBR-to-PE Links in an MPLS VPN Inter-AS Network

The MPLS Multilink PPP Support feature supports MLP between Autonomous System Boundary Router (ASBR) links for Inter-AS VPNs with Label Distribution Protocol (LDP) and with external Border Gateway Protocol (eBGP) IPv4 label distribution.

How to Configure MPLS Multilink PPP Support

The tasks in this section can be performed on customer edge-to-provider edge (CE-to-PE) links, PE-to-provider (P) links, P-to-P links, and Carrier Supporting Carrier (CSC) CE-to-PE links.

Enabling Cisco Express Forwarding

Perform the following task to enable Cisco Express Forwarding. Cisco Express Forwarding is required for the forwarding of MLP traffic.

Before you begin

Multilink PPP requires the configuration of Cisco Express Forwarding. To find out if Cisco Express Forwarding is enabled on your device, enter the**show ip cef** command. If Cisco Express Forwarding is enabled, you receive output that looks like the following:

```
Device# show ip cef
Prefix              Next Hop            Interface
10.2.61.8/24        192.168.100.1       FastEthernet1/0/0
                    192.168.101.1       FastEthernet6/1/0
```

If Cisco Express Forwarding is not enabled on your platform, the output for the **show ip cef** command looks like the following:

```
Device# show ip cef
%CEF not running
```

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip cef**
4. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**ip cef** **Example:** `Device(config)# ip cef`	Enables Cisco Express Forwarding.
Step 4	**exit** **Example:** `Device(config)# exit`	Returns to privileged EXEC mode.

Creating a Multilink Bundle

Perform this task to create a multilink bundle for the MPLS Multilink PPP Support feature. This multilink bundle can reduce the number of Interior Gateway Protocol (IGP) adjacencies and facilitate load sharing of traffic.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface multilink** *group-number*
4. **ip address** *address mask* [**secondary**]
5. **encapsulation** *encapsulation-type*
6. **ppp multilink**
7. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**interface multilink** *group-number* **Example:** `Device(config)# interface multilink 1`	Creates a multilink bundle and enters multilink interface configuration mode. • The *group-number* argument is the number of the multilink bundle (a nonzero number).
Step 4	**ip address** *address mask* [**secondary**] **Example:** `Device(config-if)# ip address 10.0.0.0 255.255.0.0`	Sets a primary or secondary IP address for an interface. • The *address* argument is the IP address. • The *mask* argument is the mask for the associated IP subnet. • The **secondary** keyword specifies that the configured address is a secondary IP address. If this keyword is omitted, the configured address is the primary IP address. This command is used to assign an IP address to the multilink interface.
Step 5	**encapsulation** *encapsulation-type* **Example:** `Device(config-if)# encapsulation ppp`	Sets the encapsulation method as PPP to be used by the interface. • The *encapsulation-type* argument specifies the encapsulation type.
Step 6	**ppp multilink** **Example:** `Device(config-if)# ppp multilink`	Enables MLP on an interface.
Step 7	**end** **Example:** `Device(config-if)# end`	Returns to privileged EXEC mode.

Assigning an Interface to a Multilink Bundle

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **controller** {**t1** | **e1**} *slot/port*
4. **channel-group** *channel-number* **timeslots** *range*
5. **exit**
6. **interface serial** *slot/subslot/port*[**.***subinterface*]
7. **ip route-cache** [**cef**]
8. **no ip address**
9. **keepalive** [*period* [*retries*]]
10. **encapsulation** *encapsulation-type*
11. **ppp multilink group** *group-number*
12. **ppp multilink**
13. **ppp authentication chap**
14. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**controller** {**t1** | **e1**} *slot/port* **Example:** `Device# controller t1 1/3`	Configures a T1 or E1 controller and enters controller configuration mode. • The **t1** keyword indicates a T1 line card. • The **e1** keyword indicates an E1 line card. • The *slot/port* arguments are the backplane slot number and port number on the interface. Refer to your hardware installation manual for the specific slot numbers and port numbers.
Step 4	**channel-group** *channel-number* **timeslots** *range*	Defines the time slots that belong to each T1 or E1 circuit.

	Command or Action	Purpose
	Example: `Device(config-controller)# channel-group 1 timeslots 1`	• The *channel-number* argument is the channel-group number. When a T1 data line is configured, channel-group numbers can be values from 0 to 23. When an E1 data line is configured, channel-group numbers can be values from 0 to 30. • The **timeslots** *range* keyword and argument specifies one or more time slots or ranges of time slots belonging to the channel group. The first time slot is numbered 1. For a T1 controller, the time slot range is from 1 to 24. For an E1 controller, the time slot range is from 1 to 31. You can specify a time slot range (for example, 1-29), individual time slots separated by commas (for example 1, 3, 5), or a combination of the two (for example 1-14, 15, 17-31).
Step 5	**exit** **Example:** `Device(config-controller)# exit`	Returns to global configuration mode.
Step 6	**interface serial** *slot/subslot/port*[**.***subinterface*] **Example:** `Device(config)# interface serial 1/0/0:1`	Configures a serial interface and enters interface configuration mode.
Step 7	**ip route-cache** [**cef**] **Example:** `Device(config-if)# ip route-cache cef`	Controls the use of switching methods for forwarding IP packets. • The **cef** keyword enables Cisco Express Forwarding operation on an interface after Cisco Express Forwarding operation was disabled.
Step 8	**no ip address** **Example:** `Device(config-if)# no ip address`	Removes any specified IP address.
Step 9	**keepalive** [*period* [*retries*]] **Example:** `Device(config-if)# keepalive`	Enables keepalive packets and specifies the number of times that the Cisco software tries to send keepalive packets without a response before bringing down the interface or before bringing the tunnel protocol down for a specific interface. • The *period* argument is an integer value, in seconds, greater than 0. The default is 10. • The *retries* argument specifies the number of times that the device continues to send keepalive packets without a response before bringing the interface down.

	Command or Action	Purpose
		Enter an integer value greater than 1 and less than 255. If you do not enter a value, the value that was previously set is used; if no value was specified previously, the default of 5 is used. If you are using this command with a tunnel interface, the command specifies the number of times that the device continues to send keepalive packets without a response before bringing the tunnel interface protocol down.
Step 10	**encapsulation** *encapsulation-type* **Example:** `Device(config-if)# encapsulation ppp`	Sets the encapsulation method used by the interface. • The *encapsulation-type* argument specifies the encapsulation type. The example specifies PPP encapsulation.
Step 11	**ppp multilink group** *group-number* **Example:** `Device(config-if)# ppp multilink group 1`	Restricts a physical link to join only one designated multilink group interface. • The *group-number* argument is the number of the multilink bundle (a nonzero number).
Step 12	**ppp multilink** **Example:** `Device(config-if)# ppp multilink`	Enables MLP on the interface.
Step 13	**ppp authentication chap** **Example:** `Device(config-if)# ppp authentication chap`	(Optional) Enables Challenge Handshake Authentication Protocol (CHAP) authentication on the serial interface.
Step 14	**end** **Example:** `Device(config-if)# end`	Returns to privileged EXEC mode.

Disabling PPP Multilink Fragmentation

Perform this task to disable PPP multilink fragmentation. PPP multilink fragmentation is enabled by default.

Enabling fragmentation reduces the delay latency among bundle links, but adds some load to the CPU. Disabling fragmentation might produce better throughput.

If your data traffic is consistently of a similar size, we recommend disabling fragmentation. In this case, the benefits of fragmentation can be outweighed by the added load on the CPU.

SUMMARY STEPS

1. **enable**

2. **configure terminal**
3. **interface** *type number*
4. **ppp multilink fragmentation disable**
5. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**interface** *type number* **Example:** `Device(config)# interface serial 1/0/0`	Configures an interface type and enters interface configuration mode. • The *type* argument indicates the type of interface to be configured. • The *number* argument specifies the port, connector, or interface card number. The numbers are assigned at the factory at the time of installation or when the interface is added to a system, and they can be displayed with the **show interfaces** command.
Step 4	**ppp multilink fragmentation disable** **Example:** `Device(config-if)# ppp multilink fragmentation disable`	Disables packet fragmentation.
Step 5	**end** **Example:** `Device(config-if)# end`	Returns to privileged EXEC mode.

Verifying the Multilink PPP Configuration

SUMMARY STEPS

1. **enable**

2. **show ip interface brief**
3. **show ppp multilink**
4. **show ppp multilink interface** *interface-bundle*
5. **show interface** *type number*
6. **show mpls forwarding-table**
7. **exit**

DETAILED STEPS

Procedure

Step 1 **enable**

Enables privileged EXEC mode. Enter your password if prompted.

Example:

```
Device> enable
Device#
```

Step 2 **show ip interface brief**

Verifies logical and physical Multilink PPP (MLP) interfaces.

Example:

Step 3 **show ppp multilink**

Verifies that you have created a multilink bundle.

Example:

Step 4 **show ppp multilink interface** *interface-bundle*

Displays information about a specific MLP interface.

Example:

Step 5 **show interface** *type number*

Displays information about serial interfaces in your configuration.

Example:

```
Device#

  Hardware is Multichannel T1
  MTU 1500 bytes, BW 64 Kbit, DLY 20000 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation PPP, LCP Open, multilink Open, crc 16, Data non-inverted
  Last input 00:00:01, output 00:00:01, output hang never
  Last clearing of "show interface" counters 00:47:13
  Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/40 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
```

```
     722 packets input, 54323 bytes, 0 no buffer
     Received 0 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     697 packets output, 51888 bytes, 0 underruns
     0 output errors, 0 collisions, 1 interface resets
     0 output buffer failures, 0 output buffers swapped out
     1 carrier transitions no alarm present
  Timeslot(s) Used:1, subrate: 64Kb/s, transmit delay is 0 flags
  Transmit queue length 25

Device#

  Hardware is Multichannel T1
  MTU 1500 bytes, BW 64 Kbit, DLY 20000 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation PPP, LCP Open, multilink Open, crc 16, Data non-inverted
  Last input 00:00:03, output 00:00:03, output hang never
  Last clearing of "show interface" counters 00:47:16
  Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/40 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     725 packets input, 54618 bytes, 0 no buffer
     Received 0 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     693 packets output, 53180 bytes, 0 underruns
     0 output errors, 0 collisions, 1 interface resets
     0 output buffer failures, 0 output buffers swapped out
     1 carrier transitions no alarm present
  Timeslot(s) Used:2, subrate: 64Kb/s, transmit delay is 0 flags
  Transmit queue length 26
```

You can also use the **show interface** command to display information about the multilink interface:

Example:

```
Device# show interface multilink6

Multilink6 is up, line protocol is up
  Hardware is multilink group interface
  Internet address is 10.30.0.2/8
  MTU 1500 bytes, BW 128 Kbit, DLY 100000 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation PPP, LCP Open, multilink Open
  Open: CDPCP, IPCP, TAGCP, loopback not set
  DTR is pulsed for 2 seconds on reset
  Last input 00:00:00, output never, output hang never
  Last clearing of "show interface" counters 00:48:43
  Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/40 (size/max)
  30 second input rate 0 bits/sec, 0 packets/sec
  30 second output rate 0 bits/sec, 0 packets/sec
     1340 packets input, 102245 bytes, 0 no buffer
     Received 0 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     1283 packets output, 101350 bytes, 0 underruns
     0 output errors, 0 collisions, 1 interface resets
     0 output buffer failures, 0 output buffers swapped out
     0 carrier transitions
```

Step 6 **show mpls forwarding-table**

Displays contents of the Multiprotocol Label Switching (MPLS) Label Forwarding Information Base (LFIB). Look for information on multilink interfaces associated with a point2point next hop.

Example:

```
Device# show mpls forwarding-table

Local  Outgoing    Prefix           Bytes tag  Outgoing   Next Hop
tag    tag or VC   or Tunnel Id     switched   interface
16     Untagged    10.30.0.1/32     0          Mu6        point2point
17     Pop tag     10.0.0.3/32      0          Mu6        point2point
18     Untagged    10.0.0.9/32[V]   0          Mu10       point2point
19     Untagged    10.0.0.11/32[V]  6890       Mu10       point2point
20     Untagged    10.32.0.0/8[V]   530        Mu10       point2point
21     Aggregate   10.34.0.0/8[V]   0
22     Untagged    10.34.0.1/32[V]  0          Mu10       point2point
```

Use the **show ip bgp vpnv4** command to display VPN address information from the Border Gateway Protocol (BGP) table.

Example:

```
Device# show ip bgp vpnv4 all summary

BGP router identifier 10.0.0.1, local AS number 100
BGP table version is 21, main routing table version 21
10 network entries using 1210 bytes of memory
10 path entries using 640 bytes of memory
2 BGP path attribute entries using 120 bytes of memory
1 BGP extended community entries using 24 bytes of memory
0 BGP route-map cache entries using 0 bytes of memory
0 BGP filter-list cache entries using 0 bytes of memory
BGP using 1994 total bytes of memory
BGP activity 10/0 prefixes, 10/0 paths, scan interval 5 secs
10.0.0.3  4 100 MsgRc52 MsgSe52  TblV21  0  0 00:46:35 State/P5xRcd
```

Step 7 **exit**

Returns to user EXEC mode.

Example:

```
Device# exit
Device>
```

Configuration Examples for MPLS Multilink PPP Support

Example: Configuring Multilink PPP on an MPLS CSC PE Device

The following example shows how to configure for Multiprotocol Label Switching (MPLS) Carrier Supporting Carrier (CSC) provider edge (PE) device.

```
!
mpls label protocol ldp
```

```
ip cef
ip vrf vpn2
 rd 200:1
 route-target export 200:1
 route-target import 200:1
!

!

 no ip address
 encapsulation ppp

 ppp multilink
 ppp multilink group 1

interface Multilink1
 ip vrf forwarding vpn2
 ip address 10.35.0.2 255.0.0.0
 no peer neighbor-route
 load-interval 30
 ppp multilink
 ppp multilink interleave
 ppp multilink group 1

!
!
router ospf 200
 log-adjacency-changes
 auto-cost reference-bandwidth 1000
 redistribute connected subnets
 passive-interface Multilink1
 network 10.0.0.7 0.0.0.0 area 200
 network 10.31.0.0 0.255.255.255 area 200
!
!

 neighbor 10.35.0.1 advertisement-interval 5
 no auto-summary
 no synchronization
 exit-address-family
```

Example: Enabling Cisco Express Forwarding

The following example shows how to enable Cisco Express Forwarding for Multilink PPP (MLP) configurations:

```
Device> enable
Device# configure terminal
Device(config)# ip cef
```

Example: Creating a Multilink Bundle

The following example shows how to create a multilink bundle for the MPLS Multilink PPP Support feature:

```
Device(config)# interface multilink 1
Device(config-if)# ip address 10.0.0.0 10.255.255.255
Device(config-if)# encapsulation ppp
Device(config-if)# ppp chap hostname group 1
Device(config-if)# ppp multilink
Device(config-if)# ppp multilink group 1
```

Example: Assigning an Interface to a Multilink Bundle

The following example shows how to create four multilink interfaces with Cisco Express Forwarding switching and Multilink PPP (MLP) enabled. Each of the newly created interfaces is added to a multilink bundle.

```
interface multilink1
 ip address 10.0.0.0 10.255.255.255
 ppp chap hostname group 1
 ppp multilink
 ppp multilink group 1

 no ip address
 encapsulation ppp
 ip route-cache cef
 no keepalive
 ppp multilink
 ppp multilink group 1

 no ip address
 encapsulation ppp
 ip route-cache cef
 no keepalive
 ppp chap hostname group 1
 ppp multilink
 ppp multilink group 1

 no ip address
 encapsulation ppp
 ip route-cache cef
 no keepalive
 ppp chap hostname group 1
 ppp multilink
 ppp multilink group 1

 no ip address
 encapsulation ppp
 ip route-cache cef
 no keepalive
 ppp chap hostname group 1
 ppp multilink
 ppp multilink group 1
```

The Cisco Support and Documentation website provides online resources to download documentation, software, and tools. Use these resources to install and configure the software and to troubleshoot and resolve technical issues with Cisco products and technologies. Access to most tools on the Cisco Support and Documentation website requires a Cisco.com user ID and password.	http://www.cisco.com/cisco/web/support/index.html

Feature Information for MPLS Multilink PPP Support

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 4: Feature Information for MPLS Multilink PPP Support

Feature Name	Releases	Feature Information
MPLS Multilink PPP Support		The MPLS Multilink PPP Support feature ensures that MPLS Layer 3 Virtual Private Networks (VPNs) with quality of service (QoS) can be enabled for bundled links. This feature supports Multiprotocol Label Switching (MPLS) over Multilink PPP (MLP) links in the edge (provider edge [PE]-to-customer edge [CE]) or in the MPLS core (PE-to-PE and PE-to-provider [P]device).

Glossary

bundle—A group of interfaces connected by parallel links between two systems that have agreed to use Multilink PPP (MLP) over those links.

CBWFQ—class-based weighted fair queueing. A queueing option that extends the standard Weighted Fair Queueing (WFQ) functionality to provide support for user-defined traffic classes.

Cisco Express Forwarding—A proprietary form of switching that optimizes network performance and scalability for networks with large and dynamic traffic patterns, such as the Internet, and for networks characterized by intensive web-based applications or interactive sessions. Although you can use Cisco Express Forwarding in any part of a network, it is designed for high-performance, highly resilient Layer 3 IP backbone switching.

EIGRP—Enhanced Interior Gateway Routing Protocol. An advanced version of the Interior Gateway Routing Protocol (IGRP) developed by Cisco. It provides superior convergence properties and operating efficiency, and combines the advantages of link-state protocols with those of distance vector protocols.

IGP—Interior Gateway Protocol. An Internet protocol used to exchange routing information within an autonomous system. Examples of common Internet IGPs include Interior Gateway Routing Protocol (IGRP), Open Shortest Path First (OSPF), and Routing Information Protocol (RIP).

IGRP—Interior Gateway Routing Protocol. An Interior Gateway Protocol (IGP) developed by Cisco to address the issues associated with routing in large, heterogeneous networks. Compare with Enhanced Interior Gateway Routing Protocol (EIGRP).

IS-IS—Intermediate System-to-Intermediate System. An Open Systems Interconnection (OSI) link-state hierarchical routing protocol, based on DECnet Phase V routing, in which IS-IS devices exchange routing information based on a single metric to determine network topology.

LCP—Link Control Protocol. A protocol that establishes, configures, and tests data link connections for use by PPP.

LFI—ink fragmentation and interleaving. The LFI feature reduces delay on slower-speed links by breaking up large datagrams and interleaving low-delay traffic packets with the smaller packets resulting from the fragmented datagram. LFI allows reserve queues to be set up so that Real-Time Protocol (RTP) streams can be mapped into a higher priority queue in the configured weighted fair queue set.

link—One of the interfaces in a bundle.

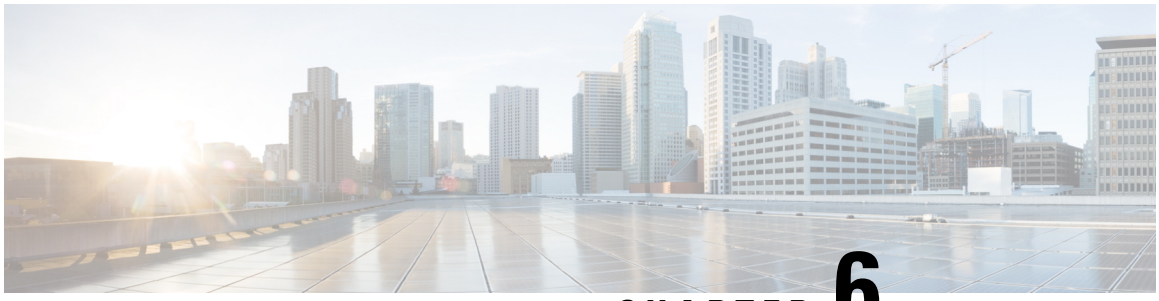
LLQ—low latency queueing. A quality of service QoS queueing feature that provides a strict priority queue (PQ) for voice traffic and weighted fair queues for other classes of traffic. It is also called priority queueing/class-based weighted fair queueing (PQ/CBWFQ).

MLP—Multilink PPP. A method of splitting, recombining, and sequencing datagrams across multiple logical links. The use of MLP increases throughput between two sites by grouping interfaces and then load balancing packets over the grouped interfaces (called a bundle). Splitting packets at one end, sending them over the bundled interfaces, and recombining them at the other end achieves load balancing.

MQC—Modular QoS CLI. MQC is a CLI structure that allows users to create traffic polices and attach these polices to interfaces. MQC allows users to specify a traffic class independently of QoS policies.

NCP—Network Control Protocol. A series of protocols for establishing and configuring different network layer protocols (such as for AppleTalk) over PPP.

OSPF—Open Shortest Path First. A link-state, hierarchical Interior Gateway Protocol (IGP) routing algorithm proposed as a successor to Routing Information Protocol (RIP) in the Internet community. OSPF features include least-cost routing, multipath routing, and load balancing. OSPF was derived from an early version of the IS-IS protocol.



PPP—Point-to-Point Protocol. A successor to the Serial Line Interface Protocol (SLIP) that provides device-to-device and host-to-network connections over synchronous and asynchronous circuits. PPP works with several network layer protocols (such as IP, Internetwork Packet Exchange [IPX], and AppleTalk Remote Access [ARA]). PPP also has built-in security mechanisms (such as Challenge Handshake Authentication Protocol [CHAP] and Password Authentication Protocol [PAP]). PPP relies on two protocols: Link Control Protocol (LCP) and Network Control Protocol (NCP).

RIP—Routing Information Protocol. A version of Interior Gateway Protocol (IGP) that is supplied with UNIX Berkeley Standard Distribution (BSD) systems. Routing Information Protocol (RIP) is the most common IGP in the Internet. It uses hop count as a routing metric.

Virtual bundle interface—An interface that represents the master link of a bundle. It is not tied to any physical interface. Data going over the bundle is transmitted and received through the master link.

WFQ—weighted fair queueing. A congestion management algorithm that identifies conversations (in the form of traffic streams), separates packets that belong to each conversation, and ensures that capacity is shared fairly among the individual conversations. WFQ is an automatic way of stabilizing network behavior during congestion and results in improved performance and reduced retransmission.

WRED—weighted random early detection. A queueing method that ensures that high-precedence traffic has lower loss rates than other traffic during times of congestion.

CHAPTER 6

6PE Multipath

The 6PE multipath feature uses multiprotocol internal BGP (MP-iBGP) to distribute IPv6 routes over the MPLS IPv4 core network and to attach an MPLS label to each route

- Information About 6PE Multipath, on page 71
- How to Configure 6PE Multipath, on page 71
- Configuration Examples for 6PE Multipath, on page 72
- Additional References, on page 73
- Feature Information for 6PE Multipath, on page 73

Information About 6PE Multipath

6PE Multipath

Internal and external BGP multipath for IPv6 allows the IPv6 device to load balance between several paths (for example, the same neighboring autonomous system or subautonomous system, or the same metric) to reach its destination. The 6PE multipath feature uses MP-iBGP to distribute IPv6 routes over the MPLS IPv4 core network and to attach an MPLS label to each route.

When MP-iBGP multipath is enabled on the 6PE device, all labeled paths are installed in the forwarding table with MPLS information (label stack) when MPLS information is available. This functionality enables 6PE to perform load balancing.

How to Configure 6PE Multipath

Configuring IBGP Multipath Load Sharing

Perform this task to configure IBGP multipath load sharing and control the maximum number of parallel IBGP routes that can be installed in a routing table.

SUMMARY STEPS

1. **enable**
2. **configure terminal**

3. **router bgp** *as-number*
4. **address-family ipv6** [**unicast**]
5. **maximum-paths ibgp** *number-of-paths*

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**router bgp** *as-number* **Example:** `Device(config)# router bgp 65000`	Enters router configuration mode for the specified routing process.
Step 4	**address-family ipv6** [**unicast**] **Example:** `Device(config-router)# address-family ipv6`	Specifies the IPv6 address family and enters address family configuration mode. • The **unicast** keyword specifies the IPv6 unicast address family. By default, the device is placed in configuration mode for the IPv6 unicast address family if the **unicast** keyword is not specified with the **address-family ipv6** command.
Step 5	**maximum-paths ibgp** *number-of-paths* **Example:** `Device(config-router)# maximum-paths ibgp 3`	Controls the maximum number of parallel IBGP routes that can be installed in a routing table.

Configuration Examples for 6PE Multipath

Example: Configuring 6PE Multipath

```
Device# show ipv6 cef internals
IPv6 CEF is enabled and running
Slow processing intvl = 1 seconds backoff level current/max 0/0
0 unresolved prefixes, 0 requiring adjacency update
```

```
IPv6 CEF default table
14 prefixes tableid 0
table version 17
root 6283F5D0
```

Feature Information for 6PE Multipath

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 5: Feature Information for 6PE Multipath

Feature Name	Releases	Feature Information
6PE Multipath		The 6PE multipath feature uses MP-iBGP to distribute IPv6 routes over the MPLS IPv4 core network and to attach an MPLS label to each route. The following commands were introduced or modified: **maximum-paths ibgp**, **router bgp**, **show ipv6 cef internals**.

CHAPTER 7

IPv6 Switching: Provider Edge Router over MPLS

Multiprotocol Label Switching (MPLS) is deployed by many service providers in their IPv4 networks. Service providers want to introduce IPv6 services to their customers, but changes to their existing IPv4 infrastructure can be expensive and the cost benefit for a small amount of IPv6 traffic does not make economic sense. Several integration scenarios have been developed to leverage an existing IPv4 MPLS infrastructure and add IPv6 services without requiring any changes to the network backbone. This document describes how to implement IPv6 over MPLS.

- Prerequisites for IPv6 Switching: Provider Edge Router over MPLS, on page 75
- Information About IPv6 Switching: Provider Edge Router over MPLS, on page 75
- How to Deploy IPv6 Switching: Provider Edge Router over MPLS, on page 77
- Configuration Examples for IPv6 Switching: Provider Edge Router over MPLS, on page 81
- Additional References for IPv6 Switching: Provider Edge Router over MPLS, on page 84
- Feature Information for IPv6 Switching: Provider Edge Router over MPLS, on page 85

Prerequisites for IPv6 Switching: Provider Edge Router over MPLS

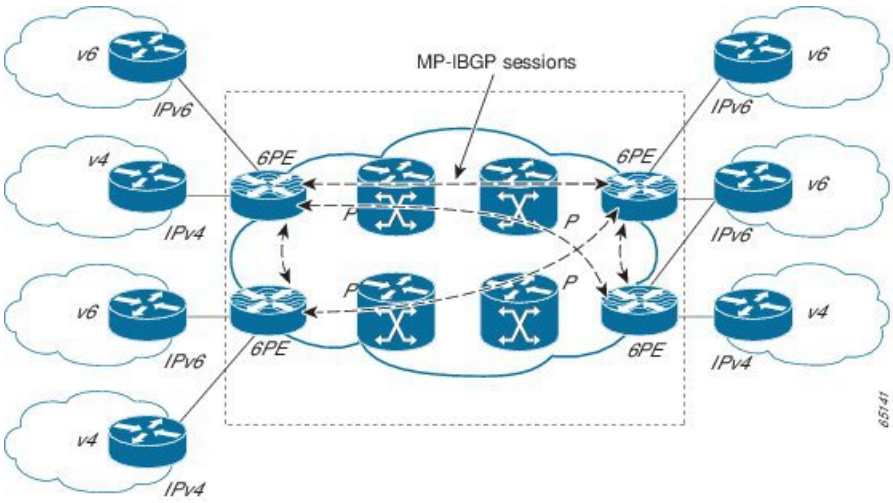
Before the IPv6 Provider Edge Router over MPLS (6PE) feature can be implemented, MPLS must be running over the core IPv4 network. If Cisco devices are used, Cisco Express Forwarding or distributed Cisco Express Forwarding must be enabled for both IPv4 and IPv6 protocols. This module assumes that you are familiar with MPLS.

Information About IPv6 Switching: Provider Edge Router over MPLS

Benefits of Deploying IPv6 over MPLS Backbones

IPv6 over MPLS backbones enables isolated IPv6 domains to communicate with each other over an MPLS IPv4 core network. This implementation requires only a few backbone infrastructure upgrades and no reconfiguration of core devices because forwarding is based on labels rather than the IP header itself, providing a very cost-effective strategy for the deployment of IPv6.

Additionally, the inherent Virtual Private Network (VPN) and MPLS traffic engineering (MPLS-TE) services available within an MPLS environment allow IPv6 networks to be combined into IPv4 VPNs or extranets over an infrastructure supporting IPv4 VPNs and MPLS-TE.



IPv6 on the Provider Edge Devices

The Cisco implementation of IPv6 Provider Edge Router over MPLS is called 6PE, and it enables IPv6 sites to communicate with each other over an MPLS IPv4 core network using MPLS label switched paths (LSPs). This feature relies on multiprotocol Border Gateway Protocol (BGP) extensions in the IPv4 network configuration on the provider edge (PE) device to exchange IPv6 reachability information in addition to an MPLS label for each IPv6 address prefix to be advertised. Edge devices are configured to be dual stack running both IPv4 and IPv6, and use the IPv4 mapped IPv6 address for IPv6 prefix reachability exchange.

A hierarchy of labels is imposed on the 6PE ingress device to keep the IPv6 traffic transparent to all the core devices. The top label provides connectivity inside the IPv4 MPLS core network and the label is distributed by Label Distribution Protocol (LDP), Tag Distribution Protocol (TDP), or Resource Reservation Protocol (RSVP). TDP and LDP can both be used for label distribution, but RSVP is used only in the context of MPLS-TE label exchange. The bottom label, automatically assigned to the IPv6 prefix of the destination, is distributed by multiprotocol BGP and used at each 6PE egress device for IPv6 forwarding.

In the figure below the 6PE devices are configured as dual stack devices able to route both IPv4 and IPv6 traffic. Each 6PE device is configured to run LDP, TDP, or RSVP (if traffic engineering is configured) to bind the IPv4 labels. The 6PE devices use multiprotocol BGP to exchange reachability information with the other 6PE devices within the MPLS domain, and to distribute IPv6 labels between them. All 6PE and core devices--P devices in Figure 3--within the MPLS domain share a common IPv4 Interior Gateway Protocol (IGP) such as Open Shortest Path First (OSPF) or Integrated Intermediate System-to-Intermediate System (IS-IS).

Figure 6: 6PE Device Topology

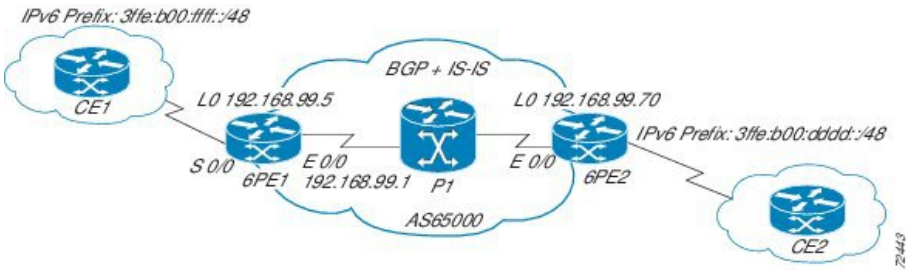
The interfaces on the 6PE devices connecting to the CE device can be configured to forward IPv6 traffic, IPv4 traffic, or both types of traffic depending on the customer requirements. 6PE devices advertise IPv6 reachability information learned from their 6PE peers over the MPLS cloud. Service providers can delegate an IPv6 prefix from their registered IPv6 prefixes over the 6PE infrastructure; otherwise, there is no impact on the CE device.

The P devices in the core of the network are not aware that they are switching IPv6 packets. Core devices are configured to support MPLS and the same IPv4 IGP as the PE devices to establish internal reachability inside

the MPLS cloud. Core devices also use LDP, TDP, or RSVP for binding IPv4 labels. Implementing the Cisco 6PE feature does not have any impact on the MPLS core devices.

Within the MPLS network, IPv6 traffic is forwarded using label switching, making the IPv6 traffic transparent to the core of the MPLS network. No IPv6 over IPv4 tunnels or Layer 2 encapsulation methods are required.

How to Deploy IPv6 Switching: Provider Edge Router over MPLS



Deploying IPv6 on the Provider Edge Devices (6PE)

Specifying the Source Address Interface on a 6PE Device

Two configuration tasks using the network shown in the figure below are required at the 6PE1 device to enable the 6PE feature.

The customer edge device--CE1 in the figure below--is configured to forward its IPv6 traffic to the 6PE1 device. The P1 device in the core of the network is assumed to be running MPLS, a label distribution protocol, an IPv4 IGP, and Cisco Express Forwarding or distributed Cisco Express Forwarding, and does not require any new configuration to enable the 6PE feature.

Figure 7: 6PE Configuration Example

Before you begin

- The 6PE devices--the 6PE1 and 6PE2 devices in the figure below--must be members of the core IPv4 network. The 6PE device interfaces attached to the core network must be running MPLS, the same label distribution protocol, and the same IPv4 IGP, as in the core network.
- The 6PE devices must also be configured to be dual stack to run both IPv4 and IPv6.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ipv6 unicast-routing**
4. **ipv6 cef**
5. **interface** *type number*
6. **ipv6 address** *ipv6-address / prefix-length | prefix-name sub-bits / prefix-length*

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**ipv6 unicast-routing** **Example:** `Device(config)# ipv6 unicast-routing`	Enables the forwarding of IPv6 unicast datagrams.
Step 4	**ipv6 cef** **Example:** `Device(config)# ipv6 cef`	Enables IPv6 Cisco Express Forwarding.
Step 5	**interface** *type number* **Example:** `Device(config)# interface`	Specifies an interface type and number and enters interface configuration mode. • In the context of this feature, the interface to be configured is the interface communicating with the CE device.
Step 6	**ipv6 address** *ipv6-address / prefix-length | prefix-name sub-bits / prefix-length* **Example:** `Device(config-if)# ipv6 address 2001:DB8:FFFF::2/64`	Configures an IPv6 address based on an IPv6 general prefix and enable IPv6 processing on an interface.

Binding and Advertising the 6PE Label to Advertise Prefixes

Perform this task to enable the binding and advertising of labels when advertising IPv6 prefixes to a specified BGP neighbor.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **router bgp** *as-number*

4. **no bgp default ipv4-unicast**
5. **neighbor** {*ip-address* | *ipv6-address* | *peer-group-name*} **remote-as** *as-number*
6. **neighbor** { *ip-address* | *ipv6-address* | *peer-group-name*} **update-source** *interface-type interface-number*
7. **address-family ipv6** [**unicast**]
8. **neighbor** {*ip-address* | *peer-group-name*| *ipv6-address*} **activate**
9. **neighbor** {*ip-address* | *ipv6-address*} **send-label**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**router bgp** *as-number* **Example:** `Device(config)# router bgp 65000`	Enters router configuration mode for the specified routing process.
Step 4	**no bgp default ipv4-unicast** **Example:** `Device(config-router)# no bgp default ipv4-unicast`	Disables the IPv4 unicast address family for the BGP routing process specified in the previous step. **Note** Routing information for the IPv4 unicast address family is advertised by default for each BGP routing session configured with the **neighbor remote-as** command unless you configure the **no bgp default ipv4-unicast**command before configuring the **neighbor remote-as** command.
Step 5	**neighbor** {*ip-address* | *ipv6-address* | *peer-group-name*} **remote-as** *as-number* **Example:** `Device(config-router)# neighbor 192.168.99.70 remote-as 65000`	Adds the IP address of the neighbor in the specified autonomous system to the BGP neighbor table of the local device.
Step 6	**neighbor** { *ip-address* | *ipv6-address* | *peer-group-name*} **update-source** *interface-type interface-number* **Example:**	Specifies the interface whose IPv4 address is to be used as the source address for the peering. • In the context of this task, the interface must have an IPv4 address with a 32-bit mask configured. Use of a

	Command or Action	Purpose
	`Device(config-router)# neighbor 192.168.99.70 update-source Loopback 0`	loopback interface is recommended. This address is used to determine the IPv6 next hop by the peer 6PE.
Step 7	**address-family ipv6** [**unicast**] **Example:** `Device(config-router)# address-family ipv6`	Specifies the IPv6 address family and enters address family configuration mode. • The **unicast** keyword specifies the IPv6 unicast address family. By default, the device is placed in configuration mode for the IPv6 unicast address family if the **unicast** keyword is not specified with the **address-family ipv6** command.
Step 8	**neighbor** {*ip-address* | *peer-group-name*| *ipv6-address*} **activate** **Example:** `Device(config-router-af)# neighbor 192.168.99.70 activate`	Enables the neighbor to exchange prefixes for the IPv6 address family with the local device.
Step 9	**neighbor** {*ip-address* | *ipv6-address*} **send-label** **Example:** `Device(config-router-af)# neighbor 192.168.99.70 send-label`	Advertises the capability of the device to send MPLS labels with BGP routes. • In IPv6 address family configuration mode this command enables binding and advertisement of labels when advertising IPv6 prefixes in BGP.

Configuring IBGP Multipath Load Sharing

Perform this task to configure IBGP multipath load sharing and control the maximum number of parallel IBGP routes that can be installed in a routing table.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **router bgp** *as-number*
4. **address-family ipv6** [**unicast**]
5. **maximum-paths ibgp** *number-of-paths*

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:**	Enables privileged EXEC mode. • Enter your password if prompted.

	Command or Action	Purpose
	`Device> enable`	
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**router bgp** *as-number* **Example:** `Device(config)# router bgp 65000`	Enters router configuration mode for the specified routing process.
Step 4	**address-family ipv6** [**unicast**] **Example:** `Device(config-router)# address-family ipv6`	Specifies the IPv6 address family and enters address family configuration mode. • The **unicast** keyword specifies the IPv6 unicast address family. By default, the device is placed in configuration mode for the IPv6 unicast address family if the **unicast** keyword is not specified with the **address-family ipv6** command.
Step 5	**maximum-paths ibgp** *number-of-paths* **Example:** `Device(config-router)# maximum-paths ibgp 3`	Controls the maximum number of parallel IBGP routes that can be installed in a routing table.

Configuration Examples for IPv6 Switching: Provider Edge Router over MPLS

Example: Provider Edge Device

The 6PE device is configured for both IPv4 and IPv6 traffic. Gigabit Ethernet interface 0/0/0 is configured with an IPv4 address and is connected to a device in the core of the network. Integrated IS-IS and TDP configurations on this device are similar to the P1 device.

Device 6PE1 exchanges IPv6 routing information with another 6PE device using internal BGP (IBGP) established over an IPv4 connection so that all the **neighbor** commands use the IPv4 address of the 6PE2 device. All the BGP peers are within autonomous system 65000, so synchronization with IGP is turned off for IPv4. In IPv6 address family configuration mode, synchronization is disabled by default.

IPv6 and Cisco Express Forwarding for IPv6 are enabled, the 6PE2 neighbor is activated, and label binding and advertisement is enabled for IPv6 prefixes using the **neighbor send-label** command. Connected and static IPV6 routes are redistributed using BGP.

Note MPLS is not supported on IPv6.

Example: Core Device

In the following example, the device in the core of the network is running MPLS, IS-IS, and IPv4 only. The Gigabit Ethernet interfaces are configured with IPv4 address and are connected to the 6PE devices. IS-IS is the IGP for this network and the P1 and 6PE devices are in the same IS-IS area 49.0001. Tag Distribution Protocol (TDP) and tag switching are enabled on both the Gigabit Ethernet interfaces. Cisco Express Forwarding is enabled in global configuration mode.

```
ip cef
!
tag-switching tdp router-id Loopback0
!
interface Loopback0
 ip address 192.168.99.200 255.255.255.255
!
interface GigabitEthernet0/0/0
 description to_6PE1
 ip address 192.168.99.2 255.255.255.252
 ip router isis
 tag-switching ip
!
interface GigabitEthernet0/1/0
 description to_6PE2
 ip address 192.168.99.66 255.255.255.252
 ip router isis
 tag-switching ip
router isis
 passive-interface Loopback0
 net 49.0001.1921.6809.9200.00
```

Example: Monitoring 6PE

In the following example, output information about an IPv6 route is displayed using the **show bgp ipv6** command with an IPv6 prefix:

```
Device# show bgp ipv6 2001:DB8:DDDD::/48

BGP routing table entry for 2001:DB8:DDDD::/48, version 15
Paths: (1 available, best #1, table Global-IPv6-Table)
  Not advertised to any peer
  Local
    ::FFFF:192.168.99.70 (metric 20) from 192.168.99.70 (192.168.99.70)
      Origin IGP, localpref 100, valid, internal, best
```

In the following example, output information about a BGP peer including the IPv6 label capability is displayed using the **show bgp ipv6 neighbors** command with an IP address:

```
Device# show bgp ipv6 neighbors 192.168.99.70

BGP neighbor is 192.168.99.70, remote AS 65000, internal link
  BGP version 4, remote router ID 192.168.99.70
  BGP state = Established, up for 00:05:17
  Last read 00:00:09, hold time is 0, keepalive interval is 60 seconds
```

```
  Neighbor capabilities:
    Route refresh: advertised and received
    Address family IPv6 Unicast: advertised and received
    ipv6 MPLS Label capability: advertised and received
  Received 54 messages, 0 notifications, 0 in queue
  Sent 55 messages, 1 notifications, 0 in queue
  Default minimum time between advertisement runs is 5 seconds

 For address family: IPv6 Unicast
  BGP table version 21880, neighbor version 21880
  Index 1, Offset 0, Mask 0x2
  Route refresh request: received 0, sent 0
  77 accepted prefixes consume 4928 bytes
  Prefix advertised 4303, suppressed 0, withdrawn 1328
  Number of NLRIs in the update sent: max 1, min 0
```

In the following example, output information linking the MPLS label with prefixes is displayed using the **show mpls forwarding-table** command. If the 6PE feature is configured, the labels are aggregated because there are several prefixes for one local label, and the prefix column contains IPv6 instead of a target prefix.

```
Device# show mpls forwarding-table

Local      Outgoing   Prefix           Bytes Label   Outgoing   Next Hop
Label      Label      or Tunnel Id     Switched      interface
16         Pop Label  10.1.1.1/32       0             Et0/0      10.0.0.1
18         No Label   nh-id(1)         0             Et2/0      10.0.2.2
19         No Label   nh-id(2)         0             Et1/0      10.0.1.2
20         No Label   nh-id(3)         0             Et1/0      10.0.1.2
22         No Label   nh-id(5)         0             Et1/0      10.0.1.2
24         No Label   nh-id(5)         0             Et2/0      10.0.2.2
```

In the following example, output information about the top of the stack label with label switching information is displayed using the **show bgp ipv6** command with the **labels** keyword:

```
Device# show bgp ipv6 labels

Network              Next Hop               In tag/Out tag
2001:DB8:DDDD::/64  ::FFFF:192.168.99.70   notag/20
```

In the following example, output information about labels from the Cisco Express Forwarding table is displayed using the **show ipv6 cef** command with an IPv6 prefix:

```
Device# show ipv6 cef 2001:DB8:DDDD::/64

2001:DB8:DDDD::/64
      nexthop ::FFFF:192.168.99.70
      fast tag rewrite with Se0/0, point2point, tags imposed {19 20}
```

In the following example, output information from the IPv6 routing table is displayed using the **show ipv6 route** command. The output shows the IPv6 MPLS virtual interface as the output interface of IPv6 routes forwarded across the MPLS cloud. This example shows output from the 6PE1 router.

The 6PE2 router has advertised the IPv6 prefix of 2001:DB8:dddd::/48 configured for the CE2 router and the next-hop address is the IPv4-compatible IPv6 address ::ffff:192.168.99.70, where 192.168.99.70 is the IPv4 address of the 6PE2 router.

```
Device# show ipv6 route

IPv6 Routing Table - 10 entries
Codes: C - Connected, L - Local, S - Static, R - RIP, B - BGP
I1 - ISIS L1, I2 - ISIS L2, IA - ISIS interarea
B 2001:DB8:DDDD::/64 [200/0]
  via ::FFFF:192.168.99.70, IPv6-mpls
```

```
B 2001:DB8:DDDD::/64 [200/0]
  via ::FFFF:192.168.99.70, IPv6-mpls
L 2001:DB8:FFFF::1/128 [0/0]
  via ::, GigabitEthernet0/0/0
C 2001:DB8:FFFF::/64 [0/0]
  via ::, GigabitEthernet0/0/0
S 2001:DB8:FFFF::/48 [1/0]
  via 2001:DB8:B00:FFFF::2, GigabitEthernet0/0/0
```

CHAPTER 8

MPLS Enhancements to Interfaces MIB

This document describes the Multiprotocol Label Switching (MPLS) enhancements to the existing Interfaces MIB (RFC 2233) to support an MPLS layer. This layer provides counters and statistics specifically for MPLS.

- Prerequisites for MPLS Enhancements to Interfaces MIB, on page 89
- Restrictions for MPLS Enhancements to Interfaces MIB, on page 89
- Information About MPLS Enhancements to Interfaces MIB, on page 90
- How to Configure MPLS Enhancements to Interfaces MIB, on page 95
- Configuration Examples for the MPLS Enhancements to Interfaces MIB, on page 97
- Additional References, on page 97
- Feature Information for MPLS Enhancements to Interfaces MIB, on page 99
- Glossary, on page 99

Prerequisites for MPLS Enhancements to Interfaces MIB

- Simple Network Management Protocol (SNMP) must be installed and enabled on the label switching routers (LSRs)
- MPLS must be enabled on the LSRs
- MPLS IP must be enabled on an interface or an MPLS traffic engineering (TE) tunnel enabled on an interface

Restrictions for MPLS Enhancements to Interfaces MIB

- Link up and link down traps for the MPLS layer are not supported in this release.
- Write capability using the SNMP SET command is not supported for the MPLS layer in this release.
- Some counters, including discard and multicast, increment on the underlying physical layer; therefore, they equal 0 because they never reach the MPLS layer.
- The high-capacity counters for the MPLS layer interfaces of the Interfaces MIB contain 64 bits of counter data. In previous versions, the high capacity counters displayed 32 bits of counter data.

The following MIB objects are affected:

- • ifHCInOctets
  • ifHCOutOctets
  • ifHCInUcastPkts
  • ifHCOutUcastPkts

When the 64-bit values are less than the value of 232, the 32-bit and 64-bit values are identical.

After the counter increases to more than 232, the counters are different; the 64-bit value is computed by the following formula:

X * (232) + Y

where:

- • X is the number of times the 32-bit counter has rolled.
  • Y is the residual value of the counter after the roll occurred. The Y value equals the 32-bit value.

When the high-capacity counter values are compared to their 32-bit values, there is a period of time that the counter values are not equal. The 64-bit values lag the 32-bit values when the counters poll the 32-bit hardware counters and computing the correct counter value. During the polling and computation interval, the following high-capacity counter values counters might be inconsistent:

- • ifInOctets
  • ifOutOctets
  • ifInUcastPkts
  • ifOutUcastPkts

The inconsistent values can occur if traffic is constantly flowing over an interface and a MIB walk is performed. The 32-bit value is correct at that moment. The 64-bit value lags slightly, because of the polling computations needed to generate it. Once traffic stops flowing over the interface, and a polling period has passed, the two counters are identical and correct.

The lag time depends on the following factors:

- • The polling interval used by the Interfaces MIB. The less time the polling interval takes, the more accurate the value is.
  • The size of the Interfaces MIB. A large MIB takes a long time to walk and might affect the values found at that instant.
  • The number of computations needed to generate the 64-bit value. The number of MPLS-enabled interfaces increases the number of 64-bit counter values that need to be computed.

Information About MPLS Enhancements to Interfaces MIB

Feature Design of the MPLS Enhancements to Interfaces MIB

The Interfaces MIB (IF MIB) provides an SNMP-based method for managing interfaces. Each entry in the IF MIB establishes indexing, statistics, and stacking relationships among underlying physical interfaces, subinterfaces, and Layer 2 protocols that exist within Cisco software.

The enhancements add an MPLS layer to the IF MIB as a Layer 2 protocol to provide statistics for traffic encapsulated as MPLS on an interface. In this structure, MPLS-specific data such as MPLS-encapsulated

traffic counters and the MPLS maximum transmission unit (MTU) resides on top of the underlying physical or virtual interface to allow separation from non-MPLS data.

The enhancements also allow you to display indexing, statistics, and stacking relationships using the ifStackTable. MPLS layer interfaces are stacked above the underlying physical or virtual interface that is actually forwarding the MPLS traffic. MPLS traffic engineering tunnels are then stacked above those MPLS layers.

The IF MIB supports several types of interfaces. A virtual interface that provides protocol statistics for MPLS-encapsulated traffic has been added. This interface is stacked above real Cisco interfaces or subinterfaces, such as Fast Ethernet (fe0/1/0) or ATM (at1/1.1).

Cisco software creates a corresponding MPLS layer above each interface capable of supporting MPLS when the MPLS encapsulation is enabled by issuing the **mpls ip** command in interface configuration mode.

You can also create the interface layer if you enable MPLS TE by using the **mpls traffic-eng tunnels** command in interface configuration mode.

Note You must also issue these commands in global configuration mode for MPLS IP or MPLS TE to be enabled.

An IF MIB entry is created when you enable either MPLS IP or MPLS TE tunnels on an interface; the entry is removed when you disable both MPLS IP and MPLS TE.

ifStackTable Objects

The table below defines the ifStackTable objects.

Table 7: ifStackTable Objects and Definitions

Object	Definition
ifStackHigherLayer	The value of ifIndex corresponding to the higher sublayer of the relationship; that is, the sublayer that runs on top of the sublayer identified by the corresponding instance of the ifStackLowerLayer. **Note** Index objects are not accessible in a MIB walk. This value is part of the object identifier (OID) for every object in the ifStackTable.
ifStackLowerLayer	The value of ifIndex corresponding to the lower sublayer of the relationship; that is, the sublayer that runs below the sublayer identified by the corresponding instance of the ifStackHigherLayer. **Note** Index objects are not accessible in a MIB walk. This value is part of the OID for every object in the ifStackTable.
ifStackStatus	Used to create and delete rows in the ifStackTable; status is always active(1) for MPLS.

ifRcvAddressTable Objects

The table below defines the ifRcvAddressTable objects.

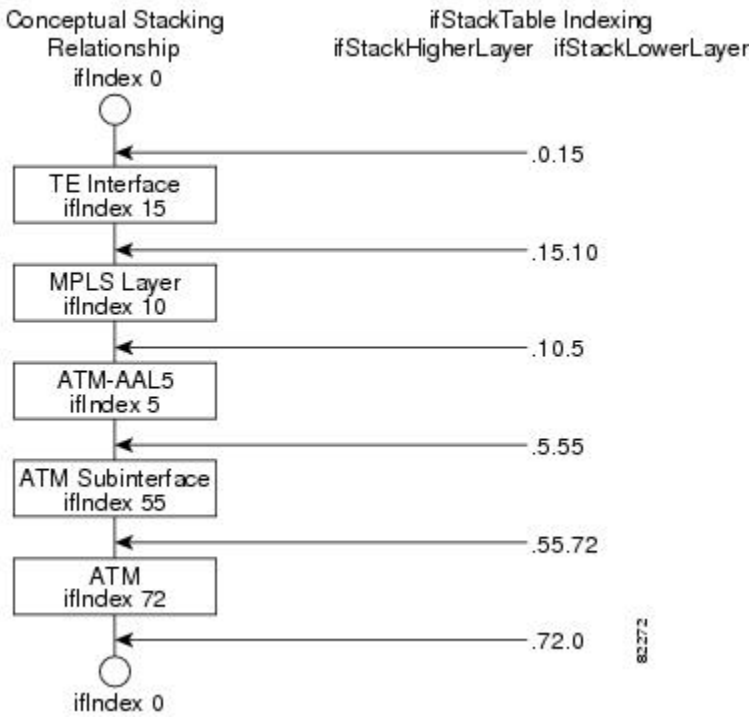
Note Entries for the MPLS layer do not appear in the ifRcvAddressTable.

Table 8: ifRcvAddressTable Objects and Descriptions

Object	Definition
ifRcvAddressAddress	An address for which the system accepts packets and frames on this entry's interface. **Note** Index objects are not accessible in a MIB walk. This value is part of the OID for every object in the ifRcvAddressTable.
ifRcvAddressStatus	Used to create and delete rows in the ifRcvAddressTable.
ifRcvAddressType	Type of storage used for each entry in the ifRcvAddressTable.

Interfaces MIB Scalar Objects

The IF MIB supports the following scalar objects:



- ifStackLastChange--The value of sysUpTime at the time of the last change of the entire interface stack. A change of the interface stack is defined to be any creation, deletion, or change in value of any instance of ifStackStatus. If the interface stack has been unchanged since the last reinitialization of the local network management subsystem, then this object contains a zero value.
- ifTableLastChange--The value of sysUpTime at the time of the last creation or deletion of an entry in the ifTable. If the number of entries has been unchanged since the last reinitialization of the local network management subsystem, then this object contains a zero value.

Stacking Relationships for MPLS Layer Interfaces

The ifStackTable within the IF MIB provides a conceptual stacking relationship between the interfaces and subinterfaces represented as entries in the ifTable.

The ifStackTable is indexed like a linked list. Each entry shows a relationship between two interfaces providing the ifIndexes of the upper and the lower interface. The entries chain together to show the entire stacking relationship. Each entry links with one another until the stack terminates with an ifIndex of 0 at the highest and lowest ends of the stack. For example, in the figure below, the indexes .10.5 show that ifIndex 10 is stacked upon ifIndex 5. There are 0 entries at the highest and lowest ends of the stack; in the figure, the indexes .0.15 and .72.0 are the highest and lowest ends of the stack, respectively.

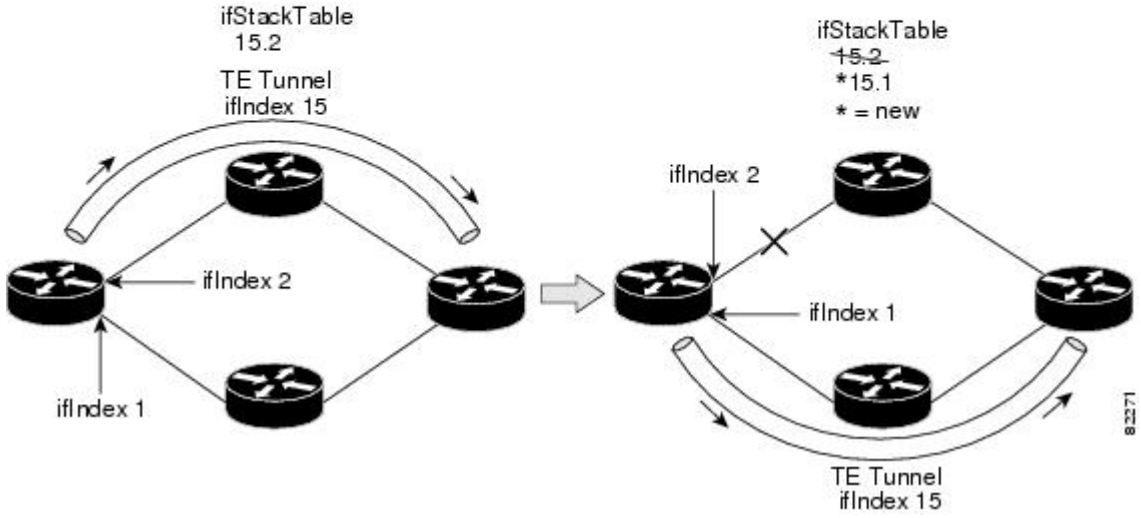
Figure 8: Sample ATM Stacking Relationship in the ifStackTable

The table below describes the indexing of the ifStackTable for the layer relationships shown in the figure above.

Note The order of the entries in the table may not be the same as that seen in the MIB walk, which has to follow SNMP ordering rules.

Table 9: Layer Relationships

Layer Relationship (in Descending Order)	ifStackHigherLayer/ifStackLowerLayer
TE interface as top layer	.0.15
TE interface stacked upon MPLS layer	.15.10
MPLS layer stacked upon ATM-AAL5	.10.5
ATM-AAL5 layer stacked upon ATM subinterface	.5.55
ATM subinterface stacked upon ATM	.55.72
ATM as bottom layer	.72.0



Stacking Relationships for Traffic Engineering Tunnels

MPLS TE tunnels are represented in Cisco software and the IF MIB as virtual interfaces. When properly signaled, TE tunnels pass traffic through MPLS over a physical interface. This process dictates that a TE tunnel is to be stacked on an MPLS layer that is stacked on an underlying interface.

TE tunnels can also change paths in response to different error or network conditions. These changes are instigated by using the RSVP-TE signaling protocol. When a change occurs, a tunnel can switch to a different MPLS interface. If no signaling path exists, no paths will be chosen and thus no MPLS interface will be used.

Because a TE tunnel is represented as an IF MIB ifTable entry, the ifStackTable also contains an entry corresponding to the TE tunnel. If the TE tunnel is successfully signaled, the ifStackTable also contains a link between the tunnel interface and one MPLS interface. Note that because it is possible for a TE tunnel to not have a corresponding signaled path, it is thus possible for a TE tunnel's ifStackTable entry to not have a corresponding lower layer. In this case, the lower layer variable contains the value of 0.

The figure below shows a TE tunnel before (left) and after (right) being rerouted and the effect on the ifStackTable. When ifIndex 2 fails, the TE tunnel is rerouted through ifIndex1, the 15.2 entry is removed from the ifStackTable, and the 15.1 entry is added.

MPLS Label Switching Router MIB Enhancements

All of the ifIndex references in the MPLS-LSR-MIB tables have changed from the ifIndex of the underlying physical or virtual interface to the ifIndex of the MPLS layer.

The table below shows the specific changes.

Table 10: MPLS-LSR-MIB ifIndex Objects Enhanced

Table	ifIndex
MPLS interface configuration table (mplsInterfaceConfTable)	mplsInterfaceConfIndex
MPLS in-segment table (mplsInSegmentTable)	mplsInSegmentIfIndex
MPLS cross-connect table (mplsXCTable)	mplsInSegmentIfIndex
MPLS out-segment table (mplsOutSegmentTable)	mplsOutSegmentIfIndex

The following objects from the mplsInterfaceConfTable are affected:

- mplsInterfaceOutPackets--Count only MPLS-encapsulated out packets
- mplsInterfaceInPackets--Count only MPLS-encapsulated in packets

Benefits of the MPLS Enhancements to Interfaces MIB

Improved Accounting Capability

By viewing the MPLS layer, you get MPLS-encapsulated traffic counters that do not include non-MPLS encapsulated traffic (for example, IP packets). Therefore, the counters are more useful for MPLS-related statistics.

TE Tunnel Interfaces

For TE tunnel interfaces, the stacking relationship reflects the current underlying MPLS interface that is in use and dynamically changes as TE tunnels reoptimize and reroute.

MPLS-Specific Information

The MPLS layer shows MPLS-specific information including the following:

- If MPLS is enabled
- MPLS counters
- MPLS MTU
- MPLS operational status

How to Configure MPLS Enhancements to Interfaces MIB

Enabling the SNMP Agent

SUMMARY STEPS

1. **enable**

2. **show running-config**
3. **configure terminal**
4. **snmp-server community** *string* [**view** *view-name*] [**ro** *number*]
5. **end**
6. **write memory**
7. **show running-config**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**show running-config** **Example:** `Router# show running-config`	Displays the running configuration of the router so that you can determine if an SNMP agent is already running on the device. If no SNMP information is displayed, continue with the next step. If any SNMP information is displayed, you can modify the information or change it as desired.
Step 3	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 4	**snmp-server community** *string* [**view** *view-name*] [**ro** *number*] **Example:** `Router(config)# snmp-server community public ro`	Configures read-only (ro) community strings for the MPLS Label Distribution Protocol (LDP) MIB. • The *string* argument functions like a password, permitting access to SNMP functionality on label switch routers (LSRs) in an MPLS network. • The optional **ro** keyword configures read-only (ro) access to the objects in the MPLS LDP MIB.
Step 5	**end** **Example:** `Router(config)# end`	Exits to privileged EXEC mode.
Step 6	**write memory** **Example:**	Writes the modified SNMP configuration into NVRAM of the router, permanently saving the SNMP settings.

	Command or Action	Purpose
	`Router# write memory`	
Step 7	**show running-config** **Example:** `Router# show running-config`	Displays the running configuration of the router so that you can determine if an SNMP agent is already running on the device. If you see any snmp-server statements, SNMP has been enabled on the router. If any SNMP information is displayed, you can modify the information or change it as desired.

Configuration Examples for the MPLS Enhancements to Interfaces MIB

MPLS Enhancements to Interfaces MIB: Examples

The following example shows how to enable an SNMP agent:

```
Router# configure terminal
Router(config)# snmp-server community
```

In the following example, SNMPv1 and SNMPv2C are enabled. The configuration permits any SNMP manager to access all objects with read-only permissions using the community string *public*.

```
Router(config)# snmp-server community public
```

In the following example, read-only access is allowed for all objects to members of access list 4 that specify the comaccess community string. No other SNMP managers have access to any objects.

```
Router(config)# snmp-server community comaccess ro 4
```

Feature Information for MPLS Enhancements to Interfaces MIB

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 11: Feature Information for MPLS Enhancements to Interfaces MIB

Feature Name	Releases	Feature Information
MPLS Enhancements to Interfaces MIB	12.0(23)S 12.3(8)T 12.2(33)SRA 12.2(33)SXH 12.2(33)SB Cisco IOS XE Release 2.1	This document describes the Multiprotocol Label Switching (MPLS) enhancements to the existing Interfaces MIB (RFC 2233) to support an MPLS layer. This layer provides counters and statistics specifically for MPLS. In Cisco IOS Release 12.0(23)S, this feature was introduced. This feature was integrated into Cisco IOS Release 12.3(8)T. This feature was integrated into Cisco IOS Release 12.2(33)SRA. This feature was integrated into Cisco IOS Release 12.2(33)SXH. This feature was integrated into Cisco IOS Release 12.2(33)SB. In Cisco IOS XE Release 2.1, this feature was implemented on the Cisco ASR 1000 Series Aggregation Services Routers. The following command was introduced or modified: **snmp-server community**.

Glossary

ATM -- Asynchronous Transfer Mode. The international standard for cell relay in which multiple service types (such as voice, video, or data) are conveyed in fixed-length (53-byte) cells. Fixed-length cells allow cell processing to occur in hardware, thereby reducing transit delays. ATM is designed to take advantage of high-speed transmission media, such as E3, SONET, and T3.

ATM-AAL5 --ATM adaptation layer 5. One of four AALs recommended by the ITU-T. AAL5 supports connection-oriented variable bit rate (VBR) services and is used predominantly for the transfer of classical IP over ATM and LAN emulation (LANE) traffic. AAL5 uses simple and efficient AAL (SEAL) and is the least complex of the current AAL recommendations. It offers low bandwidth overhead and simpler processing requirements in exchange for reduced bandwidth capacity and error-recovery capability.

encapsulation -- Wrapping of data in a particular protocol header. For example, Ethernet data is wrapped in a specific Ethernet header before network transit. Also, when bridging dissimilar networks, the entire frame from one network is simply placed in the header used by the data link layer protocol of the other network.

IETF --Internet Engineering Task Force. A task force (consisting of more than 80 working groups) that is developing standards for the Internet and the IP suite of protocols.

interface --The boundary between adjacent layers of the ISO model.

label --A short, fixed-length identifier that is used to determine the forwarding of a packet.

label switching--A term used to describe the forwarding of IP (or other network layer) packets using a label swapping algorithm based on network layer routing algorithms. The forwarding of these packets uses the exact match algorithm and rewrites the label.

LSR --label switching router. A device that forwards Multiprotocol Label Switching (MPLS) packets based on the value of a fixed-length label encapsulated in each packet.

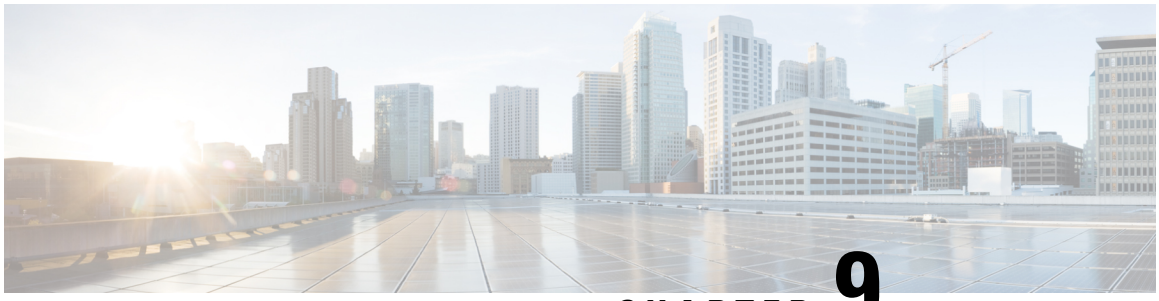
MIB --Management Information Base. A database of network management information that is used and maintained by a network management protocol such as Simple Network Management Protocol (SNMP). The value of a MIB object can be changed or retrieved by means of SNMP commands, usually through a network management system. MIB objects are organized in a tree structure that includes public (standard) and private (proprietary) branches.

MPLS --Multiprotocol Label Switching. A method for forwarding packets (frames) through a network. It enables routers at the edge of a network to apply labels to packets (frames). ATM switches or existing routers in the network core can switch packets according to the labels with minimal lookup overhead.

MPLS interface--An interface on which Multiprotocol Label Switching (MPLS) traffic is enabled.

MTU --maximum transmission unit. Maximum packet size, in bytes, that a particular interface can handle.

NMS --network management system. System responsible for managing at least part of a network. An NMS is generally a reasonably powerful and well-equipped computer, such as an engineering workstation. NMSs communicate with agents to help keep track of network statistics and resources.



OID --object identifier. Values are defined in specific MIB modules. The Event MIB allows you or an NMS to watch over specified objects and to set event triggers based on existence, threshold, and Boolean tests. An event occurs when a trigger is fired; this means that a specified test on an object returns a value of true. To create a trigger, you or a network management system (NMS) configures a trigger entry in the mteTriggerTable of the Event MIB. This trigger entry specifies the OID of the object to be watched. For each trigger entry type, corresponding tables (existence, threshold, and Boolean tables) are populated with the information required for carrying out the test. The MIB can be configured so that when triggers are activated (fired) either a Simple Network Management Protocol (SNMP) Set is performed, a notification is sent out to the interested host, or both.

SNMP --Simple Network Management Protocol. A management protocol used almost exclusively in TCP/IP networks. SNMP provides a means for monitoring and controlling network devices, and for managing configurations, statistics collection, performance, and security.

traffic engineering tunnel--A label-switched tunnel that is used for traffic engineering. Such a tunnel is set up through means other than normal Layer 3 routing; it is used to direct traffic over a path different from the one that Layer 3 routing could cause the tunnel to take.

trap --A message sent by a Simple Network Management Protocol (SNMP) agent to a network management station, console, or terminal, indicating that a significant event occurred. Traps are less reliable than notification requests, because the receiver does not send an acknowledgment when it receives a trap. The sender cannot determine if the trap was received.

tunnel --A secure communication path between two peers, such as routers.

CHAPTER 9

MPLS Label Switching Router MIB

The MPLS Label Switching Router MIB (MPLS-LSR-MIB) allows you to use the Simple Network Management Protocol (SNMP) to remotely monitor a label switch router (LSR) that is using the Multiprotocol Label Switching (MPLS) technology.

Scalability enhancements provided in the Cisco IOS 12.0(28)S release reduce the size of any MIB walk and improve the usability of the MPLS-LSR-MIB.

Note In Cisco IOS Release 12.2(33)SRB and Cisco IOS Release 12.2(33)SB, this MIB has been deprecated and replaced by MPLS-LSR-STD-MIB (RFC 3813). In those two releases and in later images, the entire MIB can be referenced by the name mplsLsrMIB for purposes of the SNMP server excluded/included command. If other MIB object names need to be referenced on the router, they must be referenced by MPLS-LSR-MIB::<table_entry_name>.

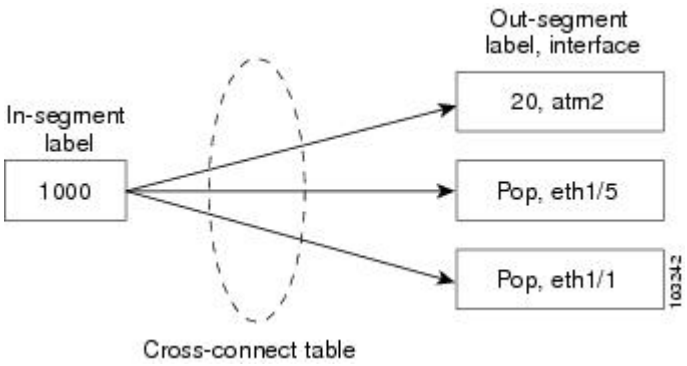
- Configuration Examples for the MPLS LSR MIB, on page 115
- Additional References, on page 116
- Feature Information for MPLS Label Switching Router MIB, on page 117
- Glossary, on page 119

Information About MPLS Label Switching Router MIB



The MPLS-LSR-MIB contains managed objects that support the retrieval of label switching information from a router. The MIB is based on Revision 05 of the IETF MPLS-LSR-MIB. The MPLS-LSR-MIB mirrors a portion of the Cisco MPLS subsystem; specifically, it mirrors the Label Forwarding Information Base (LFIB). This implementation enables a network administrator to get information on the status, character, and performance of the following:

- MPLS-capable interfaces on the LSR
- Incoming MPLS segments (labels) at an LSR and their associated parameters
- Outgoing segments (labels) at an LSR and their associated parameters

In addition, the network administrator can retrieve the status of cross-connect table entries that associate MPLS segments with each other.

The figure below shows the association of the cross-connect table with incoming and outgoing segments (labels).

Figure 9: Label Forwarding with the Cross-Connect Table

Note The out-segment table does not display “no label” entries. Labels that are displayed as “POP” are the special MPLS label 3.

The notation used in the MPLS-LSR-MIB follows the conventions defined in Abstract Syntax Notation One (ASN.1). ASN.1 defines an Open System Interconnection (OSI) language used to describe data types apart from particular computer structures and presentation techniques. Each object in the MIB incorporates a DESCRIPTION field that includes an explanation of the object’s meaning and usage, which, together with the other characteristics of the object (SYNTAX, MAX-ACCESS, and INDEX) provides sufficient information for management application development, as well as for documentation and testing.

The MPLS-LSR-MIB represents an ASN.1 notation reflecting an idealized MPLS LSR.

A network administrator can access the entries (objects) in the MPLS-LSR-MIB by means of any SNMP-based network management system (NMS). The network administrator can retrieve information in the MPLS-LSR-MIB using standard SNMP **get** and **getnext** operations.

Typically, SNMP runs as a low-priority process. The response time for the MPLS-LSR-MIB is expected to be similar to that for other MIBs. The size and structure of the MIB and other MIBs in the system influence response time when you retrieve information from the management database. Traffic through the LSR also affects SNMP performance. The busier the switch is with forwarding activities, the greater the possibility of lower SNMP performance.

MPLS-LSR-MIB Elements

The top-level components of the MPLS-LSR-MIB consist of

- Tables and scalars (mplsLsrObjects)
- Traps (mplsLsrNotifications and mplsLsrNotifyPrefix)
- Conformance (mplsLsrConformance)

This Cisco implementation does not support the notifications defined in the MIB, nor does it support the labelStackTable or the trafficParamTable.

MPLS-LSR-MIB Tables

The Cisco implementation of the MPLS-LSR-MIB supports four main tables:

- Interface configuration
- In-segment
- Out-segment
- Cross-connect

The MIB contains three supplementary tables to supply performance information. This implementation does not support the label stack and traffic parameter tables.

The following sections list the MPLS-LSR-MIB tables (main and supplementary), their functions, table objects that are supported, and table objects that are *not* supported.

MPLS interface configuration table (mplsInterfaceConfTable)

Provides information for each MPLS-capable interface on an LSR.

Supports:

- A unique interface index or zero
- Minimum and maximum values for an MPLS label received on the interface
- Minimum and maximum values for an MPLS label sent from the interface
- A value for an MPLS label sent from the interface
- Per platform (0) or per interface (1) setting
- The storage type

Does not support:

- The total usable bandwidth on the interface
- The difference between the total usable bandwidth and the bandwidth in use

MPLS interface performance table (mplsInterfacePerfTable)

Augments the MPLS interface configuration table.

Supports:

- The number of labels in the incoming direction in use
- The number of top-most labels in outgoing label stacks in use

Does not support:

- The number of top-most labels in outgoing label stacks in use
- The number of labeled packets discarded because no cross-connect entries exist

- The number of outgoing MPLS packets requiring fragmentation for transmission

MPLS in-segment table (mplsInSegmentTable)

Contains a description of incoming segments (labels) at an LSR and their associated parameters.

Administrative and operational status objects for this table control packet transmission. If administrative and operational status objects are down, the LSR does not forward packets. If these status objects are up, the LSR forwards packets.

Supports:

- A unique index identifier
- The incoming label
- The number of labels to pop from the incoming segment
- An address family number from the Internet Assigned Number Authority (IANA)
- A segment cross-connect entry association
- The segment owner
- The storage type
- The administrative status
- The operational status

Note The administrative status and operational status are always up for inSegments in the Cisco implementation. Otherwise, these entries do not appear in the table.

Does not support:

- A pointer to a traffic parameter table entry (set to the default 0.0)

MPLS in-segment performance table (mplsInSegmentPerfTable)

Augments the MPLS in-segment table, providing performance information and counters for incoming segments on an LSR.

Supports:

- The number of 32-bit octets received
- The number of 64-bit octets received
- The time of the last system failure that corresponded to one or more incoming segment discontinuities

Note The lastFailure parameter is set to zero because it has no meaning in the Cisco implementation.

Does not support:

- The total number of packets received
- The number of packets with errors
- The number of labeled packets discarded with no errors

MPLS out-segment table (mplsOutSegmentTable)

Contains a description of outgoing segments from an LSR and their associated parameters.

Administrative and operational status objects for this table control packet transmission. If administrative and operational status objects are down, the LSR does not forward packets. If these values are up, the LSR forwards packets.

Supports:

- A unique index identifier
- An interface index of the outgoing interface
- An indication of whether or not a top label is pushed onto the outgoing packet's label stack
- The label to push onto the outgoing packet's label stack (if the previous value is true)
- The next hop address type
- The IPv4 address of the next hop
- The segment cross-connect entry association
- The segment owner
- The storage type
- The administrative status
- The operational status

Note The administrative and operational status entries are always up in the Cisco implementation. Otherwise, the administrative and operational status entries do not appear in the table.

Does not support:

- An IPv6 address of the next hop
- A pointer to a traffic parameter table entry (set to the default 0.0)

MPLS out-segment performance table (mplsOutSegmentPerfTable)

Augments the MPLS out-segment table, providing performance information and counters for outgoing segments on an LSR.

Supports:

- The number of 32-bit octets sent
- The number of 64-bit octets sent

- The time of the last system failure that corresponded to one or more outgoing segment discontinuities

Does not support:

- The number of packets sent
- The number of packets that could not be sent because of errors
- The number of packets discarded with no errors

MPLS cross-connect table (mplsXCTable)

Associates inSegments (labels) with outSegments (labels) to show the manager how the LSR is currently swapping these labels.

A row in this table consists of one cross-connect entry that is indexed by the cross-connect index, the interface index of the incoming segment, the incoming label, and the out-segment index.

The administrative and operational objects for this table control packet forwarding to and from a cross-connect entry (XCEntry). The administrative status and operational status are always up in the Cisco implementation. Otherwise, the LSR would not forward packets.

Supports:

- A unique index identifier for a group of cross-connect segments
- A label switched path (LSP) to which the cross-connect entry belongs
- An index to the MPLS label stack table that identifies the stack of labels to be pushed under the top label
- An indication whether or not to restore the cross-connect entry after a failure (the default value is false)
- The cross-connect owner
- The storage type
- The administrative status (if up)
- The operational status (if up)

Note The administrative status and operational status are always up in the Cisco implementation. Otherwise, these status entries do not appear in the table.

Does not support:

- Tunnel IDs as label switched path (LSP) ID objects

Information from Scalar Objects

The MPLS-LSR-MIB supports several scalar objects. In the Cisco implementation of the MIB, the following scalar objects are hard-coded to the value indicated and are read-only objects:

- mplsOutSegmentIndexNext (0)--The value for the out-segment index when an LSR creates a new entry in the MPLS out-segment table. The 0 indicates that this is not implemented because modifications to this table are not allowed.

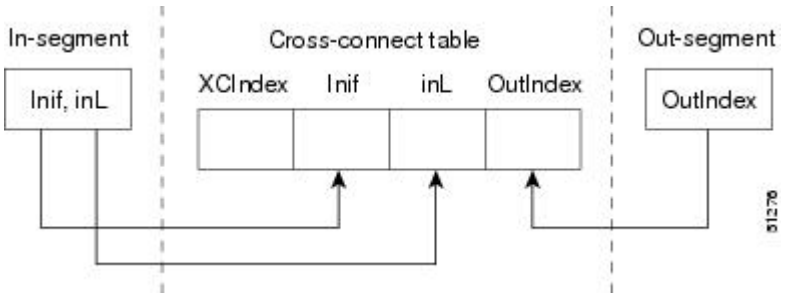
- mplsXCTIndexNext (0)--The value for the cross-connect index when an LSR creates an entry in the MPLS cross-connect table. The 0 indicates that no unassigned values are available.
- mplsMaxLabelDepth(2)--The value for the maximum stack depth.
- mplsLabelStackIndexNext (0)--The value for the label stack index when an LSR creates entries in the MPLS label stack table. The 0 indicates that no unassigned values are available.
- mplsTrafficParamIndexNext (0)--The value for the traffic parameter index when an LSR creates entries in the MPLS traffic parameter table. The 0 indicates that no unassigned values are available.

The following scalar objects do not contain information for the MPLS-LSR-MIB and are coded as false:

- mplsInSegmentTrapEnable (false)--In-segment traps are not sent when this value is false.
- mplsOutSegmentTrapEnable (false)--Out-segment traps are not sent when this value is false.
- mplsXCTrapEnable (false)--Cross-connect traps are not sent when this value is false.

No trap information exists to support the MIB. Therefore, the following traps are not supported:

- mplsInSegmentUp
- mplsInSegmentDown
- mplsOutSegmentUp
- mplsOutSegmentDown
- mplsXCUp
- mplsXCDown



Linking Table Elements

In the cross-connect table, cross-connect entries associate incoming segments and interfaces with outgoing segments and interfaces. The following objects index the cross-connect entry:

- Cross-connect index--A unique identifier for a group of cross-connect entries in the cross-connect table. In the Cisco implementation, this value is always the same as that for the outSegmentIndex, unless there is no label or if the label has been popped.
- Interface index of the in-segment--A unique index for an entry in the in-segment table that represents an incoming MPLS interface. The value 0 means platform wide, for any entries that apply to all interfaces.
- Incoming label--An entry in the in-segment table that represents the label on the incoming packet.
- Out-segment index--A unique identifier for an entry in the out-segment table that contains a top label for the outgoing packet's label stack and an interface index of the outgoing interface.

The figure below shows the links between the in-segment and the out-segment in the cross-connect table.

Figure 10: Cross-Connect Table Links

The table below shows the cross-connect table links you might see in the output from SNMP **get** operations on the MPLS-LSR-MIB objects that index a cross-connect entry. These objects include

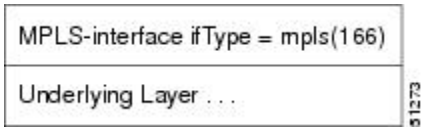
- In-Segment Values--mplsInSegmentIfIndex and mplsInSegmentLabel
- Cross-Connect Entry--mplsXCIndex
- Out-Segment Values--mplsOutSegmentIndex

Table 12: MPLS LSR Output Showing Cross-Connect Table Links

In-Segment Values	Cross-Connect Entry	Out-Segment Values
0[1], 1000	500[2], 0, 1000, 0	--
	501, 0, 1000, 501	501 = Pop (topLabel), Eth 1/5
	502, 0, 1000, 502	502 = Pop (topLabel), Eth, 1/1

1 All MPLS-enabled interfaces can receive incoming labels.
2 For this implementation of the MPLS-LSR-MIB, the cross-connect index and the out-segment index are the same. If there is no outsegment, the value will be zero.

Note The OutSegmentIndex object is not the label. The label can be retrieved from the mplsOutSegmentTopLabel object.



Interface Configuration Table and Interface MIB Links

The MPLS interface configuration table lists interfaces that support MPLS technology. An LSR creates an entry dynamically in this table for each MPLS-capable interface. An interface becomes MPLS-capable when MPLS is enabled on that interface. A non-zero index for an entry in this table points to the ifIndex for the corresponding interface entry in the MPLS-layer in the ifTable of the Interfaces Group MIB.

The ifTable contains information on each interface in the network. Its definition of an interface includes any sublayers of the internetwork layer of the interface. MPLS interfaces fit into this definition of an interface. Therefore, each MPLS-enabled interface is represented by an entry in the ifTable.

The interrelation of entries in the ifTable is defined by the interfaces stack group of the Interfaces Group MIB. The figure below shows how the stack table might appear for MPLS interfaces. The underlying layer refers to any interface that is defined for MPLS internetworking, for example, ATM, Frame Relay, or Ethernet.

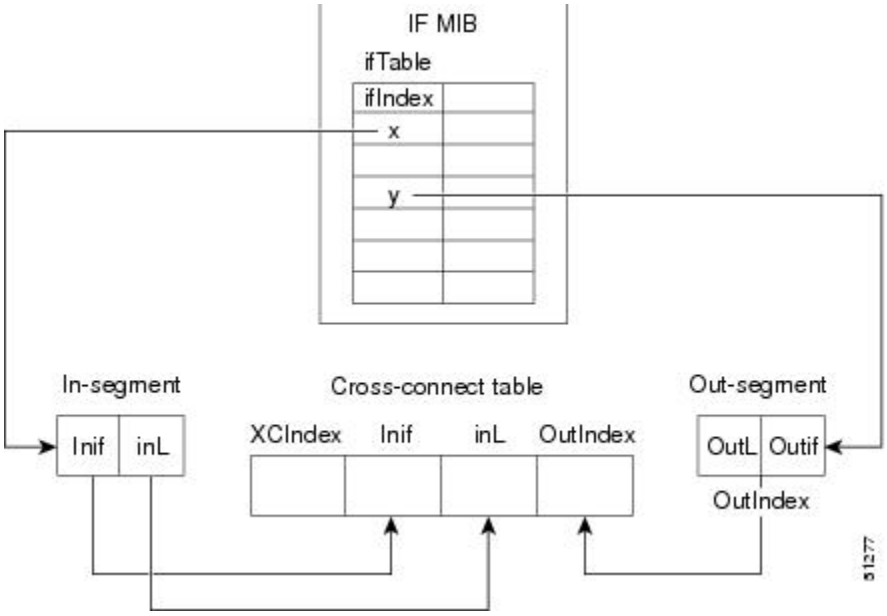


Figure 11: Interface Group MIB Stack Table for MPLS Interfaces

Note Tunnel interfaces are included in the MPLS list for the current implementation.

The incoming and outgoing packets include a reference to the interface index for the ifTable of the Interfaces Group MIB. The figure below shows the links between MPLS-LSR-MIB objects and the Interfaces Group MIB.

Figure 12: MPLS-LSR-MIB and Interfaces Group MIB Links

- For the Interfaces Group MIB (IF MIB):
  - ifTable represents the MPLS interface table.
  - ifIndex represents the index to an entry in the MPLS interface table.
- For the In-segment:
  - Inif represents the interface on the incoming segment (references an index entry in the ifTable).
  - inL represents the label on the incoming segment.
- For the Out-segment:
  - OutL represents the label on the outgoing segment.
  - Outif represents the interface on the outgoing segment (references an index entry in the ifTable).

- For the Cross-connect table:
  - XCIndex represents the index to an entry in the MPLS cross-connect table.
  - Inif represents the interface on the incoming segment.
  - inL represents the MPLS label on the incoming segment.
  - OutIndex represents an index to an entry in the MPLS out-segment table.

Using the MPLS-LSR-MIB

The MPLS-LSR-MIB enables you to display the contents of the MPLS Label Forwarding Information Base (LFIB). It gives you the same information that you can obtain using the CLI command **show mpls forwarding-table**.

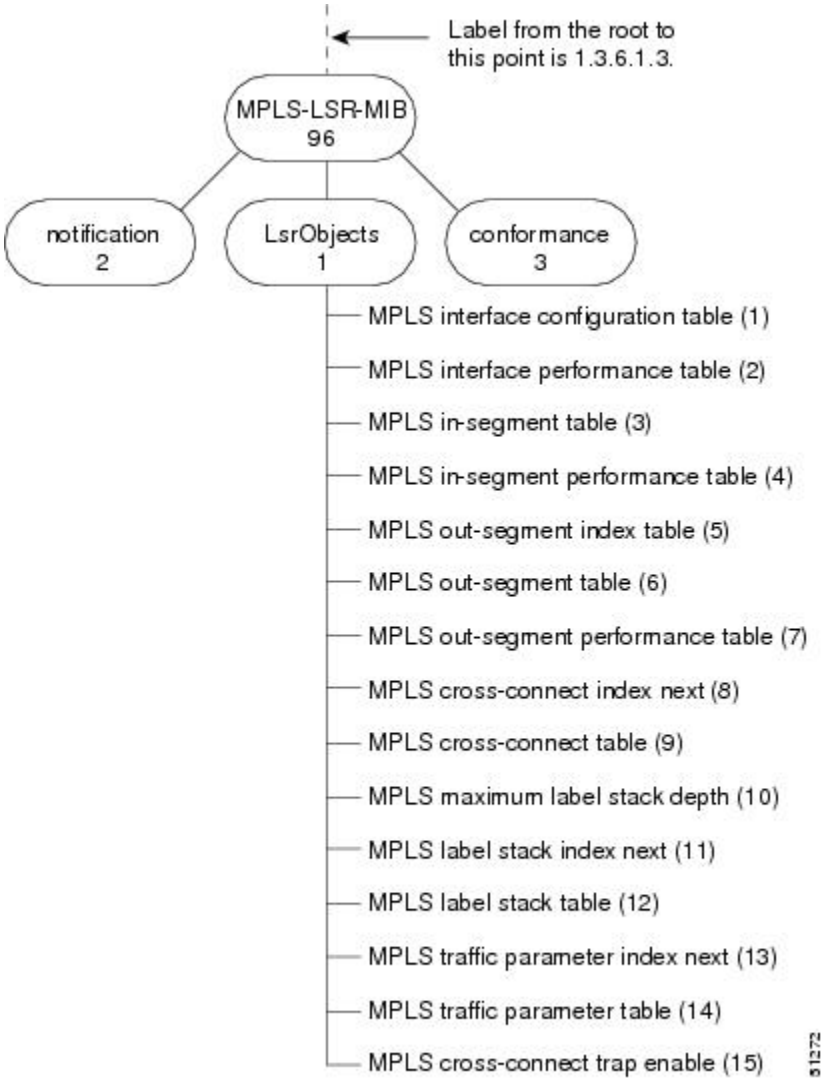
However, the MPLS-LSR-MIB approach offers these advantages over the CLI command approach:

- A more efficient use of network bandwidth
- Greater interoperability among vendors
- Greater security (SMNP Version 3)

The following paragraphs describe the MPLS-LSR-MIB structure and show, through the use of an example, how the two approaches to the information display compare.

MPLS-LSR-MIB Structure

MIB structure is represented by a tree hierarchy. Branches along the tree have short text strings and integers to identify them. Text strings describe object names, and integers allow computer software to encode compact representations of the names.



The MPLS-LSR-MIB falls on the experimental branch of the Internet MIB hierarchy. The experimental branch of the Internet MIB hierarchy is represented by the object identifier 1.3.6.1.3. This branch can also be represented by its object name *iso.org.dod.internet.experimental* . The MPLS-LSR-MIB is identified by the object name *mplsLsrMIB* , which is denoted by the number 96. Therefore, objects in the MPLS-LSR-MIB can be identified in either of the following ways:

- The object identifier--1.3.6.1.3.96.[MIB-variable]
- The object name--*iso.org.dod.internet.experimental.mplsLsrMIB.[MIB-variable]*

To display a *MIB-variable* , you enter an SNMP **get** command with an object identifier. Object identifiers are defined by the MPLS-LSR-MIB.

The figure below shows the position of the MPLS-LSR-MIB in the Internet MIB hierarchy.

Figure 13: MPLS-LSR-MIB in the Internet MIB Hierarchy

CLI Commands and the MPLS-LSR-MIB

The MPLS LFIB is the component of the Cisco MPLS subsystem that contains management information for LSRs. You can access this management information by means of either of the following:

- Using the **show mpls forwarding-table** CLI command
- Entering SNMP **get** commands on a network manager

The following examples show how you can gather LSR management information using both methods.

CLI Command Output

A **show mpls forwarding-table** CLI command allows you to look at label forwarding information for a packet on a specific MPLS LSR.

```
Router# show mpls forwarding-table
Local  Outgoing      Prefix            Bytes Tag     Outgoing   Next Hop
Tag    Tag or VC     or Tunnel Id      Switched      interface
19     Pop Tag       10.3.4.0/24       0             Et1/4      10.22.23.23
22     23            14.14.14.14/32    0             AT2/0.1    point2point
       1/36          14.14.14.14/32    0             AT2/0.2    point2point
```

MPLS-LSR-MIB Output

SNMP commands on MIB objects also allow you to look at the label forwarding information for a specific MPLS LSR.

You can do a walk-through of the MIB by running a command such as **getmany -v2c public mplsLsrMIB** on a network manager where **getmany** does repeated SNMP **getnext** operations to retrieve the contents of the MPLS-LSR-MIB.

```
mplsXCOperStatus.9729.0.19.9729 = up(1)
mplsXCOperStatus.11265.0.22.11265 = up(1)
mplsXCOperStatus.11266.0.22.11266 = up(1)
```

You can continue to scan the output of the **getmany** command for the following (from the MPLS out-segment table):

- Out-segment's top label objects (mplsOutSegmentTopLabel)

```
mplsOutSegmentTopLabel.9729 = 3
mplsOutSegmentTopLabel.11265 = 23
mplsOutSegmentTopLabel.11266 = 65572
```

Note 65572 is 1/36 in label form (1 is the high-order 16 bits. 36 is the low-order 16 bits.)

- Out-segment's interface index (mplsOutSegmentIfIndex)

```
mplsOutSegmentIfIndex.9729 = 7
mplsOutSegmentIfIndex.11265 = 28
mplsOutSegmentIfIndex.11266 = 31
```

Benefits

The benefits described in the following paragraphs are available to you with the MPLS-LSR-MIB.

Troubleshooting LSR Problems

By monitoring the cross-connect entries and the associated incoming and outgoing segments, you can see which labels are installed and how they are being swapped. Use the MPLS-LSR-MIB in place of the **show mpls forwarding** CLI command.

Monitoring of LSR Traffic Loads

By monitoring interface and packet operations on an MPLS LSR, you can identify high- and low-traffic patterns, as well as traffic distributions.

Improvement of Network Performance

By identifying potentially high-traffic areas, you can set up load sharing to improve network performance.

Verification of LSR Configuration

By comparing results from SNMP **get** commands and the **show mpls forwarding** CLI command, you can verify your LSR configuration.

Displaying of Active Label Switched Paths

By monitoring the cross-connect entries and the associated incoming segments and outgoing segments, you can determine the active LSPs.

How to Configure the MPLS LSR MIB

Prerequisites

The MPLS-LSR-MIB requires the following:

- SNMP installed and enabled on the LSR
- MPLS enabled on the LSR
- 60K of memory

Note Additional capacity is not required for runtime dynamic random-access memory (DRAM).

Enabling the SNMP Agent

The SNMP agent for the MPLS-LSR-MIB is disabled by default. To enable the SNMP agent, perform the following steps:

SUMMARY STEPS

1. **enable**
2. show running-config
3. **configure terminal**
4. **snmp-server community** *string* [**view** *view-name*] [**ro**] [*number*]
5. **end**
6. copy running-config startup-config

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	show running-config **Example:** `Router# show running-config`	Displays the running configuration of the router to determine if an SNMP agent is already running on the device. If no SNMP information is displayed, continue with the next step. If any SNMP information is displayed, you can modify the information or change it as desired.
Step 3	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 4	**snmp-server community** *string* [**view** *view-name*] [**ro**] [*number*] **Example:** `Router(config)# snmp-server community public ro`	Configures read-only (ro) SNMP community strings. This command enables the SNMP agent and permits any SNMP manager to access all objects with read-only permission using the community string public.
Step 5	**end** **Example:** `Router(config)# end`	Exits to privileged EXEC mode.
Step 6	copy running-config startup-config **Example:** `Router# copy running-config startup-config`	Copies the modified SNMP configuration into router NVRAM, permanently saving the SNMP settings. When you are working with Cisco IOS Release 10.3 or earlier, use the **write memory** command.

Verifying That the SNMP Agent Has Been Enabled

To verify that the SNMP agent has been enabled, perform the following steps:

SUMMARY STEPS

1. Access the router through a Telnet session:
2. Enter privileged mode:

3. Display the running configuration and look for SNMP information:

DETAILED STEPS

Procedure

Step 1 Access the router through a Telnet session:

Example:

```
Prompt# telnet xxx.xxx.xxx.xxx
```

where *xxx.xxx.xxx.xxx* represents the IP address of the target device.

Step 2 Enter privileged mode:

Example:

```
Router# enable
```

Step 3 Display the running configuration and look for SNMP information:

Example:

```
Router# show running-configuration
...
...
snmp-server community public RO
```

If you see any "snmp-server" statements, SNMP has been enabled on the router.

Configuration Examples for the MPLS LSR MIB

The following example shows how to enable an SNMP agent.

```
configure terminal
snmp-server community
```

In the following example, SNMPv1 and SNMPv2C are enabled. The configuration permits any SNMP manager to access all objects with read-only permissions using the community string *public* .

```
configure terminal
snmp-server community public
```

In the following example, read-only access is allowed for all objects to members of access list 4 that specify the *comaccess* community string. No other SNMP managers have access to any objects.

```
configure terminal
nmp-server community comaccess ro 4
```

Feature Information for MPLS Label Switching Router MIB

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 13: Feature Information for MPLS Label Switching Router MIB

Feature Name	Releases	Feature Information
MPLS Label Switching Router MIB	12.0(14)ST 12.2(2)T 12.0(22)S 12.2(14)S 12.2(25)S 12.0(28)S 12.2(33)SRB 12.2(33)SB	The MPLS Label Switching Router MIB (MPLS-LSR-MIB) allows you to use the Simple Network Management Protocol (SNMP) to remotely monitor a label switch router (LSR) that is using the Multiprotocol Label Switching (MPLS) technology. This feature was introduced on Cisco IOS Release 12.0(14)ST. This feature was integrated into Cisco IOS Release 12.2(2)T. This feature was implemented on the Cisco 12000 series routers and integrated into Cisco IOS Release 12.0(22)S. This feature was integrated into Cisco IOS Release 12.2(14)S and implemented on Cisco 7200 and Cisco 7500 series routers. This feature was updated to include scalability enhancements in Cisco IOS Release 12.0(28)S. In Cisco IOS Release 12.2(25)S, this feature was updated to work in the MPLS High Availability environment with the Cisco 7500 series routers. In Cisco IOS Release 12.2(33)SRB, this MIB has been deprecated and replaced by MPLS-LSR-STD-MIB (RFC 3813). In Cisco IOS Release 12.2(33)SB, this MIB has been deprecated and replaced by MPLS-LSR-STD-MIB (RFC 3813). No commands were introduced or modified.

Glossary

cross-connect (XC) --An association of in-segments and incoming Multiprotocol Label Switching (MPLS) interfaces to out-segments and outgoing MPLS interfaces.

IETF --Internet Engineering Task Force. A task force (consisting of more that 80 working groups) that is developing standards for the Internet and the IP suite of protocols.

inSegment --A label on an incoming packet that is used to determine the forwarding of the packet.

Internet Engineering Task Force --See IETF.

label --A short, fixed length identifier that is used to determine the forwarding of a packet.

Label Distribution Protocol --See LDP.

label switched path --See LSP.

label switching --Describes the forwarding of IP (or other network layer) packets by a label swapping algorithm based on network layer routing algorithms. The forwarding of these packets uses the exact match algorithm and rewrites the label.

label switch router --See LSR.

LDP --Label Distribution Protocol. A standard protocol that operates between Multiprotocol Label Switching (MPLS)-enabled routers to negotiate the labels (addresses) used to forward packets. The Cisco proprietary version of this protocol is the Tag Distribution Protocol (TDP).

LSP --label switched path. A sequence of hops in which a packet travels from one router to another router by means of label switching mechanisms. A label switched path can be established dynamically, based on normal routing mechanisms, or through configuration.

LSR --label switch router. A device that forwards Multiprotocol Label Switching (MPLS) packets based on the value of a fixed-length label encapsulated in each packet.

Management Information Base --See MIB.

MIB --Management Information Base. A database of network management information that is used and maintained by a network management protocol such as Simple Network Management Protocol (SNMP). The value of a MIB object can be changed or retrieved by means of SNMP commands, usually through a network management system. MIB objects are organized in a tree structure that includes public (standard) and private (proprietary) branches.

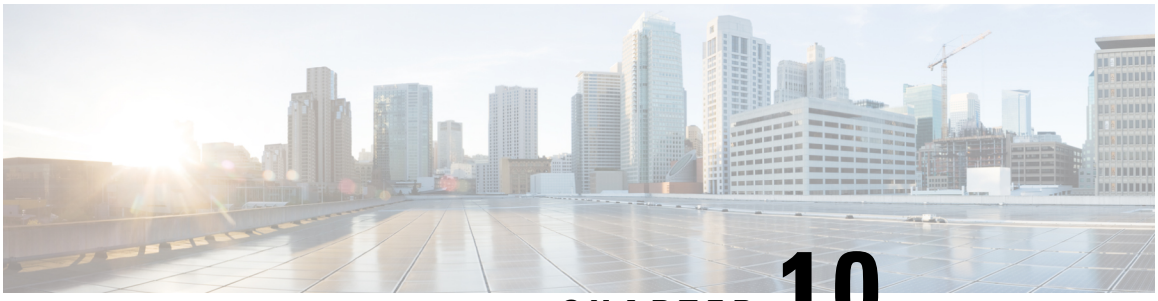
MPLS --Multiprotocol Label Switching. A switching method that forwards IP traffic through use of a label. This label instructs the routers and the switches in the network where to forward the packets. The forwarding of MPLS packets is based on preestablished IP routing information.

MPLS interface --An interface on which Multiprotocol Label Switching (MPLS) traffic is enabled.

Multiprotocol Label Switching --See MPLS.

notification request --A message sent by a Simple Network Management Protocol (SNMP) agent to a network management station, console, or terminal, indicating that a significant event occurred. SNMP notification requests are more reliable than traps, because a notification request from an SNMP agent requires that the SNMP manager acknowledge receipt of the notification request. The manager replies with an SNMP response protocol data unit (PDU). If the manager does not receive a notification message from an SNMP agent, it does not send a response. If the sender (SNMP agent) never receives a response, the notification request can be sent again.

outSegmen t--A label on an outgoing packet.



Simple Network Management Protocol --See SNMP.

SNMP --Simple Network Management Protocol. A management protocol used almost exclusively in TCP/IP networks. SNMP provides a means for monitoring and controlling network devices, and for managing configurations, statistics collection, performance, and security.

trap --A message sent by a Simple Network Management Protocol (SNMP) agent to a network management station, console, or terminal, indicating that a significant event occurred. Traps are less reliable than notification requests, because the receiver does not send an acknowledgment when it receives a trap. The sender cannot determine if the trap was received.

Note Refer to the Cisco Dictionary of Internetworking Terms and Acronyms for terms not included in this glossary.

CHAPTER 10

MPLS LSP Ping Traceroute for LDP TE and LSP Ping for VCCV

The MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV feature helps service providers monitor label switched paths (LSPs) and quickly isolate Multiprotocol Label Switching (MPLS) forwarding problems.

The feature provides the following capabilities:

- MPLS LSP ping to test LSP connectivity for IPv4 Label Distribution Protocol (LDP) prefixes, Resource Reservation Protocol (RSVP) traffic engineering (TE), and Any Transport over MPLS (AToM) forwarding equivalence classes (FECs).
- MPLS LSP traceroute to trace the LSPs for IPv4 LDP prefixes and RSVP TE prefixes.

- Prerequisites for MPLS LSP Ping Traceroute for LDP TE and LSP Ping for VCCV, on page 121
- Restrictions for MPLS LSP Ping Traceroute for LDP TE and LSP Ping for VCCV, on page 122
- Information About MPLS LSP Ping Traceroute for LDP TE and LSP Ping for VCCV, on page 123
- How to Configure MPLS LSP Ping Traceroute for LDP TE and LSP Ping for VCCV, on page 133
- Configuration Examples for MPLS LSP Ping Traceroute for LDP TE and LSP Ping for VCCV, on page 150
- Additional References, on page 176
- Feature Information for MPLS LSP Ping Traceroute for LDP TE and LSP Ping for VCCV, on page 176
- Glossary, on page 177

Prerequisites for MPLS LSP Ping Traceroute for LDP TE and LSP Ping for VCCV

Before you use the MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV feature, you should:

- Determine the baseline behavior of your MPLS network. For example:
  - Expected MPLS experimental (EXP) treatment.
  - Expected maximum size packet or maximum transmission unit (MTU) of the LSP.
  - The topology, expected label switched path, and number of links in the LSP. Trace the paths of the label switched packets including the paths for load balancing.
- Understand how to use MPLS and MPLS applications. You need to:

- Know how LDP is configured.
- Understand AToM concepts.

- Understand label switching, forwarding, and load balancing.

Before using the **ping mpls** or **trace mpls** command, you must ensure that the router is configured to encode and decode MPLS echo packets in a format that all receiving routers in the network can understand.

Restrictions for MPLS LSP Ping Traceroute for LDP TE and LSP Ping for VCCV

- You cannot use MPLS LSP traceroute to trace the path taken by AToM packets. MPLS LSP traceroute is not supported for AToM. (MPLS LSP ping is supported for AToM.) However, you can use MPLS LSP traceroute to troubleshoot the Interior Gateway Protocol (IGP) LSP that is used by AToM.
- You cannot use MPLS LSP ping to validate or trace MPLS Virtual Private Networks (VPNs).
- You cannot use MPLS LSP traceroute to troubleshoot LSPs that employ time-to-live (TTL) hiding.
- MPLS supports per-destination and per-packet (round robin) load balancing. If per-packet load balancing is in effect, you should not use MPLS LSP traceroute because LSP traceroute at a transit router consistency checks the information supplied in the previous echo response from the directly connected upstream router. When round robin is employed, the path that an echo request packet takes cannot be controlled in a way that allows a packet to be directed to TTL expire at a given router. Without that ability, the consistency checking may fail during an LSP traceroute. A consistency check failure return code may be returned.
- A platform must support LSP ping and traceroute in order to respond to an MPLS echo request packet.
- Unless the MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV feature is enabled along the entire path, you cannot get a reply if the request fails along the path at any node.
- There are certain limitations when a mixture of draft versions are implemented within a network. The version of the draft must be compatible with Cisco's implementation. Due to the way the LSP Ping draft was written, earlier versions may not be compatible with later versions because of changes to type, length, values (TLVs) formats without sufficient versioning information. Cisco attempts to compensate for this in its implementations by allowing the sending and responding routers to be configured to encode and decode echo packets assuming a certain version.
- If you want to use MPLS LSP traceroute, the network should not use TTL hiding.

Information About MPLS LSP Ping Traceroute for LDP TE and LSP Ping for VCCV

MPLS LSP Ping Traceroute for LDP TE and LSP Ping for VCCV Functionality

Internet Control Message Protocol (ICMP) ping and traceroute are often used to help diagnose the root cause when a forwarding failure occurs. However, they are not well suited for identifying LSP failures because an ICMP packet can be forwarded via IP to the destination when an LSP breakage occurs.

The MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV feature is well suited for identifying LSP breakages for the following reasons:

- An MPLS echo request packet cannot be forwarded via IP because IP TTL is set to 1 and the IP destination address field is set to a 127/8 address.
- The FEC being checked is not stored in the IP destination address field (as is the case of ICMP).

MPLS echo request and reply packets test LSPs. There are two methods by which a downstream router can receive packets:

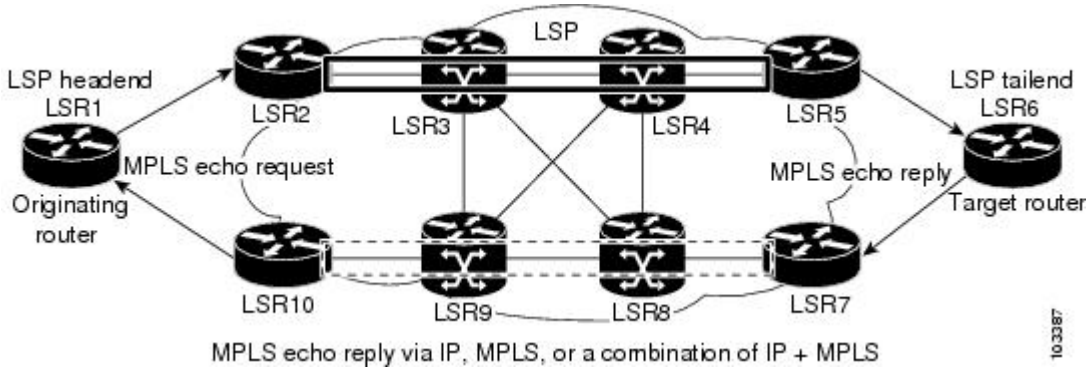
- The Cisco implementation of MPLS echo request and echo reply that was previously based on the Internet Engineering Task Force (IETF) Internet Draft Detecting MPLS Data Plane Failures (draft-ietf-mpls-lsp-ping-03.txt).
- Features described in this document that are based on the IETF RFC 4379 Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures :
  - Echo request output interface control
  - Echo request traffic pacing
  - Echo request end-of-stack explicit-null label shimming
  - Echo request request-dsmap capability
  - Request-fec checking
  - Depth limit reporting

MPLS LSP Ping Operation

MPLS LSP ping uses MPLS echo request and reply packets to validate an LSP. You can use MPLS LSP ping to validate IPv4 LDP, AToM, and IPv4 RSVP FECs by using appropriate keywords and arguments with the **ping mpls**command.

The MPLS echo request packet is sent to a target router through the use of the appropriate label stack associated with the LSP to be validated. Use of the label stack causes the packet to be forwarded over the LSP itself.

The destination IP address of the MPLS echo request packet is different from the address used to select the label stack. The destination IP address is defined as a 127.*x* .*y* .*z* /8 address. The 127.*x* .*y* .*z* /8 address prevents the IP packet from being IP switched to its destination if the LSP is broken.



An MPLS echo reply is sent in response to an MPLS echo request. The reply is sent as an IP packet and it is forwarded using IP, MPLS, or a combination of both types of switching. The source address of the MPLS

echo reply packet is an address obtained from the router generating the echo reply. The destination address is the source address of the router that originated the MPLS echo request packet.

The MPLS echo reply destination port is set to the echo request source port.

The figure below shows MPLS LSP ping echo request and echo reply paths.

Figure 14: MPLS LSP Ping Echo Request and Echo Reply Paths

If you initiate an MPLS LSP ping request at LSR1 to a FEC at LSR6, you get the results shown in the table below.

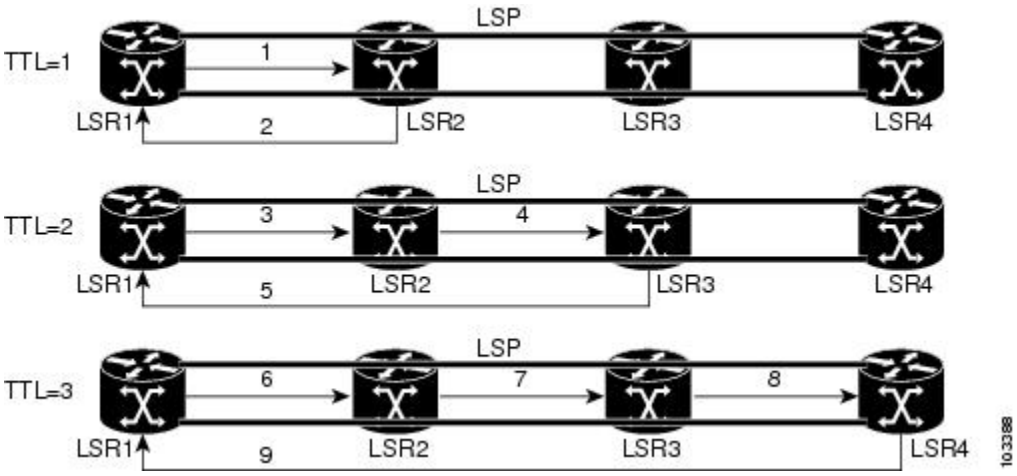
Table 14: MPLS LSP Ping Example

Step	Router	Action
1.	LSR1	Initiates an MPLS LSP ping request for an FEC at the target router LSR6 and sends an MPLS echo request to LSR2.
2.	LSR2	Receives the MPLS echo request packet and forwards it through transit routers LSR3 and LSR4 to the penultimate router LSR5.
3.	LSR5	Receives the MPLS echo request, pops the MPLS label, and forwards the packet to LSR6 as an IP packet.
4.	LSR6	Receives the IP packet, processes the MPLS echo request, and sends an MPLS echo reply to LSR1 through an alternate route.
5.	LSR7 to LSR10	Receives the MPLS echo reply and forwards it back toward LSR1, the originating router.
6.	LSR1	Receives the MPLS echo reply in response to its MPLS echo request.

MPLS LSP Traceroute Operation

MPLS LSP traceroute uses MPLS echo request and reply packets to validate an LSP. You can use MPLS LSP traceroute to validate IPv4 LDP and IPv4 RSVP FECs by using appropriate keywords and arguments with the **trace mpls** command.

The MPLS LSP Traceroute feature uses TTL settings to force expiration of the TTL along an LSP. MPLS LSP Traceroute incrementally increases the TTL value in its MPLS echo requests (TTL = 1, 2, 3, 4) to discover the downstream mapping of each successive hop. The success of the LSP traceroute depends on the transit



router processing the MPLS echo request when it receives a labeled packet with a TTL = 1. On Cisco routers, when the TTL expires, the packet is sent to the Route Processor (RP) for processing. The transit router returns an MPLS echo reply containing information about the transit hop in response to the TTL-expired MPLS packet.

The MPLS echo reply destination port is set to the echo request source port.

Note When a router traces an IPV4 FEC that goes over a traffic engineering tunnel, intermediate routers may return U (unreachable) if LDP is not running in those intermediate routers.

The figure below shows an MPLS LSP traceroute example with an LSP from LSR1 to LSR4.

Figure 15: MPLS LSP Traceroute Example

If you enter an LSP traceroute to an FEC at LSR4 from LSR1, you get the results shown in the table below.

Table 15: MPLS LSP Traceroute Example

Step	Router	MPLS Packet Type and Description	Router Action (Receive or Send)
1.	LSR1	MPLS echo request--With a target FEC pointing to LSR4 and to a downstream mapping	• Sets the TTL of the label stack to 1 • Sends the request to LSR2
2.	LSR2	MPLS echo reply	• Receives the packet with a TTL = 1 • Processes the User Datagram Protocol (UDP) packet as an MPLS echo request • Finds a downstream mapping and replies to LSR1 with its own downstream mapping, based on the incoming label
3.	LSR1	MPLS echo request--With the same target FEC and the downstream mapping received in the echo reply from LSR2	• Sets the TTL of the label stack to 2 • Sends the request to LSR2

Step	Router	MPLS Packet Type and Description	Router Action (Receive or Send)
4.	LSR2	MPLS echo request	• Receives the packet with a TTL = 2 • Decrements the TTL • Forwards the echo request to LSR3
5.	LSR3	MPLS reply packet	• Receives the packet with a TTL = 1 • Processes the UDP packet as an MPLS echo request • Finds a downstream mapping and replies to LSR1 with its own downstream mapping based on the incoming label
6.	LSR1	MPLS echo request--With the same target FEC and the downstream mapping received in the echo reply from LSR3	• Sets the TTL of the packet to 3 • Sends the request to LSR2
7.	LSR2	MPLS echo request	• Receives the packet with a TTL = 3 • Decrements the TTL • Forwards the echo request to LSR3
8.	LSR3	MPLS echo request	• Receives the packet with a TTL = 2 • Decrements the TTL • Forwards the echo request to LSR4
9.	LSR4	MPLS echo reply	• Receives the packet with a TTL = 1 • Processes the UDP packet as an MPLS echo request • Finds a downstream mapping and also finds that the router is the egress router for the target FEC • Replies to LSR1

MPLS Network Management with MPLS LSP Ping and MPLS LSP Traceroute

To manage an MPLS network, you must have the ability to monitor LSPs and quickly isolate MPLS forwarding problems. You need ways to characterize the liveliness of an LSP and reliably detect when an LSP fails to deliver user traffic.

You can use MPLS LSP ping to verify the LSP that is used to transport packets destined for IPv4 LDP prefixes, and AToM PW FECs. You can use MPLS LSP traceroute to trace LSPs that are used to carry packets destined for IPv4 LDP prefixes.

An MPLS echo request is sent through an LSP to validate it. A TTL expiration or LSP breakage causes the transit router to process the echo request before it gets to the intended destination. The router returns an MPLS echo reply that contains an explanatory reply code to the originator of the echo request.

The successful echo request is processed at the egress of the LSP. The echo reply is sent via an IP path, an MPLS path, or a combination of both back to the originator of the echo request.

Any Transport over MPLS Virtual Circuit Connection

AToM Virtual Circuit Connection Verification (VCCV) allows you to send control packets inband of an AToM PW from the originating provider edge (PE) router. The transmission is intercepted at the destination PE router, instead of being forwarded to the customer edge (CE) router. This capability allows you to use MPLS LSP ping to test the PW section of AToM virtual circuits (VCs).

LSP ping allows verification of AToM VC setup by FEC 128 or FEC 129. FEC 128-based AToM VCs can be set up by using LDP for signaling or by using a static pseudowire configuration without using any signaling component on the two endpoints. Cisco software does not distinguish between FEC 128 and FEC 129 static pseudowires while issuing MPLS ping; the same commands are used.

AToM VCCV consists of the following:

- A signaled component in which the AToM VCCV capabilities are advertised during VC label signaling
- A switching component that causes the AToM VC payload to be treated as a control packet

AToM VCCV Signaling

One of the steps involved in AToM VC setup is the signaling or communication of VC labels and AToM VCCV capabilities between AToM VC endpoints. To communicate the AToM VCCV disposition capabilities of each endpoint, the router uses an optional parameter, defined in the IETF Internet Draft *Pseudo Wire (PW) Virtual Circuit Connection Verification (VCCV)* (draft-ieft-pwe3-vccv-01).

The AToM VCCV disposition capabilities are categorized as follows:

- Applications--MPLS LSP ping and ICMP ping are applications that AToM VCCV supports to send packets inband of an AToM PW for control purposes.
- Switching modes--Type 1 and Type 2 are switching modes that AToM VCCV uses for differentiating between control and data traffic.

The table below describes AToM VCCV Type 1 and Type 2 switching modes.

Table 16: Type 1 and Type 2 AToM VCCV Switching Modes

Switching Mode	Description
Type 1	Uses a Protocol ID (PID) field in the AToM control word to identify an AToM VCCV packet
Type 2	Uses an MPLS Router Alert Label above the VC label to identify an AToM VCCV packet

Selection of AToM VCCV Switching Types

Cisco routers always use Type 1 switching, if available, when they send MPLS LSP ping packets over an AToM VC control channel. Type 2 switching accommodates those VC types and implementations that do not support or interpret the AToM control word.

The table below shows the AToM VCCV switching mode advertised and the switching mode selected by the AToM VC.

Table 17: AToM VCCV Switching Mode Advertised and Selected by AToM VC

Type Advertised	Type Selected
AToM VCCV not supported	--
Type 1 AToM VCCV switching	Type 1 AToM VCCV switching
Type 2 AToM VCCV switching	Type 2 AToM VCCV switching
Type 1 and Type 2 AToM VCCV switching	Type 1 AToM VCCV switching

An AToM VC advertises its AToM VCCV disposition capabilities in both directions: that is, from the originating router (PE1) to the destination router (PE2), and from PE2 to PE1.

In some instances, AToM VCs might use different switching types if the two endpoints have different AToM VCCV capabilities. If PE1 supports Type 1 and Type 2 AToM VCCV switching and PE2 supports only Type 2 AToM VCCV switching, there are two consequences:

- LSP ping packets sent from PE1 to PE2 are encapsulated with Type 2 switching.
- LSP ping packets sent from PE2 to PE1 use Type 1 switching.

You can determine the AToM VCCV capabilities advertised to and received from the peer by entering the **show mpls l2transport binding** command at the PE router.

Information Provided by the Router Processing LSP Ping or LSP Traceroute

The table below describes the characters that the router processing an LSP ping or LSP traceroute packet returns to the sender about the failure or success of the request.

You can also display the return code for an MPLS LSP Ping operation if you enter the **ping mpls verbose** command.

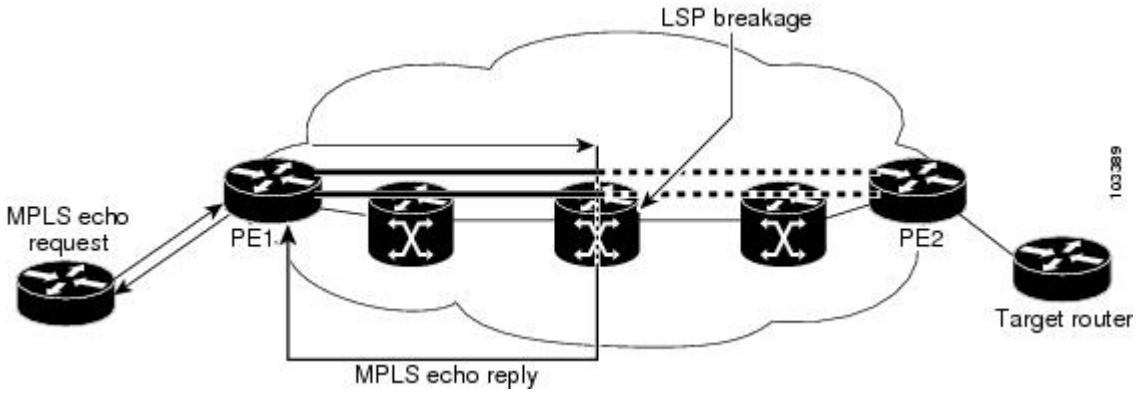
Table 18: Echo Reply Return Codes

Output Code	Echo Return Code	Meaning
x	0	No return code.
M	1	Malformed echo request.
m	2	Unsupported TLVs.
!	3	Success.
F	4	No FEC mapping.
D	5	DS Map mismatch.
I	6	Unknown Upstream Interface index.
U	7	Reserved.

Output Code	Echo Return Code	Meaning
L	8	Labeled output interface.
B	9	Unlabeled output interface.
f	10	FEC mismatch.
N	11	No label entry.
P	12	No receive interface label protocol.
p	13	Premature termination of the LSP.
X	unknown	Undefined return code.

Note Echo return codes 6 and 7 are accepted only for Version 3 (draft-ieft-mpls-ping-03).

IP Does Not Forward MPLS Echo Request Packets



MPLS echo request packets sent during an LSP ping are never forwarded by IP. The IP header destination address field in an MPLS echo request packet is a 127.*x.y.z* /8 address. Routers should not forward packets using a 127.*x.y.z* /8 address. The 127.*x.y.z* /8 address corresponds to an address for the local host.

Use of a 127.*x .y .z* address as the destination address of the UDP packet is significant because the MPLS echo request packet fails to make it to the target router if a transit router does not label switch the LSP. The use of the 127.*x .y .z* address allows for the detection of LSP breakages. The following occurs at the transit router:

- If an LSP breakage occurs at a transit router, the MPLS echo packet is not forwarded; it is consumed by the router.
- If the LSP is intact, the MPLS echo packet reaches the target router and is processed by the terminal point of the LSP.

The figure below shows the path of the MPLS echo request and reply when a transit router fails to label switch a packet in an LSP.

Figure 16: Path when Transit Router Fails to Label Switch a Packet

Note An AToM payload does not contain usable forwarding information at a transit router because the payload may not be an IP packet. An MPLS VPN packet, although an IP packet, does not contain usable forwarding information at a transit router because the destination IP address is significant only to the virtual routing and forwarding (VRF) instances at the endpoints of the MPLS network.

Compatibility Between the MPLS LSP and Ping or Traceroute Implementations

LSP ping drafts after Version 3 (draft-ietf-mpls-ping-03) have undergone numerous TLV format changes, but the versions of the draft do not always interoperate.

To allow later Cisco implementations to interoperate with draft Version 3 Cisco and non-Cisco implementations, use a global configuration mode to decode echo packets in formats understood by draft Version 3 implementations.

Unless configured otherwise, a Cisco implementation encodes and decodes echo requests assuming the version on which the IETF implementations is based.

To prevent failures reported by the replying router due to TLV version issues, you should configure all routers in the core. Encode and decode MPLS echo packets in the same draft version. For example, if the network is running RFC 4379 (Cisco Version 4) implementations but one router is capable of only Version 3 (Cisco Revision 3), configure all routers in the network to operate in Revision 3 mode.

The Cisco implementation of MPLS echo request and echo reply is based on the IETF RFC 4379. IEFT drafts subsequent to this RFC (drafts 3, 4, 5, 6, and 7) introduced TLV format differences. These differences could not be identified because the echo packet had no way to differentiate between one TLV format and another TLV format. To allow interoperability, a **revision** keyword was added for the **ping mpls** and **trace mpls** commands. The **revision** keyword enables Cisco IOS XE releases to support the existing draft changes and any changes from future versions of the IETF LSP Ping draft.

Note We recommend that you use the **mpls oam** global configuration command instead of the revision option.

Note No images are available on cisco.com to support Revision 2. It is recommended that you use only images supporting Version 3 and later when configuring TLV encode and decode modes. MPLS Multipath LSP traceroute requires Cisco Revision 4 or later.

CiscoVendorExtensions

In Cisco's Version 3 (draft-ietf-mpls-ping-03.txt) implementations, Cisco defined a vendor extension TLV in the ignore-if-not-understood TLV space. It is used for the following purposes:

- Provide an ability to track TLV versions.
- Provide an experimental Reply TOS capability.

The first capability was defined before the existence of the global configuration command for setting the echo packet encode and decode behavior. TLV version information in an echo packet overrides the configured decoding behavior. Using this TLV for TLV versions is no longer required since the introduction of the global configuration capability.

The second capability controls the reply DSCP. Draft Version 8 defines a Reply TOS TLV, so the use of the reply DSCP is no longer required.

You enable compatibility between the MPLS LSP and ping or traceroute implementation by customizing the default behavior of echo packets.

DSCP Option to Request a Specific Class of Service in an Echo Reply

Cisco software includes a reply differentiated services code point (DSCP) option that lets you request a specific class of service (CoS) in an echo reply.

The reply DSCP option is supported in the experimental mode for IETF draft-ietf-mpls-lsp-ping-03.txt. Cisco implemented a vendor-specific extension for the reply DSCP option rather than using a Reply TOS TLV. A Reply TOS TLV serves the same purpose as the **reply dscp** command in RFC 4379. This draft provides a standardized method of controlling the reply DSCP.

Note Before draft Version 8, Cisco implemented the Reply DSCP option as an experimental capability using a Cisco vendor extension TLV. If a router is configured to encode MPLS echo packets for draft Version 3 implementations, a Cisco vendor extension TLV is used instead of the Reply TOS TLV that was defined in draft Version 8.

Reply Modes for an MPLS LSP Ping and LSP Traceroute Echo Request Response

The reply mode controls how a responding router replies to an MPLS echo request sent by a **ping mpls** or **trace mpls** command. There are two reply modes for an echo request packet:

- ipv4--Reply with an IPv4 UDP packet (default)
- router-alert--Reply with an IPv4 UDP packet with router alert

Note It is useful to use ipv4 and router-alert reply modes in conjunction with each other to prevent false negatives. If you do not receive a reply via the ipv4 mode, it is useful to send a test with the router-alert reply mode. If both fail, something is wrong in the return path. The problem may be only that the Reply TOS is not set correctly.

IPv4 Reply Mode

IPv4 packet is the most common reply mode used with a **ping mpls** or **trace mpls** command when you want to periodically poll the integrity of an LSP. With this option, you do not have explicit control over whether the packet traverses IP or MPLS hops to reach the originator of the MPLS echo request. If the originating (headend) router fails to receive a reply to an MPLS echo request when you use the **reply mode ipv4** keywords, use the **reply mode router-alert** keywords.

Router-Alert Reply Mode

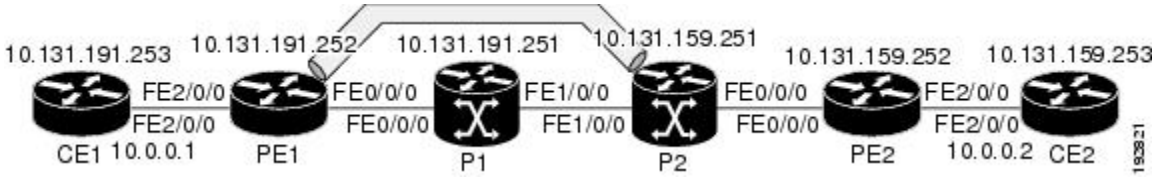
The router-alert reply mode adds the router alert option to the IP header. When an IP packet that contains an IP router alert option in its IP header or an MPLS packet with a router alert label as its outermost label arrives at a router, the router punts (redirects) the packet to the Route Processor (RP) level for handling. This forces the Cisco router to handle the packet at each intermediate hop as it moves back to the destination. Hardware and line-card forwarding inconsistencies are bypassed. Router-alert reply mode is more expensive than IPv4 mode because the reply goes hop-by-hop. It also is slower, so the sender receives a reply in a relatively longer period of time.

The table below describes how IP and MPLS packets with an IP router alert option are handled by the router switching path processes.

Table 19: Path Process Handling of IP and MPLS Router Alert Packets

Incoming Packet	Normal Switching Action	Process Switching Action	Outgoing Packet
IP packet--Router alert option in IP header	Router alert option in IP header causes the packet to be punted to the process switching path.	Forwards the packet as is	IP packet--Router alert option in IP header
		Forwards the packet as is	MPLS packet
MPLS packet--Outermost label contains a router alert	If the router alert label is the outermost label, it causes the packet to be punted to the process switching path.	Removes the outermost router alert label and forwards the packet as an IP packet	IP packet--Router alert option in IP header
		Preserves the outermost router alert label and forwards the MPLS packet	MPLS packet-- Outermost label contains a router alert.

LSP Breaks



If there is a problem forwarding MPLS packets in your network, you can determine where there are LSP breaks. This section describes MTU discovery in an LSP.

Untagged output interfaces at a penultimate hop do not impact the forwarding of IP packets through an LSP because the forwarding decision is made at the penultimate hop through use of the incoming label. However, untagged output interfaces cause AToM and MPLS VPN traffic to be dropped at the penultimate hop.

During an MPLS LSP ping, MPLS echo request packets are sent with the IP packet attribute set to "do not fragment." That is, the Don't Fragment (DF) bit is set in the IP header of the packet. This allows you to use the MPLS echo request to test for the MTU that can be supported for the packet through the LSP without fragmentation.

The figure below shows a sample network with a single LSP from PE1 to PE2 formed with labels advertised by the LDP.

Figure 17: Sample Network with LSP--Labels Advertised by LDP

You can determine the maximum receive unit (MRU) at each hop by using the MPLS Traceroute feature to trace the LSP. The MRU is the maximum size of a labeled packet that can be forwarded through an LSP.

How to Configure MPLS LSP Ping Traceroute for LDP TE and LSP Ping for VCCV

Enabling Compatibility Between the MPLS LSP and Ping or Traceroute Implementation

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mplsoam**
4. **echo revision** {**3** | **4**}
5. **echo vendor-extension**
6. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:**	Enables privileged EXEC mode. • Enter your password if prompted.

	Command or Action	Purpose
	`Router> enable`	
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**mplsoam** **Example:** `Router(config)# mpls oam`	Enters MPLS OAM configuration mode for customizing the default behavior of echo packets.
Step 4	**echo revision** {**3** | **4**} **Example:** `Router(config-mpls)# echo revision 4`	Specifies the revision number of the echo packet's default values. • 3--draft-ietf-mpls-ping-03 (Revision 2). • 4--RFC 4379 compliant (default).
Step 5	**echo vendor-extension** **Example:** `Router(config-mpls)# echo vendor-extension`	Sends the Cisco-specific extension of TLVs with echo packets.
Step 6	**exit** **Example:** `Router(config-mpls)# exit`	Returns to global configuration mode.

Validating an LDP IPv4 FEC by Using MPLS LSP Ping and MPLS LSP Traceroute

SUMMARY STEPS

1. **enable**
2. Do one of the following:
   - **ping mpls ipv4** *destination-address /destination-mask-length* [**repeat** *count*] [**exp** *exp-bits*] [**verbose**]
   - **trace mpls ipv4** *destination-address /destination-mask-length*
3. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.

Step 2	Do one of the following:
	• **ping mpls ipv4** *destination-address /destination-mask-length* [**repeat** *count*] [**exp** *exp-bits*] [**verbose**]
	• **trace mpls ipv4** *destination-address /destination-mask-length*
	Example:
	`Router# ping mpls ipv4 10.131.191.252/32 exp 5 repeat 5 verbose`
	Example:
	`Router# trace mpls ipv4 10.131.191.252/32`
		Selects an LDP IPv4 prefix FEC for validation.

Step 3	**exit** **Example:** `Router# exit`	Returns to user EXEC mode.

Validating a Layer 2 FEC by Using MPLS LSP Ping and MPLS LSP Traceroute

SUMMARY STEPS

1. **enable**
2. **ping mpls pseudowire** *ipv4-address* **vc-id** *vc-id*
3. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:**	Enables privileged EXEC mode. • Enter your password if prompted.

	Command or Action	Purpose
	`Router> enable`	
Step 2	**ping mpls pseudowire** *ipv4-address* **vc-id** *vc-id* **Example:** `Router# ping mpls pseudowire 10.131.191.252 vc-id 333`	Selects a Layer 2 FEC for validation.
Step 3	**exit** **Example:** `Router# exit`	Returns to user EXEC mode.

Using DSCP to Request a Specific Class of Service in an Echo Reply

SUMMARY STEPS

1. **enable**
2. Do one of the following:
   - **ping mpls** {**ipv4** *destination-address/destination-mask-length* | **pseudowire** *ipv4-address* **vc-id** *vc-id*} [**reply dscp** *dscp-value*]
   - **trace mpls ipv4** *destination-address/destination-mask-length* [**reply dscp** *dscp-value*]
3. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	Do one of the following: • **ping mpls** {**ipv4** *destination-address/destination-mask-length*	**pseudowire** *ipv4-address* **vc-id** *vc-id*} [**reply dscp** *dscp-value*] • **trace mpls ipv4** *destination-address/destination-mask-length* [**reply dscp** *dscp-value*] **Example:**	Controls the DSCP value of an echo reply.

	Command or Action	Purpose

	`Router# ping mpls ipv4 10.131.191.252/32 reply dscp 50`
	Example:
	`Router# trace mpls ipv4 10.131.191.252/32 reply dscp 50`	

Step 3	**exit** **Example:** `Router# exit`	Returns to user EXEC mode.

Controlling How a Responding Router Replies to an MPLS Echo Request

SUMMARY STEPS

1. **enable**
2. Do one of the following:
   - **ping mpls** {**ipv4***destination-address*/*destination-mask-length* | **pseudowire** *ipv4-address* **vc-id** *vc-id*} **reply mode** {**ipv4** | **router-alert**}
   - **trace mpls ipv4** *destination-address*/*destination-mask* **reply mode** {**ipv4** | **router-alert**}
3. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	Do one of the following: • **ping mpls** {**ipv4***destination-address*/*destination-mask-length*	**pseudowire** *ipv4-address* **vc-id** *vc-id*} **reply mode** {**ipv4**	**router-alert**} • **trace mpls ipv4** *destination-address*/*destination-mask* **reply mode** {**ipv4**	**router-alert**} **Example:**	Checks MPLS LSP connectivity. or Discovers MPLS LSP routes that packets actually take when traveling to their destinations. **Note** To specify the reply mode, you must enter the **reply mode** keyword with the **ipv4** or the **router-alert** keyword.

	Command or Action	Purpose

	`Router# ping mpls ipv4 10.131.191.252/32 reply mode ipv4`
	Example:
	`Router# trace mpls ipv4 10.131.191.252/32 reply mode router-alert`	

Step 3	**exit** **Example:** `Router# exit`	Returns to user EXEC mode.

Using MPLS LSP Ping to Discover Possible Loops

With the MPLS LSP Ping feature, loops can occur if you use the UDP destination address range, repeat option, or sweep option.

To use MPLS LSP ping to discover possible loops, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **ping mpls** {**ipv4** *destination-address/destination-mask* [**destination** *address-start address-end increment* | [**pseudowire** *ipv4-address* **vc-id** *vc-id address-end increment*]} [**repeat** *count*] [**sweep** *minimum maximum size-increment*]
3. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**ping mpls** {**ipv4** *destination-address/destination-mask* [**destination** *address-start address-end increment*	[**pseudowire** *ipv4-address* **vc-id** *vc-id address-end increment*]} [**repeat** *count*] [**sweep** *minimum maximum size-increment*] **Example:** `Router# ping mpls ipv4 10.131.159.251/32`	Checks MPLS LSP connectivity.

	Command or Action	Purpose
	`destination 127.0.0.1 127.0.0.2 1 repeat 2 sweep 1450 1475 25`	
Step 3	**exit** **Example:** `Router# exit`	Returns to user EXEC mode.

Using MPLS LSP Traceroute to Discover Possible Loops

With the MPLS LSP Traceroute feature, loops can occur if you use the UDP destination address range option and the time-to-live option.

By default, the maximum TTL is set to 30. Therefore, the traceroute output may contain 30 lines if the target of the traceroute is not reached, which can happen when an LSP problem exists. If an LSP problem occurs, there may be duplicate entries. The router address of the last point that the trace reaches is repeated until the output is 30 lines. You can ignore the duplicate entries.

SUMMARY STEPS

1. **enable**
2. **trace mpls ipv4** *destination-address* /*destination-mask* [**destination** *address-start address-end address increment*] [**ttl** *maximum-time-to-live*]
3. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**trace mpls ipv4** *destination-address* /*destination-mask* [**destination** *address-start address-end address increment*] [**ttl** *maximum-time-to-live*] **Example:** `Router# trace mpls ipv4 10.131.159.251/32 destination 127.0.0.1 127.0.0.3 1 ttl 5`	Discovers MPLS LSP routes that packets take when traveling to their destinations. The example shows how a loop can occur.
Step 3	**exit** **Example:** `Router# exit`	Returns to user EXEC mode.

What to do next

Tracking Packets Tagged as Implicit Null

SUMMARY STEPS

1. **enable**
2. **trace mpls ipv4** *destination-address*/*destination-mask*
3. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**trace mpls ipv4** *destination-address*/*destination-mask* **Example:** `Router# trace mpls ipv4 10.131.159.252/32`	Discovers MPLS LSP routes that packets actually take when traveling to their destinations.
Step 3	**exit** **Example:** `Router# exit`	Returns to user EXEC mode.

Tracking Untagged Packets

SUMMARY STEPS

1. **enable**
2. **show mpls forwarding-table** *destination-address/destination-mask*
3. **show mpls ldp discovery**
4. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**show mpls forwarding-table** *destination-address/destination-mask* **Example:** `Router# show mpls forwarding-table 10.131.159.252/32`	Displays the content of the MPLS Label Forwarding Information Base (LFIB) and displays whether the LDP is properly configured.
Step 3	**show mpls ldp discovery** **Example:** `Router# show mpls ldp discovery`	Displays the status of the LDP discovery process and displays whether the LDP is properly configured.
Step 4	**exit** **Example:** `Router# exit`	Returns to user EXEC mode.

Determining Why a Packet Could Not Be Sent

The Q return code means that the packet could not be sent. The problem can be caused by insufficient processing memory, but it probably results because an LSP could not be found that matches the FEC information that was entered on the command line.

You need to determine the reason why the packet was not forwarded so that you can fix the problem in the path of the LSP. To do so, look at the Routing Information Base (RIB), the Forwarding Information Base (FIB), the Label Information Base (LIB), and the MPLS LFIB. If there is no entry for the FEC in any of these routing or forwarding bases, there is a Q return code.

To determine why a packet could not be transmitted, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **show ip route** [*ip-address* [**mask**]]
3. **show mpls forwarding-table** [*network* {*mask* | *length*} | **labels** *label*[-*label*] | **interface** *interface* | **next-hop** *address* | **lsp-tunnel** [*tunnel-id*]]
4. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**show ip route** [*ip-address* [**mask**]] **Example:** `Router# show ip route 10.0.0.1`	Displays the current state of the routing table. When the MPLS echo reply returns a Q, troubleshooting occurs on the routing information database.
Step 3	**show mpls forwarding-table** [*network* {*mask* | *length*} | **labels** *label*[*-label*] | **interface** *interface* | **next-hop** *address* | **lsp-tunnel** [*tunnel-id*]] **Example:** `Router# show mpls forwarding-table 10.0.0.1/32`	Displays the content of the MPLS LFIB. When the MPLS echo reply returns a Q, troubleshooting occurs on a label information database and an MPLS forwarding information database.
Step 4	**exit** **Example:** `Router# exit`	Returns to user EXEC mode.

Detecting LSP Breaks when Load Balancing Is Enabled for IPv4 LDP LSPs

An ICMP ping or trace follows one path from the originating router to the target router. Round robin load balancing of IP packets from a source router discovers the various output paths to the target IP address.

For MPLS ping and traceroute, Cisco routers use the source and destination addresses in the IP header for load balancing when multiple paths exist through the network to a target router. The Cisco implementation of MPLS may check the destination address of an IP payload to accomplish load balancing (the type of checking depends on the platform).

To detect LSP breaks when load balancing is enabled for IPv4 LDP LSPs, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **ping mpls ipv4** *destination-address/destination-mask-length* [**destination** *address-start address-end increment*]
3. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**ping mpls ipv4** *destination-address/destination-mask-length* [**destination** *address-start address-end increment*] **Example:** `Router# ping mpls ipv4 10.131.159.251/32 destination 127.0.0.1/8`	Checks for load balancing paths. Enter the 127.*z.y.x* /8 destination address.
Step 3	**exit** **Example:** `Router# exit`	Returns to user EXEC mode.

Specifying the Interface Through Which Echo Packets Leave a Router

You can control the interface through which packets leave a router. Path output information is used as input to LSP ping and traceroute.

The echo request output interface control feature allows you to force echo packets through the paths that perform detailed debugging or characterizing of the LSP. This feature is useful if a PE router connects to an MPLS cloud and there are broken links. You can direct traffic through a certain link. The feature also is helpful for troubleshooting network problems.

To specify the output interface for echo requests, perform the following steps.

SUMMARY STEPS

1. **enable**
2. Enter one of the following commands:
   - **ping mpls** {**ipv4** *destination-address/destination-mask* | **pseudowire** *ipv4-address* **vc-id** *vc-id*} [**output interface** *tx-interface*]
   - **trace mpls ipv4** *destination-address/destination-mask*
3. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.

Step 2	Enter one of the following commands:
	• **ping mpls** {**ipv4** *destination-address/destination-mask* | **pseudowire** *ipv4-address* **vc-id** *vc-id*} [**output interface** *tx-interface*]
	• **trace mpls ipv4** *destination-address/destination-mask*
	Example:
	`Router# ping mpls ipv4 10.131.159.251/32 output interface fastethernet0/0/0`
	Example:
	`Router# trace mpls ipv4 10.131.159.251/32 output interface fastethernet0/0/0`
		Checks MPLS LSP connectivity.
		or
		Discovers MPLS LSP routes that packets actually take when traveling to their destinations.
		Note For this task, you must specify the **output interface** keyword.

Step 3	**exit** **Example:** `Router# exit`	Returns to user EXEC mode.

Pacing the Transmission of Packets

Echo request traffic pacing allows you to pace the transmission of packets so that the receiving router does not drop packets. To perform echo request traffic pacing, perform the following steps.

SUMMARY STEPS

1. **enable**
2. Do one of the following:
   - **ping mpls** {**ipv4** *destination-address/destination-mask* | **pseudowire** *ipv4-address* **vc-id** *vc-id*} [**interval** *ms*]]
   - **trace mpls ipv4** *destination-address/destination-mask*
3. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.

Step 2	Do one of the following:
	• **ping mpls** {**ipv4** *destination-address/destination-mask* | **pseudowire** *ipv4-address* **vc-id** *vc-id*} [**interval** *ms*]]
	• **trace mpls ipv4** *destination-address/destination-mask*
	Example:
	`Router# ping mpls ipv4 10.131.159.251/32 interval 2`
	Example:
	`Router# trace mpls ipv4 10.131.159.251/32`
		Checks MPLS LSP connectivity.
		or
		Discovers MPLS LSP routes that packets take when traveling to their destinations.
		Note
		In this task, if you use the **ping mpls** command you must specify the **interval** keyword.

Step 3	**exit** **Example:** `Router# exit`	Returns to user EXEC mode.

Interrogating the Transit Router for Its Downstream Information by Using Echo Request request-dsmap

The echo request request-dsmap capability troubleshooting feature, used in conjunction with the TTL flag, allows you to selectively interrogate a transit router. If there is a failure, you do not have to enter an **lsp traceroute** command for each previous failure; you can focus just on the failed hop.

A request-dsmap flag in the downstream mapping flags field, and procedures that specify how to trace noncompliant routers allow you to arbitrarily time-to-live (TTL) expire MPLS echo request packets with a wildcard downstream map (DSMAP).

Echo request DSMAPs received without labels indicate that the sender did not have any DSMAPs to validate. If the downstream router ID field of the DSMAP TLV in an echo request is set to the ALLROUTERs address (224.0.0.2) and there are no labels, the source router can arbitrarily query a transit router for its DSMAP information.

The **ping mpls** command allows an MPLS echo request to be TTL-expired at a transit router with a wildcard DSMAP for the explicit purpose of troubleshooting and querying the downstream router for its DSMAPs. The default is that the DSMAP has an IPv4 bitmap hashkey. You also can select hashkey 0 (none). The purpose of the **ping mpls** command is to allow the source router to selectively TTL expire an echo request at a transit router to interrogate the transit router for its downstream information. The ability to also select a multipath

(hashkey) type allows the transmitting router to interrogate a transit router for load-balancing information as is done with multipath LSP traceroute, but without having to interrogate all subsequent nodes traversed between the source router and the router on which each echo request TTL expires. Use an echo request in conjunction with the TTL setting because if an echo request arrives at the egress of the LSP with an echo request, the responding routers never return DSMAPs.

To interrogate the transit router for its downstream information so that you can focus just on the failed hop if there is a failure, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **ping mpls** {**ipv4** *destination-address/destination-mask* | **pseudowire** *ipv4-address* **vc-id** *vc-id*} [**dsmap** [**hashkey** {**none** | **ipv4 bitmap** *bitmap-size*}]]
3. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**ping mpls** {**ipv4** *destination-address/destination-mask*	**pseudowire** *ipv4-address* **vc-id** *vc-id*} [**dsmap** [**hashkey** {**none**	**ipv4 bitmap** *bitmap-size*}]] **Example:** `Router# ping mpls ipv4 10.161.251/32 dsmap hashkey ipv4 bitmap 16`	Checks MPLS LSP connectivity. **Note** In this task, you must specify the **dsmap** and **hashkey** keywords.
Step 3	**exit** **Example:** `Router# exit`	Returns to user EXEC mode.

Interrogating a Router for Its DSMAP

The router can interrogate the software or hardware forwarding layer for the depth limit that needs to be returned in the DSMAP TLV. If forwarding does not provide a value, the default is 255.

To determine the depth limit, specify the **dsmap** and **ttl** keywords in the **ping mpls** command. The transit router will be interrogated for its DSMAP. The depth limit is returned with the echo reply DSMAP. A value of 0 means that the IP header is used for load balancing. Another value indicates that the IP header load balances up to the specified number of labels.

To interrogate a router for its DSMAP, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **ping mpls** {**ipv4** *destination-address/destination-mask* | **pseudowire** *ipv4-address* **vc-id** *vc-id*} **ttl** *time-to-live* **dsmap**
3. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**ping mpls** {**ipv4** *destination-address/destination-mask*	**pseudowire** *ipv4-address* **vc-id** *vc-id*} **ttl** *time-to-live* **dsmap** **Example:** `Router# ping mpls ipv4 10.131.159.252/32 ttl 1 dsmap`	Checks MPLS LSP connectivity. **Note** You must specify the **ttl** and **dsmap** keywords.
Step 3	**exit** **Example:** `Router# exit`	Returns to user EXEC mode.

Requesting that a Transit Router Validate the Target FEC Stack

An MPLS echo request tests a particular LSP. The LSP to be tested is identified by the FEC stack.

To request that a transit router validate the target FEC stack, set the V flag from the source router by entering the **flags fec** keyword in the **ping mpls** and **trace mpls** commands. The default is that echo request packets are sent with the V flag set to 0.

To request that a transit router validate the target FEC stack, perform the following steps.

SUMMARY STEPS

1. **enable**
2. Do one of the following:
   - **ping mpls** {**ipv4** *destination-address/destination-mask* | **pseudowire** *ipv4-address* **vc-id** *vc-id*} **flags fec**

- **trace mpls ipv4** *destination-address/destination-mask* **flags fec**

3. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.

Step 2	Do one of the following:
	• **ping mpls** {**ipv4** *destination-address/destination-mask* | **pseudowire** *ipv4-address* **vc-id** *vc-id*} **flags fec**
	• **trace mpls ipv4** *destination-address/destination-mask* **flags fec**
	Example:
	`Router# ping mpls ipv4 10.131.159.252/32 flags fec`
	Example:
	`Router# trace mpls ipv4 10.131.159.252/32 flags fec`
		Checks MPLS LSP connectivity.
		or
		Discovers MPLS LSP routes that packets actually take when traveling to their destinations.
		Note
		You must enter the **flags fec** keyword.

Step 3	**exit** **Example:** `Router# exit`	Returns to user EXEC mode.

Enabling LSP Ping to Detect LSP Breakages Caused by Untagged Interfaces

For MPLS LSP ping and traceroute of LSPs carrying IPv4 FECs, you can force an explicit null label to be added to the MPLS label stack even though the label was unsolicited. This allows LSP ping to detect LSP breakages caused by untagged interfaces. LSP ping does not report that an LSP is operational when it is unable to send MPLS traffic.

An explicit null label is added to an MPLS label stack if MPLS echo request packets are forwarded from untagged interfaces that are directly connected to the destination of the LSP ping or if the IP TTL value for the MPLS echo request packets is set to 1.

When you enter an **lsp ping** command, you are testing the LSP's ability to carry IP traffic. Failure at untagged output interfaces at the penultimate hop are not detected. Explicit-null shimming allows you to test an LSP's ability to carry MPLS traffic.

To enable LSP ping to detect LSP breakages caused by untagged interfaces, specify the **force-explicit-null** keyword in the **ping mpls** or **trace mpls** commands as shown in the following steps.

SUMMARY STEPS

1. **enable**
2. Do one of the following:
   - **ping mpls** {**ipv4** *destination-address/destination-mask* | **pseudowire** *ipv4-address* **vc-id** *vc-id*} **force-explicit-null**
   - **trace mpls ipv4** *destination-address/destination-mask* **force-explicit-null**
3. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.

Step 2	Do one of the following:
	• **ping mpls** {**ipv4** *destination-address/destination-mask*
		pseudowire *ipv4-address* **vc-id** *vc-id*} **force-explicit-null**
		• **trace mpls ipv4** *destination-address/destination-mask* **force-explicit-null**
		Example:
		`Router# ping mpls ipv4 10.131.191.252/32 force-explicit null`
		Example:
		`Router# trace mpls ipv4 10.131.191.252/32 force-explicit-null`
			Checks MPLS LSP connectivity.
			or
			Discovers MPLS LSP routes that packets actually take when traveling to their destinations.
			Note
			You must enter the **force-explicit-null** keyword.

Step 3	**exit** **Example:** `Router# exit`	Returns to user EXEC mode.

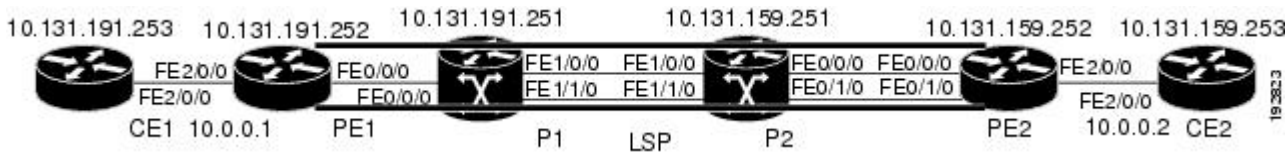
Viewing the AToM VCCV Capabilities Advertised to and Received from the Peer

To view the AToM VCCV capabilities advertised to and received from the peer, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **show mpls l2transport binding**
3. **exit**

DETAILED STEPS



Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**show mpls l2transport binding** **Example:** `Router# show mpls l2transport binding`	Displays VC label binding information.
Step 3	**exit** **Example:** `Router# exit`	Returns to user EXEC mode.

Configuration Examples for MPLS LSP Ping Traceroute for LDP TE and LSP Ping for VCCV

Examples for the MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV feature are based on the sample topology shown in the figure below.

Figure 18: Sample Topology for Configuration Examples

This section contains the following configuration examples:

Enabling Compatibility Between the MPLS LSP and Ping or Traceroute Implementation Example

The following example shows how to configure MPLS multipath LSP traceroute to interoperate with a vendor implementation that does not interpret RFC 4379 as Cisco does:

```
configure terminal
!
mpls oam
 echo revision 4
 no echo vendor-extension
 exit
```

The default echo revision number is 4, which corresponds to the IEFT draft 11.

Validating a Layer 2 FEC by Using MPLS LSP Ping Example

The following example validates a Layer 2 FEC:

```
Router# ping mpls pseudowire 10.10.10.15 108 vc-id 333

Sending 5, 100-byte MPLS Echos to 10.10.10.15,
      timeout is 2 seconds, send interval is 0 msec:
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
   'L' - labeled output interface, 'B' - unlabeled output interface,
   'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
   'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
   'P' - no rx intf label prot, 'p' - premature termination of LSP,
   'R' - transit router, 'I' - unknown upstream index,
   'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 28/32/40 ms PE-802#
```

Validating an LDP IPv4 FEC by Using MPLS LSP Ping and MPLS LSP Traceroute Example

The following example shows how to use the **ping mpls** command to test connectivity of an IPv4 LDP LSP:

```
Router# ping mpls ipv4 10.131.191.252/32 repeat 5 exp 5 verbose
Sending 5, 100-byte MPLS Echos to 10.131.191.252, timeout is 2 seconds:
Codes:
    '!' - success, 'Q' - request not sent, '.' - timeout,
    'L' - labeled output interface, 'B' - unlabeled output interface,
    'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
    'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
    'P' - no rx intf label prot, 'p' - premature termination of LSP,
    'R' - transit router, 'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.
!     10.131.191.230, return code 3
!     10.131.191.230, return code 3
!     10.131.191.230, return code 3
!     10.131.191.230, return code 3
!     10.131.191.230, return code 3
Success rate is 100 percent (5/5), round-trip min/avg/max = 100/10
```

Using DSCP to Request a Specific Class of Service in an Echo Reply Example

The following example shows how to use DSCP to request a specific CoS in an echo reply:

```
Router# ping mpls ipv4 10.131.159.252/32 reply dscp 50
 <0-63>   Differentiated services codepoint value
 af11     Match packets with AF11 dscp (001010)
 af12     Match packets with AF12 dscp (001100)
 af13     Match packets with AF13 dscp (001110)
 af21     Match packets with AF21 dscp (010010)
 af22     Match packets with AF22 dscp (010100)
 af23     Match packets with AF23 dscp (010110)
 af31     Match packets with AF31 dscp (011010)
 af32     Match packets with AF32 dscp (011100)
 af33     Match packets with AF33 dscp (011110)
 af41     Match packets with AF41 dscp (100010)
 af42     Match packets with AF42 dscp (100100)
 af43     Match packets with AF43 dscp (100110)
 cs1      Match packets with CS1(precedence 1) dscp (001000)
 cs2      Match packets with CS2(precedence 2) dscp (010000)
 cs3      Match packets with CS3(precedence 3) dscp (011000)
 cs4      Match packets with CS4(precedence 4) dscp (100000)
 cs5      Match packets with CS5(precedence 5) dscp (101000)
 cs6      Match packets with CS6(precedence 6) dscp (110000)
 cs7      Match packets with CS7(precedence 7) dscp (111000)
 default  Match packets with default dscp (000000)
 ef       Match packets with EF dscp (101110)
```

Controlling How a Responding Router Replies to an MPLS Echo Request Example

The following example checks MPLS LSP connectivity by using ipv4 reply mode:

```
Router# ping mpls ipv4 10.131.191.252/32 reply mode ipv4
```

Preventing Possible Loops with MPLS LSP Ping Example

The following example shows how a loop operates if you use the following **ping mpls** command:

```
Router# ping mpls
 ipv4
 10.131.159.251/32 destination 127.0.0.1 127.0.0.2 1 repeat 2
sweep 1450 1475 25
Sending 2, [1450..1500]-byte MPLS Echos to 10.131.159.251/32,
     timeout is 2 seconds, send interval is 0 msec:
Codes:
    '!' - success, 'Q' - request not sent, '.' - timeout,
    'L' - labeled output interface, 'B' - unlabeled output interface,
    'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
    'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
    'P' - no rx intf label prot, 'p' - premature termination of LSP,
    'R' - transit router, 'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.
Destination address 127.0.0.1
!
!
```

```
Destination address 127.0.0.2
!
!
Destination address 127.0.0.1
!
!
Destination address 127.0.0.2
!
!
```

A **ping mpls** command is sent for each packet size range for each destination address until the end address is reached. For this example, the loop continues in the same manner until the destination address, 127.0.0.5, is reached. The sequence continues until the number is reached that you specified with the **repeat** *count* keyword and argument. For this example, the repeat count is 2. The MPLS LSP ping loop sequence is as follows:

```
repeat  = 1
  destination address 1 (address-start
)
    for (size from sweep minimum
 to maximum
, counting by size-increment
)
      send an lsp ping
  destination address 2 (address-start
 +
address-
increment
)
    for (size from sweep minimum
 to maximum
, counting by size-increment
)
      send an lsp ping
  destination address 3 (address-start
 +
address-
increment
 +
address-
increment
)
     for (size from sweep minimum
 to maximum
, counting by size-increment
)
      send an lsp ping
  .
  .
  .
  until destination address = address-end
  .
  .
  .
  until repeat = count 2
```

Preventing Possible Loops with MPLS LSP Traceroute Example

The following example shows how a loop occurs if you use the following **trace mpls** command:

```
Router# trace mpls ipv4 10.131.159.251/32 destination 127.0.0.1 127.0.0.3 1 ttl 5
Tracing MPLS Label Switched Path to 10.131.159.251/32, timeout is 2 seconds
Codes:
    '!' - success, 'Q' - request not sent, '.' - timeout,
    'L' - labeled output interface, 'B' - unlabeled output interface,
    'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
    'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
    'P' - no rx intf label prot, 'p' - premature termination of LSP,
    'R' - transit router, 'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.
Destination address 127.0.0.1
  0 10.131.191.230 MRU 1500 [Labels: 19 Exp: 0]
R 1 10.131.159.226 MRU 1504 [implicit-null] 40 ms
! 2 10.131.159.225 40 ms
Destination address 127.0.0.2
  0 10.131.191.230 MRU 1500 [Labels: 19 Exp: 0]
R 1 10.131.159.226 MRU 1504 [implicit-null] 40 ms
! 2 10.131.159.225 40 ms
Destination address 127.0.0.3
  0 10.131.191.230 MRU 1500 [Labels: 19 Exp: 0]
R 1 10.131.159.226 MRU 1504 [implicit-null] 40 ms
! 2 10.131.159.225 48 ms
```

An **mpls trace** command is sent for each TTL from 1 to the maximum TTL (**ttl** *maximum-time-to-live* keyword and argument) for each destination address until the address specified with the destination *end-address* argument is reached. In this example, the maximum TTL is 5 and the end destination address is 127.0.0.3. The MPLS LSP traceroute loop sequence is as follows:

```
destination address 1 (address-start
)
  for (ttl from 1 to maximum-time-to-live
)
    send an lsp trace
destination address 2 (address-start
 + address-increment
)
  for (ttl from 1 to 5
)
    send an lsp trace
destination address 3 (address-start
 + address-increment
 + address-increment
)
  for (ttl from 1 to
maximum-time-to-live)
    send an lsp trace
.
.
.
until destination address = 4
```

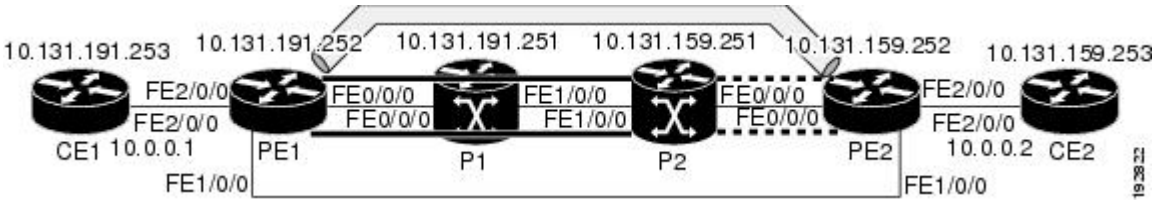
The following example shows that the trace encountered an LSP problem at the router that has an IP address of 10.6.1.6:

```
Router# traceroute mpls ipv4 10.6.7.4/32
Tracing MPLS Label Switched Path to 10.6.7.4/32, timeout is 2 seconds
Codes:
    '!' - success, 'Q' - request not sent, '.' - timeout,
    'L' - labeled output interface, 'B' - unlabeled output interface,
    'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
    'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
```

```
    'P' - no rx intf label prot, 'p' - premature termination of LSP,
    'R' - transit router, 'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.
  0 10.6.1.14 MRU 4470 [Labels: 22 Exp: 0]
R 1 10.6.1.5 MRU 4470 [Labels: 21 Exp: 0] 2 ms
R 2 10.6.1.6 4 ms                  <------ Router address repeated for 2nd to 30th TTL.
R 3 10.6.1.6 1 ms
R 4 10.6.1.6 1 ms
R 5 10.6.1.6 3 ms
R 6 10.6.1.6 4 ms
R 7 10.6.1.6 1 ms
R 8 10.6.1.6 2 ms
R 9 10.6.1.6 3 ms
R 10 10.6.1.6 4 ms
R 11 10.6.1.6 1 ms
R 12 10.6.1.6 2 ms
R 13 10.6.1.6 4 ms
R 14 10.6.1.6 5 ms
R 15 10.6.1.6 2 ms
R 16 10.6.1.6 3 ms
R 17 10.6.1.6 4 ms
R 18 10.6.1.6 2 ms
R 19 10.6.1.6 3 ms
R 20 10.6.1.6 4 ms
R 21 10.6.1.6 1 ms
R 22 10.6.1.6 2 ms
R 23 10.6.1.6 3 ms
R 24 10.6.1.6 4 ms
R 25 10.6.1.6 1 ms
R 26 10.6.1.6 3 ms
R 27 10.6.1.6 4 ms
R 28 10.6.1.6 1 ms
R 29 10.6.1.6 2 ms
R 30 10.6.1.6 3 ms                    <------ TTL 30.
```

If you know the maximum number of hops in your network, you can set the TTL to a lower value with the **trace mpls ttl** *maximum-time-to-live* command. The following example shows the same **traceroute** command as the previous example, except that this time the TTL is set to 5:

```
Router# traceroute mpls ipv4 10.6.7.4/32 ttl 5
Tracing MPLS Label Switched Path to 10.6.7.4/32, timeout is 2 seconds
Codes:
    '!' - success, 'Q' - request not sent, '.' - timeout,
    'L' - labeled output interface, 'B' - unlabeled output interface,
    'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
    'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
    'P' - no rx intf label prot, 'p' - premature termination of LSP,
    'R' - transit router, 'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.
  0 10.6.1.14 MRU 4470 [Labels: 22 Exp: 0]
R 1 10.6.1.5 MRU 4474 [No Label] 3 ms
R 2 10.6.1.6 4 ms                  <------ Router address repeated for 2nd to 5th TTL.
R 3 10.6.1.6 1 ms
R 4 10.6.1.6 3 ms
R 5 10.6.1.6 4 ms
```



Troubleshooting with LSP Ping or Traceroute Example

ICMP **ping** and **trace** commands are often used to help diagnose the root cause of a failure. When an LSP is broken, the packet may reach the target router by IP forwarding, thus making the ICMP ping and traceroute features unreliable for detecting MPLS forwarding problems. The MPLS LSP ping or traceroute and AToM

VCCV features extend this diagnostic and troubleshooting ability to the MPLS network and handle inconsistencies (if any) between the IP and MPLS forwarding tables, inconsistencies in the MPLS control and data plane, and problems with the reply path.

The figure below shows a sample topology with an LDP LSP.

Figure 19: Sample Topology with LDP LSP

This section contains the following subsections:

Configuration for Sample Topology

These are sample topology configurations for the troubleshooting examples in the following sections (see the figure above). There are the six sample router configurations.

Router CE1 Configuration

Following is the configuration for the CE1 router:

```
!
version 2.3
service timestamps debug datetime msec
service timestamps log datetime msec
no service password-encryption
!
hostname CE1
!
boot-start-marker
boot-end-marker
!
enable password lab
!
clock timezone EST -5
ip subnet-zero
!
!

Verification That the LSP Is Configured Correctly

Use the output from the **show** commands in this section to verify that the LSP is configured correctly.

A **show mpls forwarding-table** command shows that tunnel 1 is in the MPLS forwarding table.

```
PE1# show mpls forwarding-table 10.131.159.252
Local  Outgoing    Prefix            Bytes tag  Outgoing   Next Hop
tag    tag or VC   or Tunnel Id      switched   interface
22     18
[T] 10.131.159.252/32 0          Tu1        point2point
[T]     Forwarding through a TSP tunnel.
        View additional tagging info with the 'detail' option
```

A **trace mpls** command issued at PE1 verifies that packets with 16 as the outermost label and 18 as the end-of-stack label are forwarded from PE1 to PE2.

```
PE1# trace mpls ipv4 10.131.159.252/32
Tracing MPLS Label Switched Path to 10.131.159.252/32, timeout is 2 seconds
Codes:
    '!' - success, 'Q' - request not sent, '.' - timeout,
    'L' - labeled output interface, 'B' - unlabeled output interface,
    'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
    'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
    'P' - no rx intf label prot, 'p' - premature termination of LSP,
    'R' - transit router, 'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.
   0 10.131.191.252 MRU 1496 [Labels: 16/18 Exp: 0/0] L 1 10.131.191.229
   MRU 1508 [Labels: 18 Exp: 0] 0 ms L 2 10.131.159.225
   MRU 1504 [Labels: implicit-null Exp: 0] 0 ms ! 3 10.131.159.234 20 ms
   PE1#
```

The MPLS LSP Traceroute to PE2 is successful, as indicated by the exclamation point (!).

Discovery of LSP Breaks

Use the output of the commands in this section to discover LSP breaks.

An LDP target session is established between routers PE1 and P2, as shown in the output of the following **show mpls ldp discovery** command:

```
PE1# show mpls ldp discovery
 Local LDP Identifier:
    10.131.191.252:0
    Discovery Sources:
    Interfaces:
        FastEthernet0/0/0 (ldp): xmit/recv
            LDP Id: 10.131.191.251:0
        Tunnel1 (ldp): Targeted -> 10.131.159.251
    Targeted Hellos:
        10.131.191.252 -> 10.131.159.252 (ldp): active/passive, xmit/recv
            LDP Id: 10.131.159.252:0
        10.131.191.252 -> 10.131.159.251 (ldp): active, xmit/recv
LDP Id: 10.131.159.251:0
```

Enter the following command on the P2 router in global configuration mode:

```
P2(config)# no mpls ldp discovery targeted-hello accept
```

The LDP configuration change causes the targeted LDP session between the headend and tailend of the TE tunnel to go down. Labels for IPv4 prefixes learned by P2 are not advertised to PE1. Thus, all IP prefixes reachable by P2 are reachable by PE1 only through IP (not MPLS). In other words, packets destined for those prefixes through Tunnel 1 at PE1 will be IP switched at P2 (which is undesirable).

The following **show mpls ldp discovery** command shows that the LDP targeted session is down:

```
PE1# show mpls ldp discovery
 Local LDP Identifier:
    10.131.191.252:0
    Discovery Sources:
    Interfaces:
        FastEthernet0/0/0 (ldp): xmit/recv
            LDP Id: 10.131.191.251:0
        Tunnel1 (ldp): Targeted -> 10.131.159.251
    Targeted Hellos:
        10.131.191.252 -> 10.131.159.252 (ldp): active/passive, xmit/recv
            LDP Id: 10.131.159.252:0
        10.131.191.252 -> 10.131.159.251 (ldp): active, xmit
```

Enter the **show mpls forwarding-table** command at the PE1 router. The display shows that the outgoing packets are untagged as a result of the LDP configuration changes.

```
PE1# show mpls forwarding-table 10.131.159.252
Local  Outgoing    Prefix            Bytes tag  Outgoing   Next Hop
tag    tag or VC   or Tunnel Id      switched   interface
22     Untagged[T] 10.131.159.252/32 0          Tu1        point2point
[T]     Forwarding through a TSP tunnel.
        View additional tagging info with the 'detail' option
```

A **ping mpls** command entered at the PE1 router displays the following:

```
PE1# ping mpls ipv4 10.131.159.252/32 repeat 1
Sending 1, 100-byte MPLS Echos to 10.131.159.252/32,
      timeout is 2 seconds, send interval is 0 msec:
Codes:
    '!' - success, 'Q' - request not sent, '.' - timeout,
    'L' - labeled output interface, 'B' - unlabeled output interface,
    'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
    'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
    'P' - no rx intf label prot, 'p' - premature termination of LSP,
    'R' - transit router, 'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.
R
Success rate is 0 percent (0/1)
```

The **ping mpls** command fails. The R indicates that the sender of the MPLS echo reply had a routing entry but no MPLS FEC. Entering the **verbose** keyword with the**ping mpls** command displays the MPLS LSP echo reply sender address and the return code. You should be able to determine where the breakage occurred by telnetting to the replying router and inspecting its forwarding and label tables. You might need to look at the neighboring upstream router as well, because the breakage might be on the upstream router.

```
PE1# ping mpls ipv4 10.131.159.252/32 repeat 1 verbose
Sending 1, 100-byte MPLS Echos to 10.131.159.252/32,
      timeout is 2 seconds, send interval is 0 msec:
Codes:
    '!' - success, 'Q' - request not sent, '.' - timeout,
    'L' - labeled output interface, 'B' - unlabeled output interface,
    'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
    'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
    'P' - no rx intf label prot, 'p' - premature termination of LSP,
    'R' - transit router, 'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.
R   10.131.159.225, return code 6
Success rate is 0 percent (0/1)
```

Alternatively, use the LSP **traceroute** command to figure out which router caused the breakage. In the following example, for subsequent values of TTL greater than 2, the same router keeps responding (10.131.159.225). This suggests that the MPLS echo request keeps getting processed by the router regardless of the TTL. Inspection of the label stack shows that P1 pops the last label and forwards the packet to P2 as an IP packet. This explains why the packet keeps getting processed by P2. MPLS echo request packets cannot be forwarded by use of the destination address in the IP header because the address is set to a 127/8 address.

```
PE1# trace mpls ipv4 10.131.159.252/32 ttl 5
Tracing MPLS Label Switched Path to 10.131.159.252/32, timeout is 2 seconds
Codes:
    '!' - success, 'Q' - request not sent, '.' - timeout,
    'L' - labeled output interface, 'B' - unlabeled output interface,
    'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
    'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
    'P' - no rx intf label prot, 'p' - premature termination of LSP,
    'R' - transit router, 'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.
  0 10.131.191.230 MRU 1496 [Labels: 22/19 Exp: 0/0]
R 1 10.131.159.226 MRU 1500 [Labels: 19 Exp: 0] 40 ms
R 2 10.131.159.229 MRU 1504 [implicit-null] 28 ms
! 3 10.131.159.230 40 ms
pe1#
```

MTU Discovery in an LSP Example

The following example shows the results of a **trace mpls** command when the LSP is formed with labels created by LDP:

```
PE1# trace mpls ipv4 10.131.159.252/32
Tracing MPLS Label Switched Path to 10.131.159.252/32, timeout is 2 seconds
Codes:
    '!' - success, 'Q' - request not sent, '.' - timeout,
    'L' - labeled output interface, 'B' - unlabeled output interface,
    'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
    'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
    'P' - no rx intf label prot, 'p' - premature termination of LSP,
    'R' - transit router, 'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.
  0 10.131.191.230 MRU 1496 [Labels: 22/19 Exp: 0/0]
R 1 10.131.159.226 MRU 1500 [Labels: 19 Exp: 0] 40 ms
R 2 10.131.159.229 MRU 1504 [implicit-null] 28 ms
! 3 10.131.159.230 40 ms
pe1#
```

You can determine the MRU for the LSP at each hop through the use of the **show mpls forwarding detail** command:

```
PE1# show mpls forwarding 10.131.159.252 detail
Local  Outgoing    Prefix            Bytes tag  Outgoing   Next Hop
tag    tag or VC   or Tunnel Id      switched   interface
22     19          10.131.159.252/32 0          Tu1        point2point
       MAC/Encaps=14/22, MRU=1496, Tag Stack{22 19}, via Et0/0
       AABBCC009700AABBCC0098008847 00016000000013000
       No output feature configured
```

To determine how large an echo request will fit on the LSP, first calculate the size of the IP MTU by using the **show interface** *interface-name* command:

```
PE1# show interface e0/0
FastEthernet0/0/0 is up, line protocol is up
  Hardware is Lance, address is aabb.cc00.9800 (bia aabb.cc00.9800)
  Internet address is 10.131.191.230/30
  MTU 1500 bytes, BW 10000 Kbit, DLY 1000 usec, rely 255/255, load 1/255
  Encapsulation ARPA, loopback not set
  Keepalive set (10 sec)
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input 00:00:01, output 00:00:01, output hang never
  Last clearing of "show interface" counters never
  Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/40 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     377795 packets input, 33969220 bytes, 0 no buffer
     Received 231137 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
     0 input packets with dribble condition detected
     441772 packets output, 40401350 bytes, 0 underruns
     0 output errors, 0 collisions, 10 interface resets
     0 babbles, 0 late collision, 0 deferred
     0 lost carrier, 0 no carrier
     0 output buffer failures, 0 output buffers swapped out
```

The IP MTU in the **show interface** *interface-name* example is 1500 bytes. Subtract the number of bytes corresponding to the label stack from the MTU number. The output of the **show mpls forwarding** command indicates that the Tag stack consists of one label (21). Therefore, the largest MPLS echo request packet that can be sent in the LSP is 1500 - (2 x 4) = 1492.

You can validate this by using the following **mpls ping** command:

```
PE1# ping mpls ipv4 10.131.159.252/32 sweep 1492 1500 1 repeat 1
Sending 1, [1492..1500]-byte MPLS Echos to 10.131.159.252/32,
     timeout is 2 seconds, send interval is 0 msec:
Codes:
    '!' - success, 'Q' - request not sent, '.' - timeout,
    'L' - labeled output interface, 'B' - unlabeled output interface,
    'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
    'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
    'P' - no rx intf label prot, 'p' - premature termination of LSP,
    'R' - transit router, 'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.
!QQQQQQQQ
Success rate is 11 percent (1/9), round-trip min/avg/max = 40/40/40 ms
```

In this command, echo packets that have a range in size from 1492 to 1500 bytes are sent to the destination address. Only packets of 1492 bytes are sent successfully, as indicated by the exclamation point (!). Packets of byte sizes 1493 to 1500 are source-quenched, as indicated by the Qs.

You can pad an MPLS echo request so that a payload of a given size can be tested. The pad TLV is useful when you use the MPLS echo request to discover the MTU that is supportable by an LSP. MTU discovery is extremely important for applications like AToM that contain non-IP payloads that cannot be fragmented.

Tracking Packets Tagged as Implicit Null Example

In the following example, Tunnel 1 is shut down, and only an LSP formed with LDP labels is established. An implicit null is advertised between the P2 and PE2 routers. Entering an MPLS LSP traceroute command at the PE1 router results in the following output that shows that packets are forwarded from P2 to PE2 with an

implicit-null label. Address 10.131.159.229 is configured for the P2 Fast Ethernet 0/0/0 out interface for the PE2 router.

```
PE1# trace mpls ipv4 10.131.159.252/32
Tracing MPLS Label Switched Path to 10.131.159.252/32, timeout is 2 seconds
Codes:
    '!' - success, 'Q' - request not sent, '.' - timeout,
    'L' - labeled output interface, 'B' - unlabeled output interface,
    'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
    'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
    'P' - no rx intf label prot, 'p' - premature termination of LSP,
    'R' - transit router, 'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.
  0 10.131.191.230 MRU 1496 [Labels: 22/19 Exp: 0/0]
R 1 10.131.159.226 MRU 1500 [Labels: 19 Exp: 0] 40 ms
R 2 10.131.159.229 MRU 1504 [implicit-null] 28 ms
! 3 10.131.159.230 40 ms
pe1#
```

Tracking Untagged Packets Example

Untagged cases are valid configurations for IGP LSPs that could cause problems for MPLS VPNs.

A **show mpls forwarding-table** command and a **show mpls ldp discovery** command issued at the P2 router show that LDP is properly configured:

```
P2# show mpls forwarding-table 10.131.159.252
Local  Outgoing    Prefix            Bytes tag  Outgoing   Next Hop
tag    tag or VC   or Tunnel Id      switched   interface
19     Pop tag     10.131.159.252/32 0          fe0/0/0    10.131.159.230
P2# show mpls ldp discovery
 Local LDP Identifier:
    10.131.159.251:0
    Discovery Sources:
    Interfaces:
        FastEthernet0/0/0 (ldp): xmit/recv
            LDP Id: 10.131.159.252:0
        FastEthernet1/0/0 (ldp): xmit/recv
            LDP Id: 10.131.191.251:0
```

The **show mpls ldp discovery** command output shows that Fast Ethernet interface 0/0/0, which connects PE2 to P2, is sending and receiving packets.

If a **no mpls ip** command is entered on Fast Ethernet interface 0/0/0, this could prevent an LDP session between the P2 and PE2 routers from being established. A **show mpls ldp discovery** command entered on the PE router shows that the MPLS LDP session with the PE2 router is down.

```
P2# show mpls ldp discovery
 Local LDP Identifier:
    10.131.159.251:0
    Discovery Sources:
    Interfaces:

FastEthernet0/0/0 (ldp): xmit
        FastEthernet1/0/0 (ldp): xmit/recv
            LDP Id: 10.131.191.251:0
```

If the MPLS LDP session to PE2 goes down, the LSP to 10.131.159.252 becomes untagged, as shown by the **show mpls forwarding-table** command:

```
P2# show mpls forwarding-table 10.131.159.252/32
Local  Outgoing    Prefix           Bytes tag  Outgoing   Next Hop
tag    tag or VC   or Tunnel Id     switched   interface
19     Untagged    10.131.159.252/32 864       fe0/0/0    10.131.159.230
```

Untagged cases would provide an MPLS LSP traceroute reply with packets tagged with No Label, as shown in the following display. You may need to reestablish an MPLS LSP session from interface P2 to PE2 by entering an **mpls ip** command on the output interface from P2 to PE2, which is Fast Ethernet 0/0/0 in this example:

```
PE1# trace mpls ipv4 10.131.159.252/32
Tracing MPLS Label Switched Path to 10.131.159.252/32, timeout is 2 seconds
Codes:
    '!' - success, 'Q' - request not sent, '.' - timeout,
    'L' - labeled output interface, 'B' - unlabeled output interface,
    'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
    'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
    'P' - no rx intf label prot, 'p' - premature termination of LSP,
    'R' - transit router, 'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.
  0 10.131.191.230 MRU 1500 [Labels: 20 Exp: 0]
R 1 10.131.159.226 MRU 1500 [Labels: 19 Exp: 0] 80 ms
R 2 10.131.159.229 MRU 1504 [No Label] 28 ms       <----No MPLS session from P2 to PE2.
! 3 10.131.159.230 40 ms
```

Determining Why a Packet Could Not Be Sent Example

The following example shows a **ping mpls** command when an MPLS echo request is not sent. The transmission failure is shown by the returned Qs.

```
PE1# ping mpls ipv4 10.0.0.1/32
Sending 5, 100-byte MPLS Echos to 10.0.0.1/32,
      timeout is 2 seconds, send interval is 0 msec:
Codes:
    '!' - success, 'Q' - request not sent, '.' - timeout,
    'L' - labeled output interface, 'B' - unlabeled output interface,
    'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
    'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
    'P' - no rx intf label prot, 'p' - premature termination of LSP,
    'R' - transit router, 'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.
QQQQQ
Success rate is 0 percent (0/5)
```

The following **show mpls forwarding-table** command and **show ip route** command demonstrate that the IPv4 address (10.0.0.1)address is not in the LFIB or RIB routing table. Therefore, the MPLS echo request is not sent.

```
PE1# show mpls forwarding-table 10.0.0.1
Local  Outgoing    Prefix           Bytes tag  Outgoing   Next Hop
tag    tag or VC   or Tunnel Id     switched   interface
PE1# show ip route 10.0.0.1
% Subnet not in table
```

Detecting LSP Breaks when Load Balancing Is Enabled for IPv4 LSPs Example

In the following examples, different paths are followed to the same destination. The output from these examples demonstrates that load balancing occurs between the originating router and the target router.

To ensure that Fast Ethernet interface 1/0/0 on the PE1 router is operational, enter the following commands on the PE1 router:

```
PE1# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
PE1(config)# interface fastethernet 1/0/0
PE1(config-if)# no shutdown
PE1(config-if)# end
*Dec 31 19:14:10.034: %LINK-3-UPDOWN: Interface FastEthernet1/0/0, changed state to up
*Dec 31 19:14:11.054: %LINEPROTO-5-UPDOWN: Line protocol on Interface FastEthernet1/0/0,
changed state to upend
PE1#
*Dec 31 19:14:12.574: %SYS-5-CONFIG_I: Configured from console by console
*Dec 31 19:14:19.334: %OSPF-5-ADJCHG: Process 1, Nbr 10.131.159.252 on FastEthernet1/0/0
from LOADING to FULL, Loading Done
PE1#
```

The following **show mpls forwarding-table** command displays the possible outgoing interfaces and next hops for the prefix 10.131.159.251/32:

```
PE1# show mpls forwarding-table 10.131.159.251/32
Local  Outgoing    Prefix            Bytes tag  Outgoing   Next Hop
tag    tag or VC   or Tunnel Id      switched   interface
21     19          10.131.159.251/32 0          fe0/0/0    10.131.191.229
       20          10.131.159.251/32 0          fe1/0/0    10.131.159.245
```

The following **ping mpls** command to 10.131.159.251/32 with a destination UDP address of 127.0.0.1 shows that the selected path has a path index of 0:

```
Router# ping mpls ipv4
 10.131.159.251/32 destination
 127.0.0.1/32
Sending 1, 100-byte MPLS Echos to 10.131.159.251/32,
      timeout is 2 seconds, send interval is 0 msec:
Codes:
    '!' - success, 'Q' - request not sent, '.' - timeout,
    'L' - labeled output interface, 'B' - unlabeled output interface,
    'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
    'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
    'P' - no rx intf label prot, 'p' - premature termination of LSP,
    'R' - transit router, 'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.

```

To see the actual path chosen, enter the **debug mpls lspv** command with the **packet** and **data** keywords.

Note The load balancing algorithm attempts to uniformly distribute packets across the available output paths by hashing based on the IP header source and destination addresses. The selection of the *address-start* , *address-end* , and *address-increment* arguments for the **destination** keyword may not provide the expected results.

Specifying the Interface Through Which Echo Packets Leave a Router Example

The following example tests load balancing from the upstream router:

```
Router# ping mpls ipv4 10.131.161.251/32 ttl 1 repeat 1 dsmap hashkey ipv4 bitmap 8

Sending 1, 100-byte MPLS Echos to 10.131.161.251/32,
     timeout is 2 seconds, send interval is 0 msec:
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
  'L' - labeled output interface, 'B' - unlabeled output interface,
  'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
```

```
  'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
  'P' - no rx intf label prot, 'p' - premature termination of LSP,
  'R' - transit router, 'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.
L
Echo Reply received from 10.131.131.2

Success rate is 0 percent (0/1)
```

The multipath addresses cause a packet to transit to the router with the output label stack. The **ping mpls** command is useful for determining the number of output paths, but when the router is more than one hop away a router cannot always use those addresses to get the packet to transit through the router being interrogated. This situation exists because the change in the IP header destination address may cause the packet to be load-balanced differently by routers between the source router and the responding router. Load balancing is affected by the source address in the IP header. The following example tests load-balancing reporting from the upstream router:

```
Router# ping mpls ipv4 10.131.161.251/32 ttl 1 repeat 1 dsmap hashkey ipv4 bitmap 8

Sending 1, 100-byte MPLS Echos to 10.131.161.251/32,
     timeout is 2 seconds, send interval is 0 msec:
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,

Interrogating a Router for Its DSMAP Example

The following example interrogates the software and hardware forwarding layer for their depth limit that needs to be returned in the DSMAP TLV.

```
Router# ping mpls ipv4 10.131.159.252/32 ttl 1 dsmap
Sending 1, 100-byte MPLS Echos to 10.131.159.252/32,
     timeout is 2 seconds, send interval is 0 msec:
Codes:
  '!' - success, 'Q' - request not sent, '.' - timeout,
  'L' - labeled output interface, 'B' - unlabeled output interface,
  'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
  'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
  'P' - no rx intf label prot, 'p' - premature termination of LSP,
  'R' - transit router, 'X' - unknown return code, 'x' - return code 0
```

```
Type escape sequence to abort.

Feature Information for MPLS LSP Ping Traceroute for LDP TE and LSP Ping for VCCV

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 20: Feature Information for MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV

Feature Name	Releases	Feature Information
MPLS Embedded Management LSP Ping/Traceroute for LDP	Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Aggregation Services Routers.
MPLS Embedded Management LSP Ping/Trace for LDP and Resource Reservation Protocol (RSVP) IPv4 Forwarding Equivalence Classes (FECs)	Cisco IOS XE Release 2.3	The MPLS Embedded Management LSP Ping/Trace for LDP feature was modified to include support for RSVP IPv4 FECs.
MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV	Cisco IOS XE Release 2.3	The MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV feature helps service providers monitor label switched paths and quickly isolate MPLS forwarding problems. The following commands were introduced or modified: **debug mpls lspv**, **echo**, **mpls oam**, **ping mpls**, **show mpls oam**, **echo statistics**, **trace mpls**.

Glossary

FEC --forwarding equivalence class. A set of packets that can be handled equivalently for forwarding purposes and are thus suitable for binding to a single label. Examples include the set of packets destined for one address prefix and the packets in any flow.

flow --A set of packets traveling between a pair of hosts, or between a pair of transport protocol ports on a pair of hosts. For example, packets with the same source address, source port, destination address, and destination port might be considered a flow.

A flow is also a stream of data traveling between two endpoints across a network (for example, from one LAN station to another). Multiple flows can be transmitted on a single circuit.

fragmentation --The process of breaking a packet into smaller units when they are to be transmitted over a network medium that cannot support the original size of the packet.

ICMP -- Internet Control Message Protocol. A network layer Internet protocol that reports errors and provides other information relevant to IP packet processing. It is documented in RFC 792.

LFIB --Label Forwarding Information Base. A data structure and way of managing forwarding in which destinations and incoming labels are associated with outgoing interfaces and labels.

localhost --A name that represents the host router (device). The localhost uses the reserved loopback IP address 127.0.0.1.

LSP --label switched path. A connection between two routers in which MPLS forwards the packets.

LSPV --Label Switched Path Verification. An LSP Ping subprocess. It encodes and decodes MPLS echo requests and replies, and it interfaces with IP, MPLS, and AToM switching for sending and receiving MPLS echo requests and replies. At the MPLS echo request originator router, LSPV maintains a database of outstanding echo requests for which echo responses have not been received.

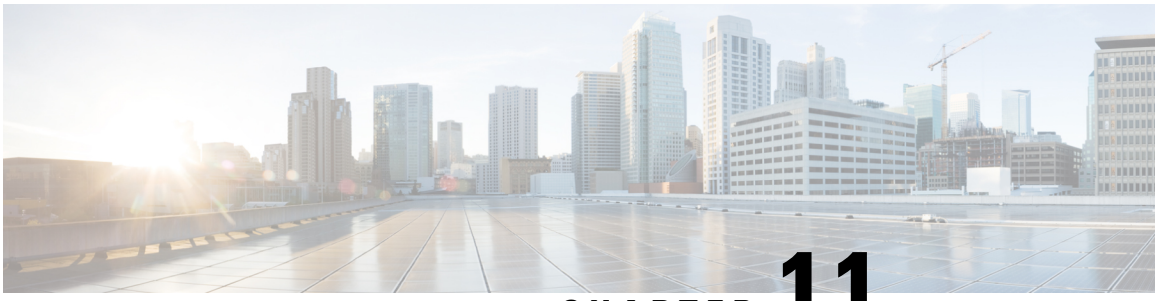
MPLS router alert label--An MPLS label of 1. An MPLS packet with a router alert label is redirected by the router to the Route Processor (RP) processing level for handling. This allows these packets to bypass any forwarding failures in hardware routing tables.

MRU --maximum receive unit. Maximum size, in bytes, of a labeled packet that can be forwarded through an LSP.

MTU --maximum transmission unit. Maximum packet size, in bytes, that a particular interface can send or receive.

punt --Redirect packets with a router alert from the line card or interface to Route Processor (RP) level processing for handling.

PW --pseudowire. A form of tunnel that carries the essential elements of an emulated circuit from one provider edge (PE) router to another PE router over a packet-switched network.



RP --Route Processor. The processor module in a Cisco 7000 series router that contains the CPU, system software, and most of the memory components that are used in the router. It is sometimes called a supervisory processor.

RSVP --Resource Reservation Protocol. A protocol that supports the reservation of resources across an IP network. Applications running on IP end systems can use RSVP to indicate to other nodes the nature (bandwidth, jitter, maximum burst, and so on) of the packet streams they want to receive. RSVP depends on IPv6. Is is also known as Resource Reservation Setup Protocol.

TLV --type, length, values. A block of information included in a Cisco Discovery Protocol address.

TTL hiding--Time-to-live is a parameter you can set that indicates the maximum number of hops a packet should take to reach its destination.

UDP --User Datagram Protocol. Connectionless transport layer protocol in the TCP/IP protocol stack. UDP is a simple protocol that exchanges datagrams without acknowledgments or guaranteed delivery, so error processing and retransmission must be handled by other protocols. UDP is defined in RFC 768.

CHAPTER 11

MPLS LSP Ping, Traceroute, and AToM VCCV

As Multiprotocol Label Switching (MPLS) deployments increase and the traffic types they carry increase, the ability of service providers to monitor label switched paths (LSPs) and quickly isolate MPLS forwarding problems is critical to their ability to offer services. The MPLS LSP Ping, Traceroute, and AToM VCCV feature helps them mitigate these challenges.

The MPLS LSP Ping, Traceroute, and AToM VCCV feature can detect when an LSP fails to deliver user traffic.

- You can use MPLS LSP Ping to test LSP connectivity for IPv4 Label Distribution Protocol (LDP) prefixes, traffic engineering (TE) Forwarding Equivalence Classes (FECs), and AToM FECs.
- You can use MPLS LSP Traceroute to trace the LSPs for IPv4 LDP prefixes and TE tunnel FECs.
- Any Transport over MPLS Virtual Circuit Connection Verification (AToM VCCV) allows you to use MPLS LSP Ping to test the pseudowire (PW) section of an AToM virtual circuit (VC).

Internet Control Message Protocol (ICMP) ping and trace are often used to help diagnose the root cause when a forwarding failure occurs. The MPLS LSP Ping, Traceroute, and AToM VCCV feature extends this diagnostic and troubleshooting ability to the MPLS network and aids in the identification of inconsistencies between the IP and MPLS forwarding tables, inconsistencies in the MPLS control and data plane, and problems with the reply path.

The MPLS LSP Ping, Traceroute, and AToM VCCV feature uses MPLS echo request and reply packets to test LSPs. The Cisco implementation of MPLS echo request and echo reply are based on the Internet Engineering Task Force (IETF) Internet-Draft *Detecting MPLS Data Plane Failures.*

- Feature Information for MPLS LSP Ping, Traceroute, and AToM VCCV, on page 210
- Glossary, on page 211

Prerequisites for MPLS LSP Ping, Traceroute, and AToM VCCV

Before you use the MPLS LSP Ping, Traceroute, and AToM VCCV feature, you should:

- Determine the baseline behavior of your Multiprotocol Label Switching (MPLS) network. For example:

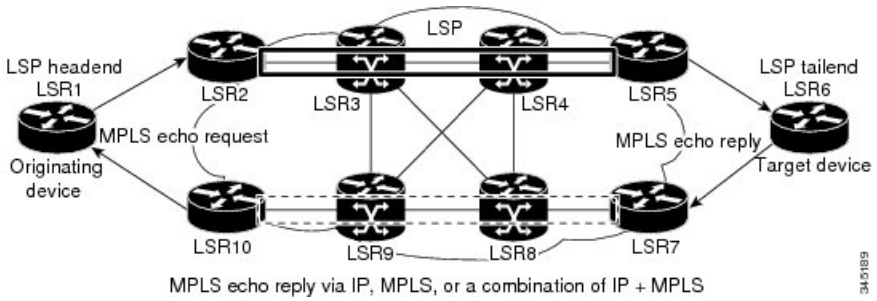
  - What is the expected MPLS experimental (EXP) treatment?
  - What is the expected maximum size packet or maximum transmission unit (MTU) of the label switched path?
  - What is the topology? What are the expected label switched paths? How many links in the label switching path (LSP)? Trace the paths of the label switched packets including the paths for load balancing.
- Understand how to use MPLS and MPLS applications, including traffic engineering, Any Transport over MPLS (AToM), and Label Distribution Protocol (LDP). You need to
  - Know how LDP is configured
  - Understand AToM concepts
- Understand label switching, forwarding, and load balancing.

Restrictions for MPLS LSP Ping, Traceroute, and AToM VCCV

- You cannot use MPLS LSP Traceroute to trace the path taken by Any Transport over Multiprotocol Label Switching (AToM) packets. MPLS LSP Traceroute is not supported for AToM. (MPLS LSP Ping is supported for AToM.) However, you can use MPLS LSP Traceroute to troubleshoot the Interior Gateway Protocol (IGP) LSP that is used by AToM.
- You cannot use MPLS LSP Ping or Traceroute to validate or trace MPLS Virtual Private Networks (VPNs).
- You cannot use MPLS LSP Traceroute to troubleshoot label switching paths (LSPs) that employ time-to-live (TTL) hiding.

Information About MPLS LSP Ping, Traceroute, and AToM VCCV

MPLS LSP Ping Operation



MPLS LSP Ping uses Multiprotocol Label Switching (MPLS) echo request and reply packets to validate a label switched path (LSP). Both an MPLS echo request and an MPLS echo reply are User Datagram Protocol (UDP) packets with source and destination ports set to 3503.

The MPLS echo request packet is sent to a target device through the use of the appropriate label stack associated with the LSP to be validated. Use of the label stack causes the packet to be switched inband of the LSP (that is, forwarded over the LSP itself). The destination IP address of the MPLS echo request packet is different from the address used to select the label stack. The destination address of the UDP packet is defined as a 127.*x* .*y* .*z* /8 address. This prevents the IP packet from being IP switched to its destination if the LSP is broken.

An MPLS echo reply is sent in response to an MPLS echo request. It is sent as an IP packet and forwarded using IP, MPLS, or a combination of both types of switching. The source address of the MPLS echo reply packet is an address from the device generating the echo reply. The destination address is the source address of the device in the MPLS echo request packet.

The figure below shows the echo request and echo reply paths for MPLS LSP Ping.

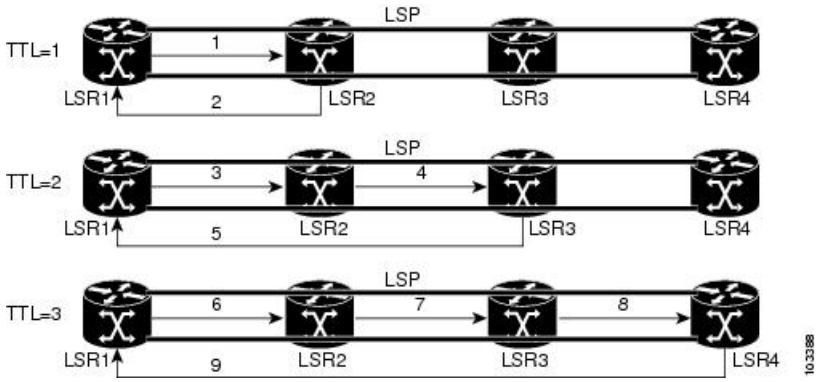
Figure 20: MPLS LSP Ping Echo Request and Echo Reply Paths

If you initiate an MPLS LSP Ping request at LSR1 to a Forwarding Equivalence Class (FEC), at LSR6, you get the results shown in the table below .

Table 21: MPLS LSP Ping Example

Step	Device	Action
1.	LSR1	Initiates an MPLS LSP Ping request for an FEC at the target device LSR6 and sends an MPLS echo request to LSR2.
1.	LSR2	Receives and forwards the MPLS echo request packet through transit devices LSR3 and LSR4 to the penultimate device LSR5.
1.	LSR5	Receives the MPLS echo request, pops the MPLS label, and forwards the packet to LSR6 as an IP packet.
1.	LSR6	Receives the IP packet, processes the MPLS echo request, and sends an MPLS echo reply to LSR1 through an alternate route.
1.	LSR7 to LSR10	Receive and forward the MPLS echo reply back toward LSR1, the originating device.
1.	LSR1	Receives the MPLS echo reply in response to the MPLS echo request.

You can use MPLS LSP Ping to validate IPv4 Label Distribution Protocol (LDP), Any Transport over MPLS (AToM), and IPv4 Resource Reservation Protocol (RSVP) FECs by using appropriate keywords and arguments with the command:



MPLS LSP Traceroute Operation

MPLS LSP Traceroute also uses Multiprotocol Label Switching (MPLS) echo request and reply packets to validate a label switched path (LSP). The echo request and echo reply are User Datagram Protocol (UDP) packets with source and destination ports set to 3503.

The MPLS LSP Traceroute feature uses time-to-live (TTL) settings to force expiration of the TTL along an LSP. MPLS LSP Traceroute incrementally increases the TTL value in its MPLS echo requests (TTL = 1, 2, 3, 4, ...) to discover the downstream mapping of each successive hop. The success of the LSP traceroute depends on the transit device processing the MPLS echo request when it receives a labeled packet with a TTL of 1. On Cisco devices, when the TTL expires, the packet is sent to the Route Processor (RP) for processing. The transit device returns an MPLS echo reply containing information about the transit hop in response to the TTL-expired MPLS packet.

The figure below shows an MPLS LSP Traceroute example with an LSP from LSR1 to LSR4.

Figure 21: MPLS LSP Traceroute Example

If you enter an LSP traceroute to a Forwarding Equivalence Class (FEC) at LSR4 from LSR1, you get the results shown in the table below.

Table 22: MPLS LSP Traceroute Example

Step	Device	MPLS Packet Type and Description	Device Action
1.	LSR1	MPLS echo request—With a target FEC pointing to LSR4 and to a downstream mapping.	• Sets the TTL of the label stack to 1. • Sends the request to LSR2.
1.	LSR2	MPLS echo reply.	Receives packet with TTL = 1. • Processes the UDP packet as an MPLS echo request. • Finds a downstream mapping, replies to LSR1 with its own downstream mapping based on the incoming label, and sends a reply.
1.	LSR1	MPLS echo request—With the same target FEC and the downstream mapping received in the echo reply from LSR2.	• Sets the TTL of the label stack to 2. • Sends the request to LSR2.
1.	LSR2	MPLS echo request.	Receives packet with TTL = 2. • Decrements the TTL. • Forwards the echo request to LSR3.
1.	LSR3	MPLS reply packet.	Receives packet with TTL = 1. • Processes the UDP packet as an MPLS echo request. • Finds a downstream mapping and replies to LSR1 with its own downstream mapping based on the incoming label.
1.	LSR1	MPLS echo request—With the same target FEC and the downstream mapping received in the echo reply from LSR3.	• Sets the TTL of the packet to 3. • Sends the request to LSR2.

Step	Device	MPLS Packet Type and Description	Device Action
1.	LSR2	MPLS echo request.	Receives packet with TTL = 3. • Decrements the TTL. • Forwards the echo request to LSR3.
1.	LSR3	MPLS echo request.	Receives packet with TTL = 2 • Decrements the TTL. • Forwards the echo request to LSR4.
1.	LSR4	MPLS echo reply.	Receives packet with TTL = 1. • Processes the UDP packet as an MPLS echo request. • Finds a downstream mapping and also finds that the device is the egress device for the target FEC. • Replies to LSR1.

You can use MPLS LSP Traceroute to validate IPv4 Label Distribution Protocol (LDP) and IPv4 RSVP FECs by using appropriate keywords and arguments with the **trace mpls** command:

By default, the TTL is set to 30. Therefore, the traceroute output always contains 30 lines, even if an LSP problem exists. This might mean duplicate entries in the output, should an LSP problem occur. The device address of the last point that the trace reaches is repeated until the output is 30 lines. You can ignore the duplicate entries. The following example shows that the trace encountered an LSP problem at the device that has an IP address of 10.6.1.6:

```
Device# traceroute mpls ipv4 10.6.7.4/32
Tracing MPLS Label Switched Path to 10.6.7.4/32, timeout is 2 seconds
Codes: '!' - success, 'Q' - request not transmitted,
       '.' - timeout, 'U' - unreachable,
       'R' - downstream router but not target
Type escape sequence to abort.
  0 10.6.1.14 MRU 4470 [Labels: 22 Exp: 0]
R 1 10.6.1.5 MRU 4470 [Labels: 21 Exp: 0] 2 ms
R 2 10.6.1.6 4 ms                  <------ Router address repeated for 2nd to 30th TTL.
R 3 10.6.1.6 1 ms
R 4 10.6.1.6 1 ms
R 5 10.6.1.6 3 ms
R 6 10.6.1.6 4 ms
R 7 10.6.1.6 1 ms
R 8 10.6.1.6 2 ms
R 9 10.6.1.6 3 ms
R 10 10.6.1.6 4 ms
R 11 10.6.1.6 1 ms
R 12 10.6.1.6 2 ms
R 13 10.6.1.6 4 ms
R 14 10.6.1.6 5 ms
R 15 10.6.1.6 2 ms
R 16 10.6.1.6 3 ms
R 17 10.6.1.6 4 ms
R 18 10.6.1.6 2 ms
R 19 10.6.1.6 3 ms
```

```
R 20 10.6.1.6 4 ms
R 21 10.6.1.6 1 ms
R 22 10.6.1.6 2 ms
R 23 10.6.1.6 3 ms
R 24 10.6.1.6 4 ms
R 25 10.6.1.6 1 ms
R 26 10.6.1.6 3 ms
R 27 10.6.1.6 4 ms
R 28 10.6.1.6 1 ms
R 29 10.6.1.6 2 ms
R 30 10.6.1.6 3 ms                    <------ TTL 30.
```

If you know the maximum number of hops in your network, you can set the TTL to a smaller value with the **trace mpls ttl** *maximum-time-to-live* command. The following example shows the same **traceroute** command as the previous example, except that this time the TTL is set to 5.

```
Device# traceroute mpls ipv4 10.6.7.4/32 ttl 5
Tracing MPLS Label Switched Path to 10.6.7.4/32, timeout is 2 seconds
Codes: '!' - success, 'Q' - request not transmitted,
       '.' - timeout, 'U' - unreachable,
       'R' - downstream router but not target
Type escape sequence to abort.
  0 10.6.1.14 MRU 4470 [Labels: 22 Exp: 0]
R 1 10.6.1.5 MRU 4474 [No Label] 3 ms
R 2 10.6.1.6 4 ms                  <------ Router address repeated for 2nd to 5th TTL.
R 3 10.6.1.6 1 ms
R 4 10.6.1.6 3 ms

Any Transport over MPLS Virtual Circuit Connection Verification

AToM Virtual Circuit Connection Verification (AToM VCCV) allows the sending of control packets inband of an AToM pseudowire (PW) from the originating provider edge (PE) device. The transmission is intercepted at the destination PE device, instead of being forwarded to the customer edge (CE) device. This capability allows you to use MPLS LSP Ping to test the PW section of AToM virtual circuits (VCs).

AToM VCCV consists of the following:

- A signaled component in which the AToM VCCV capabilities are advertised during VC label signaling
- A switching component that causes the AToM VC payload to be treated as a control packet

AToM VCCV Signaling

One of the steps involved in Any Transport over Multiprotocol Label Switching (AToM) virtual circuit (VC) setup is the signaling of VC labels and AToM Virtual Circuit Connection Verification (VCCV) capabilities between AToM VC endpoints. The device uses an optional parameter, defined in the Internet Draft *draft-ieft-pwe3-vccv-01.txt,* to communicate the AToM VCCV disposition capabilities of each endpoint.

The AToM VCCV disposition capabilities are categorized as follows:

- Applications—MPLS LSP Ping and Internet Control Message Protocol (ICMP) Ping are applications that AToM VCCV supports to send packets inband of an AToM PW for control purposes.
- Switching modes—Type 1 and Type 2 are switching modes that AToM VCCV uses for differentiating between control and data traffic.

The table below describes AToM VCCV Type 1 and Type 2 switching modes.

Table 23: Type 1 and Type 2 AToM VCCV Switching Modes

Switching Mode	Description
Type 1	Uses a Protocol ID (PID) field in the AToM control word to identify an AToM VCCV packet.
Type 2	Uses an MPLS Router Alert Label above the VC label to identify an AToM VCCV packet.

Selection of AToM VCCV Switching Types

Cisco devices always use Type 1 switching, if available, when they send MPLS LSP Ping packets over an Any Transport over Multiprotocol Label Switching (AToM) virtual circuit (VC) control channel. Type 2 switching accommodates those VC types and implementations that do not support or interpret the AToM control word.

The table below shows the AToM Virtual Circuit Connection Verification (VCCV) switching mode advertised and the switching mode selected by the AToM VC.

Table 24: AToM VCCV Switching Mode Advertised and Selected by AToM Virtual Circuit

Type Advertised	Type Selected
AToM VCCV not supported	–
Type 1 AToM VCCV switching	Type 1 AToM VCCV switching
Type 2 AToM VCCV switching	Type 2 AToM VCCV switching
Type 1 and Type 2 AToM VCCV switching	Type 1 AToM VCCV switching

An AToM VC advertises its AToM VCCV disposition capabilities in both directions: that is, from the originating device (PE1) to the destination device (PE2), and from PE2 to PE1.

In some instances, AToM VCs might use different switching types if the two endpoints have different AToM VCCV capabilities. If PE1 supports Type 1 and Type 2 AToM VCCV switching and PE2 supports only Type 2 AToM VCCV switching, there are two consequences:

- LSP ping packets sent from PE1 to PE2 are encapsulated with Type 2 switching.
- LSP ping packets sent from PE2 to PE1 use Type 1 switching.

You can determine the AToM VCCV capabilities advertised to and received from the peer by entering the **show mpls l2transport binding** command at the PE device. For example:

```
Device# show mpls l2transport binding

  Destination Address: 10.131.191.252,  VC ID: 333
    Local Label:  16
        Cbit: 1,    VC Type: FastEthernet,    GroupID: 0
        MTU: 1500,   Interface Desc: n/a
        VCCV Capabilities: Type 1, Type 2
    Remote Label: 19
        Cbit: 1,    VC Type: FastEthernet,    GroupID: 0
        MTU: 1500,   Interface Desc: n/a
        VCCV Capabilities: Type 1
```

Command Options for ping mpls and trace mpls

MPLS LSP Ping and Traceroute command options are specified as keywords and arguments on the **ping mpls** and **trace mpls** commands.

The **ping mpls** command provides the options displayed in the command syntax below:

The **trace mpls** command provides the options displayed in the command syntax below:

Selection of FECs for Validation

A label switched path (LSP) is formed by labels. Devices learn labels through the Label Distribution Protocol (LDP), traffic engineering (TE), Any Transport over Multiprotocol Label Switching (AToM), or other MPLS applications. You can use MPLS LSP Ping and Traceroute to validate an LSP used for forwarding traffic for a given Forwarding Equivalence Class (FEC). The table below lists the keywords and arguments for the **ping mpls** and **traceroute mpls** commands that allow the selection of an LSP for validation.

Table 25: Selection of LSPs for Validation

FEC Type	ping mpls Keyword and Argument	traceroute mpls Keyword and Argument
LDP IPv4 prefix	**ipv4** *destination-address destination-mask*	**ipv4** *destination-address destination-mask*
MPLS TE tunnel	**traffic-eng** *tunnel-interface tunnel-number*	**traffic-eng** *tunnel-interface tunnel-number*
AToM VC	**pseudowire** *ipv4-address* **vc-id** *vc-id*	MPLS LSP Traceroute does not support the AToM tunnel LSP type for this release.

Reply Mode Options for MPLS LSP Ping and Traceroute

The reply mode is used to control how the responding device replies to a Multiprotocol Label Switching (MPLS) echo request sent by an MPLS LSP Ping or MPLS LSP Traceroute command. The table below describes the reply mode options.

Table 26: Reply Mode Options for a Responding Device

Option	Description
ipv4	Reply with an IPv4 User Datagram Protocol (UDP) packet (default). This is the most common reply mode selected for use with an MPLS LSP Ping and Traceroute command when you want to periodically poll the integrity of a label switched path (LSP). With this option, you do not have explicit control over whether the packet traverses IP or MPLS hops to reach the originator of the MPLS echo request. If the headend device fails to receive a reply, select the router-alert option, “Reply with an IPv4 UDP packet with a router alert.” The responding device sets the IP precedence of the reply packet to 6. You implement this option using the **reply mode ipv4** keywords.

Option	Description
router-alert	Reply with an IPv4 UDP packet with a device alert. This reply mode adds the router alert option to the IP header. This forces the packet to be special handled by the Cisco device at each intermediate hop as it moves back to the destination. This reply mode is more expensive, so use the router-alert option only if you are unable to get a reply with the ipv4 option, “Reply with an IPv4 UDP packet.” You implement this option using the **reply mode router-alert** keywords

The reply with an IPv4 UDP packet implies that the device should send an IPv4 UDP packet in reply to an MPLS echo request. If you select the ipv4 reply mode, you do not have explicit control over whether the packet uses IP or MPLS hops to reach the originator of the MPLS echo request. This is the mode that you would normally use to test and verify LSPs.

The reply with an IPv4 UDP packet that contains a device alert forces the packet to go back to the destination and be processed by the Route Processor (RP) process switching at each intermediate hop. This bypasses hardware/line card forwarding table inconsistencies. You should select this option when the originating (headend) devices fail to receive a reply to the MPLS echo request.

You can instruct the replying device to send an echo reply with the IP router alert option by using one of the following commands:

or

However, the reply with a router alert adds overhead to the process of getting a reply back to the originating device. This method is more expensive to process than a reply without a router alert and should be used only if there are reply failures. That is, the reply with a router alert label should only be used for MPLS LSP Ping or MPLS LSP Traceroute when the originating (headend) device fails to receive a reply to an MPLS echo request.

Packet Handling Along Return Path with an IP MPLS Router Alert

When an IP packet that contains an IP router alert option in its IP header or a Multiprotocol Label Switching (MPLS) packet with a router alert label as its outermost label arrives at a device, the device punts (redirects) the packet to the Route Processor (RP) process level for handling. This allows these packets to bypass the forwarding failures in hardware routing tables. The table below describes how IP and MPLS packets with an IP router alert option are handled by the device switching path processes.

Table 27: Switching Path Process Handling of IP and MPLS Router Alert Packets

Incoming Packet	Normal Switching Action	Process Switching Action	Outgoing Packet
IP packet—Router alert option in IP header	A rRouter alert option in the IP header causes the packet to be punted to the process switching path.	Forwards the packet as is.	IP packet—Router alert option in IP header.
	A router alert option in theIP header causes the packet to be punted to the process switching path.	Adds a router alert as the outermost label and forwards as an MPLS packet.	MPLS packet— Outermost label contains a router alert.

Incoming Packet	Normal Switching Action	Process Switching Action	Outgoing Packet
MPLS packet—Outermost label contains a router alert	If the router alert label is the outermost label, the packet is punted to the process switching path.	Removes the outermost router alert label, adds an IP router alert option to the IP header, and forwards as an IP packet.	IP packet—Router alert option in IP header.
	If the router alert label is the outermost label, the packet is punted to the process switching path.	Preserves the outermost router alert label and forwards the MPLS packet.	MPLS packet— Outermost label contains a router alert.

Other MPLS LSP Ping and Traceroute Command Options

The table below describes other MPLS LSP Ping and Traceroute command options that can be specified as keywords or arguments with the **ping mpls** command, or with both the **ping mpls** and **trace mpls** commands. Options available to use only on the **ping mpls** command are indicated as such.

Table 28: Other MPLS LSP Ping and Traceroute and AToM VCCV Options

Option	Description
Datagram size	Size of the packet with the label stack imposed. Specified with the **size** *packet-size* keyword and argument. The default size is 100. For use with the MPLS LSP Ping feature only.
Padding	Padding (the pad time-length-value [TLV]) is used as required to fill the datagram so that the MPLS echo request (User Datagram Protocol [UDP] packet with a label stack) is the size specified. Specify with the **pad** *pattern* keyword and argument. For use with the MPLS LSP Ping feature only.
Sweep size range	Parameter that enables you to send a number of packets of different sizes, ranging from a start size to an end size. This parameter is similar to the Internet Control Message Protocol (ICMP) ping sweep parameter. The lower boundary on the sweep range varies depending on the label switched path (LSP) type. You can specify a sweep size range when you use the **ping mpls** command. Use the **sweep** *minimum maximum size-increment* keyword and arguments. For use with the MPLS LSP Ping feature only.
Repeat count	Number of times to resend the same packet. The default is 5 times. You can specify a repeat count when you use the **ping mpls** command. Use the **repeat** *count* keyword and argument. For use with the MPLS LSP Ping feature only.
MPLS echo request source address	Routable address of the sender. The default address is loopback0. This address is used as the destination address in the Multiprotocol Label Switching (MPLS) echo response. Use the **source** *source-address* keyword and argument. For use with the MPLS LSP Ping and Traceroute features.

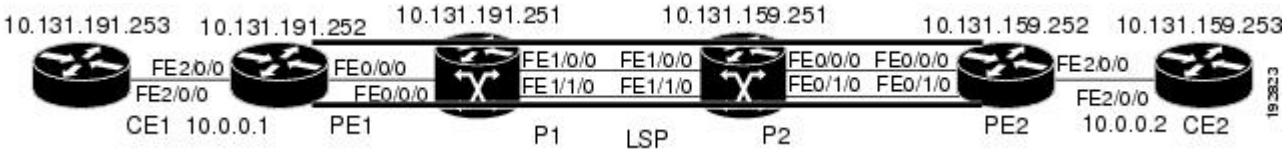
Option	Description
UDP destination address	A valid 127/8 address. You have the option to specify a single *x.y.z* or a range of numbers between 0.0.0 and *x.y.z* , where *x.y.z* are numbers between 0 and 255 and correspond to 127.*x.y.z*. Use the **destination** {*address* | *address-start address-end increment*} keyword and arguments. The MPLS echo request destination address in the UDP packet is not used to forward the MPLS packet to the destination device. The label stack that is used to forward the echo request routes the MPLS packet to the destination device. The 127/8 address guarantees that the packets are routed to the localhost (the default loopback address of the device processing the address) if the UDP packet destination address is used for forwarding. In addition, the destination address is used to affect load balancing when the destination address of the IP payload is used for load balancing. For use with IPv4 and Any Transport over MPLS (AToM) Forwarding Equivalence Classes (FECs) with the MPLS LSP Ping feature and with IPv4 FECs with the MPLS LSP Traceroute feature.
Time-to-live (TTL)	A parameter you can set that indicates the maximum number of hops a packet should take to reach its destination. The time-to-live (TTL) field in a packet is decremented by 1 each time it travels through a device. For MPLS LSP Ping, the TTL is a value after which the packet is discarded and an MPLS echo reply is sent back to the originating device. Use the **ttl** *time-to-live* keyword and argument. For MPLS LSP Traceroute, the TTL is a maximum time to live and is used to discover the number of downstream hops to the destination device. MPLS LSP Traceroute incrementally increases the TTL value in its MPLS echo requests (TTL = 1, 2, 3, 4, ...) to accomplish this. Use the **ttl** *time-to-live* keyword and argument.
Timeouts	A parameter you can specify to control the timeout in seconds for an MPLS request packet. The range is from 0 to 3600 seconds. The default is 2. Set with the **timeout** *seconds* keyword and argument. For use with the MPLS LSP Ping and Traceroute features.
Intervals	A parameter you can specify to set the time in milliseconds between successive MPLS echo requests. The default is 0. Set with the **interval** *msec* keyword and argument.
Experimental bits	Three experimental bits in an MPLS header used to specify precedence for the MPLS echo reply. (The bits are commonly called EXP bits.) The range is from 0 to 7, and the default is 0. Specify with the **exp** *exp-bits* keyword and argument. For use with the MPLS LSP Ping and Traceroute features.

Option	Description
Verbose	Option that provides additional information for the MPLS echo reply--source address and return codes. For the MPLS LSP Ping feature, this option is implemented with the **verbose** keyword. For use with the MPLS LSP Ping feature only.

MPLS LSP Ping options described in the table above can be implemented by using the following syntax:

```
ping mpls
{ipv4 destination-address destination-mask [destination address-start address-end increment]

 [ttl time-to-live] | pseudowire ipv4-address
 vc-id vc-id
[destination address-start address-end increment] | traffic-eng tunnel-interface
tunnel-number
[ttl time-to-live]}
[source source-address] [repeat count]
[{size packet-size} | {sweep minimum maximum size-Increment}]
[pad pattern]
[timeout seconds] [intervalmsec]
[exp exp-bits] [verbose
```



MPLS LSP Traceroute options described in the table below can be implemented by the use of the following syntax:

```
trace mpls
 {ipv4 destination-address destination-mask
 [destination address-start address-end address-increment] | traffic-eng tunnel-interface
tunnel-number}
[source source-address] [timeout seconds]
[ttl maximum-time-to-live]
[exp exp-bits]
```

Option Interactions and Loops

Usage examples for the MPLS LSP Ping and Traceroute and AToM VCCV feature in this and subsequent sections are based on the sample topology shown in the figure below.

Figure 22: Sample Topology for Configuration Examples

The interaction of some MPLS LSP Ping and Traceroute and AToM VCCV options can cause loops. See the following topic for a description of the loops you might encounter with the **ping mpls** and **trace mpls** commands:

Possible Loops with MPLS LSP Ping

With the MPLS LSP Ping feature, loops can occur if you use the repeat count option, the sweep size range option, or the User Datagram Protocol (UDP) destination address range option.

```
ping mpls
 {ipv4 destination-address/destination-mask
[destination address-start address-end increment] | pseudowire ipv4-address
 vc-id vc-id
 [destination address-start address-end increment] |
traffic-eng tunnel-interface tunnel-number}
[repeat count]
[sweep minimum maximum size-increment]
```

Following is an example of how a loop operates if you use the following keywords and arguments on the **ping mpls** command:

```
Device# ping mpls
 ipv4
 10.131.159.251/32 destination 127.0.0.1 127.0.0.1 0.0.0.1 repeat 2
sweep 1450 1475 25
Sending 2, [1450..1500]-byte MPLS Echos to 10.131.159.251/32,
     timeout is 2 seconds, send interval is 0 msec:
Codes: '!' - success, 'Q' - request not transmitted,
       '.' - timeout, 'U' - unreachable,
       'R' - downstream router but not target
Type escape sequence to abort.
Destination address 127.0.0.1
!
!
Destination address 127.0.0.1
!
!
Destination address 127.0.0.1
!
!
Destination address 127.0.0.1
!
!
```

An **mpls ping** command is sent for each packet size range for each destination address until the end address is reached. For this example, the loop continues in the same manner until the destination address, 127.0.0.1, is reached. The sequence continues until the number is reached that you specified with the **repeat** *count* keyword and argument. For this example, the repeat count is 2. The MPLS LSP Ping loop sequence is as follows:

```
repeat  = 1
  destination address 1 (address-start
)
    for (size from sweep
 minimum
 to maximum
, counting by size-increment
)
      send an lsp ping
  destination address 2 (address-start
 +
address-
increment
)
    for (size from sweep
 minimum
 to maximum
, counting by size-increment
)
      send an lsp ping
```

```
  destination address 3 (address-start
 +
address-
increment
 +
address-
increment
)
     for (size from sweep
 minimum
 to maximum
, counting by size-increment
)
      send an lsp ping
.
.
.
  until destination address = address-end
.
.
.
until repeat = count
```

Possible Loop with MPLS LSP Traceroute

With the MPLS LSP Traceroute feature, loops can occur if you use the User Datagram Protocol (UDP) destination address range option and the time-to-live option.

Here is an example of how a loop operates if you use the following keywords and arguments on the **trace mpls** command:

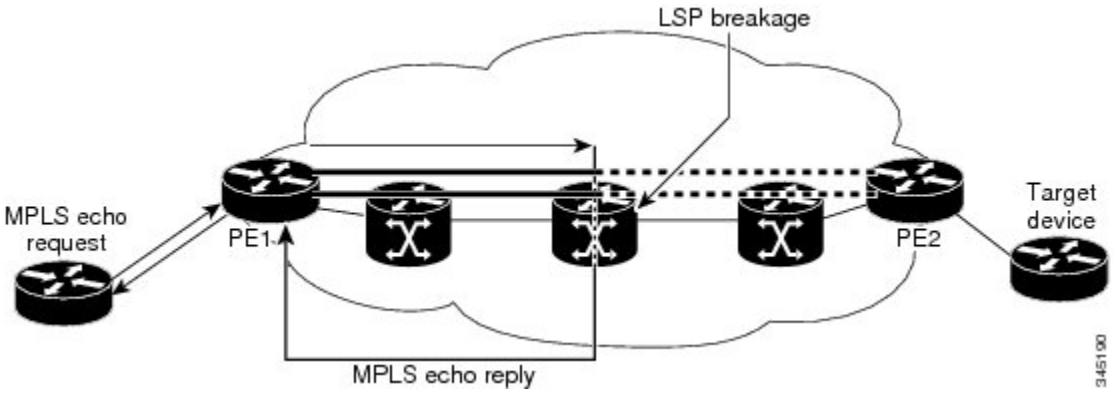
```
Device# trace mpls
ipv4
 10.131.159.251/32 destination 127.0.0.1 127.0.0.1 1 ttl 5
Tracing MPLS Label Switched Path to 10.131.159.251/32, timeout is 2 seconds
Codes: '!' - success, 'Q' - request not transmitted,
       '.' - timeout, 'U' - unreachable,
       'R' - downstream router but not target
Type escape sequence to abort.
Destination address 127.0.0.1
  0 10.131.191.230 MRU 1500 [Labels: 19 Exp: 0]
R 1 10.131.159.226 MRU 1504 [implicit-null] 40 ms
! 2 10.131.159.225 40 ms
Destination address 127.0.0.2
  0 10.131.191.230 MRU 1500 [Labels: 19 Exp: 0]
R 1 10.131.159.226 MRU 1504 [implicit-null] 40 ms
! 2 10.131.159.225 40 ms
Destination address 127.0.0.3
  0 10.131.191.230 MRU 1500 [Labels: 19 Exp: 0]
R 1 10.131.159.226 MRU 1504 [implicit-null] 40 ms
! 2 10.131.159.225 48 ms
```

An **mpls trace** command is sent for each TTL from 1 to the maximum TTL (**ttl** *maximum-time-to-live* keyword and argument) for each destination address until the address specified with the destination *end-address* argument is reached. For this example, the maximum TTL is 5 and the end destination address is 127.0.0.1. The MPLS LSP Traceroute loop sequence is as follows:

```
destination address 1 (address-start
)
  for (ttl
 from 1 to maximum-time-to-live
```

```
)
    send an lsp trace
destination address 2 (address-start
 + address-increment
)
  for (ttl
 from 1 to maximum-time-to-live
)
    send an lsp trace
destination address 3 (address-start
 + address-increment
 + address-increment
)
  for (ttl
 from 1 to
maximum-time-to-live)
    send an lsp trace
.
.
.
until destination address = address-end
```

MPLS Echo Request Packets Not Forwarded by IP



Multiprotocol Label Switching (MPLS) echo request packets sent during a label switched path (LSP) ping are never forwarded by IP. The IP header destination address field in an MPLS echo request packet is a 127.*x.y.z* /8 address. Devices should not forward packets using a 127.*x.y.z* /8 address. The 127.*x.y.z* /8 address corresponds to an address for the local host.

The use of a 127.*x .y .z* address as a destination address of the User Datagram Protocol (UDP) packet is significant in that the MPLS echo request packet fails to make it to the target device if a transit device does not label switch the LSP. This allows for the detection of LSP breakages.

- If an LSP breakage occurs at a transit device, the MPLS echo packet is not forwarded, but consumed by the device.
- If the LSP is intact, the MPLS echo packet reaches the target device and is processed by the terminal point of the LSP.

The figure below shows the path of the MPLS echo request and reply when a transit device fails to label switch a packet in an LSP.

Figure 23: Path When Transit Device Fails to Label Switch a Packet

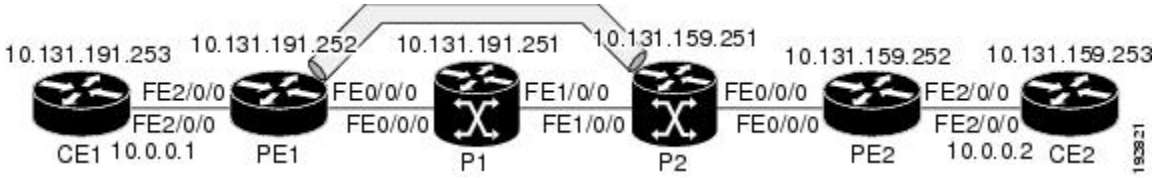
Note An Any Transport over MPLS (AToM) payload does not contain usable forwarding information at a transit device because the payload might not be an IP packet. An MPLS virtual private network (VPN) packet, although an IP packet, does not contain usable forwarding information at a transit device because the destination IP address is only significant to the virtual routing and forwarding (VRF) instances at the endpoints of the MPLS network.

Information Provided by the Device Processing LSP Ping or LSP Traceroute

The table below describes the characters that the device processing an LSP ping or LSP traceroute packet returns to the sender about the failure or success of the request.

You can also view the return code for an MPLS LSP Ping operation if you enter the **ping mpls verbose** command.

Table 29: LSP Ping and Traceroute Reply Characters



Character	Meaning
Period "."	A timeout occurs before the target device can reply.
U	The target device is unreachable.
R	The device processing the Multiprotocol Label Switching (MPLS) echo request is a downstream device but is not the destination.
Exclamation mark "!"	Replying device is an egress for the destination.
Q	Echo request was not successfully transmitted. This could be returned because of insufficient memory or more probably because no label switched path (LSP) exists that matches the Forwarding Equivalence Class (FEC) information.
C	Replying device rejected the echo request because it was malformed.

MTU Discovery in an LSP

During an MPLS LSP Ping, Multiprotocol Label Switching (MPLS) echo request packets are sent with the IP packet attribute set to do not fragment. That is, the DF bit is set in the IP header of the packet. This allows you to use the MPLS echo request to test for the MTU that can be supported for the packet through the label switched path (LSP) without fragmentation.

The figure below shows a sample network with a single LSP from PE1 to PE2 formed with labels advertised by means of LDP.

Figure 24: Sample Network with LSP—Labels Advertised by LDP

You can determine the maximum receive unit (MRU) at each hop by tracing the LSP using the MPLS Traceroute feature. The MRU is the maximum size of a labeled packet that can be forwarded through an LSP. The following example shows the results of a **trace mpls** command when the LSP is formed with labels created by the Label Distribution Protocol (LDP):

```
Device# trace mpls ipv4 10.131.159.252/32
Tracing MPLS Label Switched Path to 10.131.159.252/32, timeout is 2 seconds
Codes: '!' - success, 'Q' - request not transmitted,
       '.' - timeout, 'U' - unreachable,
       'R' - downstream router but not target
Type escape sequence to abort.
  0 10.131.191.230 MRU 1496 [Labels: 22/19 Exp: 0/0]
R 1 10.131.159.226 MRU 1500 [Labels: 19 Exp: 0] 40 ms
R 2 10.131.159.229 MRU 1504 [implicit-null] 28 ms
! 3 10.131.159.230 40 ms
```

You can determine the MRU for the LSP at each hop through the use of the **show forwarding detail** command:

```
Device# show mpls forwarding 10.131.159.252 detail

Local  Outgoing    Prefix            Bytes tag  Outgoing   Next Hop
tag    tag or VC   or Tunnel Id      switched   interface
22     19          10.131.159.252/32 0          Tu1        point2point
        MAC/Encaps=14/22, MRU=1496, Tag Stack{22 19}, via Et0/0
        AABBCC009700AABBCC0098008847 0001600000013000
        No output feature configured
```

To determine the maximum sized echo request that will fit on the LSP, you can find the IP MTU by using the **show interface** *type number* command.

```
Device# show interface e0/0

FastEthernet0/0/0 is up, line protocol is up
  Hardware is Lance, address is aabb.cc00.9800 (bia aabb.cc00.9800)
  Internet address is 10.131.191.230/30
  MTU 1500 bytes, BW 10000 Kbit, DLY 1000 usec, rely 255/255, load ½55
  Encapsulation ARPA, loopback not set
  Keepalive set (10 sec)
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input 00:00:01, output 00:00:01, output hang never
  Last clearing of "show interface" counters never
  Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/40 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     377795 packets input, 33969220 bytes, 0 no buffer
     Received 231137 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
     0 input packets with dribble condition detected
     441772 packets output, 40401350 bytes, 0 underruns
```

```
     0 output errors, 0 collisions, 10 interface resets
     0 babbles, 0 late collision, 0 deferred
     0 lost carrier, 0 no carrier
     0 output buffer failures, 0 output buffers swapped out
```

The IP MTU in the **show interface** *type number* example is 1500 bytes. Subtract the number of bytes corresponding to the label stack from the MTU number. From the output of the **show mpls forwarding** command, the Tag stack consists of one label (21). Therefore, the largest MPLS echo request packet that can be sent in the LSP, shown in the figure above, is 1500 - (2 x 4) = 1492.

You can validate this by using the following **ping mpls** command:

```
Device# ping mpls ipv4 10.131.159.252/32 sweep 1492 1500 1 repeat 1
Sending 1, [1492..1500]-byte MPLS Echos to 10.131.159.252/32,
     timeout is 2 seconds, send interval is 0 msec:
Codes: '!' - success, 'Q' - request not transmitted,
       '.' - timeout, 'U' - unreachable,
       'R' - downstream router but not target
Type escape sequence to abort.
!QQQQQQQQ
Success rate is 11 percent (1/9), round-trip min/avg/max = 40/40/40 ms
```

In this command, only packets of 1492 bytes are sent successfully, as indicated by the exclamation point (!). Packets of byte sizes 1493 to 1500 are source-quenched, as indicated by the Q.

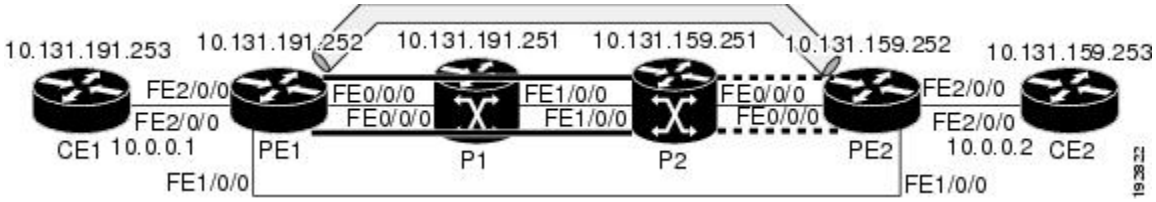
You can pad an MPLS echo request so that a payload of a given size can be tested. The pad TLV is useful when you use the MPLS echo request to discover the MTU supportable by an LSP. MTU discovery is extremely important for applications like AToM that contain non-IP payloads that cannot be fragmented.

LSP Network Management

To manage a Multiprotocol Label Switching (MPLS) network you must have the ability to monitor label switched paths (LSPs) and quickly isolate MPLS forwarding problems. You need ways to characterize the liveliness of an LSP and reliably detect when a label switched path fails to deliver user traffic.

You can use MPLS LSP Ping to verify the LSP that is used to transport packets destined for IPv4 Label Distribution Protocol (LDP) prefixes, traffic engineering (TE) tunnels, and Any Transport over MPLS pseudowire Forwarding Equivalence Classes (AToM PW FECs). You can use MPLS LSP Traceroute to trace LSPs that are used to carry packets destined for IPv4 LDP prefixes and TE tunnel FECs.

An MPLS echo request is sent through an LSP to validate it. A TTL expiration or LSP breakage causes the transit device to process the echo request before it gets to the intended destination and returns an MPLS echo reply that contains an explanatory reply code to the originator of the echo request.



The successful echo request is processed at the egress of the LSP. The echo reply is sent via an IP path, an MPLS path, or a combination of both back to the originator of the echo request.

ICMP ping and trace Commands and Troubleshooting

Internet Control Message Protocol (ICMP) **ping** and **trace** commands are often used to help diagnose the root cause of a failure. When a label switched path (LSP) is broken, the packet might make its way to the target device by way of IP forwarding, thus making ICMP ping and traceroute unreliable for detecting Multiprotocol Label Switching (MPLS) forwarding problems. The MPLS LSP Ping, Traceroute and AToM VCCV feature extends this diagnostic and troubleshooting ability to the MPLS network and handles inconsistencies between the IP and MPLS forwarding tables, inconsistencies in the MPLS control and data plane, and problems with the reply path.

The figure below shows a sample topology with a Label Distribution Protocol (LDP) LSP and traffic engineering (TE) tunnel LSP.

Figure 25: Sample Topology with LDP and TE Tunnel LSPs

This section contains the following topics:

MPLS LSP Ping and Traceroute Discovers LSP Breakage

Configuration for Sample Topology

These are sample topology configurations for the troubleshooting examples in the following sections (see the figure above). There are the six sample device configurations.

Device CE1 Configuration

```
version 12.0
!
hostname ce1
!

Verifying That the LSP Is Set Up Correctly

A **show mpls forwarding-table** command shows that tunnel 1 is in the Multiprotocol Label Switching (MPLS) forwarding table.

```
Device# show mpls forwarding-table 10.131.159.252

Local  Outgoing    Prefix            Bytes tag  Outgoing   Next Hop
tag    tag or VC   or Tunnel Id      switched   interface
22     19
     [T] 10.131.159.252/32 0          Tu1
        point2point
[T]     Forwarding through a TSP tunnel.
        View additional tagging info with the 'detail' option
```

A **show mpls traffic-eng tunnels tunnel 1** command entered at PE1 displays information about tunnel 1 and verifies that it is forwarding packets with an out label of 22.

```
Device# show mpls traffic-eng tunnels tunnel 1

Name: PE1_t1                           (Tunnel1) Destination: 10.131.159.251
  Status:

    Prior LSP:
      ID: path option 1 [3]
      Removal Trigger: tunnel shutdown
```

A **trace mpls** command issued at PE1 verifies that packets with 22 as the outermost label and 19 as the end of stack label are forwarded from PE1 to PE2.

```
Device# trace mpls ipv4 10.131.159.252/32
Tracing MPLS Label Switched Path to 10.131.159.252/32, timeout is 2 seconds
Codes: '!' - success, 'Q' - request not transmitted,
       '.' - timeout, 'U' - unreachable,
       'R' - downstream router but not target
Type escape sequence to abort.
  0 10.131.191.230 MRU 1496 [Labels: 22/19
 Exp: 0/0]
R 1 10.131.159.226 MRU 1504 [Labels: 19 Exp: 0] 40 ms
R 2 10.131.159.229 MRU 1504 [implicit-null] 28 ms
! 3 10.131.159.230 40 ms
```

The MPLS LSP Traceroute to PE2 is successful, as indicated by the exclamation point (!).

Discovering LSP Breakage

A Label Distribution Protocol (LDP) target-session is established between devices PE1 and P2, as shown in the output of the following **show mpls ldp discovery** command:

```
Device# show mpls ldp discovery

 Local LDP Identifier:
    10.131.191.252:0
    Discovery Sources:
    Interfaces:
         (ldp): xmit/recv
            LDP Id: 10.131.191.251:0
        Tunnel1 (ldp): Targeted -> 10.131.159.251
    Targeted Hellos:
        10.131.191.252 -> 10.131.159.252 (ldp): active/passive, xmit/recv
            LDP Id: 10.131.159.252:0
        10.131.191.252 -> 10.131.159.251 (ldp): active, xmit/recv
            LDP Id: 10.131.159.251:0
```

Enter the following command on the P2 device in global configuration mode:

```
Device# no mpls ldp discovery targeted-hello accept
```

The LDP configuration change causes the targeted LDP session between the headend and tailend of the traffic engineering (TE) tunnel to go down. Labels for IPv4 prefixes learned by P2 are not advertised to PE1. Thus, all IP prefixes reachable by P2 are reachable by PE1 only through IP (not MPLS). In other words, packets destined for those prefixes through Tunnel 1 at PE1 will be IP switched at P2 (which is undesirable).

The following **show mpls ldp discovery** command shows that the LDP targeted-session is down:

```
Device# show mpls ldp discovery

 Local LDP Identifier:
    10.131.191.252:0
    Discovery Sources:
    Interfaces:
        (ldp): xmit/recv
            LDP Id: 10.131.191.251:0
        Tunnel1 (ldp): Targeted -> 10.131.159.251
    Targeted Hellos:
        10.131.191.252 -> 10.131.159.252 (ldp): active/passive, xmit/recv
            LDP Id: 10.131.159.252:0
        10.131.191.252 -> 10.131.159.251 (ldp): active, xmit
```

Enter the **show mpls forwarding-table** command at the PE1 device. The display shows that the outgoing packets are untagged as a result of the LDP configuration changes.

```
Device# show mpls forwarding-table 10.131.159.252

Local  Outgoing    Prefix            Bytes tag  Outgoing   Next Hop
tag    tag or VC   or Tunnel Id      switched   interface
22     Untagged[T]
 10.131.159.252/32 0          Tu1        point2point
[T]     Forwarding through a TSP tunnel.
        View additional tagging info with the 'detail' option
```

A **ping mpls** command entered at the PE1 device displays the following:

```
Device# ping mpls ipv4 10.131.159.252/32 repeat 1
Sending 1, 100-byte MPLS Echos to 10.131.159.252/32,
      timeout is 2 seconds, send interval is 0 msec:
Codes: '!' - success, 'Q' - request not transmitted,
       '.' - timeout, 'U' - unreachable,
       'R' - downstream router but not target
Type escape sequence to abort.
R
Success rate is 0 percent (0/1)
```

The **ping mpls** command fails. The R indicates that the sender of the Multiprotocol Label Switching (MPLS) echo reply had a routing entry but no MPLS Forwarding Equivalence Class (FEC) . Entering the **ping mpls verbose** command displays the MPLS label switched path (LSP) echo reply sender address and the return code. You should be able to solve the problem by Telneting to the replying device and inspecting its forwarding and label tables. You might need to look at the neighboring upstream device as well, because the breakage might be on the upstream device.

```
Device# ping mpls ipv4 10.131.159.252/32 repeat 1 verbose
Sending 1, 100-byte MPLS Echos to 10.131.159.252/32,
      timeout is 2 seconds, send interval is 0 msec:
Codes: '!' - success, 'Q' - request not transmitted,
       '.' - timeout, 'U' - unreachable,
```

```
       'R' - downstream router but not target
Type escape sequence to abort.
R   10.131.159.225, return code 6
Success rate is 0 percent (0/1)
```

Alternatively, use the LSP **traceroute** command to figure out which device caused the breakage. In the following example, for subsequent values of TTL greater than 2, the same device keeps responding (10.131.159.225). This suggests that the MPLS echo request keeps getting processed by the device regardless of the TTL. Inspection of the label stack shows that P1 pops the last label and forwards the packet to P2 as an IP packet. This explains why the packet keeps getting processed by P2. MPLS echo request packets cannot be forwarded by use of the destination address in the IP header because the address is set to a 127/8 address.

```
Device# trace mpls ipv4 10.131.159.252/32 ttl 5
Tracing MPLS Label Switched Path to 10.131.159.252/32, timeout is 2 seconds
Codes: '!' - success, 'Q' - request not transmitted,
       '.' - timeout, 'U' - unreachable,
       'R' - downstream router but not target
Type escape sequence to abort.
  0 10.131.191.230 MRU 1500 [Labels: 22 Exp: 0]
R 1 10.131.159.226 MRU 1504 [implicit-null] 40 ms
R 2 10.131.159.225 40 ms
R 3 10.131.159.225 40 ms
R 4 10.131.159.225 40 ms
R 5 10.131.159.225 40 ms
```

MPLS LSP Traceroute Tracks Untagged Cases

This troubleshooting section contains examples of how to use MPLS LSP Traceroute to determine potential issues with packets that are tagged as implicit null and packets that are untagged.

Untagged output interfaces at a penultimate hop do not impact the forwarding of IP packets through a label switched path (LSP) because the forwarding decision is made at the penultimate hop through use of the incoming label. The untagged case causes Any Transport over Multiprotocol Label Switching (AToM) and MPLS virtual private network (VPN) traffic to be dropped at the penultimate hop.

Troubleshooting Implicit Null Cases

In the following example, Tunnel 1 is shut down, and only a label switched path (LSP) formed with Label Distribution Protocol (LDP) labels is established. An implicit null is advertised between the P2 and PE2 devices. Entering an MPLS LSP Traceroute at the PE1 device results in the following display:

```
Device# trace mpls ipv4 10.131.159.252/32
Tracing MPLS Label Switched Path to 10.131.159.252/32, timeout is 2 seconds
Codes: '!' - success, 'Q' - request not transmitted,
       '.' - timeout, 'U' - unreachable,
       'R' - downstream router but not target
Type escape sequence to abort.
  0 10.131.191.230 MRU 1500 [Labels: 20 Exp: 0]
R 1 10.131.159.226 MRU 1500 [Labels: 19 Exp: 0] 80 ms
R 2 10.131.159.229 MRU 1504 [implicit-null] 28 ms
! 3 10.131.159.230 40 ms
```

This output shows that packets are forwarded from P2 to PE2 with an implicit-null label. Address 10.131.159.229 is configured for the P2 Fast Ethernet 0/0/0 out interface for the PE2 device.

Troubleshooting Untagged Cases

Untagged cases are valid configurations for Interior Gateway Protocol (IGP) label switched paths (LSPs) that could cause problems for Multiprotocol Label Switching (MPLS) virtual private networks (VPNs).

A **show mpls forwarding-table** command and a **show mpls ldp discovery** command issued at the P2 device show that the Label Distribution Protocol (LDP) is properly set up:

```
Device# show mpls forwarding-table 10.131.159.252

Local  Outgoing    Prefix            Bytes tag  Outgoing   Next Hop
tag    tag or VC   or Tunnel Id      switched   interface
19     Pop tag     10.131.159.252/32 0          Et0/0      10.131.159.230
Device# show mpls ldp discovery
 Local LDP Identifier:
    10.131.159.251:0
    Discovery Sources:
    Interfaces:
           (ldp): xmit/recv
            LDP Id: 10.131.159.252:0
        FastEthernet1/0/0 (ldp): xmit/recv
            LDP Id: 10.131.191.251:0
```

The **show mpls ldp discovery** command output shows that, which connects PE2 to P2, is sending and receiving packets.

If a **no mpls ip** command is entered on , this could prevent an LDP session between the P2 and PE2 devices from being established. A **show mpls ldp discovery** command entered on the PE device shows that the MPLS LDP session with the PE2 device is down:

```
Device# show mpls ldp discovery

 Local LDP Identifier:
    10.131.159.251:0
    Discovery Sources:
    Interfaces:
        (ldp): xmit
        FastEthernet1/0/0 (ldp): xmit/recv
            LDP Id: 10.131.191.251:0
```

If the MPLS LDP session to PE2 goes down, the LSP to 10.131.159.252 becomes untagged, as shown by the **show mpls forwarding-table** command:

```
Device# show mpls forwarding-table 10.131.159.252

Local  Outgoing    Prefix            Bytes tag  Outgoing   Next Hop
tag    tag or VC   or Tunnel Id      switched   interface
19     Untagged
    10.131.159.252/32 864        Et0/0      10.131.159.230
```

Untagged cases would provide an MPLS LSP Traceroute reply with packets tagged with No Label, as shown in the following display:

```
Device# trace mpls ipv4 10.131.159.252/32
Tracing MPLS Label Switched Path to 10.131.159.252/32, timeout is 2 seconds
Codes: '!' - success, 'Q' - request not transmitted,
       '.' - timeout, 'U' - unreachable,
       'R' - downstream router but not target
Type escape sequence to abort.
  0 10.131.191.230 MRU 1500 [Labels: 20 Exp: 0]
```

```
R 1 10.131.159.226 MRU 1500 [Labels: 19 Exp: 0] 80 ms
R 2 10.131.159.229 MRU 1504 [No Label] 28 ms
! 3 10.131.159.230 40 ms
```

MPLS LSP Ping and Traceroute Returns a Q

The Q return code always means that the packet could not be transmitted. The problem can be caused by insufficient memory, but it probably results because a label switched path (LSP) could not be found that matches the Forwarding Equivalence Class (FEC), information that was entered on the command line.

The reason that the packet was not forwarded needs to be determined. To do so, look at the Routing Information Base (RIB), the Forwarding Information Base (FIB), the Label Information Base (LIB), and the MPLS Label Forwarding Information Base (LFIB). Lack of an entry for the FEC in any one of these routing/forwarding bases would return a Q.

The table below lists commands that you can use for troubleshooting when the MPLS echo reply returns a Q.

Table 30: Troubleshooting a Q

Database	Command to View Contents
Routing Information Base	**show ip route**
Label Information Base and MPLS Forwarding Information Base	**show mpls forwarding-table detail**

The following example shows a **ping mpls** command where the MPLS echo request is not transmitted, as shown by the returned Qs:

```
Device# ping mpls ipv4 10.0.0.1/32
Sending 5, 100-byte MPLS Echos to 10.0.0.1/32,
      timeout is 2 seconds, send interval is 0 msec:
Codes: '!' - success, 'Q' - request not transmitted,
       '.' - timeout, 'U' - unreachable,
       'R' - downstream router but not target
Type escape sequence to abort.
QQQQQ
Success rate is 0 percent (0/5)
```

A **show mpls forwarding-table** command and a **show ip route** command demonstrate that the address is not in either routing table:

```
Device# show mpls forwarding-table 10.0.0.1

Local  Outgoing    Prefix           Bytes tag  Outgoing   Next Hop
tag    tag or VC   or Tunnel Id     switched   interface
Device# show ip route 10.0.0.1

% Subnet not in table
```

The MPLS echo request is not transmitted because the IPv4 address (10.0.0.1) is not found in either the LFIB or the RIB routing table.

Load Balancing for IPv4 LDP LSPs

An Internet Control Message Protocol (ICMP) ping or trace follows one path from the originating device to the target device. Round robin load balancing of IP packets from a source device is used to discover the various output paths to the target IP address.

For MPLS LSP Ping and Traceroute, Cisco devices use the source and destination addresses in the IP header for load balancing when multiple paths exist through the network to a target device. The Cisco implementation of MPLS might check the destination address of an IP payload to accomplish load balancing (this checking depends on the platform).

To check for load balancing paths, you use the 127.*z.y.x* /8 destination address in the **ping mpls ipvr** *ip-address address-mask* **destination** *address-start address-end address-increment* command. The following examples show that different paths are followed to the same destination. This demonstrates that load balancing occurs between the originating device and the target device.

To ensure that the Fast Ethernet interface 1/0/0 on the PE1 device is operational, you enter the following commands on the PE1 device:

```
Device# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Device(config)# interface fastethernet 1/0/0
Device(config-if)# no shutdown
Device(config-if)# end
*Dec 31 19:14:10.034: %LINK-3-UPDOWN: Interface FastEthernet1/0/0, changed state to up
*Dec 31 19:14:11.054: %LINEPROTO-5-UPDOWN: Line protocol on Interface FastEthernet1/0/0,
changed state to upend
PE1#
*Dec 31 19:14:12.574: %SYS-5-CONFIG_I: Configured from console by console
*Dec 31 19:14:19.334: %OSPF-5-ADJCHG: Process 1, Nbr 10.131.159.252 on FastEthernet1/0/0
from LOADING to FULL, Loading Done
PE1#
```

The following **show mpls forwarding-table** command displays the possible outgoing interfaces and next hops for the prefix 10.131.159.251/32:

```
Device# show mpls forwarding-table 10.131.159.251

Local  Outgoing    Prefix            Bytes tag  Outgoing   Next Hop
tag    tag or VC   or Tunnel Id      switched   interface
21     19          10.131.159.251/32 0          FE0/0/0 10.131.191.229
       20          10.131.159.251/32 0          FE1/0/0 10.131.159.245
```

The following **ping mpls** command to 10.131.159.251/32 with a destination UDP address of 127.0.0.1 shows that the path selected has a path index of 0:

```
Device# ping mpls ipv4
 10.131.159.251/32 destination
 127.0.0.1 repeat 1
Sending 1, 100-byte MPLS Echos to 10.131.159.251/32,
      timeout is 2 seconds, send interval is 0 msec:
Codes: '!' - success, 'Q' - request not transmitted,
       '.' - timeout, 'U' - unreachable,
       'R' - downstream router but not target
Type escape sequence to abort.
!
Success rate is 100 percent (1/1), round-trip min/avg/max = 40/40/40 ms

Feature Information for MPLS LSP Ping, Traceroute, and AToM VCCV

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 31: Feature Information for MPLS LSP Ping, Traceroute, and AToM VCCV

Feature Name	Releases	Feature Information
MPLS LSP Ping, Traceroute, and AToM VCCV	12.0(27)S 12.2(28)SB 12.2(33)SXH Cisco IOS XE Release 2.3 Cisco IOS XE Release 3.5S	You can use MPLS LSP Ping to test label switched path (LSP) connectivity for IPv4 Label Distribution Protocol (LDP) prefixes, traffic engineering (TE) Forwarding Equivalence Classes (FECs), and Any Transport over MPLS (AToM) FECs. You can use MPLS LSP Traceroute to trace the LSPs for IPv4 LDP prefixes and TE tunnel FECs. AToM VCCV allows you to use MPLS LSP Ping to test the pseudowire (PW) section of an AToM virtual circuit (VC). In Cisco IOS Release 12.2(28)SB, this feature was enhanced to support the Cisco 10000 series router. This feature was integrated into Cisco IOS Release 12.2(33)SXH and Cisco IOS XE Release 2.3. In Cisco IOS XE Release 3.5S, support was added for the Cisco ASR 903 Router. The following commands were introduced or modified: **debug mpls lspv**, **ping mpls**, **trace mpls**.

Glossary

FEC—Forwarding Equivalence Class. A set of packets that can be handled equivalently for forwarding purposes and are thus suitable for binding to a single label. Examples include the set of packets destined for one address prefix and any flow.

flow—Generally, a set of packets traveling between a pair of hosts, or a pair of transport protocol ports on a pair of hosts. For example, packets with the same source address, source port, destination address, and destination port might be considered a flow.

A flow is also a stream of data traveling between two endpoints across a network (for example, from one LAN station to another). Multiple flows can be transmitted on a single circuit.

fragmentation—Process of breaking a packet into smaller units when transmitting over a network medium that cannot support the original size of the packet.

ICMP— Internet Control Message Protocol. A network layer Internet protocol that reports errors and provides other information relevant to IP packet processing. It is documented in RFC 792.

LFIB—label forwarding information base. A data structure and way of managing forwarding in which destinations and incoming labels are associated with outgoing interfaces and labels.

localhost—A name that represents the host name of a device. The localhost uses the reserved loopback IP address 127.0.0.1.

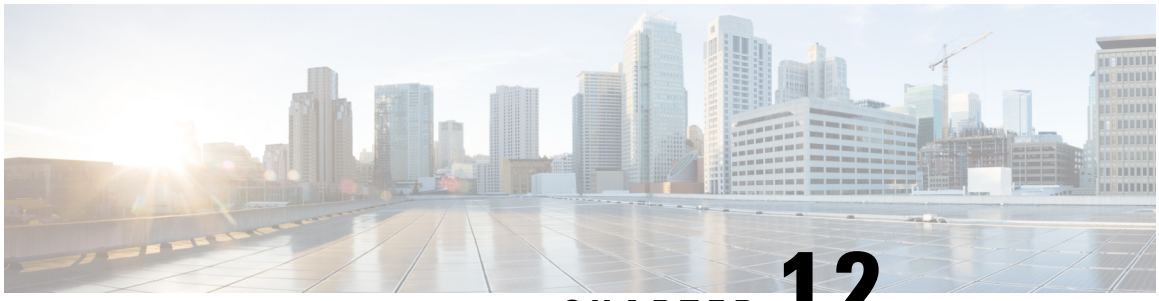
LSP—label switched path. A connection between two devices that uses MPLS to carry the packets.

LSPV—Label Switched Path Verification. An LSP Ping subprocess that encodes and decodes MPLS echo requests and replies; interfaces with IP, MPLS, and AToM switching for sending and receiving MPLS echo requests and replies; and, at the MPLS echo request originator device, maintains a database of outstanding echo requests for which echo responses have not been received.

MPLS router alert label—An MPLS label of 1. An MPLS packet with a router alert label is redirected by the device to the Route Processor (PR) processing level for handling. This allows these packets to bypass any forwarding failures in hardware routing tables.

MRU—maximum receive unit. Maximum size, in bytes, of a labeled packet that can be forwarded through an LSP.

MTU—maximum transmission unit. Maximum packet size, in bytes, that a particular interface can handle.



punt—Redirect packets with a router alert from the line card or interface to Route Processor (RP) level processing for handling.

PW—pseudowire. A mechanism that carries the essential elements of an emulated circuit from one provider edge (PE) device to another PE device over a packet-switched network.

RP—Route Processor. Processor module in the Cisco 7000 series routers that contains the CPU, system software, and most of the memory components that are used in the device. It is sometimes called a supervisory processor.

RSVP—Resource Reservation Protocol. A protocol that supports the reservation of resources across an IP network. Applications running on IP end systems can use RSVP to indicate to other nodes the nature (bandwidth, jitter, maximum burst, and so on) of the packet streams they want to receive. RSVP depends on IPv6. Is is also known as Resource Reservation Setup Protocol.

UDP—User Datagram Protocol. Connectionless transport layer protocol in the TCP/IP protocol stack. UDP is a simple protocol that exchanges datagrams without acknowledgments or guaranteed delivery, requiring that error processing and retransmission be handled by other protocols. UDP is defined in RFC 768.

CHAPTER 12

MPLS EM - MPLS LSP Multipath Tree Trace

The MPLS EM—MPLS LSP Multipath Tree Trace feature provides the means to discover all possible equal-cost multipath (ECMP) routing paths of a label switched path (LSP) between an egress and ingress router. Once discovered, these paths can be retested on a periodic basis using Multiprotocol Label Switching (MPLS) LSP ping or traceroute. This feature is an extension to the MPLS LSP traceroute functionality for the tracing of IPv4 LSPs.

You can use the MPLS EM—MPLS LSP Multipath Tree Trace feature to discover all paths for an IPv4 LSP.

This implementation of the MPLS EM—MPLS LSP Multipath Tree Trace feature is based on RFC 4379, Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures .

For information on the use of MPLS LSP ping and traceroute, see the MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV feature module.

Cisco MPLS Embedded Management (EM) is a set of standards and value-added services that facilitate the deployment, operation, administration, and management of MPLS-based networks according to the fault, configuration, accounting, performance, and security (FCAPS) model.

- Glossary, on page 245

Prerequisites for MPLS EMMPLS EM - MPLS LSP Multipath Tree Trace MPLS LSP Multipath Tree Trace

The following are prerequisites for using the MPLS EM—MPLS LSP Multipath Tree Trace feature:

- You must understand the concepts and know how to use MPLS LSP ping or traceroute as described in the MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV document.
- The routers in your network must be using an implementation based on RFC 4379, Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures .

- You should know the following about your MPLS network:
  - The topology
  - The number of links in your network
  - The expected number of LSPs, and how many LSPs
- Understand label switching, forwarding, and load balancing.

Restrictions for MPLS EM - MPLS LSP Multipath Tree Trace

- All restrictions that apply to the MPLS LSP Ping and LSP Traceroute features also apply to the MPLS EM—MPLS LSP Multipath Tree Trace feature:
  - You cannot use the MPLS LSP Multipath Tree Trace feature to trace the path taken by AToM packets. The MPLS LSP Multipath Tree Trace feature is not supported for AToM. (MPLS LSP Ping is supported for AToM.) However, you can use the MPLS LSP Multipath Tree Trace feature to troubleshoot the Interior Gateway Protocol (IGP) LSP that is used by AToM.
  - You cannot use the MPLS LSP Multipath Tree Trace feature to validate or trace MPLS Virtual Private Networks (VPNs). Multiple LSP paths are not discovered unless all routers in the MPLS core support an RFC 4379 implementation of Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures .
- MPLS LSP multipath tree trace is not expected to operate in networks that support time-to-live (TTL) hiding.

Information About MPLS EM - MPLS LSP Multipath Tree Trace

Overview of MPLS LSP Multipath Tree Trace

As the number of MPLS deployments increases, the number of traffic types the MPLS networks carry could increase. In addition, load balancing on label switch routers (LSRs) in the MPLS network provides alternate paths for carrying MPLS traffic to a target router. The ability of service providers to monitor LSPs and quickly isolate MPLS forwarding problems is critical to their ability to offer services.

Prior to the release of the MPLS EM—MPLS LSP Multipath Tree Trace feature no automated way existed to discover all paths between provider edge (PE) routers. Troubleshooting forwarding problems between PEs was cumbersome.

The release of the MPLS EM—MPLS LSP Multipath Tree Trace feature provides an automated way to discover all paths from the ingress PE router to the egress PE router in multivendor networks that use IPv4 load balancing at the transit routers. Once the PE-to-PE paths are discovered, use MPLS LSP ping and MPLS LSP traceroute to periodically test them.

The MPLS EM—MPLS LSP Multipath Tree Trace feature requires the Cisco RFC-compliant implementation that is based on RFC 4379. If you do not have a Cisco software release that supports RFC 379, MPLS LSP multipath tree trace does not operate to discover all PE-to-PE paths.

Discovery of IPv4 Load Balancing Paths by MPLS LSP Multipath Tree Trace

IPv4 load balancing at a transit router is based on the incoming label stack and the source and destination addresses in the IP header. The outgoing label stack and IP header source address remain constant for each branch being traced.

When you execute MPLS LSP multipath tree trace on the source LSR, the router needs to find the set of IP header destination addresses to use all possible output paths. The source LSR starts path discovery by sending a transit router a bitmap in an MPLS echo request. The transit router returns information in an MPLS echo request that contains subsets of the bitmap in a downstream map (DS Map) in an echo reply. The source router can then use the information in the echo reply to interrogate the next router. The source router interrogates each successive router until it finds one bitmap setting that is common to all routers along the path. The router uses TTL expiry to interrogate the routers to find the common bits.

For example, you could start path discovery by entering the following command at the source router:

```
Router# trace mpls multipath ipv4 10.131.101.129/32 hashkey ipv4 bitmap 16
```

This command sets the IP address of the target router as 10.131.101.192 255.255.255.255 and configures:

- The default hash key type to 8, which requests that an IPv4 address prefix and bit mask address set be returned in the DS Map in the echo reply.
- The bitmap size to 16. This means that MPLS LSP multipath tree trace uses 16 addresses (starting with 127.0.0.1) in the discovery of all paths of an LSP between the source router and the target router.

If you enter the **trace mpls multipath ipv4 10.131.101.129/32** command, MPLS LSP multipath tree trace uses the default hash type of 8 or IPv4 and a default bitmap size of 32. Your choice of a bitmap size depends on the number of routes in your network. If you have a large number of routes, you might need to use a larger bitmap size.

Echo Reply Return Codes Sent by the Router Processing Multipath LSP Tree Trace

The table below describes the characters that the router processing a multipath LSP tree trace packet returns to the sender about the failure or success of the request.

Table 32: Echo Reply Return Codes

Output Code	Echo Return Code	Meaning
Period "."	—	A timeout occurred before the target router could reply.
x	0	No return code.
M	1	Malformed request.
m	2	Unsupported type, length, values (TLVs).
!	3	Success.
F	4	No Forwarding Equivalence Class (FEC) mapping.
D	5	DS Map mismatch.

Output Code	Echo Return Code	Meaning
R	6	Downstream router but not target.
U	7	Reserved.
L	8	Labeled output interface.
B	9	Unlabeled output interface.
f	10	FEC mismatch.
N	11	No label entry.
P	12	No receive interface label protocol.
p	13	Premature termination of the LSP.
X	unknown	Undefined return code.

MPLS Embedded Management Configuration

Before using the **ping mpls**, **trace mpls**, or **trace mpls multipath** command, you should consider ensuring that the router is configured to encode and decode MPLS echo packets in a format that all receiving routers in the network can understand.

LSP ping drafts after Version 3 (draft-ietf-mpls-ping-03) have undergone numerous TLV format changes, but the implementations based on different drafts might not interoperate properly.

To allow later Cisco implementations to interoperate with draft Version 3 Cisco and non-Cisco implementations, a global configuration mode (MPLS OAM configuration) allows you to encode and decode echo packets in formats specified by draft Version 3 implementations.

Unless configured otherwise, a Cisco implementation encodes and decodes echo requests assuming the version on which the Internet Engineering Task Force (IETF) implementation is based.

To allow for seamless interoperability with earlier Revision 1 and 3 images, you can use MPLS Operation, Administration, and Maintenance (OAM) configuration mode parameters to force the default behavior of the Revision 4 images to be compliant or compatible in networks with Revision 1 or Revision 3 images.

To prevent failures reported by the replying router due to TLV version issues, you should configure all routers in the core. Encode and decode MPLS echo packets in the same draft version. For example, if the network is running RFC 4379 (Cisco Revision 4) implementations but one router is capable of only Version 3 (Cisco Revision 3), configure all routers in the network to operate in Revision 3 mode.

Cisco Revision 4 is the default version. The default version is the latest LSP Ping version supported by the image on the router.

How to Configure MPLS EM - MPLS LSP Multipath Tree Trace

Customizing the Default Behavior of MPLS Echo Packets

Perform the following task to customize the default behavior of MPLS echo packets. You might need to customize the default echo packet encoding and decoding behavior to allow later implementations of the Detecting MPLS Data Plane Failures (RFC 4379) to be deployed in networks running earlier versions of the draft.

Before you begin

MPLS LSP Multipath Tree Trace requires RFC 4379 (Revision 4).

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls oam**
4. **echo revision** {**3** | **4**}
5. [**no**] **echo vendor-extension**
6. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**mpls oam** **Example:** `Router(config)# mpls oam`	Enters MPLS OAM configuration mode and customizes the default behavior of echo packets.
Step 4	**echo revision** {**3**	**4**} **Example:**	Customizes the default behavior of echo packets. • The **revision** keyword set echo packet attributes to one of the following:

	Command or Action	Purpose
	`Router(config-mpls)# echo revision 4`	• **3** = draft-ietf-mpls-ping-03 (Revision 2) • **4** = RFC 4379 compliant (default) **Note** The MPLS LSP Multipath Tree Trace feature requires Revision 4.
Step 5	[**no**] **echo vendor-extension** **Example:** `Router(config-mpls)# echo vendor-extension`	Customizes the default behavior of echo packets. • The **vendor-extension** keyword sends the Cisco-specific extension of TLVs with the echo packets. • The **no** form of the command allows you to disable a Cisco vendor's extension TLVs that another vendor's noncompliant implementations may not support. The router default is **echo vendor-extension**.
Step 6	**end** **Example:** `Router(config-mpls)# end`	Exits to privileged EXEC mode.

Configuring MPLS LSP Multipath Tree Trace

Perform the following task to configure MPLS multipath LSP traceroute. This task helps discover all LSPs from an egress router to an ingress router.

Before you begin

Cisco LSP ping or traceroute implementations based on draft-ietf-mpls-lsp-ping-11 are capable in some cases of detecting the formatting of the sender of an MPLS echo request. However, certain cases exist in which an echo request or echo reply might not contain the Cisco extension TLV. To avoid complications due to certain cases where the echo packets are decoded assuming the wrong TLV formats, configure all routers in the network to operate in the same mode.

For an MPLS LSP multipath tree trace to be successful, the implementation in your routers must support RFC 4379 on all core routers.

If all routers in the network support RFC-4379 and another vendor's implementation exists that is not capable of properly handling Cisco's vendor TLV, the routers supporting the RFC-compliant or later configuration must include commands to disable the Cisco vendor TLV extensions.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls oam**
4. **echo revision 4**

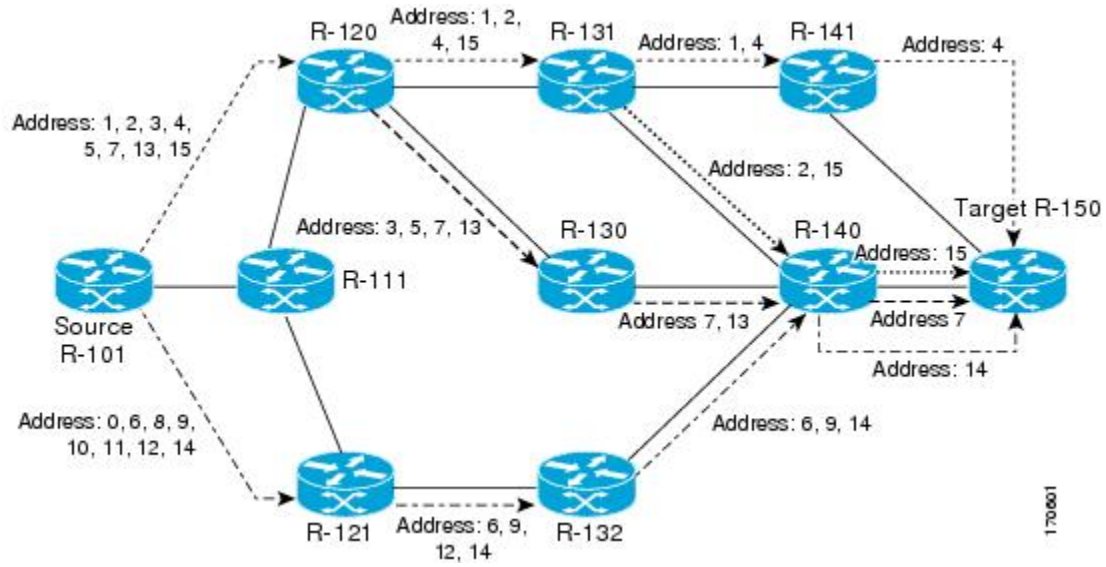
5. [**no**] **echo vendor-extension**
6. **end**
7. **trace mpls multipath ipv4** *destination-ip-address/destination mask-length*
8. **debug mpls lspv multipath**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**mpls oam** **Example:** `Router(config)# mpls oam`	Enters MPLS OAM configuration mode.
Step 4	**echo revision 4** **Example:** `Router(config-mpls)# echo revision 4`	Customizes the default behavior of echo packets. • The **revision 4** keywords set echo packet attributes to the default Revision 4 (RFC 4379 compliant). **Note** The MPLS LSP Multipath Tree Trace feature requires Revision 4.
Step 5	[**no**] **echo vendor-extension** **Example:** `Router(config-mpls) echo vendor-extension`	(Optional) Customizes the default behavior of echo packets. • The **vendor-extension** keyword sends the Cisco-specific extension of TLVs with the echo packets. • The **no** form of the command allows you to disable a Cisco vendor's extension TLVs that another vendor's noncompliant implementations may not support. The router default is **echo vendor-extension**.
Step 6	**end** **Example:** `Router(config-mpls)# end`	Exits to privileged EXEC mode.

	Command or Action	Purpose
Step 7	**trace mpls multipath ipv4** *destination-ip-address/destination mask-length* **Example:** `Router# trace mpls multipath ipv4 10.131.161.251/32`	Discovers all LSPs from an egress router to an ingress router. • The **ipv4** keyword specifies the destination type as an LDP IPv4 address. • The *destination-ip-address* argument is the address prefix of the target to be tested. • The *destination-mask-length* argument is the number of bits in the network mask of the target address. The **/** keyword before this argument is required.
Step 8	**debug mpls lspv multipath** **Example:** `Router# debug mpls lspv multipath`	Displays multipath information related to the MPLS LSP Multipath Tree Trace feature.



Discovering IPv4 Load Balancing Paths Using MPLS LSP Multipath Tree Trace

Perform the following task to discover IPv4 load balancing paths using MPLS LSP Multipath Tree Trace.

A Cisco router load balances MPLS packets based on the incoming label stack and the source and destination addresses in the IP header. The outgoing label stack and IP header source address remain constant for each path being traced. The router needs to find the set of IP header destination addresses to use all possible output paths. This might require exhaustive searching of the 127.x.y.z/8 address space. Once you discover all paths from the source LSR to the target or destination LSR with MPLS LSP Multipath Tree Trace, you can use MPLS LSP traceroute to monitor these paths.

The figure below shows how MPLS LSP Multipath Tree Trace discovers LSP paths in a sample network. In the figure below, the bitmap size is 16 and the numbers 0 to 15 represent the bitmapped addresses that MPLS LSP Multipath Tree Trace uses to discover all the paths from the source LSR R-101 to the target LSR R-150. The figure below illustrates how the **trace mpls multipath** command discovers all LSP paths in the sample network.

Figure 26: MPLS LSP Multipath Tree Trace Path Discovery in a Sample Network

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls oam**
4. **echo revision 4**
5. **end**
6. **trace mpls multipath ipv4** *destination-address*/*destination-mask-length* **hashkey ipv4 bitmap** *bitmap-size*

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**mpls oam** **Example:** `Router(config)# mpls oam`	Enters MPLS OAM configuration mode and sets the echo packet attribute to Revision 4 (RFC 4379 compliant).

	Command or Action	Purpose
Step 4	**echo revision 4** **Example:** `Router(config-mpls)# echo revision 4`	Customizes the default behavior of echo packets. • The **revision 4** keywords set echo packet attributes to the default Revision 4 (RFC 4379 compliant). **Note** The MPLS LSP Multipath Tree Trace feature requires Revision 4.
Step 5	**end** **Example:** `Router(config-mpls)# end`	Exits to privileged EXEC mode.
Step 6	**trace mpls multipath ipv4** *destination-address*/*destination-mask-length* **hashkey ipv4 bitmap** *bitmap-size* **Example:** `Router# trace mpls multipath ipv4 10.131.161.251/32 hashkey ipv4 bitmap 16`	Discovers all MPLS LSPs from an egress router to an ingress router. • The **ipv4** keyword specifies the destination type as an LDP IPv4 address. • The *destination-address* argument is the address prefix of the target to be tested. • The *destination-mask-length* argument is the number of bits in the network mask of the target address. The / keyword before this argument is required. • The **hashkey ipv4** keywords set the hashkey type to IPv4 addresses. • The **bitmap** *bitmap-size* keyword and arguments set the bitmap size for multipath discovery.

Monitoring LSP Paths Discovered by MPLS LSP Multipath Tree Trace Using MPLS LSP Traceroute

Perform the following task to monitor LSP paths discovered by MPLS LSP Multipath Tree Trace using MPLS LSP traceroute. You can take output directly from the **trace mpls multipath** command and add it to a **trace mpls** command periodically to verify that the path is still operating.

The figure below shows the mapping of the output of a **trace mpls multipath** command to a **trace mpls** command.

Figure 27: Mapping of trace mpls multipath Command Output to a trace mpls Command

Each path you discover with MPLS LSP Multipath Tree Trace can be tested in this manner periodically to monitor the LSP paths in your network.

SUMMARY STEPS

1. **enable**
2. **trace mpls multipath ipv4** *destination-address*/*destination-mask-length* **hashkey ipv4 bitmap** *bitmap-size*
3. **trace mpls ipv4** *destination-address*/*destination-mask-length* [**output interface** *tx-interface*] [**source** *source-address*] [**destination** *address-start*
4. **exit**

DETAILED STEPS

Procedure

Step 1 **enable**

Use this command to enable privileged EXEC mode. Enter your password if prompted. For example:

Example:

```
Router> enable
Router#
```

Step 2 **trace mpls multipath ipv4** *destination-address*/*destination-mask-length* **hashkey ipv4 bitmap** *bitmap-size*

Use this command to discover all MPLS LSPs from an egress router to an ingress router. For example:

Example:

```
Router# trace mpls multipath ipv4 10.1.1.150/32 hashkey ipv4 bitmap 16

Starting LSP Multipath Traceroute for 10.1.1.150/32
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
  'L' - labeled output interface, 'B' - unlabeled output interface,
  'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
  'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
  'P' - no rx intf label prot, 'p' - premature termination of LSP,
```

```
  'R' - transit router, 'I' - unknown upstream index,
  'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.
LLLL!
Path 0 found,
 output interface Fe0/0/0 source 10.1.111.101 destination 127.0.0.0
LLL!
Path 1 found,
 output interface Fe0/0/0 source 10.1.111.101 destination 127.0.0.1
L!
Path 2 found,
 output interface Fe0/0/0 source 10.1.111.101 destination 127.0.0.5
LL!
Path 3 found,
 output interface Fe0/0/0 source 10.1.111.101 destination 127.0.0.7
Paths (found/broken/unexplored) (4/0/0)
 Echo Request (sent/fail) (14/0)
 Echo Reply (received/timeout) (14/0)
 Total Time Elapsed 468 ms
```

The output of the **trace mpls multipath ipv4** command in the example shows the result of path discovery with MPLS LSP Multipath Tree Trace. In this example, the command sets the bitmap size to 16. Path discovery starts by MPLS LSP Multipath Tree Trace using 16 bitmapped addresses as it locates LSP paths from the source router to the target router with prefix and mask 10.1.1.150/32. MPLS LSP Multipath Tree Trace starts using the 127.x.y.z/8 address space with 127.0.0.1.

Step 3 **trace mpls ipv4** *destination-address/destination-mask-length* [**output interface** *tx-interface*] [**source** *source-address*] [**destination** *address-start*

Use this command to verify that the paths discovered when you entered a **trace mpls multipath ipv4** command are still operating. For example, the output for Path 0 in the previous **trace mpls multipath ipv4** command in Step 2 is:

Example:

```
output interface Fe0/0/0 source 10.1.111.101 destination 127.0.0.0
```

If you put the output for path 0 in the **trace mpls** command, you see the following results:

Example:

```
Router# trace mpls ipv4 10.1.1.150/32 output interface Fe0/0/0 source 10.1.111.101 destination
127.0.0.0

Tracing MPLS Label Switched Path to 10.1.1.150/32, timeout is 2 seconds
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
  'L' - labeled output interface, 'B' - unlabeled output interface,
  'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
  'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
  'P' - no rx intf label prot, 'p' - premature termination of LSP,
  'R' - transit router, 'I' - unknown upstream index,
  'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.
  0 10.1.111.101 MRU 1500 [Labels: 33 Exp: 0]
L 1 10.1.111.111 MRU 1500 [Labels: 34 Exp: 0] 40 ms
L 2 10.2.121.121 MRU 1500 [Labels: 34 Exp: 0] 32 ms
L 3 10.3.132.132 MRU 1500 [Labels: 32 Exp: 0] 16 ms
L 4 10.4.140.240 MRU 1504 [Labels: implicit-null Exp: 0] 20 ms
! 5 10.5.150.50 20 ms
```

You can take output directly from the**trace mpls multipath** command and add it to a **trace mpls** command periodically to verify that the path is still operating (see the figure above).

Step 4 **exit**

Use this command to exit to user EXEC mode. for example:

Example:

```
Router# exit
Router>
```

Using DSCP to Request a Specific Class of Service in an Echo Reply

A reply differentiated services code point (DSCP) option lets you request a specific class of service (CoS) in an echo reply.

The reply DSCP option is supported in the experimental mode for IETF draft-ietf-mpls-lsp-ping-03.txt. Cisco implemented a vendor-specific extension for the reply DSCP option rather than using a Reply TOS TLV. A Reply TOS TLV serves the same purpose as the **reply dscp** command in IETF draft-ietf-mpls-lsp-ping-11.txt. This draft provides a standardized method of controlling the reply DSCP.

Note Before RFC 4379, Cisco implemented the Reply DSCP option as an experimental capability using a Cisco vendor extension TLV. If a router is configured to encode MPLS echo packets for draft Version 3 implementations, a Cisco vendor extension TLV is used instead of the = Reply TOS TLV that was defined in draft Version 8.

To use DSCP to request a specific CoS in an echo reply, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **trace mpls multipath ipv4** *destination-address/destination-mask-length* [**reply dscp** *dscp-value*]
3. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**trace mpls multipath ipv4** *destination-address/destination-mask-length* [**reply dscp** *dscp-value*] **Example:**	Discovers all MPLS LSPs from an ingress router to an egress router and controls the DSCP value of an echo reply. • The **ipv4** keyword specifies the destination type as an LDP IPv4 address.

	Command or Action	Purpose
	`Router# trace mpls multipath ipv4 10.131.191.252/32 reply dscp 50`	• The *destination-address* argument is the address prefix of the target to be tested. • The *destination-mask-length* argument is the number of bits in the network mask of the target address. The / keyword before this argument is required. • The **reply dscp** *dscp-value* keywords and argument are the DSCP value of an echo reply. A Reply TOS TLV serves the same purpose as the **reply dscp** command in IETF draft-ietf-mpls-lsp-ping-11.txt. **Note** To specify a DSCP value, you must enter the **reply dscp** *dscp-value* keywords and argument.
Step 3	**exit** **Example:** `Router# exit`	Returns to user EXEC mode.

Controlling How a Responding Router Replies to an MPLS Echo Request

This section contains information about and instructions for controlling how a responding router replies to an MPLS echo request. You should understand the following information before you configure a reply mode for the echo request response:

Reply Modes for an MPLS LSP Multipath Tree Trace Echo Request Response

The reply mode controls how a responding router replies to an MPLS echo request sent by a **trace mpls multipath** command. There are two reply modes for an echo request packet:

- ipv4—Reply with an IPv4 User Datagram Protocol (UDP) packet (default)
- router-alert—Reply with an IPv4 UDP packet with router alert

Note Use the ipv4 and router-alert reply modes with each other to prevent false negatives. If you do not receive a reply via the ipv4 mode, send a test with the router-alert reply mode. If both fail, something is wrong in the return path. The problem might be due to an incorrect ToS setting.

IPv4 UDP Reply Mode: The IPv4 UDP reply mode is the most common reply mode used with a **trace mpls multipath** command when you want to periodically poll the integrity of an LSP. With this option, you do not have explicit control over whether the packet traverses IP or MPLS hops to reach the originator of the MPLS echo request. If the originating (headend) router fails to receive a reply to an MPLS echo request when you use the **reply mode ipv4** keywords, use the **reply mode router-alert** keywords.

Router-aler Reply Mode: The router-alert reply mode adds the router alert option to the IP header. When an IP packet that contains an IP router alert option in its IP header or an MPLS packet with a router alert label

as its outermost label arrives at a router, the router punts (redirects) the packet to the Route Processor (RP) process level for handling. This forces the RP of each intermediate router to specifically handle the packet at each intermediate hop as it moves back to the destination. Hardware and line-card forwarding inconsistencies are thus bypassed. Router-alert reply mode is slower than IPv4 mode because the reply requires process-level RP handling at each hop.

The table below describes how an incoming IP packet with an IP router alert is handled by the router switching path processes when the outgoing packet is an IP packet or an MPLS packet. It also describes how an MPLS packet with a router alert option is handled by the router switching path processes when the outgoing packet is an IP packet or an MPLS packet.

Table 33: Path Process Handling of IP and MPLS Router Alert Packets

Incoming Packet	Outgoing Packet	Normal Switching Action	Process Switching Action
IP packet—Router alert option in IP header	IP packet—Router alert option in IP header	Router alert option in IP header causes the packet to be punted to the process switching path.	Forwards the packet as is
	MPLS packet		Forwards the packet as is
MPLS packet—Outermost label contains a router alert	IP packet—Router alert option in IP header	If the router alert label is the outermost label, it causes the packet to be punted to the process switching path.	Removes the outermost router alert label and forwards the packet as an IP packet
	MPLS packet— Outermost label contains a router alert		Preserves the outermost router alert label and forwards the MPLS packet

SUMMARY STEPS

1. **enable**
2. **trace mpls multipath ipv4** *destination-address/destination-mask-length* **reply mode** {**ipv4** | **router-alert**}
3. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**trace mpls multipath ipv4** *destination-address/destination-mask-length* **reply mode** {**ipv4**	**router-alert**} **Example:**	Discovers all MPLS LSPs from an ingress router to an egress router and specifies the reply mode. • The **ipv4** keyword specifies the destination type as an LDP IPv4 address.

	Command or Action	Purpose

	`Router# trace mpls multipath ipv4 10.131.191.252/32 reply mode router-alert`	• The *destination-address* argument is the address prefix of the target to be tested.
		• The *destination-mask-length* argument is the number of bits in the network mask of the target address. The / keyword before this argument is required.
		• The **reply mode** keyword requires that you enter one of the following keywords to specify the reply mode:
		  • The **ipv4** keyword—Reply with an IPv4 UDP packet (default).
		  • The **router-alert** keyword—Reply with an IPv4 UDP packet with router alert.
		Note
		To specify the reply mode, you must enter the **reply mode** keyword with the **ipv4** or **router-alert** keyword.

Step 3	**exit** **Example:** `Router# exit`	Returns to user EXEC mode.

Specifying the Output Interface for Echo Packets Leaving a Router for MPLS LSP Multipath Tree Trace

Perform the following task to specify the output interface for echo packets leaving a router for the MPLS LSP Multipath Tree Trace feature. You can use this task to test the LSPs reachable through a given interface.

Echo Request Output Interface Control: You can control the interface through which packets leave a router. Path output information is used as input to LSP ping and traceroute.

The echo request output interface control feature allows you to force echo packets through the paths that perform detailed debugging or characterizing of the LSP. This feature is useful if a PE router connects to an MPLS cloud and there are broken links. You can direct traffic through a certain link. The feature also is helpful for troubleshooting network problems.

SUMMARY STEPS

1. **enable**
2. **trace mpls multipath ipv4** *destination-address*/*destination-mask-length* [**output interface** *tx-interface*]
3. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**trace mpls multipath ipv4** *destination-address*/*destination-mask-length* [**output interface** *tx-interface*] **Example:** `Router# trace mpls multipath ipv4 10.131.159.251/32 output interface fastethernet0/0/0`	Discovers all MPLS LSPs from an ingress router to an egress router and specifies the interface through which echo packets leave a router. • The **ipv4** keyword specifies the destination type as an LDP IPv4 address. • The *destination-address* argument is the address prefix of the target to be tested. • The *destination-mask-length* argument is the number of bits in the network mask of the target address. The / keyword before this argument is required. • The **output interface** *tx-interface* keywords and argument specify the output interface for the MPLS echo request. **Note** You must specify the **output interface** keywords.
Step 3	**exit** **Example:** `Router# exit`	Returns to user EXEC mode.

Setting the Pace of MPLS Echo Request Packet Transmission for MPLS LSP Multipath Tree Trace

Perform the following task to set the pace of MPLS echo request packet transmission for the MPLS LSP Multipath Tree Trace feature. Echo request traffic pacing allows you to set the pace of the transmission of packets so that the receiving router does not drop packets. If you have a large amount of traffic on your network you might increase the size of the interval to help ensure that the receiving router does not drop packets.

SUMMARY STEPS

1. **enable**
2. **trace mpls multipath ipv4** *destination-address*/*destination-mask-length* [**interval** *milliseconds*]
3. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**trace mpls multipath ipv4** *destination-address/destination-mask-length* [**interval** *milliseconds*] **Example:** `Router# trace mpls multipath ipv4 10.131.159.251/32 interval 100`	Discovers all MPLS LSPs from an egress router to an ingress router and sets the time in milliseconds between successive MPLS echo requests. • The **ipv4** keyword specifies the destination type as an LDP IPv4 address. • The *destination-address* argument is the address prefix of the target to be tested. • The *destination-mask* argument is the number of bits in the network mask of the target address. The / keyword before this argument is required. • The **interval** *milliseconds* keyword and argument set the time between successive MPLS echo requests in milliseconds. The default is 0 milliseconds. **Note** To pace the transmission of packets, you must specify the **interval** keyword.
Step 3	**exit** **Example:** `Router# exit`	Returns to user EXEC mode.

Enabling MPLS LSP Multipath Tree Trace to Detect LSP Breakages

Perform the following task to enable MPLS LSP Multipath Tree Trace to detect LSP breakages caused by an interface that lacks an MPLS configuration. If an interface is not configured for MPLS, then it cannot forward MPLS packets.

Explicit Null Label Shimming Tests LSP Ability to Carry MPLS Traffic: For an MPLS LSP Multipath Tree Trace of LSPs carrying IPv4 FECs, you can force an explicit null label to be added to the MPLS label stack even though the label was unsolicited. This allows MPLS LSP Multipath Tree Trace to detect LSP breakages caused by an interface that is not configured for MPLS. MPLS LSP Multipath Tree Trace does not report that an LSP is functioning when it is unable to send MPLS traffic.

An explicit null label is added to an MPLS label stack if MPLS echo request packets are forwarded from an interface not configured for MPLS that is directly connected to the destination of the MPLS LSP Multipath Tree Trace or if the IP TTL value for the MPLS echo request packets is set to 1.

When you enter a **trace mpls multipath** command, you are looking for all MPLS LSP paths from an egress router to an ingress router. Failure at output interfaces that are not configured for MPLS at the penultimate hop are not detected. Explicit-null shimming allows you to test an LSP's ability to carry MPLS traffic.

SUMMARY STEPS

1. **enable**
2. **trace mpls multipath ipv4** *destination-address*/*destination-mask-length* **force-explicit-null**
3. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**trace mpls multipath ipv4** *destination-address*/*destination-mask-length* **force-explicit-null** **Example:** `Router# trace mpls multipath ipv4 10.131.191.252/32 force-explicit-null`	Discovers all MPLS LSPs from an egress router to an ingress router and forces an explicit null label to be added to the MPLS label stack. • The **ipv4** keyword specifies the destination type as an LDP IPv4 address. • The *destination-address* argument is the address prefix of the target to be tested. • The *destination-mask-length* argument is the number of bits in the network mask of the target address. The / keyword before this argument is required. • The **force-explicit-null** keyword forces an explicit null label to be added to the MPLS label stack even though the label was unsolicited. **Note** You must enter the **force-explicit-null** keyword to enable MPLS LSP Multipath Tree Trace to detect LSP breakages caused by an interface that is not configured for MPLS.
Step 3	**exit** **Example:** `Router# exit`	Returns to user EXEC mode.

Requesting That a Transit Router Validate the Target FEC Stack for MPLS LSP Multipath Tree Trace

Perform the following task to request that a transit router validate the target FEC stack for the MPLS LSP Multipath Tree Trace feature.

An MPLS echo request tests a particular LSP. The LSP to be tested is identified by the FEC stack.

During an MPLS LSP Multipath Tree Trace, the echo packet validation rules do not require that a transit router validate the target FEC stack TLV. A downstream map TLV containing the correct received labels must be present in the echo request for target FEC stack checking to be performed.

To request that a transit router validate the target FEC stack, set the V flag from the source router by entering the **flags fec** keywords in the **trace mpls multipath** command. The default is that echo request packets are sent with the V flag set to 0.

SUMMARY STEPS

1. **enable**
2. **trace mpls multipath ipv4** *destination-address*/*destination-mask-length* [**flags fec**] [**ttl** *maximum-time-to-live*]
3. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**trace mpls multipath ipv4** *destination-address*/*destination-mask-length* [**flags fec**] [**ttl** *maximum-time-to-live*] **Example:** `Router# trace mpls multipath ipv4 10.131.159.252/32 flags fec ttl 5`	Discovers all MPLS LSPs from an egress router to an ingress router and requests validation of the target FEC stack by a transit router. • The **ipv4** keyword specifies the destination type as an LDP IPv4 address. • The *destination-address* argument is the address prefix of the target to be tested. • The *destination-mask-length* argument is the number of bits in the network mask of the target address. The / keyword before this argument is required. • The **flags fec** keywords requests that target FEC stack validation be done at a transit router. • The **ttl** *maximum-time-to-live* keyword and argument pair specify a maximum hop count.

	Command or Action	Purpose
		Note For a transit router to validate the target FEC stack, you must enter the **flags fec** and **ttl** keywords.
Step 3	**exit** **Example:** `Router# exit`	Returns to user EXEC mode.

Setting the Number of Timeout Attempts for MPLS LSP Multipath Tree Trace

Perform the following task to set the number of timeout attempts for the MPLS LSP Multipath Tree Trace feature.

A retry is attempted if an outstanding echo request times out waiting for the corresponding echo reply.

SUMMARY STEPS

1. **enable**
2. **trace mpls multipath ipv4** *destination-address*/*destination-mask-length* [**retry-count** *retry-count-value*]
3. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**trace mpls multipath ipv4** *destination-address*/*destination-mask-length* [**retry-count** *retry-count-value*] **Example:** `Router# trace mpls multipath ipv4 10.131.159.252/32 retry-count 4`	Sets the number of retry attempts during an MPLS LSP Multipath Tree Trace. • The **ipv4** keyword specifies the destination type as an LDP IPv4 address. • The *destination-address* argument is the address prefix of the target to be tested. • The *destination-mask-length* argument is the number of bits in the network mask of the target address. The / keyword before this argument is required. • The **retry-count** *retry-count-value* keyword and argument sets the number of retry attempts after a timeout occurs.

	Command or Action	Purpose
		A retry-count value of "0" means infinite retries. A retry-count value from 0 to10 is suggested. You might want to increase the retry value to greater than 10, if 10 is too small a value. The default retry-count value is 3. **Note** To set the number of retries after a timeout, you must enter the **retry-count** keyword.
Step 3	**exit** **Example:** `Router# exit`	Returns to user EXEC mode.

Configuration Examples for MPLS EM - MPLS LSP Multipath Tree Trace

Customizing the Default Behavior of MPLS Echo Packets Example

The following example shows how to customize the behavior of MPLS echo packets so that the MPLS LSP Multipath Tree Trace feature interoperates with a vendor implementation that does not interpret RFC 4379 as Cisco does:

```
configure terminal
!
mpls oam
 echo revision 4
 no echo vendor-extension
 end
```

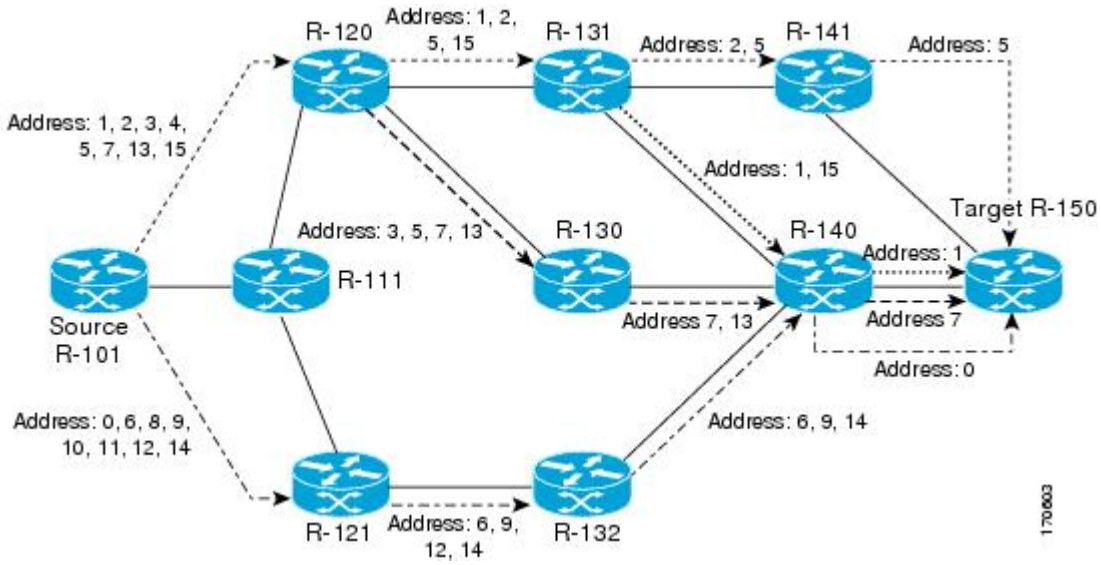
The **echo revision** command is included in this example for completeness. The default echo revision number is 4, which corresponds to RFC 4379.

Configuring MPLS LSP Multipath Tree Trace Example

The following example shows how to configure the MPLS LSP Multipath Tree Trace feature to interoperate with a vendor implementation that does not interpret RFC 4379 as Cisco does:

```
configure terminal
!
mpls oam
 echo revision 4
 no echo vendor-extension
 end
!
trace mpls multipath ipv4 10.131.161.151/32
```

The **echo revision** command is included in this example for completeness. The default echo revision number is 4, which corresponds to the RFC 4379.



Discovering IPv4 Load Balancing Paths Using MPLS LSP Multipath Tree Trace Example

The following example shows how to use the MPLS LSP Multipath Tree Trace feature to discover IPv4 load balancing paths. The example is based on the sample network shown in the figure below. In this example, the bitmap size is set to 16. Therefore, path discovery starts by the MPLS LSP Multipath Tree Trace feature using 16 bitmapped addresses as it locates LSP paths from the source router R-101 to the target router R-150 with prefix and mask 10.1.1.150/32. The MPLS LSP Multipath Tree Trace feature starts using the 127.x.y.z/8 address space with 127.0.0.0.

```
Router# trace mpls multipath
ipv4 10.1.1.150/32 hashkey ipv4 bitmap 16
Starting LSP Multipath Traceroute for 10.1.1.150/32
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
  'L' - labeled output interface, 'B' - unlabeled output interface,
  'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
  'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
  'P' - no rx intf label prot, 'p' - premature termination of LSP,
  'R' - transit router, 'I' - unknown upstream index,
  'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.
LLLL!

Paths (found/broken/unexplored) (4/0/0)
 Echo Request (sent/fail) (14/0)
 Echo Reply (received/timeout) (14/0)
 Total Time Elapsed 468 ms
```

The output of the **trace mpls multipath** command in the example shows the result of path discovery with the MPLS LSP Multipath Tree Trace feature as shown in the figure below.

Figure 28: MPLS LSP Multipath Tree Trace Path Discovery in a Sample Network

Using DSCP to Request a Specific Class of Service in an Echo Reply Example

The following example shows how to use DSCP to request a specific CoS in an echo reply:

```
Router# trace mpls multipath ipv4 10.1.1.150/32 reply dscp 50
Starting LSP Multipath Traceroute for 10.1.1.150/32
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
  'L' - labeled output interface, 'B' - unlabeled output interface,
  'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
  'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
  'P' - no rx intf label prot, 'p' - premature termination of LSP,
  'R' - transit router, 'I' - unknown upstream index,
  'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.

 Echo Reply (received/timeout) (14/0)
 Total Time Elapsed 448 ms
```

Controlling How a Responding Router Replies to an MPLS Echo Request Example

The following example shows how to control how a responding router replies to an MPLS echo request:

```
Router# trace mpls multipath ipv4 10.1.1.150/32 reply mode router-alert
Starting LSP Multipath Traceroute for 10.1.1.150/32
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
  'L' - labeled output interface, 'B' - unlabeled output interface,
  'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
  'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
  'P' - no rx intf label prot, 'p' - premature termination of LSP,
  'R' - transit router, 'I' - unknown upstream index,
  'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.
LLLL!

Specifying the Output Interface for Echo Packets Leaving a Router for MPLS LSP Multipath Tree Trace Example

The following example shows how to specify the output interface for echo packets leaving a router for the MPLS LSP Multipath Tree Trace feature:

```
Router# trace mpls multipath ipv4 10.1.1.150/32 output interface fastethernet0/0/0

Tracing MPLS Label Switched Path to 10.1.1.150/32, timeout is 2 seconds
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
  'L' - labeled output interface, 'B' - unlabeled output interface,
  'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
  'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
  'P' - no rx intf label prot, 'p' - premature termination of LSP,
  'R' - transit router, 'I' - unknown upstream index,
  'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.

Setting the Pace of MPLS Echo Request Packet Transmission for MPLS LSP Multipath Tree Trace Example

The following examples show how set the pace of MPLS echo request packet transmission for the MPLS LSP Multipath Tree Trace feature. The time between successive MPLS echo requests is set to 300 milliseconds in the first example and 400 milliseconds in the second example:

```
Router# trace mpls multipath ipv4 10.131.159.252/32 interval 300
Starting LSP Multipath Traceroute for 10.131.159.252/32
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
  'L' - labeled output interface, 'B' - unlabeled output interface,
  'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
  'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
  'P' - no rx intf label prot, 'p' - premature termination of LSP,
  'R' - transit router, 'I' - unknown upstream index,
  'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.
LL!
Path 0 found,
 output interface Et1/0 source 10.2.3.2 destination 127.0.0.0
Paths (found/broken/unexplored) (1/0/0)
 Echo Request (sent/fail) (3/0)
 Echo Reply (received/timeout) (3/0)
 Total Time Elapsed 1604 ms
Router# trace mpls multipath ipv4 10.131.159.252/32 interval 400
Starting LSP Multipath Traceroute for 10.131.159.252/32
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
  'L' - labeled output interface, 'B' - unlabeled output interface,
  'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
  'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
  'P' - no rx intf label prot, 'p' - premature termination of LSP,
  'R' - transit router, 'I' - unknown upstream index,
  'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.
LL!
Path 0 found,
 output interface Et1/0 source 10.2.3.2 destination 127.0.0.0
Paths (found/broken/unexplored) (1/0/0)
 Echo Request (sent/fail) (3/0)
 Echo Reply (received/timeout) (3/0)
 Total Time Elapsed 1856 ms
```

Notice that the elapsed time increases as you increase the interval size.

Enabling MPLS LSP Multipath Tree Trace to Detect LSP Breakages Example

The following examples shows how to enable the MPLS LSP Multipath Tree Trace feature to detect LSP breakages caused by an interface that lacks an MPLS configuration:

```
Router# trace mpls multipath ipv4 10.1.1.150/32 force-explicit-null

Starting LSP Multipath Traceroute for 10.1.1.150/32
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
  'L' - labeled output interface, 'B' - unlabeled output interface,
  'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
```

```
  'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
  'P' - no rx intf label prot, 'p' - premature termination of LSP,
  'R' - transit router, 'I' - unknown upstream index,
  'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.
LLLL!
Path 0 found,
 output interface Fe0/0/0 source 10.1.111.101 destination 127.0.0.0
LLL!
Path 1 found,
 output interface Fe0/0/0 source 10.1.111.101 destination 127.0.0.1
L!
Path 2 found,
 output interface Fe0/0/0 source 10.1.111.101 destination 127.0.0.5
LL!
Path 3 found,
 output interface Fe0/0/0 source 10.1.111.101 destination 127.0.0.7
Paths (found/broken/unexplored) (4/0/0)
 Echo Request (sent/fail) (14/0)
 Echo Reply (received/timeout) (14/0)
 Total Time Elapsed 460 ms
```

This example shows the additional information provided when you add the **verbose** keyword to the command:

```
Router# trace mpls multipath ipv4 10.1.1.150/32 force-explicit-null verbose
Starting LSP Multipath Traceroute for 10.1.1.150/32
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
 'L' - labeled output interface, 'B' - unlabeled output interface,
 'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
 'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
 'P' - no rx intf label prot, 'p' - premature termination of LSP,
 'R' - transit router, 'I' - unknown upstream index,
 'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.

Requesting That a Transit Router Validate the Target FEC Stack for MPLS LSP Multipath Tree Trace Example

The following example shows how to request that a transit router validate the target FEC stack for the MPLS LSP Multipath Tree Trace feature:

```
Router# trace mpls multipath ipv4 10.1.1.150/32 flags fec ttl 5

Starting LSP Multipath Traceroute for 10.1.1.150/32
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
  'L' - labeled output interface, 'B' - unlabeled output interface,
  'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
  'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
  'P' - no rx intf label prot, 'p' - premature termination of LSP,
  'R' - transit router, 'I' - unknown upstream index,
```

```
  'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.
LLLL!
Path 0 found,
 output interface Fe0/0/0 source 10.1.111.101 destination 127.0.0.0
LLL!
Path 1 found,
 output interface Fe0/0/0 source 10.1.111.101 destination 127.0.0.1
L!
Path 2 found,
 output interface Fe0/0/0 source 10.1.111.101 destination 127.0.0.5
LL!
Path 3 found,
 output interface Fe0/0/0 source 10.1.111.101 destination 127.0.0.7
Paths (found/broken/unexplored) (4/0/0)
 Echo Request (sent/fail) (14/0)
 Echo Reply (received/timeout) (14/0)
 Total Time Elapsed 464 ms
```

Target FEC stack validation is always done at the egress router when the **flags fec** keywords are specified in the **trace mpls multipath** command.

Setting the Number of Timeout Attempts for MPLS LSP Multipath Tree Trace Example

The following example sets the number of timeout attempts for the MPLS LSP Multipath Tree Trace feature to four:

```
Router# trace mpls multipath ipv4 10.1.1.150/32 retry-count 4

Starting LSP Multipath Traceroute for 10.1.1.150/32
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
  'L' - labeled output interface, 'B' - unlabeled output interface,
  'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
  'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
  'P' - no rx intf label prot, 'p' - premature termination of LSP,
  'R' - transit router, 'I' - unknown upstream index,
  'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.
LLLL!
Path 0 found,
 output interface Fe0/0/0 source 10.1.111.101 destination 127.0.0.0
LLL!
Path 1 found,
 output interface Fe0/0/0 source 10.1.111.101 destination 127.0.0.1
L!
Path 2 found,
 output interface Fe0/0/0 source 10.1.111.101 destination 127.0.0.5
LL!
Path 3 found,
 output interface Fe0/0/0 source 10.1.111.101 destination 127.0.0.7
Paths (found/broken/unexplored) (4/0/0)
 Echo Request (sent/fail) (14/0)
 Echo Reply (received/timeout) (14/0)
 Total Time Elapsed 460 ms
```

The following output shows a **trace mpls multipath** command that found one unexplored path, one successful path, and one broken path:

```
Router# trace mpls multipath ipv4 10.1.1.150/32 retry-count 4

Starting LSP Multipath Traceroute for 10.1.1.150/32
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
  'L' - labeled output interface, 'B' - unlabeled output interface,
  'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
  'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
  'P' - no rx intf label prot, 'p' - premature termination of LSP,
  'R' - transit router, 'I' - unknown upstream index,
  'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.

Feature Information for MPLS EM - MPLS LSP Multipath Tree Trace

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 34: Feature Information for MPLS EM—MPLS LSP Multipath Tree Trace

Feature Name	Releases	Feature Information
MPLS EM—MPLS LSP Multipath Tree Trace	Cisco IOS XE Release 2.3	The MPLS EM—MPLS LSP Multipath Tree Trace feature provides the means to discover all the possible paths of a label switched path (LSP) between an egress and ingress router. Once discovered, these paths can be retested on a periodic basis using Multiprotocol Label Switching (MPLS) LSP ping or traceroute. This feature is an extension to the MPLS LSP traceroute functionality for the tracing of IPv4 LSPs. MPLS Embedded Management (EM) is a set of standards and value-added services that facilitate the deployment, operation, administration, and management of MPLS-based networks in line with the fault, configuration, accounting, performance, and security (FCAPS) model. In Cisco IOS XE Release 2.3, this feature was introduced on the Cisco ASR 1000 Series Aggregation Services Routers.
		The following commands were introduced or modified: **debug mpls lspv**, **echo**, **mpls oam**, **trace mpls**, **trace mpls multipath**.

Glossary

ECMP —equal-cost multipath. Multiple routing paths of equal cost that may be used for packet forwarding.

FEC —Forwarding Equivalence Class. A set of packets that can be handled equivalently for forwarding purposes and are thus suitable for binding to a single label. Examples include the set of packets destined for one address prefix and the packets in any flow.

flow —A set of packets traveling between a pair of hosts, or between a pair of transport protocol ports on a pair of hosts. For example, packets with the same source address, source port, destination address, and destination port might be considered a flow.

A flow is also a stream of data traveling between two endpoints across a network (for example, from one LAN station to another). Multiple flows can be transmitted on a single circuit.

localhost —A name that represents the host router (device). The localhost uses the reserved loopback IP address 127.0.0.1.

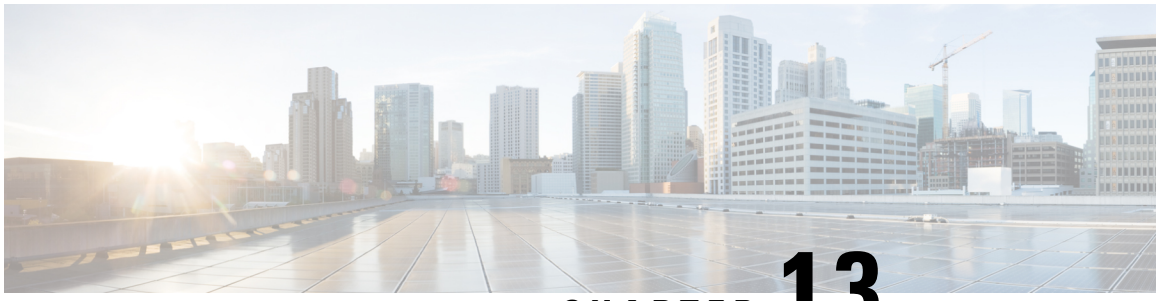
LSP —label switched path. A connection between two routers in which Multiprotocol Label Switching (MPLS) forwards the packets.

LSPV —Label Switched Path Verification. An LSP ping subprocess. It encodes and decodes Multiprotocol Label Switching (MPLS) echo requests and replies, and it interfaces with IP, MPLS, and AToM switching for sending and receiving MPLS echo requests and replies. At the MPLS echo request originator router, LSPV maintains a database of outstanding echo requests for which echo responses have not been received.

MPLS router alert label —An Multiprotocol Label Switching (MPLS) label of 1. An MPLS packet with a router alert label is redirected by the router to the Route Processor (PR) processing level for handling. This allows these packets to bypass any forwarding failures in hardware routing tables.

OAM —Operation, Administration, and Management.

punt —Redirect packets with a router alert from the line card or interface to Route Processor (RP) level processing for handling.



RP —Route Processor. The processor module contains the CPU, system software, and most of the memory components that are used in the router.

TTL —time-to-live. A parameter you can set that indicates the maximum number of hops a packet should take to reach its destination.

TLV —type, length, values. A block of information included in a Cisco Discovery Protocol address.

UDP —User Datagram Protocol. Connectionless transport layer protocol in the TCP/IP protocol stack. UDP is a simple protocol that exchanges datagrams without acknowledgments or guaranteed delivery, so error processing and retransmission must be handled by other protocols. UDP is defined in RFC 768.

XDR —eXternal Data Representation. Standard for machine-independent data structures developed by Sun Microsystems. Used to transport messages between the Route Processor (RP) and the line card.

CHAPTER 13

MPLS Label Distribution Protocol MIB

This document describes the Simple Network Management Protocol (SNMP) agent support provided in Cisco software for the MPLS Label Distribution Protocol Management Information Base (MPLS LDP MIB).

- Restrictions for MPLS LDP MIB, on page 247
- Information About MPLS LDP MIB, on page 247
- How to Configure MPLS LDP MIB, on page 253
- Configuration Examples for MPLS LDP MIB, on page 258
- Additional References, on page 258
- Feature Information for MPLS LDP MIB, on page 259

Restrictions for MPLS LDP MIB

The MPLS LDP MIB is limited to read-only (RO) permission for MIB objects, except for MIB object mplsLdpSessionUpDownTrapEnable, which is writable by the SNMP agent.

Setting this object to a value of true enables both the mplsLdpSessionUp and mplsLdpSessionDown notifications on the Label Switched Router (LSR); conversely, setting this object to a value of false disables both of these notifications. The value of the mplsLdpSessionUpDownTrapEnable object is stored in NVRAM on the MPLS LDP MIB host.

For a description of notification events, see the Events Generating MPLS LDP MIB Notifications section.

Most MPLS LDP MIB objects are set up automatically during the LDP peer discovery (Hello) process and the subsequent negotiation of parameters and establishment of LDP sessions between the LDP peers.

Information About MPLS LDP MIB

MPLS LDP Overview

Multiprotocol Label Switching (MPLS) is a packet forwarding technology that uses a short, fixed-length value called a label in packets to determine the next hop for packet transport through an MPLS network by means of label switching routers (LSRs).

A fundamental MPLS principle is that LSRs in an MPLS network must agree on the definition of the labels being used for packet forwarding operations. Label agreement is achieved in an MPLS network by means of procedures defined in the Label Distribution Protocol (LDP).

LDP operations begin with a discovery (Hello) process, during which an LDP entity (a local LSR) finds a cooperating LDP peer in the network and negotiates basic operating procedures between them. The recognition and identification of a peer by means of this discovery process results in a Hello adjacency, which represents the context within which label binding information is exchanged between the local LSR and its LDP peer. An LDP function then creates an active LDP session between the two LSRs to effect the exchange of label binding information. The result of this process, when carried to completion with respect to all the LSRs in an MPLS network, is a label switched path (LSP), which constitutes an end-to-end packet transmission pathway between the communicating network devices.

By means of LDP, LSRs can collect, distribute, and release label binding information to other LSRs in an MPLS network, thereby enabling the hop-by-hop forwarding of packets in the network along normally routed paths.

MPLS LDP MIB Overview

The MPLS LDP MIB has been implemented to enable standard, SNMP-based network management of the label switching features in Cisco software. Providing this capability requires SNMP agent code to execute on a designated network management station (NMS) in the network. The NMS serves as the medium for user interaction with the network management objects in the MPLS LDP MIB.

The SNMP agent embodies a layered structure that is compatible with Cisco software and presents a network administrative and management interface to the objects in the MPLS LDP MIB and, thence, to the rich set of label switching capabilities supported by Cisco software.

By means of an SNMP agent, you can access MPLS LDP MIB objects using standard SNMP **get** operations to accomplish a variety of network management tasks. All the objects in the MPLS LDP MIB follow the conventions defined in the Internet Engineering Task Force (IETF) draft MIB entitled *draft-ietf-mpls-ldp-mib-08.txt*, which defines network management objects in a structured and standardized manner. This draft MIB is continually evolving toward the status of a standard. Accordingly, the MPLS LDP MIB will be implemented in a manner that tracks the evolution of this IETF document.

Slight differences that exist between the IETF draft MIB and the implementation of equivalent functions in Cisco software require some minor translations between the MPLS LDP MIB objects and the internal data structures of Cisco software. Such translations are accomplished by the SNMP agent, which runs in the background on the NMS workstation as a low priority process.

The MPLS LDP MIB provides the following functions:

- The MPLS LDP MIB can generate and send event notification messages to signal changes in the status of LDP sessions.
- You can enable and disable event notification messages by using SNMP CLI commands.
- You can specify the name or the IP address of an NMS workstation where event notification messages are sent to serve network administrative and management purposes.
- You can store the configuration pertaining to an event notification message in nonvolatile memory (NVRAM) of the NMS.

The structure of the MPLS LDP MIB conforms to Abstract Syntax Notation One (ASN.1), thereby forming a highly structured and idealized database of network management objects.

Using any standard SNMP application, you can retrieve and display information from the MPLS LDP MIB by means of standard SNMP GET operations. Similarly, you can traverse and display information in the MIB by means of SNMP GETNEXT operations.

Note Because the MPLS LDP MIB was not given an Internet Assigned Numbers Authority (IANA) Experimental OID at the time of its implementation, Cisco chose to implement the MIB under the Cisco Experimental OID number: ciscoExperiment 1.3.6.1.4.1.9.10 mplsLdpMIB 1.3.6.1.4.1.9.10.65 If the MPLS LDP MIB is assigned an IANA Experimental OID number, Cisco will deprecate all objects in the MIB under the Cisco Experimental OID and reposition the objects under the IANA Experimental OID.

Benefits of Using MPLS LDP MIB

The MPLS LDP MIB provides the following benefits:

- Establishing LDP sessions between peer devices in an MPLS network
- Retrieving MIB parameters relating to the operation of LDP entities, such as:
  - Well-known LDP discovery port
  - Maximum transmission unit (MTU)
  - Proposed KeepAlive timer interval
  - Loop detection
  - Session establishment thresholds
  - Range of VPI/VCI pairs to be used in forming labels
- Gathering statistics related to LDP operations, such as:
  - Count of the total established sessions for an LDP entity
  - Count of the total attempted sessions for an LDP entity
- Monitoring the time remaining for Hello adjacencies
- Monitoring the characteristics and status of LDP peers, such as:
  - Type of internetwork layer address of LDP peers
  - Actual internetwork layer address of LDP peers
  - Default MTU of the LDP peer
  - Number of seconds the LDP peer proposes as the value of the KeepAlive interval
  - Establishment of VPI/VCI label ranges to be made known to LDP peers
- Monitoring the characteristics and status of LDP sessions, such as:
  - Determining the LDP version being used by the LDP session
  - Determining the KeepAlive hold time remaining for an LDP session
  - Determining the state of an LDP session (whether the session is active or not)
  - Determining the range of VPI/VCI pairs to be used by an LDP session
  - Determining the last active interface of an LDP session

Description of MPLS LDP MIB Elements

The MPLS LDP MIB includes the following elements:

- LDP entity--Relates to an instance of LDP for purposes of exchanging label spaces.

- LDP peer--Refers to a remote LDP entity (that is, a nonlocal LSR).
- LDP session--Refers to an active LDP process between a local LSR and a remote LDP peer.
- Hello adjacency--Refers to the result of an LDP discovery process which affirms the state of two LSRs in an MPLS network as being adjacent to each other (that is, as being LDP peers).

A Hello adjacency constitutes the working context between two LSRs in an MPLS network. The adjacency is used for the exchange of label binding information.

These MPLS LDP MIB elements are briefly described under separate headings below.

In effect, the MPLS LDP MIB provides a network management database that supports real-time access to the various MIB objects within, reflecting the current state of MPLS LDP operations in the network. This network management information database is accessible by means of standard SNMP commands issued from an NMS in the MPLS/LDP operating environment.

The MPLS LDP MIB supports the following network management and administrative activities:

- Retrieving MPLS LDP MIB parameters pertaining to LDP operations
- Monitoring the characteristics and the status of LDP peers
- Monitoring the status of LDP sessions between LDP peers
- Monitoring Hello adjacencies in the network
- Gathering statistics regarding LDP sessions

LDP Entities

An LDP entity is uniquely identified by an LDP identifier having the object name *mplsLdpEntityLdpId* . This object consists of the router ID (four octets) and an interface number (two octets). The router ID encodes an IP address assigned to the LSR. The interface number identifies a specific label space available within the LSR.

An LDP entity represents a label space that is targeted for distribution to an LDP peer. In the case of an interface-specific LDP entity, the label space is distributed to a single LDP peer by means of a single LDP session.

Conversely, a platform-wide LDP entity can be associated with multiple LDP peers. In this case, the label space is distributed to multiple LDP peers by means of a separate LDP session pertaining to each peer.

LDP Peers

If an LSR has a label space to advertise to another LSR, or to multiple LSRs, there would be one LDP session for each LSR receiving the label space information. The receiver of the label space information is referred to as an LDP peer.

Per-interface label spaces are advertised to a single LDP peer by means of a single LDP session. *Per-platform* label spaces are advertised to multiple LDP peers by means of multiple LDP sessions.

The possible existence of multiple per-platform LDP peers dictates not only that an LDP entity be identified by its unique LDP tag, but also by its LDP index. In this case, the label space is the same, but the LDP Index differentiates the LDP session over which the label space is distributed to multiple LDP peers.

LDP Sessions

LDP sessions between local entities and remote peers distribute label spaces. There is always a one-to-one correspondence between an LDP peer and an LDP session. A single LDP session is a label distribution protocol instance that communicates across one or more network links with a single LDP peer. In the case of a platform-wide local LDP entity, there may be multiple LDP sessions and a corresponding number of remote LDP peers.

LDP Hello Adjacencies

An LDP session is an LDP instance that communicates across one or more network links to a peer protocol instance. An LDP Hello adjacency exists for each link on which LDP runs. Multiple link adjacencies exist whenever there are multiple links to the same LDP peer. In the case of a platform-wide label space, for example, there is a separate LDP peer/LDP session relationship for each LSR to which a label space may be advertised.

MPLS LDP MIB Object Categories

The MPLS LDP MIB contains numerous definitions of managed objects for the MPLS Label Distribution Protocol, as defined in the IETF draft document entitled *draft-ietf-mpls-ldp-08.txt* .

The managed objects in the MPLS LDP MIB are structured according to the following categories:

- MPLS LDP Textual Conventions
- MPLS LDP Objects
- MPLS Label Distribution Protocol Entity Objects
- LDP Entity Objects for Generic Labels
- LDP Entity Objects for ATM
- MPLS LDP Entity Configured ATM Label Range Table
- MPLS Entity Objects for Frame Relay
- Frame Relay Label Range Components
- MPLS LDP Entity Statistics Table
- MPLS LDP Entity Peer Table
- MPLS LDP Hello Adjacency Table
- MPLS LDP Sessions Table
- MPLS LDP ATM Session Information
- MPLS LDP Frame Relay Session Information
- MPLS LDP Session Statistics Table
- Address Message/Address Withdraw Message Information
- MPLS LDP LIB Table
- MPLS LDP FEC Table
- Notifications

- Module Conformance Statement

Events Generating MPLS LDP MIB Notifications

When you enable MPLS LDP MIB notification functionality by issuing the **snmp-server enable traps mpls ldp** command, notification messages are generated and sent to a designated NMS in the network to signal the occurrence of specific events within Cisco software.

The MPLS LDP MIB objects that announce LDP status transitions and event notifications include the following:

- mplsLdpSessionUp--This message is generated when an LDP entity (a local LSR) establishes an LDP session with another LDP entity (an adjacent LDP peer in the network).
- mplsLdpSessionDown--This message is generated when an LDP session between a local LSR and its adjacent LDP peer is terminated.

The up and down notifications indicate the last active interface in the LDP session.

- mplsLdpPathVectorLimitMismatch--This message is generated when a local LSR establishes an LDP session with its adjacent peer LSR, but the two LSRs have dissimilar path vector limits.

The value of the path vector limit can range from 0 to 255; a value of 0 indicates that loop detection is off; any value other than 0 up to 255 indicates that loop detection is on and, in addition, specifies the maximum number of hops through which an LDP message can pass before a loop condition in the network is sensed.

We recommend that all LDP-enabled routers in the network be configured with the same path vector limit. Accordingly, the mplsLdpPathVectorLimitMismatch object exists in the MPLS LDP MIB to provide a warning message to the NMS when two routers engaged in LDP operations have a dissimilar path vector limits.

- mplsLdpFailedInitSessionThresholdExceeded--This message is generated when a local LSR and an adjacent LDP peer attempt to set up an LDP session between them, but fail to do so after a specified number of attempts. The default number of attempts is 8. This default value is implemented in Cisco software and cannot be changed by either the CLI or an SNMP agent.

Eight failed attempts to establish an LDP session between a local LSR and an LDP peer, due to any type of incompatibility between the devices, causes this notification message to be generated.

In general, Cisco routers support the same features across multiple platforms. Therefore, the most likely incompatibility to occur between Cisco LSRs is a mismatch of their respective ATM VPI/VCI label ranges.

For example, if you specify a range of valid labels for an LSR that does not overlap the range of its adjacent LDP peer, the routers try eight times to create an LDP session between themselves before the mplsLdpFailedInitSessionThresholdExceeded notification is generated and sent to the NMS as an informational message.

Operationally, the LSRs whose label ranges do not overlap continue their attempt to create an LDP session between themselves after the eight retry limit is exceeded. In such cases, the LDP threshold exceeded notification alerts the network administrator to the existence of a condition in the network that may warrant attention.

RFC 3036, LDP Specification , details the incompatibilities that can exist between Cisco routers and/or other vendor LSRs in an MPLS network. Among such incompatibilities, for example, are the following:

- • Nonoverlapping ATM VPI/VCI ranges (as noted above) or nonoverlapping Frame-Relay DLCI ranges between LSRs attempting to set up an LDP session

- Unsupported label distribution method
- Dissimilar protocol data unit (PDU) sizes
- Dissimilar LDP feature support

How to Configure MPLS LDP MIB

Enabling the SNMP Agent for the MPLS LDP MIB

By default, the SNMP agent for the MPLS LDP MIB is disabled. To enable the SNMP agent on the host NMS workstation, perform the following procedure.

SUMMARY STEPS

1. **enable**
2. **show running-config**
3. **configure terminal**
4. **snmp-server community** *string* [**view** *view-name*] [**ro** | **rw**] [*acl-number*]
5. **do copy running-config startup-config**
6. **exit**
7. **show running-config** [**interface** | **map-class**]

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**show running-config** **Example:** `Router# show running-config`	Displays the running configuration to determine if an SNMP agent is already running. • If no SNMP information is displayed, continue with the next step. If any SNMP information is displayed, you can modify the information or change it as needed.
Step 3	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 4	**snmp-server community** *string* [**view** *view-name*] [**ro** | **rw**] [*acl-number*]	Sets up the community access string to permit access to the SNMP protocol.

	Command or Action	Purpose
	Example: `Router(config)# snmp-server community comaccess ro`	• The *string* argument acts like a password and permits access to the SNMP protocol. • The **view** *view-name* keyword and argument pair specifies the name of a previously defined view. The view defines the objects available to the community. • The **ro** keyword specifies read-only access. Authorized management stations are only able to retrieve MIB objects. • The **rw** keyword specifies read/write access. Authorized management stations are able to both retrieve and modify MIB objects. • The *acl-number* argument is an integer from 1 to 99 that specifies an access list of IP addresses that are allowed to use the community string to gain access to the SNMP agent.
Step 5	**do copy running-config startup-config** **Example:** `Router(config)# do copy running-config startup-config`	Saves the modified configuration to nonvolatile memory (NVRAM) as the startup configuration file. • The **do** command allows you to perform EXEC level commands in configuration mode.
Step 6	**exit** **Example:** `Router(config)# exit`	Returns to privileged EXEC mode.
Step 7	**show running-config** [**interface** | **map-class**] **Example:** `Router# show running-config | include smnp-server`	(Optional) Displays the configuration information currently on the router, the configuration for a specific interface, or map-class information. • Use the **show running-config** command to check that the **snmp-server** statements appear in the output.

Configuring the Router to Send SNMP Traps

Perform this task to configure the router to send traps to a host.

The **snmp-server host** command specifies which hosts receive traps. The **snmp-server enable traps** command globally enables the trap production mechanism for the specified traps.

For a host to receive a trap, an **snmp-server host** command must be configured for that host, and, generally, the trap must be enabled globally through the **snmp-server enable traps** command.

Note Although you can set the *community-string* argument using the **snmp-server host** command by itself, we recommend that you define this string using the **snmp-server community** command prior to using the **snmp-server host** command.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server host** *host-addr* [**traps** | **informs**] [**version** {**1** | **2c** | **3** [**auth** | **noauth** | **priv**]}] *community-string* [**udp-port** *port*] [*notification-type*] [**vrf** *vrf-name*]
4. **snmp-server enable traps mpls ldp** [**session-down**] [**session-up**] [**pv-limit**] [**threshold**]
5. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.

Step 3	**snmp-server host** *host-addr* [**traps** | **informs**] [**version** {**1** | **2c** | **3** [**auth** | **noauth** | **priv**]}] *community-string* [**udp-port** *port*] [*notification-type*] [**vrf** *vrf-name*]
	Example:
	`Router(config)# snmp-server host 172.20.2.160 traps comaccess mpls-ldp`
		Specifies the recipient of an SNMP notification operation.
		• The *host-addr* argument specifies the name or Internet address of the host (the targeted recipient).
		• The **traps** keyword sends SNMP traps to this host. This is the default.
		• The **informs** keyword sends SNMP informs to this host.
		• The **version** keyword specifies the version of the SNMP used to send the traps. Version 3 is the most secure model, because it allows packet encryption with the **priv** keyword. If you use the **version** keyword, you must specify one of the following:
		  • **1**--SNMPv1. This option is not available with informs.
		  • **2c**--SNMPv2C.

	Command or Action	Purpose
		• **3**--SNMPv3. The following three optional keywords can follow the **version 3** keyword (**auth**, **noauth**, **priv**). • The *community-string* argument is a password-like community string sent with the notification operation. • The **udp-port** *port* keyword argument pair names the UDP port of the host to use. The default is 162. • The *notification-type* argument specifies the type of notification to be sent to the host. If no type is specified, all notifications are sent. • The **vrf** *vrf-name* keyword argument pair specifies the VRF table that should be used to send SNMP notifications.
Step 4	**snmp-server enable traps mpls ldp** [**session-down**] [**session-up**] [**pv-limit**] [**threshold**] **Example:** `Router(config)# snmp-server enable traps mpls ldp session-down session-up`	Enables the router to send MPLS VPN- specific SNMP notifications (traps and informs). • The **session-down** keyword controls (enables or disables) LDP session down notifications (mplsLdpSessionDown). This message is generated when an LDP session between the router and its adjacent LDP peer is terminated. • The **session-up** keyword controls (enables or disables) LDP session up notifications (mplsLdpSessionUp). This notification is generated when the router establishes an LDP session with another LDP entity (an adjacent LDP peer in the network). • The **pv-limit** keyword controls (enables or disables) path-vector (PV) limit notifications (mplsLdpPathVectorLimitMismatch). This notification is generated when the router establishes an LDP session with its adjacent peer LSR, but the two LSRs have dissimilar path vector limits. • The **threshold** keyword controls (enables or disables) PV limit notifications (mplsLdpFailedInitSessionThresholdExceeded). This notification is generated after eight failed attempts to establish an LDP session between the router and an LDP peer. The failure can be the result of any type of incompatibility between the devices.
Step 5	**exit** **Example:** `Router(config)# exit`	(Optional) Exits to privileged EXEC mode.

Verifying the Status of the SNMP Agent

To verify that the SNMP agent has been enabled on the host NMS workstation, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **show running-config**
3. **exit**

DETAILED STEPS

Procedure

Step 1 **enable**

Use this command to enable privileged EXEC mode. Enter your password if prompted. For example:

Example:

```
Router> enable
Router#
```

Step 2 **show running-config**

Use this command to display the running configuration on the host NMS and examine the output for SNMP information. For example:

Example:

```
Router# show running-config
.
.
.
snmp-server community public RO
snmp-server community private RO
```

The presence of any snmp-server statement in the output that takes the form shown above verifies that the SNMP agent has been enabled on the host NMS workstation.

Step 3 **exit**

Use this command to exit to user EXEC mode. For example:

Example:

```
Router# exit
Router>
```

Configuration Examples for MPLS LDP MIB

Enabling the SNMP Agent Examples

The following example shows how to enable an SNMP agent on the host NMS:

```
Router# configure terminal
Router(config)# snmp-server community
```

The following example shows how to enable SNMPv1 and SNMPv2C on the host NMS. The configuration permits any SNMP agent to access all MPLS LDP MIB objects with read-only permission using the community string public.

```
Router(config)# snmp-server community public
```

The following example shows how to allow read-only access to all MPLS LDP MIB objects relating to members of access list 4 that specify the comaccess community string. No other SNMP agents will have access to any of the MPLS LDP MIB objects.

```
Router(config)# snmp-server community comaccess ro 4
```

The following example shows how to enable the session up and session down LDP notifications:

```
Router(config)# snmp-server enable traps mpls ldp session-up
Router(config)# snmp-server enable traps mpls ldp session-down
```

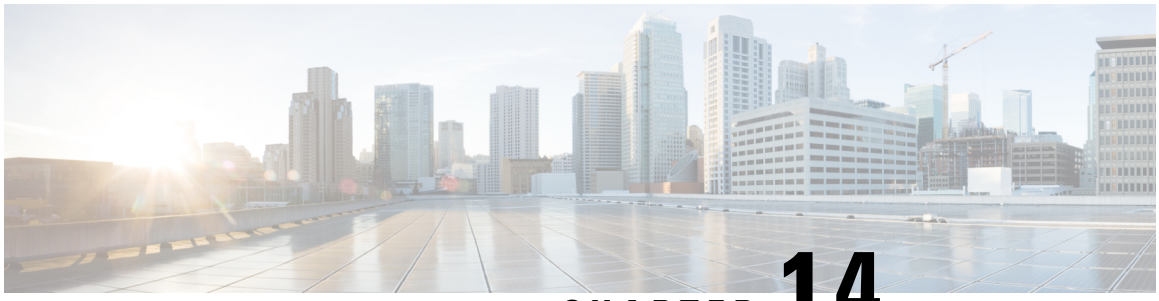
Technical Assistance

Description	Link
The Cisco Support website provides extensive online resources, including documentation and tools for troubleshooting and resolving technical issues with Cisco products and technologies. To receive security and technical information about your products, you can subscribe to various services, such as the Product Alert Tool (accessed from Field Notices), the Cisco Technical Services Newsletter, and Really Simple Syndication (RSS) Feeds. Access to most tools on the Cisco Support website requires a Cisco.com user ID and password.	http://www.cisco.com/techsupport



Feature Information for MPLS LDP MIB

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 35: Feature Information for MPLS LDP MIB

Feature Name	Releases	Feature Information
MPLS LDP MIB	12.0(11)ST 12.2(2)T 12.0(21)ST 12.2(13)T 12.0(30)S 12.2(27)SBC 12.2(28)SB 12.2(33)SRA 12.2(33)SXH Cisco IOS XE Release 2.1	The MPLS LDP MIB has been implemented to enable standard, SNMP-based network management of the label switching features in Cisco software. In Cisco IOS Release 12.0(11)ST, this feature was introduced to provide SNMP agent support when using the MPLS LDP MIB on Cisco 7200, Cisco 7500, and Cisco 12000 series routers. In Cisco IOS Release 12.2(2)T, this feature was integrated to provide SNMP agent support when using the MPLS LDP MIB on Cisco 7200 and Cisco 7500 series routers. In Cisco IOS Release 12.0(21)ST, the **snmp-server enable traps mpls ldp** command was introduced. The **snmp-server enable traps mpls ldp** command was integrated into Cisco IOS Release 12.2(13)T. This feature was integrated into Cisco IOS Release 12.0(30)S. This feature was integrated into Cisco IOS Release 12.2(27)SBC. This feature was integrated into Cisco IOS Release 12.2(28)SB. This feature was integrated into Cisco IOS Release 12.2(33)SRA. This feature was integrated into Cisco IOS Release 12.2(33)SXH. This feature was integrated into Cisco IOS XE Release 2.1 and implemented on the Cisco ASR 1000 Series Aggregation Services Routers. The following commands were introduced or modified: **snmp-server enable traps mpls ldp**
MPLS LDP—MIB Notifications	Cisco IOS XE Release 2.1	This feature provides SNMP traps for critical MPLS LDP events. This feature was introduced on the Cisco ASR 1000 Series Aggregation Services Routers. The following commands were introduced or modified: **snmp-server enable traps mpls ldp**

CHAPTER 14

MPLS Label Distribution Protocol MIB Version 8 Upgrade

The MPLS Label Distribution Protocol (LDP) MIB Version 8 Upgrade feature enhances the LDP MIB to support the Internet Engineering Task Force (IETF) draft Version 8.

- Prerequisites for MPLS LDP MIB Version 8 Upgrade, on page 261
- Restrictions for MPLS LDP MIB Version 8 Upgrade, on page 261
- Information About MPLS LDP MIB Version 8 Upgrade, on page 262
- How to Configure MPLS LDP MIB Version 8 Upgrade, on page 282
- Configuration Examples for MPLS LDP MIB Version 8 Upgrade, on page 293
- Additional References, on page 295
- Feature Information for MPLS LDP MIB Version 8 Upgrade, on page 296
- Glossary, on page 298

Prerequisites for MPLS LDP MIB Version 8 Upgrade

- Simple Network Management Protocol (SNMP) must be installed and enabled on the label switch routers (LSRs).
- Multiprotocol Label Switching (MPLS) must be enabled on the LSRs.
- LDP must be enabled on the LSRs.

Restrictions for MPLS LDP MIB Version 8 Upgrade

This implementation of the MPLS LDP MIB is limited to read-only (RO) permission for MIB objects, except for MIB object *mplsLdpSessionUpDownTrapEnable* , which has been extended to be writable by the SNMP agent.

Setting this object to a value of true enables both the *mplsLdpSessionUp* and *mplsLdpSessionDown* notifications on the LSR; conversely, setting this object to a value of false disables both of these notifications.

For a description of notification events, see the Events Generating MPLS LDP MIB Notifications in MPLS LDP MIB Version 8 Upgrade section.

Most MPLS LDP MIB objects are set up automatically during the LDP peer discovery (hello) process and the subsequent negotiation of parameters and establishment of LDP sessions between the LDP peers.

The following tables are not implemented in this feature:

- mplsLdpEntityFrParmsTable
- mplsLdpEntityConfFrLRTable
- mplsLdpFrameRelaySesTable
- mplsFecTable
- mplsLdpSesInLabelMapTable
- mplsXCsFecsTable
- mplsLdpSesPeerAddrTable

Information About MPLS LDP MIB Version 8 Upgrade

Feature Design of MPLS LDP MIB Version 8 Upgrade

MPLS is a packet forwarding technology that uses a short, fixed-length value called a label in packets to specify the next hop for packet transport through an MPLS network by means of label switch routers (LSRs).

A fundamental MPLS principle is that LSRs in an MPLS network must agree on the definition of the labels being used for packet forwarding operations. Label agreement is achieved in an MPLS network by means of procedures defined in the LDP.

LDP operations begin with a discovery (hello) process, during which an LDP entity (a local LSR) finds a cooperating LDP peer in the network, and the two negotiate basic operating procedures. The recognition and identification of a peer by means of this discovery process results in a hello adjacency, which represents the context within which label binding information is exchanged between the local LSR and its LDP peer. LDP then creates an active LDP session between the two LSRs to effect the exchange of label binding information. When this process is carried to completion with respect to all of the LSRs in an MPLS network, the result is a label-switched path (LSP), which constitutes an end-to-end packet transmission pathway between the communicating network devices.

By means of LDP, LSRs can collect, distribute, and release label binding information to other LSRs in an MPLS network, thereby enabling the hop-by-hop forwarding of packets in the network along normally routed paths.

The MPLS LDP MIB has been implemented to enable standard, SNMP-based network management of the label switching features in Cisco software. Providing this capability requires SNMP agent code to execute on a designated network management station (NMS) in the network. The NMS serves as the medium for user interaction with the network management objects in the MPLS LDP MIB.

The SNMP agent code has a layered structure that is compatible with Cisco software and presents a network administrative and management interface to the objects in the MPLS LDP MIB and, thence, to the rich set of label switching capabilities supported by Cisco software.

By means of an SNMP agent, you can access MPLS LDP MIB objects using standard SNMP GET operations, and you can use those objects to accomplish a variety of network management tasks. All the objects in the

MPLS LDP MIB follow the conventions defined in the IETF draft MIB entitled *draft-ietf-mpls-ldp-mib-08.txt,* which defines network management objects in a structured and standardized manner. This draft MIB is evolving and is soon expected to be a standard. Accordingly, the MPLS LDP MIB will be implemented in such a way that it tracks the evolution of this IETF document.

However, slight differences exist between the IETF draft MIB and the implementation of equivalent Cisco functions. As a result, some minor translations between the MPLS LDP MIB objects and the internal Cisco data structures are needed. Such translations are accomplished by the SNMP agent, which runs in the background on the NMS workstation as a low-priority process.

The extensive Cisco label switching capabilities provide an integrated approach to managing the large volumes of traffic carried by WANs. These capabilities are integrated into the Layer 3 network services, thus optimizing the routing of high-volume traffic through Internet service provider backbones while, at the same time, ensuring the resistance of the network to link or node failures.

The MPLS Label Distribution Protocol MIB Version 8 Upgrade supports the following functions:

- Tag Distribution Protocol (TDP) (This protocol might not be supported in all software releases.)
- Generation and sending of event notification messages that signal changes in the status of LDP sessions
- Enabling and disabling of event notification messages by means of extensions to existing SNMP CLI commands
- Specification of the name or the IP address of an NMS workstation in the operating environment to which Cisco event notification messages are to be sent to serve network administrative and management purposes
- Storage of the configuration pertaining to an event notification message in NVRAM of the NMS

The structure of the MPLS LDP MIB conforms to Abstract Syntax Notation One (ASN.1), so the MIB forms a highly structured and idealized database of network management objects.

Using any standard SNMP application, you can retrieve and display information from the MPLS LDP MIB by means of standard SNMP GET and GETNEXT operations.

Note Because the MPLS LDP MIB was not given an Internet Assigned Numbers Authority (IANA) experimental object identifier (OID) at the time of its implementation, Cisco chose to implement the MIB under the ciscoExperimental OID number, as follows: ciscoExperimental 1.3.6.1.4.1.9.10 mplsLdpMIB 1.3.6.1.4.1.9.10.65 If the MPLS LDP MIB is assigned an IANA Experimental OID number, Cisco will replace all objects in the MIB under the ciscoExperimental OID and reposition the objects under the IANA Experimental OID.

Enhancements in Version 8 of the MPLS LDP MIB

Version 8 of the MPLS LDP MIB contains the following enhancements:

- TDP support (This protocol might not be supported in all software releases.)
- Upgraded objects
- New indexing that is no longer based on the number of sessions
- Multiple SNMP context support for Virtual Private Networks (VPNs)

Benefits of MPLS LDP MIB Version 8 Upgrade

- Supports TDP and LDP (TDP might not be supported in all software releases.)
- Establishes LDP sessions between peer devices in an MPLS network
- Retrieves MIB parameters relating to the operation of LDP entities, such as:
  - Well-known LDP discovery port
  - Maximum transmission unit (MTU)
  - Proposed keepalive timer interval
  - Loop detection
  - Session establishment thresholds
  - Range of virtual path identifier/virtual channel identifier (VPI/VCI) pairs to be used in forming labels
- Gathers statistics related to LDP operations, such as error counters.
- Monitors the time remaining for hello adjacencies
- Monitors the characteristics and status of LDP peers, such as:
  - Internetwork layer address of LDP peers
  - Loop detection of the LDP peers
  - Default MTU of the LDP peer
  - Number of seconds the LDP peer proposes as the value of the keepalive interval
- Monitors the characteristics and status of LDP sessions, such as:
  - Displaying the error counters.
  - Determining the LDP version being used by the LDP session
  - Determining the keepalive hold time remaining for an LDP session
  - Determining the state of an LDP session (whether the session is active or not)
  - Displaying the label ranges for platform-wide and interface-specific sessions
  - Displaying the ATM parameters.

Description of MPLS LDP MIB Elements for MPLS LDP MIB Version 8 Upgrade

LDP operations related to an MPLS LDP MIB involve the following functional elements:

- LDP entity--Relates to an instance of LDP for purposes of exchanging label spaces; describes a potential session.
- LDP peer--Refers to a remote LDP entity (that is, a nonlocal LSR).
- LDP session--Refers to an active LDP process between a local LSR and a remote LDP peer.
- Hello adjacency--Refers to the result of an LDP discovery process that affirms the state of two LSRs in an MPLS network as being adjacent to each other (that is, as being LDP peers). When the neighbor is discovered, the neighbor becomes a hello adjacency. An LDP session can be established with the hello adjacency. After the session is established, label bindings can be exchanged between the LSRs.

These MPLS LDP MIB elements are briefly described under separate headings below.

In effect, the MPLS LDP MIB provides a network management database that supports real-time access to the various MIB objects in the database. This database reflects the current state of MPLS LDP operations in the network. You can access this network management information database by means of standard SNMP commands issued from an NMS in the MPLS LDP operating environment.

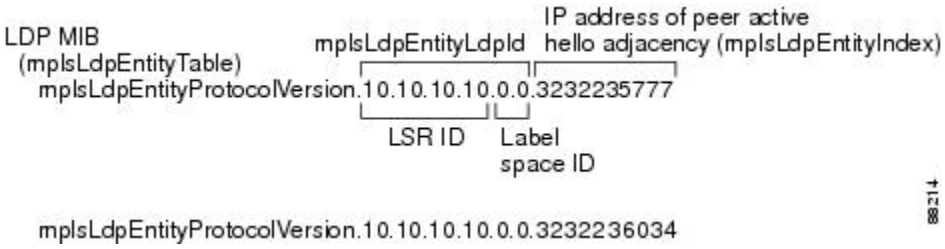
The MPLS LDP MIB supports the following network management and administrative activities:

- Retrieving MPLS LDP MIB parameters pertaining to LDP operations
- Monitoring the characteristics and the status of LDP peers
- Monitoring the status of LDP sessions between LDP peers
- Monitoring hello adjacencies in the network
- Gathering statistics regarding LDP sessions

LDP Entities

An LDP entity is uniquely identified by an LDP identifier that consists of the mplsLdpEntityLdpId and the mplsLdpEntityIndex (see the figure below).

- The mplsLdpEntityLdpId consists of the local LSR ID (four octets) and the label space ID (two octets). The label space ID identifies a specific label space available within the LSR.
- The mplsLdpEntityIndex consists of the IP address of the peer active hello adjacency, which is the 32-bit representation of the IP address assigned to the peer LSR.

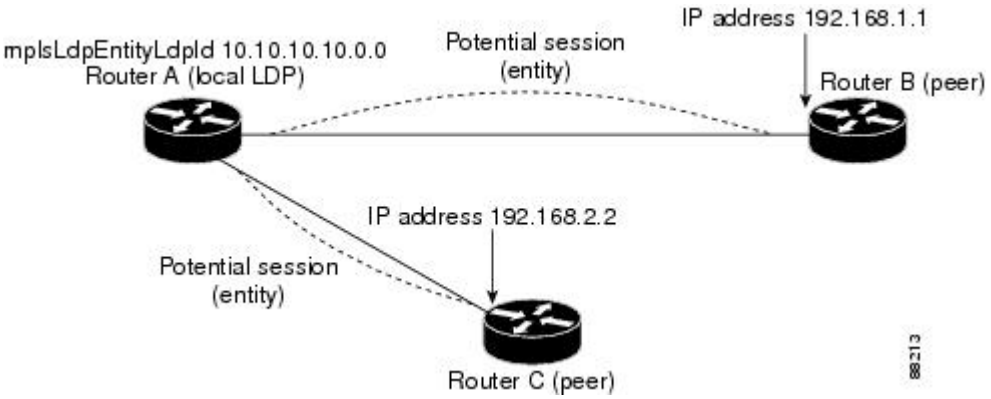


The mplsldpEntityProtocolVersion is a sample object from the mplsLdpEntityTable.

The figure shows the following indexing:

- mplsLdpEntityLdpId = 10.10.10.10.0.0
- LSR ID = 10.10.10.10
- Label space ID = 0.0

The mplsLdpEntityLdpId or the LDP ID consists of the LSR ID and the label space ID.



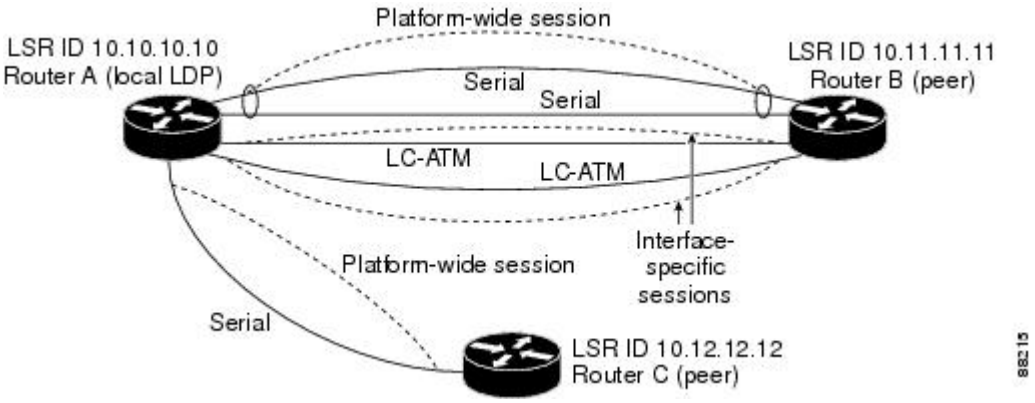
- The IP address of peer active hello adjacency or the mplsLdpEntityIndex = 3232235777, which is the 32-bit representation of the IP address assigned to the peer's active hello adjacency.

An LDP entity represents a label space that has the potential for a session with an LDP peer. An LDP entity is set up when a hello adjacency receives a hello message from an LDP peer.

In the figure below, Router A has potential sessions with two remote peers, Routers B and C. The mplsLdpEntityLdpId is 10.10.10.10.0.0, and the IP address of the peer active hello adjacency

(mplsLdpEntityIndex) is 3232235777, which is the 32-bit representation of the IP address 192.168.1.1 for Router B.

LDP Sessions and Peers



LDP sessions exist between local entities and remote peers for the purpose of distributing label spaces. There is always a one-to-one correspondence between an LDP peer and an LDP session. A single LDP session is an LDP instance that communicates across one or more network links with a single LDP peer.

LDP supports the following types of sessions:

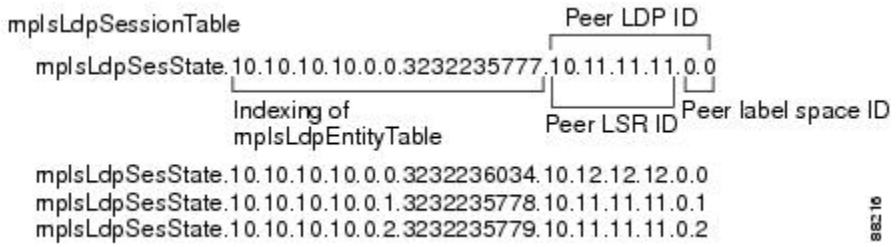
- Interface-specific--An interface-specific session uses interface resources for label space distributions. For example, each label-controlled ATM (LC-ATM) interface uses its own VPIs/VCIs for label space distributions. Depending on its configuration, an LDP platform can support zero, one, or more interface-specific sessions. Each LC-ATM interface has its own interface-specific label space and a nonzero label space ID.
- Platform-wide--An LDP platform supports a single platform-wide session for use by all interfaces that can share the same global label space. For Cisco platforms, all interface types except LC-ATM use the platform-wide session and have a label space ID of zero.

When a session is established between two peers, entries are created in the mplsLdpPeerTable and the mplsLdpSessionTable because they have the same indexing.

In the figure below, Router A has two remote peers, Routers B and C. Router A has a single platform-wide session that consists of two serial interfaces with Router B and another platform-wide session with Router C. Router A also has two interface-specific sessions with Router B.

The figure below shows entries that correspond to the mplsLdpPeerTable and the mplsLdpSessionTable in the figure above.

In the figure below, mplsLdpSesState is a sample object from the mplsLdpSessionTable on Router A. There are four mplsLdpSesState sample objects shown (top to bottom). The first object represents a platform-wide session associated with two serial interfaces. The next two objects represent interface-specific sessions for the LC-ATM interfaces on Routers A and B. These interface-specific sessions have nonzero peer label space IDs. The last object represents a platform-wide session for the next peer, Router C.



The indexing is based on the entries in the mplsLdpEntityTable. It begins with the indexes of the mplsLdpEntityTable and adds the following:

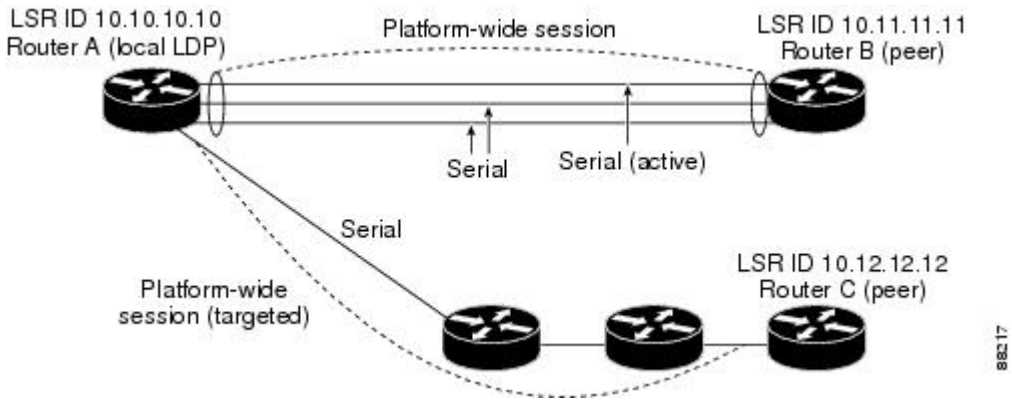
- Peer LDP ID = 10.11.11.11.0.0

The peer LDP ID consists of the peer LSR ID (four octets) and the peer label space ID (two octets).

- Peer LSR ID = 10.11.11.11
- Peer label space ID = 0.0

The peer label space ID identifies a specific peer label space available within the LSR.

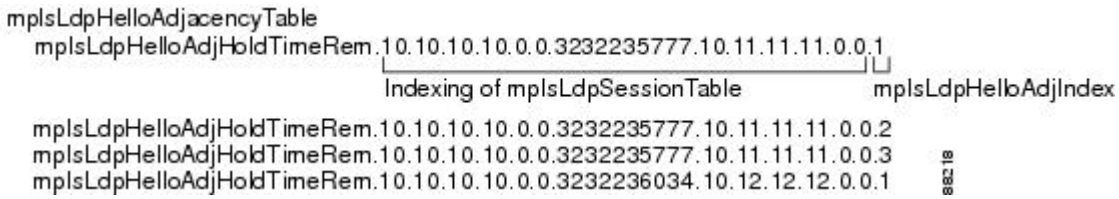
LDP Hello Adjacencies



An LDP hello adjacency is a network link between a router and its peers. An LDP hello adjacency enables two adjacent peers to exchange label binding information.

An LDP hello adjacency exists for each link on which LDP runs. Multiple LDP hello adjacencies exist whenever there is more than one link in a session between a router and its peer, such as in a platform-wide session.

A hello adjacency is considered active if it is currently engaged in a session, or nonactive if it is not currently engaged in a session.



A targeted hello adjacency is not directly connected to its peer and has an unlimited number of hops between itself and its peer. A linked hello adjacency is directly connected between two routers.

In the figure below, Router A has two remote peers, Routers B and C. Router A has a platform-wide session with Router B that consists of three serial interfaces, one of which is active and another platform-wide (targeted) session with Router C.

The figure below shows entries in the mplsLdpHelloAdjacencyTable. There are four mplsLdpHelloAdjHoldTime sample objects (top to bottom). They represent the two platform-wide sessions and the four serial links shown in the figure above.

The indexing is based on the mplsLdpSessionTable. When the mplsLdpHelloAdjIndex enumerates the different links within a single session, the active link is mplsLdpHelloAdjIndex = 1.

Events Generating MPLS LDP MIB Notifications in MPLS LDP MIB Version 8 Upgrade

When you enable MPLS LDP MIB notification functionality by issuing the **snmp-server enable traps mpls ldp** command, notification messages are generated and sent to a designated NMS in the network to signal the occurrence of specific events within the network.

The MPLS LDP MIB objects involved in LDP status transitions and event notifications include the following:

- mplsLdpSessionUp--This message is generated when an LDP entity (a local LSR) establishes an LDP session with another LDP entity (an adjacent LDP peer in the network).
- mplsLdpSessionDown--This message is generated when an LDP session between a local LSR and its adjacent LDP peer is terminated.
- mplsLdpPathVectorLimitMismatch--This message is generated when a local LSR establishes an LDP session with its adjacent peer LSR, but the two LSRs have dissimilar path vector limits.

The value of the path vector limit can range from 0 through 255; a value of 0 indicates that loop detection is off; any value other than zero up to 255 indicates that loop detection is on and, in addition, specifies the maximum number of hops through which an LDP message can pass before a loop condition in the network is sensed.

We recommend that all LDP-enabled routers in the network be configured with the same path vector limit. Accordingly, the mplsLdpPathVectorLimitMismatch object exists in the MPLS LDP MIB to provide a warning message to the NMS when two routers engaged in LDP operations have different path vector limits.

Note This notification is generated only if the distribution method is downstream-on-demand.

- mplsLdpFailedInitSessionThresholdExceeded--This message is generated when a local LSR and an adjacent LDP peer attempt to set up an LDP session between them, but fail to do so after a specified number of attempts. The default number of attempts is 8. This default value is implemented and cannot be changed.

Eight failed attempts to establish an LDP session between a local LSR and an LDP peer, due to any type of incompatibility between the devices, causes this notification message to be generated. Cisco routers support the same features across multiple platforms.

Therefore, the most likely incompatibility to occur between Cisco LSRs is a mismatch of their respective ATM VPI/VCI label ranges.

For example, if you specify a range of valid labels for an LSR that does not overlap the range of its adjacent LDP peer, the routers try eight times to create an LDP session between themselves before the mplsLdpFailedInitSessionThresholdExceeded notification is generated and sent to the NMS as an informational message.

The LSRs whose label ranges do not overlap continue their attempt to create an LDP session between themselves after the eight-retry threshold is exceeded.

In such cases, the LDP threshold exceeded notification alerts the network administrator about a condition in the network that might warrant attention.

RFC 3036, *LDP Specification* , details the incompatibilities that can exist between Cisco routers and/or other vendor LSRs in an MPLS network.

Among such incompatibilities, for example, are the following:

- • Nonoverlapping ATM VPI/VCI ranges (as noted above) or nonoverlapping Frame-Relay DLCI ranges between LSRs attempting to set up an LDP session
  - Unsupported label distribution method
  - Dissimilar protocol data unit (PDU) sizes
  - Dissimilar types of LDP feature support

MIB Tables in MPLS LDP MIB Version 8 Upgrade

Version 8 of the MPLS LDP MIB consists of the following tables:

- mplsLdpEntityTable --Contains entries for every active LDP hello adjacency. Nonactive hello adjacencies appear in the mplsLdpHelloAdjacencyTable, rather than this table. This table is indexed by the local LDP identifier for the interface and the IP address of the peer active hello adjacency.

The advantage of showing the active hello adjacency instead of sessions in this table is that the active hello adjacency can exist even if an LDP session is not active (cannot be established). Previous implementations of the IETF MPLS-LDP MIB used sessions as the entries in this table. This approach was inadequate because as sessions went down, the entries in the entity table would disappear completely because the agent code could no longer access them. This resulted in the MIB failing to provide information about failed LDP sessions.

Directed adjacencies are also shown in this table. These entries, however, are always up administratively (adminStatus) and operationally (operStatus), because the adjacencies disappear if the directed session fails.

Nondirected adjacencies might disappear from the MIB on some occasions, because adjacencies are deleted if the underlying interface becomes operationally down, for example.

- mplsLdpEntityConfGenLRTable --Contains entries for every LDP-enabled interface that is in the global label space. (For Cisco, this applies to all interfaces except LC-ATM. LC-ATM entities are shown in the mplsLdpEntityConfAtmLRTable instead.) Indexing is the same as it is for the mplsLdpEntityTable, except two indexes have been added, mplsLdpEntityConfGenLRMin and mplsLdpEntityConfGenLRMax. These additional indexes allow more than one label range to be defined. However, in the current Cisco implementation, only one global label range is allowed.
- mplsLdpEntityAtmParmsTable --Contains entries for every LDP-enabled LC-ATM interface. This table is indexed the same as the mplsLdpEntityTable although only LC-ATM interfaces are shown.
- mplsLdpEntityConfAtmLRTable --Contains entries for every LDP-enabled LC-ATM interface. Indexing is the same as it is for the mplsLdpEntityTable, except two indexes have been added, mplsLdpEntityConfAtmLRMinVpi and mplsLdpEntityConfAtmLRMinVci. These additional indexes allow more than one label range to be defined. However, in the current Cisco implementation, only one label range per LC-ATM interface is allowed.
- mplsLdpEntityStatsTable --Augments the mplsLdpEntityTable and shares the exact same indexing for performing GETand GETNEXT operations. This table shows additional statistics for entities.
- mplsLdpPeerTable --Contains entries for all peer sessions. This table is indexed by the local LDP identifier of the session, the IP address of the peer active hello adjacency, and the peer's LDP identifier.
- mplsLdpHelloAdjacencyTable --Contains entries for all hello adjacencies. This table is indexed by the local LDP identifier of the associated session, the IP address of the peer active hello adjacency, the LDP identifier for the peer, and an arbitrary index that is set to the list position of the adjacency.
- mplsLdpSessionTable --Augments the mplsLdpPeerTable and shares the same indexing for performing GET and GETNEXT operations. This table shows all sessions.
- mplsLdpAtmSesTable --Contains entries for LC-ATM sessions. Indexing is the same as it is for the mplsLdpPeerTable, except two indexes have been added, mplsLdpSesAtmLRLowerBoundVpi and mplsLdpSesAtmLRLowerBoundVci. These additional indexes allow more than one label range to be defined. However, in the current Cisco implementation, only one label range per LC-ATM interface is allowed.
- mplsLdpSesStatsTable --Augments the mplsLdpPeerTable and shares the exact same indexing for performing GET and GETNEXT operations. This table shows additional statistics for sessions.

mplsLdpEntityTable

The table below lists the mplsLdpEntityTable objects and their descriptions.

Table 36: mplsLdpEntityTable Objects and Descriptions

Object	Description
mplsLdpEntityEntry	Represents an LDP entity, which is a potential session between two peers.
mplsLdpEntityLdpId	The LDP identifier (not accessible) consists of the local LSR ID (four octets) and the label space ID (two octets).

Object	Description
mplsLdpEntityIndex	A secondary index that identifies this row uniquely. It consists of the IP address of the peer active hello adjacency, which is the 32-bit representation of the IP address assigned to the LSR (not accessible).
mplsLdpEntityProtocolVersion	The version number of the LDP protocol to be used in the session initialization message.
mplsLdpEntityAdminStatus	The administrative status of this LDP entity is always up. If the hello adjacency fails, this entity disappears from the mplsLdpEntityTable.
mplsLdpEntityOperStatus	The operational status of this LDP entity. Values are unknown(0), enabled(1), and disabled(2).
mplsLdpEntityTcpDscPort	The TCP discovery port for LDP or TDP. The default value is 646 (LDP).
mplsLdpEntityUdpDscPort	The UDP discovery port for LDP or TDP. The default value is 646 (LDP).
mplsLdpEntityMaxPduLength	The maximum PDU length that is sent in the common session parameters of an initialization message.
mplsLdpEntityKeepAliveHoldTimer	The two-octet value that is the proposed keepalive hold time for this LDP entity.
mplsLdpEntityHelloHoldTimer	The two-octet value that is the proposed hello hold time for this LDP entity.
mplsLdpEntityInitSesThreshold	The threshold for notification when this entity and its peer are engaged in an endless sequence of initialization messages. The default value is 8 and cannot be changed by SNMP or CLI.
mplsLdpEntityLabelDistMethod	The specified method of label distribution for any given LDP session. Values are downstreamOnDemand(1) and downstreamUnsolicited(2).
mplsLdpEntityLabelRetentionMode	Can be configured to use either conservative(1) for LC-ATM or liberal(2) for all other interfaces.
mplsLdpEntityPVLMisTrapEnable	Indicates whether the mplsLdpPVLMismatch trap should be generated. If the value is enabled(1), the trap is generated. If the value is disabled(2), the trap is not generated. The default is disabled(2). **Note** The mplsLdpPVLMismatch trap is generated only if mplsLdpEntityLabelDistMethod is downstreamOnDemand(1).

Object	Description
mplsLdpEntityPVL	If the value of this object is 0, loop detection for path vectors is disabled. Otherwise, if this object has a value greater than zero, loop detection for path vectors is enabled, and the path vector limit is this value. **Note** The mplsLdpEntityPVL object is non-zero only if mplsLdpEntityLabelDistMethod is downstreamOnDemand(1).
mplsLdpEntityHopCountLimit	If the value of this object is 0, loop detection using hop counters is disabled. If the value of this object is greater than 0, loop detection using hop counters is enabled, and this object specifies this entity's maximum allowable value for the hop count. **Note** The mplsLdpEntityHopCountLimit object is non-zero only if mplsLdpEntityLabelDistMethod is downstreamOnDemand(1).
mplsLdpEntityTargPeer	If this LDP entity uses a targeted adjacency, this object is set to true(1). The default value is false(2).
mplsLdpEntityTargPeerAddrType	The type of the internetwork layer address used for the extended discovery. This object indicates how the value of mplsLdpEntityTargPeerAddr is to be interpreted.
mplsLdpEntityTargPeerAddr	The value of the internetwork layer address used for the targeted adjacency.
mplsLdpEntityOptionalParameters	Specifies the optional parameters for the LDP initialization message. If the value is generic(1), no optional parameters are sent in the LDP initialization message associated with this entity. LC-ATM uses atmParameters(2) to specify that a row in the mplsLdpEntityAtmParmsTable corresponds to this entry. **Note** Frame Relay parameters are not supported.
mplsLdpEntityDiscontinuityTime	The value of sysUpTime on the most recent occasion when one or more of this entity’s counters suffered a discontinuity. The relevant counters are the specific instances of any Counter32 or Counter64 object contained in the mplsLdpEntityStatsTable that are associated with this entity. If no such discontinuities have occurred since the last reinitialization of the local management subsystem, this object contains a 0 value.
mplsLdpEntityStorType	The storage type for this entry is a read-only implementation that is always volatile.
mplsLdpEntityRowStatus	This object is a read-only implementation that is always active.

mplsLdpEntityConfGenLRTable

The table below lists the mplsLdpEntityConfGenLRTable objects and their descriptions.

Table 37: mplsLdpEntityConfGenLRTable Objects and Descriptions

Object	Description
mplsLdpEntityConfGenLREntry	A row in the LDP Entity Configurable Generic Label Range table. One entry in this table contains information on a single range of labels; the range is defined by an upper boundary (VPI/VCI pair) and a lower boundary (VPI/VCI pair). The current implementation supports one label range per entity.
mplsLdpEntityConfGenLRMin	The minimum label configured for this range (not accessible).
mplsLdpEntityConfGenLRMax	The maximum label configured for this range (not accessible).
mplsLdpEntityConfGenIfIndxOrZero	This value represents the SNMP IF-MIB index for the platform-wide entity. If the active hello adjacency is targeted, the value is 0.
mplsLdpEntityConfGenLRStorType	The storage type for this entry is a read-only implementation that is always volatile.
mplsLdpEntityConfGenLRRowStatus	This object is a read-only implementation that is always active.

mplsLdpEntityAtmParmsTable

The table below lists the mplsLdpEntityAtmParmsTable objects and their descriptions.

Table 38: mplsLdpEntityAtmParmsTable Objects and Descriptions

Object	Description
mplsLdpEntityAtmParmsEntry	Represents the ATM parameters and ATM information for this LDP entity.
mplsLdpEntityAtmIfIndxOrZero	This value represents the SNMP IF-MIB index for the interface-specific LC-ATM entity.
mplsLdpEntityAtmMergeCap	Denotes the merge capability of this entity.
mplsLdpEntityAtmLRComponents	Number of label range components in the initialization message. This also represents the number of entries in the mplsLdpEntityConfAtmLRTable that correspond to this entry.
mplsLdpEntityAtmVcDirectionality	If the value of this object is bidirectional(0), a given VCI within a given VPI is used as a label for both directions independently of one another. If the value of this object is unidirectional(1), a given VCI within a VPI designates one direction.

Object	Description
mplsLdpEntityAtmLsrConnectivity	The peer LSR can be connected indirectly by means of an ATM VP, so that the VPI values can be different on the endpoints. For that reason, the label must be encoded entirely within the VCI field. Values are direct(1), the default, and indirect(2).
mplsLdpEntityDefaultControlVpi	The default VPI value for the non-MPLS connection.
mplsLdpEntityDefaultControlVci	The default VCI value for the non-MPLS connection.
mplsLdpEntityUnlabTrafVpi	VPI value of the VCC supporting unlabeled traffic. This non-MPLS connection is used to carry unlabeled (IP) packets.
mplsLdpEntityUnlabTrafVci	VCI value of the VCC supporting unlabeled traffic. This non-MPLS connection is used to carry unlabeled (IP) packets.
mplsLdpEntityAtmStorType	The storage type for this entry is a read-only implementation that is always volatile.
mplsLdpEntityAtmRowStatus	This object is a read-only implementation that is always active.

mplsLdpEntityConfAtmLRTable

The table below lists the mplsLdpEntityConfAtmLRTable objects and their descriptions.

Table 39: mplsLdpEntityConfAtmLRTable Objects and Descriptions

Object	Description
mplsLdpEntityConfAtmLREntry	A row in the LDP Entity Configurable ATM Label Range Table. One entry in this table contains information on a single range of labels; the range is defined by an upper boundary (VPI/VCI pair) and a lower boundary (VPI/VCI pair). This is the same data used in the initialization message. This label range should overlap the label range of the peer.
mplsLdpEntityConfAtmLRMinVpi	The minimum VPI number configured for this range (not accessible).
mplsLdpEntityConfAtmLRMinVci	The minimum VCI number configured for this range (not accessible).
mplsLdpEntityConfAtmLRMaxVpi	The maximum VPI number configured for this range (not accessible).
mplsLdpEntityConfAtmLRMaxVci	The maximum VCI number configured for this range (not accessible).
mplsLdpEntityConfAtmLRStorType	The storage type for this entry is a read-only implementation that is always volatile.
mplsLdpEntityConfAtmLRRowStatus	This object is a read-only implementation that is always active.

mplsLdpEntityStatsTable

The table below lists the mplsLdpEntityStatsTable objects and their descriptions.

Table 40: mplsLdpEntityStatsTable Objects and Descriptions

Object	Description
mplsLdpEntityStatsEntry	These entries augment the mplsLdpEntityTable by providing additional information for each entry.
mplsLdpAttemptedSessions	Not supported in this feature.
mplsLdpSesRejectedNoHelloErrors	A count of the session rejected/no hello error notification messages sent or received by this LDP entity.
mplsLdpSesRejectedAdErrors	A count of the session rejected/parameters advertisement mode error notification messages sent or received by this LDP entity.
mplsLdpSesRejectedMaxPduErrors	A count of the session rejected/parameters max PDU length error notification messages sent or received by this LDP entity.
mplsLdpSesRejectedLRErrors	A count of the session rejected/parameters label range notification messages sent or received by this LDP entity.
mplsLdpBadLdpIdentifierErrors	A count of the number of bad LDP identifier fatal errors detected by the session associated with this LDP entity.
mplsLdpBadPduLengthErrors	A count of the number of bad PDU length fatal errors detected by the session associated with this LDP entity.
mplsLdpBadMessageLengthErrors	A count of the number of bad message length fatal errors detected by the session associated with this LDP entity.
mplsLdpBadTlvLengthErrors	A count of the number of bad Type-Length-Value (TLV) length fatal errors detected by the session associated with this LDP entity.
mplsLdpMalformedTlvValueErrors	A count of the number of malformed TLV value fatal errors detected by the session associated with this LDP entity.
mplsLdpKeepAliveTimerExpErrors	A count of the number of session keepalive timer expired errors detected by the session associated with this LDP entity.
mplsLdpShutdownNotifReceived	A count of the number of shutdown notifications received related to the session associated with this LDP entity.
mplsLdpShutdownNotifSent	A count of the number of shutdown notifications sent related to the session associated with this LDP entity.

mplsLdpPeerTable

The table below lists the mplsLdpPeerTable objects and their descriptions.

Table 41: mplsLdpPeerTable Objects and Descriptions

Object	Description
mplsLdpPeerEntry	Information about a single peer that is related to a session (not accessible). **Note** This table is augmented by the mplsLdpSessionTable.
mplsLdpPeerLdpId	The LDP identifier of this LDP peer (not accessible) consists of the peer LSR ID (four octets) and the peer label space ID (two octets).
mplsLdpPeerLabelDistMethod	For any given LDP session, the method of label distribution. Values are downstreamOnDemand(1) and downstreamUnsolicited(2).
mplsLdpPeerLoopDetectionForPV	An indication of whether loop detection based on path vectors is disabled or enabled for this peer. For downstream unsolicited distribution (mplsLdpPeerLabelDistMethod is downstreamUnsolicited(2)), this object always has a value of disabled(0) and loop detection is disabled. For downstream-on-demand distribution (mplsLdpPeerLabelDistMethod is downstreamOnDemand(1)), this object has a value of enabled(1), provided that loop detection based on path vectors is enabled.
mplsLdpPeerPVL	If the value of mplsLdpPeerLoopDetectionForPV for this entry is enabled(1), this object represents that path vector limit for this peer. If the value of mplsLdpPeerLoopDetectionForPV for this entry is disabled(0), this value should be 0.

mplsLdpHelloAdjacencyTable

The table below lists the mplsLdpHelloAdjacencyTable objects and their descriptions.

Table 42: mplsLdpHelloAdjacencyTable Objects and Descriptions

Object	Description
mplsLdpHelloAdjacencyEntry	Each row represents a single LDP hello adjacency. An LDP session can have one or more hello adjacencies (not accessible).
mplsLdpHelloAdjIndex	An identifier for this specific adjacency (not accessible). The active hello adjacency has mplsLdpHelloAdjIndex equal to 1.
mplsLdpHelloAdjHoldTimeRem	The time remaining for this hello adjacency. This interval changes when the next hello message, which corresponds to this hello adjacency, is received.
mplsLdpHelloAdjType	This adjacency is the result of a link hello if the value of this object is link(1). Otherwise, this adjacency is a result of a targeted hello and its value is targeted(2).

mplsLdpSessionTable

The table below lists the mplsLdpSessionTable objects and their descriptions.

Table 43: mplsLdpSessionTable Objects and Descriptions

Object	Description
mplsLdpSessionEntry	An entry in this table represents information on a single session between an LDP entity and an LDP peer. The information contained in a row is read-only. This table augments the mplsLdpPeerTable.
mplsLdpSesState	The current state of the session. All of the states are based on the LDP or TDP state machine for session negotiation behavior. The states are as follows: • nonexistent(1) • initialized(2) • openrec(3) • opensent(4) • operational(5)
mplsLdpSesProtocolVersion	The version of the LDP protocol which this session is using. This is the version of the LDP protocol that has been negotiated during session initialization.
mplsLdpSesKeepAliveHoldTimeRem	The keepalive hold time remaining for this session.
mplsLdpSesMaxPduLen	The value of maximum allowable length for LDP PDUs for this session. This value could have been negotiated during the session initialization.
mplsLdpSesDiscontinuityTime	The value of sysUpTime on the most recent occasion when one or more of this session's counters suffered a discontinuity. The relevant counters are the specific instances of any Counter32 or Counter64 object contained in the mplsLdpSesStatsTable associated with this session. The initial value of this object is the value of sysUpTime when the entry was created in this table.

mplsLdpAtmSesTable

The table below lists the mplsLdpAtmSesTable objects and their descriptions.

Table 44: mplsLdpAtmSesTable Objects and Descriptions

Objects	Description
mplsLdpAtmSesEntry	An entry in this table represents information on a single label range intersection between an LDP entity and an LDP peer (not accessible).

Objects	Description
mplsLdpAtmSesLRLowerBoundVpi	The minimum VPI number for this range (not accessible).
mplsLdpAtmSesLRLowerBoundVci	The minimum VCI number for this range (not accessible).
mplsLdpAtmSesLRUpperBoundVpi	The maximum VPI number for this range (read-only).
mplsLdpAtmSesLRUpperBoundVci	The maximum VCI number for this range (read-only).

mplsLdpSesStatsTable

The table below lists the mplsLdpSesStatsTable objects and their descriptions.

Table 45: mplsLdpSesStatsTable Objects and Descriptions

Object	Description
mplsLdpSesStatsEntry	An entry in this table represents statistical information on a single session between an LDP entity and an LDP peer. This table augments the mplsLdpPeerTable.
mplsLdpSesStatsUnkMesTypeErrors	This object is the count of the number of unknown message type errors detected during this session.
mplsLdpSesStatsUnkTlvErrors	This object is the count of the number of unknown TLV errors detected during this session.

VPN Contexts in MPLS LDP MIB Version 8 Upgrade

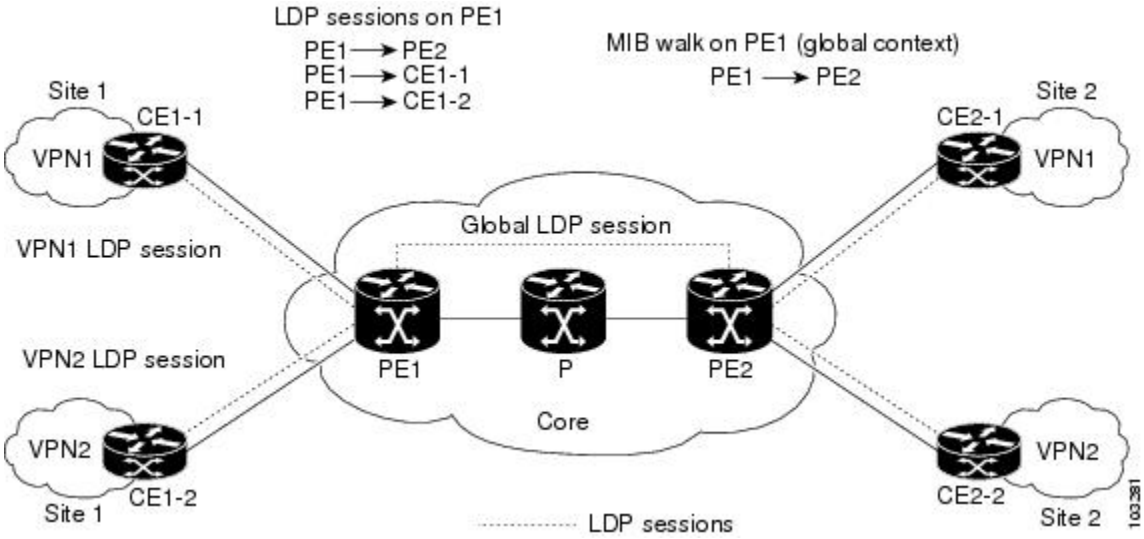
Within an MPLS Border Gateway Protocol (BGP) 4 Virtual Private Network (VPN) environment, separate LDP processes can be created for each VPN. These processes and their associated data are called LDP contexts. Each context is independent from all others and contains data specific only to that context.

This feature adds support for different contexts for different MPLS VPNs. Users of the MIB can view MPLS LDP processes for a given MPLS VPN. The VPN Aware LDP MIB feature does not change the syntax of the IETF MPLS-LDP MIB. It changes the number and types of entries within the tables.

The IETF MPLS-LDP MIB can show information about only one context at a time. You can specify a context, either a global context or an MPLS VPN context, using an SMNP security name.

The following sections describe topics related to the VPN Aware LDP MIB feature:

SNMP Context



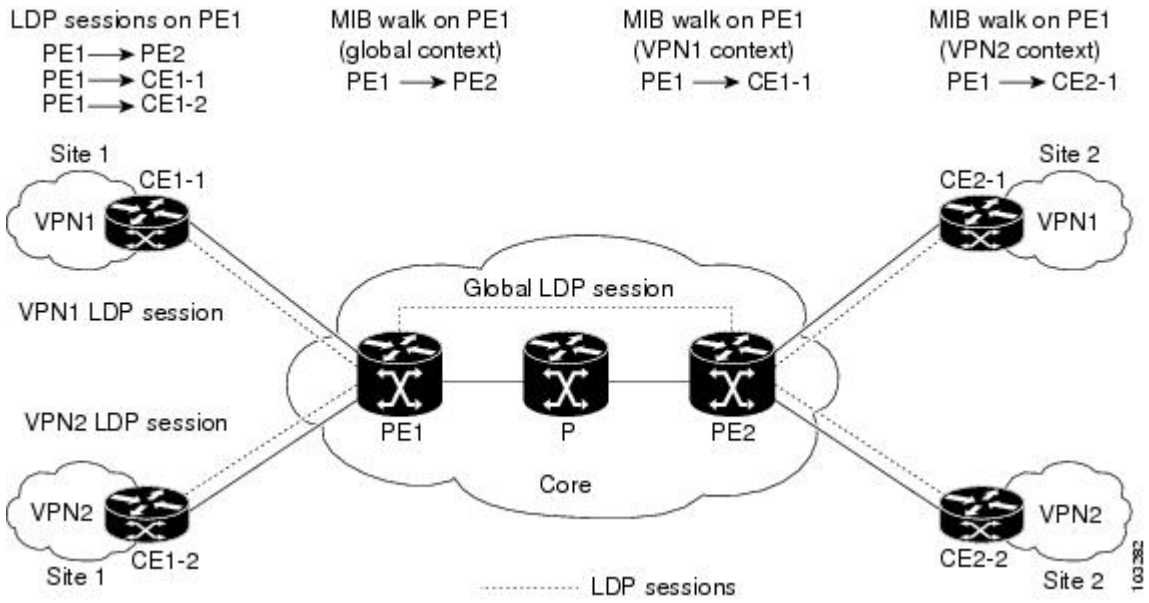
SNMP contexts provide VPN users with a secure way of accessing MIB data. When a VPN is associated with a context, that VPN's specific MIB data exists in that context. Associating a VPN with a context enables service providers to manage networks with multiple VPNs. Creating and associating a context with a VPN enables a provider to prevent the users of one VPN from accessing information about users of other VPNs on the same networking device.

VPN Aware LDP MIB Sessions

Before the VPN Aware LDP MIB features, an SNMP query to the MPLS LDP MIB returned information about global sessions only. A query did not return information about LDP sessions in a VPN context. The IETF MPLS LDP MIB retrieved information from global routing tables, but did not retrieve information from VPN routing and forwarding instances (VRFs) that store per-VPN routing data. The MPLS LDP MIB looked only at LDP processes in the global context and ignored all other sessions. A query on a VRF returned no information. You can view LDP processes in a VPN context.

The figure below shows a sample MPLS VPN network with the MPLS LDP sessions prior to the implementation of the VPN Aware LDP MIB feature.

Figure 29: MPLS LDP Sessions Setup Before VPN Aware LDP MIB Feature



A MIB walk prior to this software release displayed only global session information.

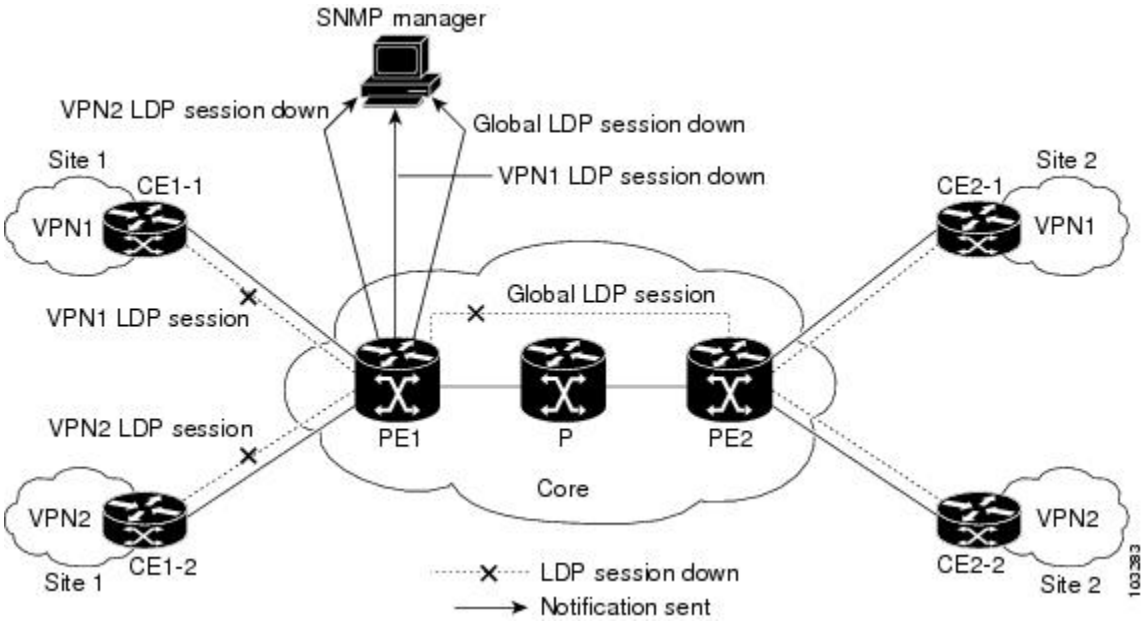
With the VPN Aware LDP MIB enhancement, an SNMP query to the IETF MPLS-LDP-MIB supports both global and VPN contexts. This feature allows you to enter LDP queries on any VRF and on the core (global context). A query can differentiate between LDP sessions from different VPNs. LDP session information for a VPN stays in the context of that VPN. Therefore, the information from one VPN is not available to a user of a different VPN. The VPN Aware update to the LDP MIB also allows you to view LDP processes operating in a Carrier Supporting Carrier (CSC) network.

In an MPLS VPN, a service provider edge router (PE) might contain VRFs for several VPNs as well as a global routing table. To set up separate LDP processes for different VPNs on the same device, you need to configure each VPN with a unique securityName, contextName, and View-based Access Control Model (VACM) view. The VPN securityName must be configured for the IETF MPLS LDP MIB.

The figure below shows LDP sessions for a sample MPLS VPN network with the VPN Aware LDP MIB feature.

Figure 30: MPLS LDP Sessions with the VPN Aware LDP MIB Feature

With the VPN Aware LDP MIB feature, you can do MIB queries or MIB walks for an MPLS VPN LDP session or a global LDP session.



Note To verify LDP session information for a specific VPN, use the **show mpls ldp neighbor vrf** *vpn-name* **detail** command.

VPN Aware LDP MIB Notifications

Before the VPN Aware LDP MIB feature, all notification messages for MPLS LDP sessions were sent to the same designated network management station (NMS) in the network. The notifications were enabled with the **snmp-server enable traps mpls ldp** command.

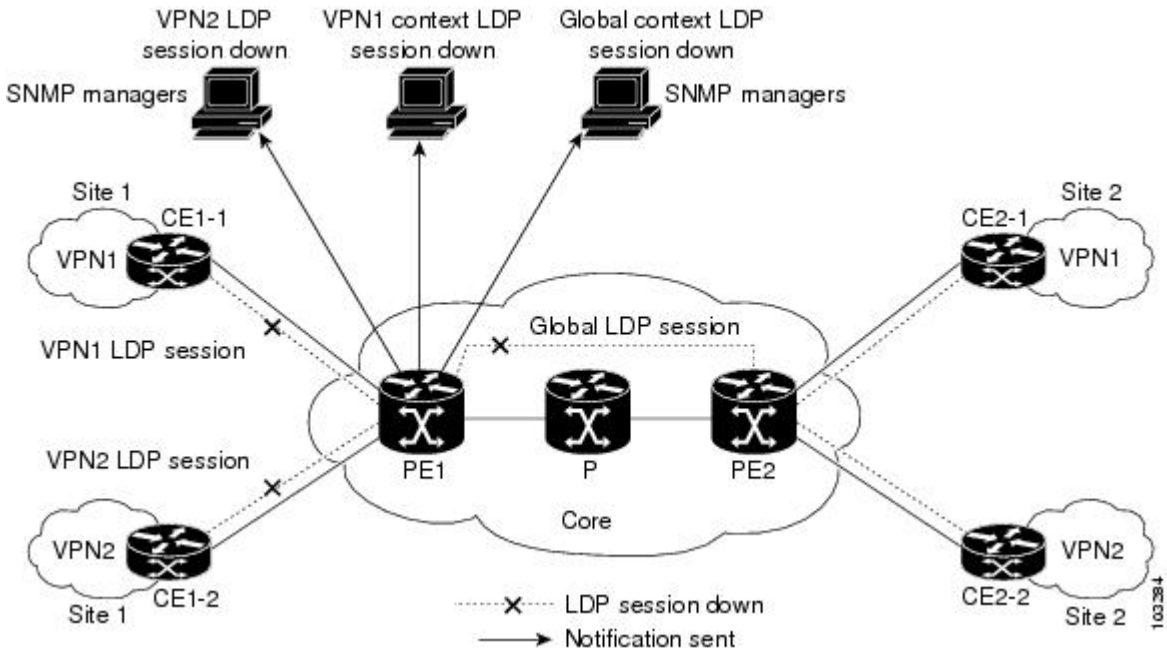
The figure below shows LDP notifications that were sent before the implementation of the VPN Aware LDP MIB feature.

Figure 31: LDP Notifications Sent Before the VPN Aware LDP MIB Feature

The VPN Aware LDP MIB feature supports LDP notifications for multiple LDP contexts for VPNs. LDP notifications can be generated for the core (global context) and for different VPNs. You can cause notifications be sent to different NMS hosts for different LDP contexts. LDP notifications associated with a specific VRF are sent to the NMS designated for that VRF. LDP global notifications are sent to the NMS configured to receive global traps.

To enable LDP context notifications for the VPN Aware LDP MIB feature, use either the SNMP object mplsLdpSessionsUpDownEnable (in the global LDP context only) or the following extended global configuration commands.

To enable LDP notifications for the global context, use the following commands on a PE router:



```
Router(config)# snmp-server host host-address traps community mpls-ldp
Router(config)# snmp-server enable traps mpls ldp
```

To enable LDP notifications for a VPN context, use the following commands on a PE router:

```
Router(config)# snmp-server host host-address vrf vrf-name version {v1|v2c|v3}
community community-string udp-port upd-port mpls-ldp
Router(config)# snmp-server enable traps mpls ldp
```

The figure below shows LDP notifications with the VPN Aware LDP MIB feature.

Figure 32: LDP Notifications With the VPN Aware LDP MIB Feature

How to Configure MPLS LDP MIB Version 8 Upgrade

Enabling the SNMP Agent

SUMMARY STEPS

1. **enable**
2. **show running-config**
3. **configure terminal**
4. **snmp-server community** *string* [**view** *view-name*] [**ro** *number*]
5. **end**
6. **write memory**
7. **show running-config**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:**	Enables privileged EXEC mode. • Enter your password if prompted.

	Command or Action	Purpose
	`Router> enable`	
Step 2	**show running-config** **Example:** `Router# show running-config`	Displays the running configuration of the router so that you can determine if an SNMP agent is already running on the device. If no SNMP information is displayed, continue with the next step. If any SNMP information is displayed, you can modify the information or change it as desired.
Step 3	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 4	**snmp-server community** *string* [**view** *view-name*] [**ro** *number*] **Example:** `Router(config)# snmp-server community public ro`	Configures read-only (ro) community strings for the MPLS Label Distribution Protocol (LDP) MIB. • The *string* argument functions like a password, permitting access to SNMP functionality on label switch routers (LSRs) in an MPLS network. • The optional **ro** keyword configures read-only (ro) access to the objects in the MPLS LDP MIB.
Step 5	**end** **Example:** `Router(config)# end`	Exits to privileged EXEC mode.
Step 6	**write memory** **Example:** `Router# write memory`	Writes the modified SNMP configuration into NVRAM of the router, permanently saving the SNMP settings.
Step 7	**show running-config** **Example:** `Router# show running-config`	Displays the running configuration of the router so that you can determine if an SNMP agent is already running on the device. If you see any snmp-server statements, SNMP has been enabled on the router. If any SNMP information is displayed, you can modify the information or change it as desired.

Enabling Distributed Cisco Express Forwarding

Perform this task to enable Cisco Express Forwarding or distributed Cisco Express Forwarding.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip cef distributed**
4. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**ip cef distributed** **Example:** `Router(config)# ip cef distributed`	Enables distributed Cisco Express Forwarding.
Step 4	**end** **Example:** `Router(config)# end`	Exits to privileged EXEC mode.

Enabling MPLS Globally

Perform this task to enable MPLS globally.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls ip**
4. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**mpls ip** **Example:** `Router(config)# mpls ip`	Enables MPLS forwarding of IPv4 packets along normally routed paths for the platform.
Step 4	**end** **Example:** `Router(config)# end`	Exits to privileged EXEC mode.

Enabling LDP Globally

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls label protocol** {**ldp** | **tdp**}
4. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.

	Command or Action	Purpose
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**mpls label protocol** {**ldp** | **tdp**} **Example:** `Router(config)# mpls label protocol ldp`	Specifies the platform default label distribution protocol. TDP might not be supported in all software releases.
Step 4	**end** **Example:** `Router(config)# end`	Exits to privileged EXEC mode.

Enabling MPLS on an Interface

Perform this task to enable MPLS on an interface.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type slot/subslot/port* [**.***subinterface-number*]
4. **mpls ip**
5. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**interface** *type slot/subslot/port* [**.***subinterface-number*] **Example:**	Configures an interface type and enters interface configuration mode.

	Command or Action	Purpose
	`Router(config)# interface FastEthernet 1/0/0`	
Step 4	**mpls ip** **Example:** `Router(config-if)# mpls ip`	Enables MPLS forwarding of IPv4 packets along normally routed paths for a particular interface.
Step 5	**end** **Example:** `Router(config-if)# end`	Exits to privileged EXEC mode.

Enabling LDP on an Interface

Perform this task to enable LDP on an interface.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type slot / subslot / port* [**.** *subinterface-number*]
4. **mpls label protocol ldp**
5. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**interface** *type slot / subslot / port* [**.** *subinterface-number*] **Example:** `Router(config)# interface FastEthernet 1/0/0`	Configures an interface type and enters interface configuration mode.

	Command or Action	Purpose
Step 4	**mpls label protocol ldp** **Example:** `Router(config-if)# mpls label protocol ldp`	Specifies the label distribution protocol to be used on a given interface.
Step 5	**end** **Example:** `Router(config-if)# end`	Exits to privileged EXEC mode.

Configuring a VPN Aware LDP MIB

Configuring SNMP Support for a VPN

Perform this task to configure SNMP support for a Virtual Private Network (VPN) or a remote VPN.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server host** *host-address* [**traps** | **informs**] [**version** {**1** | **2c** | **3** [**auth** | **noauth** | **priv**]}] *community-string* [**udp-port** *port*] [*notification-type*] [**vrf** *vrf-name*]
4. **snmp-server engineID remote** *ip-address* [**udp-port** *udp-port-number*] [**vrf** *vrf-name*] *engineid-string*
5. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**snmp-server host** *host-address* [**traps** | **informs**] [**version** {**1** | **2c** | **3** [**auth** | **noauth** | **priv**]}] *community-string* [**udp-port** *port*] [*notification-type*] [**vrf** *vrf-name*] **Example:**	Specifies the recipient of an SNMP notification operation and specifies the Virtual Private Network (VPN) routing and forwarding (VRF) instance table to be used for the sending of SNMP notifications.

	Command or Action	Purpose
	`Router(config)# snmp-server host example.com vrf trap-vrf`	
Step 4	**snmp-server engineID remote** *ip-address* [**udp-port** *udp-port-number*] [**vrf** *vrf-name*] *engineid-string* **Example:** `Router(config)# snmp-server engineID remote 172.16.20.3 vrf traps-vrf 80000009030000B064EFE100`	Configures a name for the remote SNMP engine on a router.
Step 5	**end** **Example:** `Router(config)# end`	Exits to privileged EXEC mode.

Configuring an SNMP Context for a VPN

Perform this task to configure an SNMP context for a VPN. This sets up a unique SNMP context for a VPN, which allows you to access the VPN's LDP session information.

SNMP Context

SNMP contexts provide VPN users with a secure way of accessing MIB data. When a VPN is associated with a context, that VPN's specific MIB data exists in that context. Associating a VPN with a context enables service providers to manage networks with multiple VPNs. Creating and associating a context with a VPN enables a provider to prevent the users of one VPN from accessing information about users of other VPNs on the same networking device.

VPN Route Distinguishers

A route distinguisher (RD) creates routing and forwarding tables for a VPN. Cisco software adds the RD to the beginning of the customer's IPv4 prefixes to change them into globally unique VPN-IPv4 prefixes.

Either the RD is an autonomous system number (ASN)-relative RD, in which case it is composed of an autonomous system number and an arbitrary number, or it is an IP-address-relative RD, in which case it is composed of an IP address and an arbitrary number. You can enter an RD in either of these formats:

- 16-bit ASN: your 32-bit number, for example, 101:3.
- 32-bit IP address: your 16-bit number, for example, 192.168.122.15:1.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server context** *context-name*
4. **ip vrf** *vrf-name*
5. **rd** *route-distinguisher*
6. **context** *context-name*

7. **route-target** [**import** | **export** | **both**] *route-target-ext-community*
8. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**snmp-server context** *context-name* **Example:** `Router(config)# snmp-server context context1`	Creates and names an SNMP context.
Step 4	**ip vrf** *vrf-name* **Example:** `Router(config)# ip vrf vrf1`	Configures a Virtual Private Network (VPN) routing and forwarding instance (VRF) table and enters VRF configuration mode.
Step 5	**rd** *route-distinguisher* **Example:** `Router(config-vrf)# rd 100:120`	Creates a VPN route distinguisher.
Step 6	**context** *context-name* **Example:** `Router(config-vrf)# context context1`	Associates an SNMP context with a particular VRF.
Step 7	**route-target** [**import** | **export** | **both**] *route-target-ext-community* **Example:** `Router(config-vrf)# route-target export 100:1000`	(Optional) Creates a route-target extended community for a VRF.
Step 8	**end** **Example:** `Router(config)# end`	Exits to privileged EXEC mode.

Associating an SNMP VPN Context with SNMPv1 or SNMPv2

Perform this task to associate an SNMP VPN context with SNMPv1 or SNMPv2. This allows you to access LDP session information for a VPN using SNMPv1 or SNMPv2.

SNMPv1 or SNMPv2 Security: SNMPv1 and SNMPv2 are not as secure as SNMPv3. SNMP Versions 1 and 2 use plain text communities and do not perform the authentication or security checks that SNMP Version 3 performs.

To configure the VPN Aware LDP MIB feature when using SNMP Version 1 or SNMP Version 2, you need to associate a community name with a VPN. This association causes SNMP to process requests coming in for a particular community string only if they come in from the configured VRF. If the community string contained in the incoming packet does not have an associated VRF, the packet is processed only if it came in through a non-VRF interface. This process prevents users outside the VPN from using a clear text community string to query the VPN data. However, this is not as secure as using SNMPv3.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server user** *username group-name* [**remote** *host* [**udp-port** *port*]] {**v1** | **v2c** | **v3** [**encrypted**] [**auth** {**md5** | **sha**} *auth-password*]} [**access** *access-list*]
4. **snmp-server group** *group-name* {**v1** | **v2c** | **v3**{**auth** | **noauth** | **priv**}} [**context** *context-name*] [**read** *readview*] [**write** *writeview*] [**notify** *notifyview*] [**access** *access-list*]
5. **snmp-server view** *view-name oid-tree* {**included** | **excluded**}
6. **snmp-server enable traps** [*notification-type*]
7. **snmp-server host** *host-address* [**traps** | **informs**] [**version** {**1** | **2c** | **3** [**auth** | **noauth** | **priv**]}] *community-string* [**udp-port** *port*] [**notification-type**] [**vrf** *vrf-name*]
8. **snmp mib community-map** *community-name* [**context** *context-name*] [**engineid** *engine-id*] [**security-name** *security-name*] **target-list** *vpn-list-name*
9. **snmp mib target list** *vpn-list-name* {**vrf** *vrf-name* | **host** *ip-address*}
10. **no snmp-server trap authentication vrf**
11. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.

	Command or Action	Purpose
Step 3	**snmp-server user** *username group-name* [**remote** *host* [**udp-port** *port*]] {**v1** | **v2c** | **v3** [**encrypted**] [**auth** {**md5** | **sha**} *auth-password*]} [**access** *access-list*] **Example:** `Router(config)# snmp-server user customer1 group1 v1`	Configures a new user to an SNMP group.
Step 4	**snmp-server group** *group-name* {**v1** | **v2c** | **v3**{**auth** | **noauth** | **priv**}} [**context** *context-name*] [**read** *readview*] [**write** *writeview*] [**notify** *notifyview*] [**access** *access-list*] **Example:** `Router(config)# snmp-server group group1 v1 context context1 read view1 write view1 notify view1`	Configures a new SNMP group or a table that maps SNMP users to SNMP views. • Use the **context** *context-name* keyword and argument to associate the specified SNMP group with a configured SNMP context.
Step 5	**snmp-server view** *view-name oid-tree* {**included** | **excluded**} **Example:** `Router(config)# snmp-server view view1 ipForward included`	Creates or updates a view entry.
Step 6	**snmp-server enable traps** [*notification-type*] **Example:** `Router(config)# snmp-server enable traps`	Enables all SNMP notifications (traps or informs) available on your system.
Step 7	**snmp-server host** *host-address* [**traps** | **informs**] [**version** {**1** | **2c** | **3** [**auth** | **noauth** | **priv**]}] *community-string* [**udp-port** *port*] [**notification-type**] [**vrf** *vrf-name*] **Example:** `Router(config)# snmp-server host 10.0.0.1 vrf customer1 public udp-port 7002`	Specifies the recipient of an SNMP notification operation.
Step 8	**snmp mib community-map** *community-name* [**context** *context-name*] [**engineid** *engine-id*] [**security-name** *security-name*] **target-list** *vpn-list-name* **Example:** `Router(config)# snmp mib community-maps community1 context context1 target-list commAVpn`	Associates an SNMP community with an SNMP context, Engine ID, or security name.
Step 9	**snmp mib target list** *vpn-list-name* {**vrf** *vrf-name* | **host** *ip-address*} **Example:**	Creates a list of target VRFs and hosts to associate with an SNMP community.

	Command or Action	Purpose
	`Router(config)# snmp mib target list commAVpn vrf vrf1`	
Step 10	**no snmp-server trap authentication vrf** **Example:** `Router(config)# no snmp-server trap authentication vrf`	(Optional) Disables all SNMP authentication notifications (traps and informs) generated for packets received on VRF interfaces. • Use this command to disable authentication traps only for those packets on VRF interfaces with incorrect community associations.
Step 11	**exit** **Example:** `Router(config) exit`	Exits to privileged EXEC mode.

Verifying MPLS LDP MIB Version 8 Upgrade

Perform a MIB walk using your SNMP management tool to verify that the MPLS LDP MIB Version 8 Upgrade feature is functioning.

Configuration Examples for MPLS LDP MIB Version 8 Upgrade

MPLS LDP MIB Version 8 Upgrade Examples

The following example shows how to enable an SNMP agent on the host NMS:

```
Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# snmp-server community
```

The following example shows how to enable SNMPv1 and SNMPv2C on the host NMS. The configuration permits any SNMP agent to access all MPLS LDP MIB objects that have read-only permission using the community string public.

```
Router(config)# snmp-server community public
```

The following example shows how to allow read-only access to all MPLS LDP MIB objects relating to members of access list 4 that specify the comaccess community string. No other SNMP agents will have access to any of the MPLS LDP MIB objects.

```
Router(config)# snmp-server community comaccess ro 4
```

The following example shows how to enable LDP globally and then on an interface:

```
Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

```
Router(config)# mpls label protocol ldp
Router(config)# interface FastEthernet1/0/0
Router(config-if)# mpls label protocol ldp
Router(config-if)# end
```

Configuring a VPN Aware SNMP Context for SNMPv1 or SNMPv2 Example

The following configuration example shows how to configure a VPN Aware SNMP context for the MPLS LDP MIB Version 8 with SNMPv1 or SNMPv2:

```
snmp-server context A
snmp-server context B
ip vrf CustomerA
 rd 100:110
 context A
 route-target export 100:1000
 route-target import 100:1000
!
ip vrf CustomerB
 rd 100:120
 context B
 route-target export 100:2000
 route-target import 100:2000
!
interface FastEthernet0/3/1
 description Belongs to VPN A
 ip vrf forwarding CustomerA
 ip address 10.0.0.0 255.255.0.0

interface FastEthernet0/3/2
 description Belongs to VPN B
 ip vrf forwarding CustomerB
 ip address 10.0.0.1 255.255.0.0
snmp-server user commA grp1A v1
snmp-server user commA grp2A v2c
snmp-server user commB grp1B v1
snmp-server user commB grp2B v2c
snmp-server group grp1A v1 context A read viewA write viewA notify viewA
snmp-server group grp1B v1 context B read viewB write viewB notify viewB
snmp-server view viewA ipForward included
snmp-server view viewA ciscoPingMIB included
snmp-server view viewB ipForward included
snmp-server view viewB ciscoPingMIB included
snmp-server enable traps
snmp-server host 10.0.0.3 vrf CustomerA commA udp-port 7002
snmp-server host 10.0.0.4 vrf CustomerB commB udp-port 7002
snmp mib community-map  commA context A target-list commAvpn
! Configures source address validation
snmp mib community-map  commB context B target-list commBvpn
! Configures source address validation
snmp mib target list commAvpn vrf CustomerA
! Configures a list of VRFs or from which community commA is valid
snmp mib target list commBvpn vrf CustomerB
! Configures a list of VRFs or from which community commB is valid
```

Feature Information for MPLS LDP MIB Version 8 Upgrade

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 46: Feature Information for MPLS LDP MIB Version 8 Upgrade

Feature Name	Releases	Feature Information
MPLS LDP MIB Version 08 Upgrade	12.0(11)ST 12.2(2)T 12.0(21)ST 12.0(22)S 12.0(24)S 12.2(18)S 12.2(33)SRB 12.2(33)SB Cisco IOS XE Release 2.1	The MPLS Label Distribution Protocol (LDP) MIB Version 8 Upgrade feature enhances the LDP MIB to support the Internet Engineering Task Force (IETF) draft Version 8. In Cisco IOS Release 12.0(11)ST, this feature was introduced to provide SNMP agent support for the MPLS LDP MIB on the Cisco 7200, Cisco 7500, and Cisco 12000 series routers. In Cisco IOS Release 12.2(2)T, this feature was added to this release to provide SNMP agent support for the MPLS LDP MIB on Cisco 7200 and Cisco 7500 series routers. In Cisco IOS Release 12.0(21)ST, this feature was added to this release to provide SNMP agent and LDP notification support for the MPLS LDP MIB on Cisco 7200, Cisco 7500, and Cisco 12000 series Internet routers. In Cisco IOS Release 12.0(22)S, Version 1 was integrated into Cisco IOS Release 12.0(22)S. In Cisco IOS Release 12.0(24)S, this feature was upgraded to Version 8 in Cisco IOS Release 12.0(24)S. This feature was integrated into Cisco IOS Release 12.2(18)S. In Cisco IOS Release 12.2(33)SRB, this MIB was deprecated and replaced by MPLS-LDP-STD-MIB (RVC 3815). In Cisco IOS Release 12.2(33)SB, this MIB was deprecated and replaced by MPLS-LDP-STD-MIB (RVC 3815). This feature was integrated into Cisco IOS XE Release 2.1 and implemented on Cisco ASR 1000 Series Aggregation Services Routers.
		The following commands were introduced or modified: **context**, **show mpls ldp neighbor**, **snmp mib community-map**, **snmp mib target list**, **snmp-server community**, **snmp-server context**, **snmp-server enable traps** (MPLS), **snmp-server group**, **snmp-server host**, **snmp-server trap authentication vrf**.
MPLS VPN-VPN Aware LDP MIB	12.0(27)S 12.2(28)SB 12.2(33)SRA 12.2(33)SXH 12.4(20)T	The MPLS VPN-VPN Aware LDP MIB allows you to enter LDP queries on any VRF and on the core (global context). In Cisco IOS Release 12.0(27)S, support for the MPLS VPN-VPN Aware LDP MIB feature was added. In Cisco IOS Release 12.2(28)SB, this feature was integrated. In Cisco IOS Release 12.2(33)SRA, this feature was integrated. In Cisco IOS Release 12.2(33)SXH, this feature was integrated. In Cisco IOS Release 12.4(20)T, this feature was integrated.

Glossary

ATM -- Asynchronous Transfer Mode. The international standard for cell relay in which multiple service types (such as voice, video, or data) are conveyed in fixed-length (53-byte) cells. Fixed-length cells allow cell processing to occur in hardware, thereby reducing transit delays. ATM is designed to take advantage of high-speed transmission media, such as E3, SONET, and T3 .

downstream-on-demand distribution--A label distribution method in which a downstream label switch router (LSR) sends a binding upstream only if the upstream LSR requests it.

downstream unsolicited distribution--A label distribution method in which labels are dispersed if a downstream label switch router (LSR) needs to establish a new binding with its neighboring upstream LSR. For example, an edge LSR might enable a new interface with another subnet. The LSR then announces to the upstream router a binding to reach this network.

informs --A type of notification message that is more reliable than a conventional trap notification message, because the informs message notification requires acknowledgment, but a trap notification does not.

label --A short, fixed-length data identifier that tells switching nodes how to forward data (packets or cells).

label distribution--The techniques and processes that are used by label switch routers (LSRs) to exchange label binding information for supporting hop-by-hop forwarding along normally routed paths.

LDP --Label Distribution Protocol. The protocol that supports Multiprotocol Label Switching (MPLS) hop-by-hop forwarding and the distribution of bindings between labels and network prefixes.

LSP --label switched path. A configured connection between two label switch routers (LSRs) in which label-switching techniques are used for packet forwarding; also a specific path through an Multiprotocol Label Switching (MPLS) network.

LSR --label switch router. A Multiprotocol Label Switching (MPLS) node that can forward native Layer 3 packets. The LSR forwards a packet based on the value of a label attached to the packet.

MIB --Management Information Base. A database of network management information that is used and maintained by a network management protocol such as Simple Network Management Protocol (SNMP). The value of a MIB object can be changed or retrieved by the use of SNMP commands, usually through a network management system. MIB objects are organized in a tree structure that includes public (standard) and private (proprietary) branches.

MPLS --Multiprotocol Label Switching. A switching method for the forwarding of IP traffic through the use of a label. This label instructs the routers and the switches in the network where to forward the packets based on preestablished IP routing information.

MPLS label distribution--A constraint-based routing algorithm for routing label-switched path (LSP) tunnels.

NMS --network management station. A powerful, well-equipped computer (typically an engineering workstation) that is used by a network administrator to communicate with other devices in the network. An NMS is typically used to manage network resources, gather statistics, and perform a variety of network administration and configuration tasks. In the context of Simple Network Management Protocol (SNMP), an NMS is a device that performs SNMP queries to the SNMP agent of a managed device to retrieve or modify information.

notification --A message sent by a Simple Network Management Protocol (SNMP) agent to a network management station, console, or terminal to indicate that a significant network event has occurred. See also trap.

RSVP --Resource Reservation Protocol. A protocol that supports the reservation of resources across an IP network. Applications running on IP end systems can use RSVP to indicate to other nodes the nature of the packet streams they want to receive by specifying such items as bandwidth, jitter, and maximum burst.

RTR --Response Time Reporter. A tool that allows you to monitor network performance, network resources, and applications by measuring response times and availability.

SNMP --Simple Network Management Protocol. A network management protocol used almost exclusively in TCP/IP networks. SNMP enables a user to monitor and control network devices, manage configurations, collect statistics, monitor performance, and ensure network security.

SNMP communities--Authentication scheme that enables an intelligent network device to validate SNMP requests.

SNMPv2c --Version 2c of the Simple Network Management Protocol. SNMPv2c supports centralized as well as distributed network management strategies and includes improvements in the Structure of Management Information (SMI), protocol operations, management architecture, and security.

SNMPv3 --Version 3 of the Simple Network Management Protocol. Interoperable standards-based protocol for network management. SNMPv3 provides secure access to devices by a combination of authenticating and encrypting packets over the network.

TLV --Type-Length-Value. A mechanism used by several routing protocols to carry a variety of attributes. Cisco Discovery Protocol (CDP), Label Discovery Protocol (LDP), and Border Gateway Protocol (BGP) are examples of protocols that use TLVs. BGP uses TLVs to carry attributes such as Network Layer Reachability Information (NLRI), Multiple Exit Discriminator (MED), and local preference.

trap --A message sent by a Simple Network Management Protocol (SNMP) agent to a network management station, console, or terminal to indicate that a significant network event has occurred. Traps (notifications) are less reliable than inform requests, because the receiver of the trap does not send an acknowledgment of receipt; furthermore, the sender of the trap cannot determine if the trap was received. See also notification.

VCC --virtual channel connection. A logical circuit, made up of virtual channel links (VCLs), that carries data between two endpoints in an ATM network. Sometimes called a virtual circuit connection.

VCI --virtual channel identifier. A 16-bit field in the header of an ATM cell. The VCI, together with the virtual path identifier (VPI), is used to identify the next network virtual channel link (VCL) as the cell passes through a series of ATM switches on its way to its final destination.

VCL --virtual channel link. The logical connection that exists between two adjacent switches in an ATM network.

VPI --virtual path identifier. An 8-bit field in the header of an ATM cell. The VPI, together with the virtual channel identifier (VCI), is used to identify the next network virtual channel link (VCL) as the cell passes through a series of ATM switches on its way to its final destination.

VPN --Virtual Private Network. A network that enables IP traffic to use tunneling to travel securely over a public TCP/IP network.

VRF --VPN routing and forwarding instance. A VRF consists of an IP routing table, a derived forwarding table, a set of interfaces that use the forwarding table, and a set of rules and routing protocols that determine what goes into the forwarding table. In general, a VRF includes the routing information that defines a customer VPN site that is attached to a PE router.

CHAPTER 15

MPLS VPN--MIB Support

This document describes the Simple Network Management Protocol (SNMP) agent support in Cisco software for Multiprotocol Label Switching (MPLS) Virtual Private Network (VPN) management, as implemented in the draft *MPLS/BGP Virtual Private Network Management Information Base Using SMIv2* (*draft-ietf-ppvpn-mpls-vpn-mib-05.txt*). This document also describes the cMplsNumVrfRouteMaxThreshCleared notification, which is implemented as part of the proprietary MIB CISCO-IETF-PPVNP-MPLS-VPN-MIB.

- Prerequisites for MPLS VPN--MIB Support, on page 301
- Restrictions for MPLS VPN--MIB Support, on page 301
- Information About MPLS VPN--MIB Support, on page 302
- How to Configure MPLS VPN--MIB Support, on page 318
- Configuration Examples for MPLS VPN--MIB Support, on page 324
- Additional References, on page 325
- Feature Information for MPLS VPN--MIB Support, on page 326
- Glossary, on page 326

Prerequisites for MPLS VPN--MIB Support

- SNMP is installed and enabled on the label switching routers.
- MPLS is enabled on the label switching routers.
- Multiprotocol Border Gateway Protocol (BGP) is enabled on the label switching routers.
- Cisco Express Forwarding is enabled on the label switching routers.

Restrictions for MPLS VPN--MIB Support

- Configuration of the MIB using the **snmp set**command is not supported, except for trap-related objects, such as mplsVpnNotificationEnable and mplsVpnVrfSecIllegalLabelRcvThresh.
- The mplsVpnVrfBgpNbrPrefixTable is not supported.

Information About MPLS VPN--MIB Support

MPLS VPN Overview

The MPLS VPN technology allows service providers to offer intranet and extranet VPN services that directly connect their customers' remote offices to a public network with the same security and service levels that a private network offers. Each VPN is associated with one or more VPN routing and forwarding (VRF) instances. A VRF is created for each VPN defined on a router and contains most of the information needed to manage and monitor MPLS VPNs: an IP routing table, a derived Cisco Express Forwarding table, a set of interfaces that use this forwarding table, and a set of rules and routing protocol parameters that control the information that is included in the routing table.

MPLS VPN MIB Overview

The Provider-Provisioned VPN (PPVPN)-MPLS-VPN MIB provides access to MPLS VRF information, and interfaces included in the VRF, and other configuration and monitoring information.

The PPVPN-MPLS-VPN MIB provides the following benefits:

- A standards-based SNMP interface for retrieving information about critical MPLS VPN events.
- VRF information to assist in the management and monitoring of MPLS VPNs.
- Information, in conjunction with the Interfaces MIB, about interfaces assigned to VRFs.
- Performance statistics for all VRFs on a router.
- The generation and queueing of notifications that call attention to major changes in the operational status of MPLS VPN enabled interfaces; the forwarding of notification messages to a designated network management system (NMS) for evaluation and action by network administrators.
- Advanced warning when VPN routing tables are approaching or exceed their capacity.
- Warnings about the reception of illegal labels on a VRF-enabled interface. Such receptions may indicate misconfiguration or an attempt to violate security.

This document also describes the CISCO-IETF-PPVPN-MPLS-VPN-MIB, which contains the cMplsNumVrfRouteMaxThreshCleared notification.

MPLS VPN MIB and the IETF

SNMP agent code operating with the PPVPN-MPLS-VPN MIB enables a standardized, SNMP-based approach to managing MPLS VPNs in Cisco software.

The PPVPN-MPLS-VPN MIB is based on the Internet Engineering Task Force draft MIB specification *draft-ietf-ppvpn-mpls-vpn-mib-05.txt* , which includes objects describing features that support MPLS VPN events. This IETF draft MIB, which undergoes revisions from time to time, is becoming a standard. Accordingly, the Cisco implementation of the PPVPN-MPLS-VPN MIB is expected to track the evolution of the IETF draft MIB, and may change accordingly.

Some slight differences between the IETF draft MIB and the actual implementation of MPLS VPNs within Cisco software require some minor translations between the PPVPN-MPLS-VPN MIB and the internal data

structures of Cisco software. These translations are accomplished by means of the SNMP agent code. Also, while running as a low priority process, the SNMP agent provides a management interface to Cisco software. SNMP adds little overhead on the normal functions of the device.

The SNMP objects defined in the PPVPN-MPLS-VPN MIB can be viewed by any standard SNMP utility. The network administrator can retrieve information in the PPVPN-MPLS-VPN MIB using standard SNMP get and getnext operations for SNMP v1, v2, and v3.

All PPVPN-MPLS-VPN MIB objects are based on the IETF draft MIB; thus, no Cisco-specific SNMP application is required to support the functions and operations pertaining to the PPVPN-MPLS-VPN MIB features.

Capabilities Supported by PPVPN-MPLS-VPN MIB

The PPVPN-MPLS-VPN MIB provides you with the ability to do the following:

- Gather routing and forwarding information for MPLS VPNs on a router.
- Expose information in the VRF routing table.
- Gather information on BGP configuration related to VPNs and VRF interfaces and statistics.
- Emit notification messages that signal changes when critical MPLS VPN events occur.
- Enable, disable, and configure notification messages for MPLS VPN events by using extensions to existing SNMP command-line interface (CLI) commands.
- Specify the IP address of NMS in the operating environment to which notification messages are sent.
- Write notification configurations into nonvolatile memory.

Functional Structure of the PPVPN-MPLS-VPN MIB

The SNMP agent code supporting the PPVPN-MPLS-VPN MIB follows the existing model for such code in Cisco software and is, in part, generated by the Cisco software tool set, based on the MIB source code.

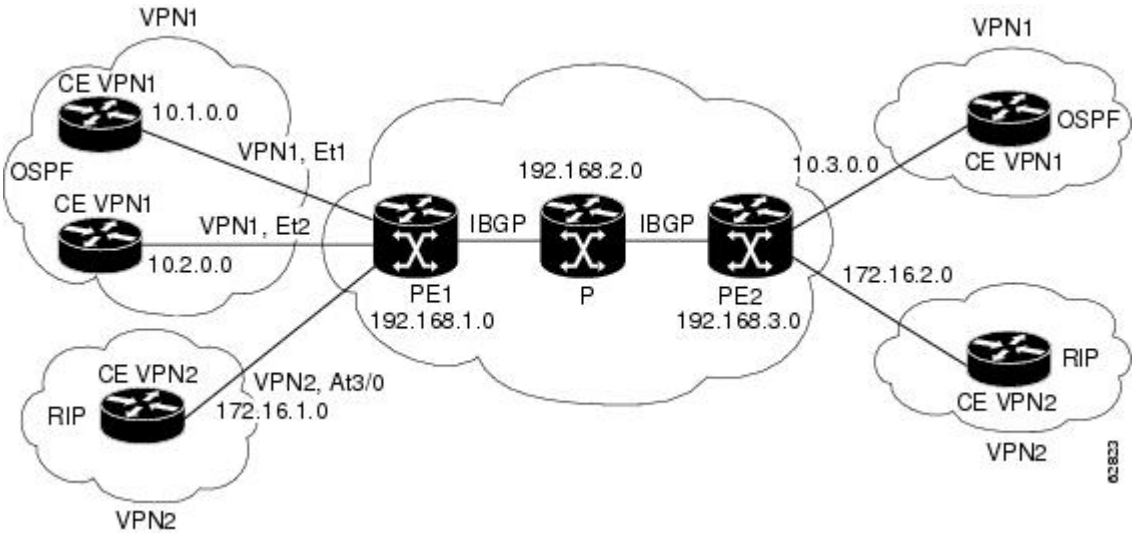
The SNMP agent code, which has a layered structure that is common to MIB support code in Cisco software, consists of four layers:

- Platform-independent layer--This layer is generated primarily by the MIB development Cisco software tool set and incorporates platform- and implementation-independent functions. The Cisco MIB development tool set creates a standard set of files associated with a MIB.
- Application interface layer--The functions, names, and template code for MIB objects in this layer are also generated by the MIB development Cisco software tool set.
- Application-specific layer--This layer provides an interface between the application interface layer and the API and data structures layer below and performs tasks needed to retrieve required information from Cisco software, such as searching through data structures.
- API and data structures layer--This layer contains the data structures or APIs within Cisco software that are retrieved or called in order to set or retrieve SNMP management information.

Supported Objects in PPVPN-MPLS-VPN MIB

The PPVPN-MPLS-VPN MIB contains numerous tables and object definitions that provide read-only SNMP management support for the MPLS VPN feature in Cisco IOS software. The PPVPN-MPLS-VPN MIB conforms to Abstract Syntax Notation One (ASN.1), thus reflecting an idealized MPLS VPN database.

Using any standard SNMP network management application, you can retrieve and display information from the PPVPN-MPLS-VPN MIB using GET operations; similarly, you can traverse information in the MIB database for display using GETNEXT operations.



The PPVPN-MPLS-VPN MIB tables and objects are described briefly in the following sections:

The figure below shows a simple MPLS VPN configuration. This configuration includes two customer MPLS VPNs, labeled VPN1 and VPN2, and a simple provider network that consists of two provider edge (PE) routers, labeled PE1 and PE2, and a provider core router labeled P. The figure below shows the following sample configuration:

- VRF names--VPN1 and VPN2
- Interfaces associated with VRFs--Et1, Et2, and At3/0
- Routing protocols--Open Shortest Path First. Link-state (OSPF), Routing Information Protocol (RIP), and internal Border Gateway Protocol (IBGP)
- Routes associated with VPN1--10.1.0.0, 10.2.0.0, and 10.3.0.0
- Routes associated with VPN2--172.16.1.0 and 172.16.2.0
- Routes associated with the provider network--192.168.1.0, 192.168.2.0, and 192.168.3.0

This configuration is used in this document to explain MPLS VPN events that are monitored and managed by the PPVPN-MPLS-VPN MIB.

Figure 33: Sample MPLS VPN Configuration

Scalar Objects

The table below shows the supported PPVPN-MPLS-VPN MIB scalar objects.

Table 47: PPVPN-MPLS-VPN MIB Scalar Objects

MIB Object	Function
mplsVpnConfiguredVrfs	The number of VRFs configured on the router, including VRFs recently deleted.
mplsVpnActiveVrfs	The number of VRFs that are active on the router. An active VRF is assigned to at least one interface that is in the operationally up state.
mplsVpnConnectedInterfaces	The total number of interfaces assigned to any VRF.
mplsVpnNotificationEnable	A value that indicates whether all the PPVPN-MPLS-VPN MIB notifications are enabled: • Setting this object to true enables all notifications defined in the PPVPN-MPLS-VPN MIB. • Setting this object to false disables all notifications defined in the MIB. This is one of the few objects that is writable.
mplsVpnVrfConfMaxPossibleRoutes	A number that indicates the amount of routes that this router is capable of storing. This value cannot be determined because it is based on the amount of available memory in the system. Therefore, this object is set to zero (0).

MIB Tables

The PPVPN-MPLS-VPN MIB implementation supports the following tables described in this section:

mplsVpnVrfTable

Each VRF is referenced by its VRF name (mplsVpnVrfName). The table below lists the MIB objects and their functions for this table.

Table 48: PPVPN-MPLS-VPN MIB Objects for the mplsVpnVrfTable

MIB Object	Function
mplsVpnVrfName	The name associated with this VRF. When this object is used as an index to a table, the first octet is the string length, and subsequent octets are the ASCII codes of each character. For example, “vpn1” is represented as 4.118.112.110.49.

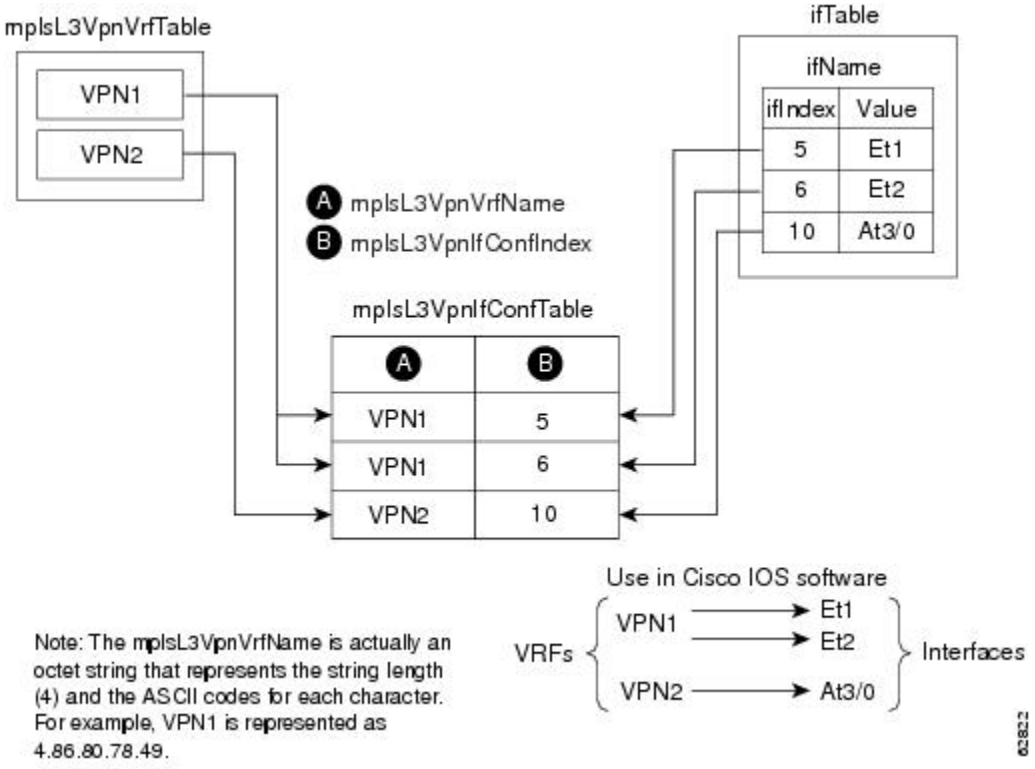
mplsVpnVrfDescription	The description of the VRF. This is specified with the following configuration command:
	`Router(config)# ip vrf`
	` vrf-name`
	`Router(config-vrf)# description`
	` vrf-description`

mplsVpnVrfRouteDistinguisher	The route distinguisher for this VRF. This is specified with the following configuration command:
	`Router(config)# ip vrf`
	`vrf-name`
	`Router(config-vrf)# rd`
	` route-distinguisher`

MIB Object	Function
mplsVpnVrfCreationTime	The value of the sysUpTime when this VRF entry was created.
mplsVpnVrfOperStatus	The operational status of this VRF. A VRF is up (1) when at least one interface associated with the VRF is up. A VRF is down (2) when: • No interfaces exist whose ifOperStatus = up (1). • No interfaces are associated with this VRF.
mplsVpnVrfActiveInterfaces	The number of interfaces assigned to this VRF that are operationally up.
mplsVpnVrfAssociatedInterfaces	The number of interfaces assigned to this VRF, independent of the operational status.

mplsVpnVrfConfMidRouteThreshold	The middle route threshold. If the amount of routes in the VRF crosses this threshold, an mplsNumVrfRouteMidThreshExceeded notification is sent (if notifications are enabled and configured). You can set this value in configuration mode as a percentage of the maximum with the **maximum routes** *limit* {*warn-threshold* | **warn-only**} command, as follows:
	`Router(config)# ip vrf vpn1`
	`Router(config-vrf)# maximum routes 1000 50`
	The middle or warn threshold is set for VRF vpn1 as 50 percent of the maximum route threshold.
	The following command sets a middle threshold of 1000 routes. An mplsNumVrfRouteMidThreshExceeded notification is sent when this threshold is exceeded. However, additional routes are still allowed because a maximum route threshold is not set with this command.
	`Router(config-vrf)# maximum routes 1000 warn-only`

mplsVpnVrfConfHighRouteThreshold	The maximum route threshold. If the number of routes in the VRF crosses this threshold, an mplsNumVrfRouteMaxThreshExceeded notification is sent (if notifications are enabled and configured). You can set this value in configuration mode with the **maximum routes** *limit* {*warn-threshold* | **warn-only**} command as follows:
	`Router(config)# ip vrf vpn2`
	`Router(config-vrf)# maximum routes 1000 75`
	The maximum route threshold is set for 1000 routes for VRF vpn2 with a middle or warn threshold of 75 percent of this threshold.



mplsVpnVrfConfMaxRoutes	This value is the same as the mplsVpnVrfConfHighRouteThreshold.
mplsVpnVrfConfLastChanged	The value of sysUpTime when the configuration of the VRF changes or interfaces are assigned or unassigned from the VRF. **Note** This object is updated only when values in this table change.
mplsVpnVrfConfRowStatus	Read-only implementation. This object normally reads “active (1),” but may read “notInService (2),” if a VRF was recently deleted.

MIB Object	Function
mplsVpnVrfConfStorageType	Read-only implementation. This object always reads “volatile (2).”

mplsVpnInterfaceConfTable

In Cisco software, a VRF is associated with one MPLS VPN. Zero or more interfaces can be associated with a VRF. A VRF uses an interface that is defined in the ifTable of the Interfaces Group of MIB II (IFMIB). The IFMIB defines objects for managing interfaces. The ifTable of this MIB contains information on each interface in the network. The mplsVpnInterfaceConfTable associates a VRF from the mplsVpnVrfTable with a forwarding interface from the ifTable. The figure below shows the relationship between VRFs and interfaces defined in the ifTable and the mplsVpnInterfaceConfTable.

Figure 34: VRFs, the Interfaces MIB, and the mplsVpnInterfaceConfTable

Entries in the VPN interface configuration table (mplsVpnInterfaceConfTable) represent the interfaces that are assigned to each VRF. The information available in this table is also displayed with the **show ip vrf** command.

The mplsVpnInterfaceConfTable shows how interfaces are assigned to VRFs. A label switch router (LSR) creates an entry in this table for every interface capable of supporting MPLS VPNs.

The mplsVpnInterfaceConfTable is indexed by the following:

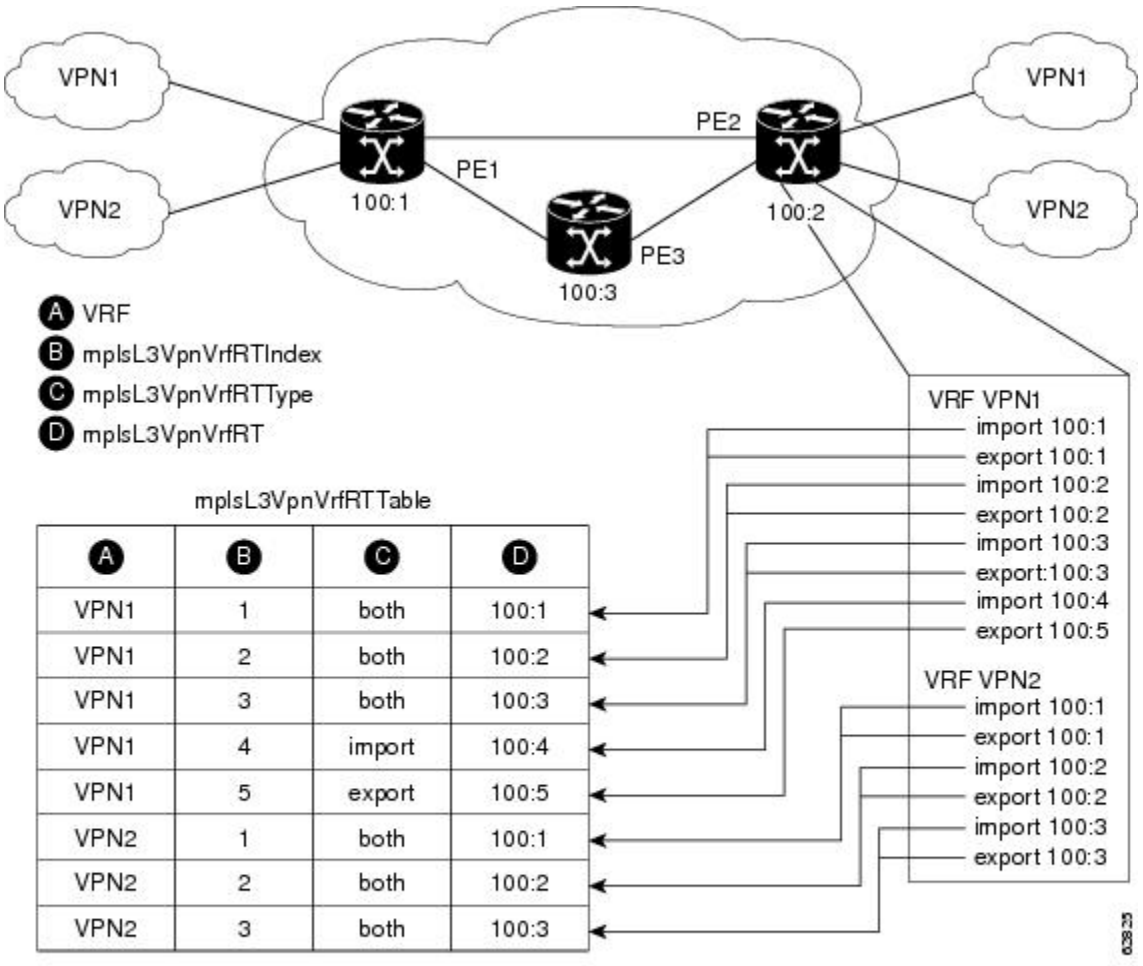
- mplsVpnVrfName--The VRF name
- mplsVpnInterfaceConfIndex--An identifier that is the same as the ifIndex from the Interface MIB of the interface assigned to the VRF

The table below lists the MIB objects and their functions for this table.

Table 49: PPVPN-MPLS-VPN MIB Objects for the mplsVpnInterfaceConfTable

MIB Object	Function
mplsVpnInterfaceConfIndex	Provides the interface MIB ifIndex of this interface that is assigned to a VRF.
mplsVpnInterfaceLabelEdgeType	Indicates whether the interface is a provider edge interface (1) or a customer edge interface (2). This value is always providerEdge (1) because in Cisco IOS, customerEdge interfaces are not assigned to VRFs and do not appear in this table.
mplsVpnInterfaceVpnClassification	Specifies what type of VPN this interface is providing: carrier supporting carrier (CsC) (1), enterprise (2), or InterProvider (3). This value is set to enterprise (2) if MPLS is not enabled and to carrier supporting carrier (1) if MPLS is enabled on this interface.
mplsVpnInterfaceVpnRouteDistProtocol	Indicates the route distribution protocols that are being used to redistribute routes with BGP on this interface: BGP (2), OSPF (3), or RIP (4). In Cisco software, router processes are defined and redistributed on a per-VRF basis, not per-interface. Therefore, all interfaces assigned to the same VRF have the same value for this object.
mplsVpnInterfaceConfStorageType	Read-only implementation. This object always reads “volatile (2).”
mplsVpnInterfaceConfRowStatus	Read-only implementation. This object normally reads “active (1),” but may read “notInService (2),” if a VRF was recently deleted.

mplsVpnVrfRouteTargetTable



The route target table (mplsVpnVrfRouteTargetTable) describes the route target communities that are defined for a particular VRF. An LSR creates an entry in this table for each target configured for a VRF supporting an MPLS VPN instance.

The distribution of VPN routing information is controlled through the use of VPN route target communities, implemented by BGP extended communities. Distribution of VPN routing information works as follows:

- When a VPN route learned from a customer edge (CE) router is injected into BGP, a list of VPN route target extended community attributes is associated with it. Typically the list of route target community values is set from an export list of route targets associated with the VRF from which the route was learned.
- An import list of route target extended communities is associated with each VRF. The import list defines route target extended community attributes a route must have for the route to be imported into the VRF. For example, if the import list for a particular VRF includes route target communities A, B, and C, then any VPN route that carries any of those route target extended communities--A, B, or C--is imported into the VRF.

The figure below shows a sample configuration and its relationship to an mplsVpnVrfRouteTargetTable. A route target table exists on each PE router. Routers with route distinguishers (RDs) 100:1, 100:2, and 100:3 are shown in the sample configuration. Routers with RDs 100:4 and 100:5 are not shown in the figure, but are included in the route targets for PE2 and in the mplsVpnVrfRouteTargetTable.

Figure 35: Sample Configuration and the mplsVpnVrfRouteTargetTable

mplsL3VpnVrfRTTable

A	B	C	D
VPN1	1	both	100:1
VPN1	2	both	100:2
VPN1	3	both	100:3
VPN1	4	import	100:4
VPN1	5	export	100:5
VPN2	1	both	100:1
VPN2	2	both	100:2
VPN2	3	both	100:3

Note: The mplsL3VpnVrfName is actually an octet string that represents the string length (4) and the ASCII codes for each character. For example, VPN1 is represented as 4.86.80.78.49.

The mplsVpnVrfRouteTargetTable shows the import and export route targets for each VRF. The table is indexed by the following:

- mplsVpnVrfName--The VRF name
- mplsVpnVrfRouteTargetIndex--The route target entry identifier
- mplsVpnVrfRouteTargetType--A value specifying whether the entry is an import route target, export route target, or is defined as both

The table below lists the MIB objects and their functions for this table.

Table 50: PPVPN-MPLS-VPN MIB Objects for the mplsVpnVrfRouteTargetTable

MIB Object	Function
mplsVpnVrfRouteTargetIndex	A value that defines each route target's position in the table.
mplsVpnVrfRouteTargetType	Determines which type of route target the entry represents: import (1), export (2), or both (3).
mplsVpnVrfRouteTarget	Determines the route distinguisher for this target.
mplsVpnVrfRouteTargetDescr	Description of the route target. This object is not supported. Therefore, the object is the same as mplsVpnVrfRouteTarget.
mplsVpnVrfRouteTargetRowStatus	Read-only implementation. This object normally reads "active (1)," but may read "notInService (2)," if a VRF was recently deleted.

mplsVpnVrfBgpNbrAddrTable

The BGP neighbor address table (mplsVpnVrfBgpNbrAddrTable) represents the MPLS external Border Gateway Protocol (eBGP) neighbors that are defined for a particular VRF. An LSR creates an entry for every BGP neighbor that is defined in the VRF's address-family.

The mplsVpnVrfBgpNbrAddrTable is indexed by the following:

- mplsVpnVrfName--The VRF name
- mplsVpnInterfaceConfIndex--An identifier that is the same as the ifIndex from the Interface MIB of the interface assigned to the VRF
- mplsVpnVrfBgpNbrIndex--The IP address of the neighbor

The table below lists the MIB objects and their functions for this table.

Table 51: PPVPN-MPLS-VPN MIB Objects for the mplsVpnVrfBgpNbrAddrTable

MIB Object	Function
mplsVpnVrfBgpNbrIndex	The IPv4 address of the eBGP neighbor.
mplsVpnVrfBgpNbrRole	The role of this eBGP neighbor: customer edge (1) or provider edge (2). If the object mplsVpnInterfaceVpnClassification is CSC, then this value is provider edge (2); otherwise, this value is customer edge (1).
mplsVpnVrfBgpNbrType	Address type of this eBGP neighbor. The MIB supports only IPv4 (1). Therefore, this object returns "ipv4 (1)."
mplsVpnVrfBgpNbrAddr	IP address of the eBGP neighbor.
mplsVpnVrfBgpNbrRowStatus	Read-only implementation. This object normally reads "active (1)," but may read "notInService (2)" if a VRF was recently deleted.
mplsVpnVrfBgpNbrStorageType	Read-only implementation. This object always reads "volatile (2)."

mplsVpnVrfSecTable

The VRF security table (mplsVpnVrfSecTable) provides information about security for each VRF. An LSR creates an entry in this table for every VRF capable of supporting MPLS VPN.

The mplsVpnVrfSecTable *augments* the mplsVpnVrfTable and has the same indexing.

The table below lists the MIB objects and their functions for this table.

Table 52: PPVPN-MPLS-VPN MIB Objects for the mplsVpnVrfSecTable

MIB Object	Function
mplsVpnVrfSecIllegalLabelViolations	The number of illegally received labels on a VRF interface. Only illegal labels are counted by this object, therefore the object only applies to a VRF interface that is MPLS enabled (CSC situation). This counter is incremented whenever a label is received that is above or below the valid label range, not in the global label forwarding table, or is received on the wrong VRF (that is, table IDs for the receiving interface and appropriate VRF label forwarding table do not match).
mplsVpnVrfSecIllegalLabelRcvThresh	Notification threshold for illegal labels received on this VRF. When the number of illegal labels received on this interface crosses this threshold, an mplsNumVrfSecIllegalLabelThreshExceeded notification is sent (if the notification is enabled and configured). This object is one of the few in this MIB agent that supports the SNMP SET operation, which allows you to change this value.

mplsVpnVrfPerfTable

The VRF performance table (mplsVpnVrfPerfTable) provides statistical performance information for each VRF. An LSR creates an entry in this table for every VRF capable of supporting MPLS VPN.

The mplsVpnVrfPerfTable *augments* the mplsVpnVrfTable and has the same indexing.

The table below lists the MIB objects and their functions for this table.

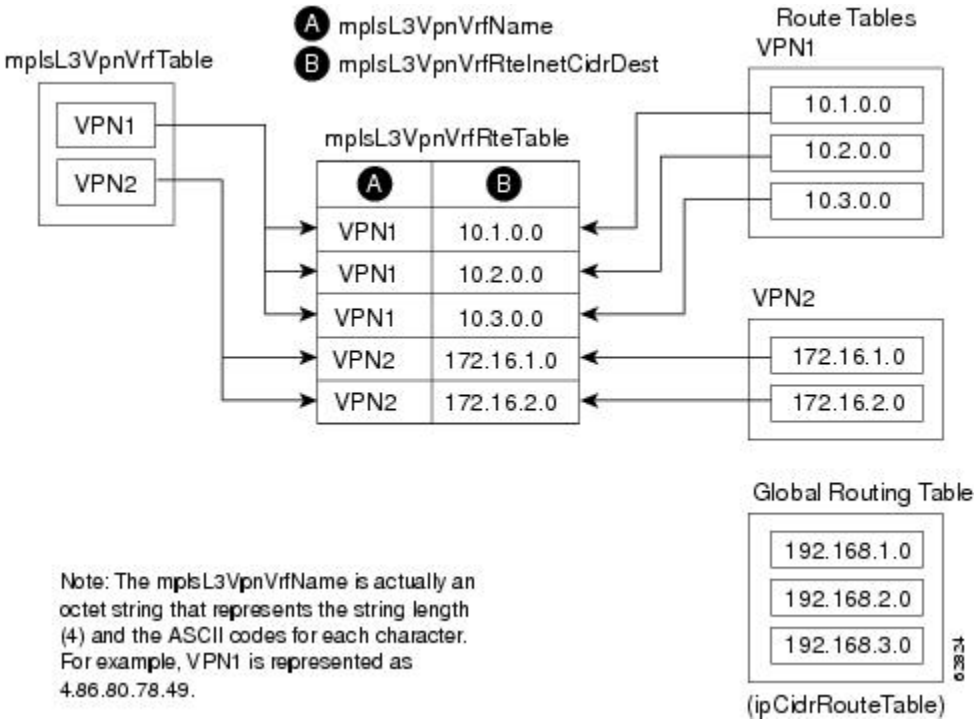
Table 53: PPVPN-MPLS-VPN MIB Objects for the mplsVpnVrfPerfTable

MIB Objects	Functions
mplsVpnVrfPerfRoutesAdded	The number of routes added to this VRF over the course of its lifetime.
mplsVpnVrfPerfRoutesDeleted	The number of routes removed from this VRF.
mplsVpnVrfPerfCurrNumRoutes	The number of routes currently defined within this VRF.

mplsVpnVrfRouteTable

The VRF routing table (mplsVpnVrfRouteTable) provides the IP routing table information for each VRF. The information available in this table can also be accessed with the **show ip route vrf** *vrf-name* command. For example, for PE1 in the figure above:

- With the **show ip route vrf vpn1** command, you would see results like the following:



```
Router# show ip route vrf vpn1
Codes: C - connected, S - static, I - IGRP, R - RIP, M - mobile, B - BGP
D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2, E - EGP
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
* - candidate default, U - per-user static route, o - ODR
P - periodic downloaded static route
!
Gateway of last resort is not set
!
     10.0.0.0/32 is subnetted, 3 subnets
B       10.3.0.0 [200/0] via 192.168.2.1, 04:36:33
C       10.1.0.0/16 is directly connected, FastEthernet1
C       10.2.0.0/16 [200/0] directly connected FastEthernet2, 04:36:33
```

- With the **show ip route vrf vpn2** command, you would see results like the following:

```
Router# show ip route vrf vpn2
Codes: C - connected, S - static, I - IGRP, R - RIP, M - mobile, B - BGP
D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2, E - EGP
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
* - candidate default, U - per-user static route, o - ODR
P - periodic downloaded static route
!
Gateway of last resort is not set
!
     172.16.0.0/32 is subnetted, 2 subnets
B       172.16.2.0 [200/0] via 192.168.2.1, 04:36:33
C       172.16.1.0 is directly connected, ATM 3/0
```

The figure below shows the relationship of the routing tables, the VRFs, and the mplsVpnVrfRouteTable. You can display information about the VPN1 and VPN2 route tables using the **show ip route vrf** *vrf-name* command. The global route table is the same as ipCidrRouteTable in the IP-FORWARD-MIB. You can display information about the global route table with the **show ip route** command.

Figure 36: Route Table, VRFs, and the mplsVpnVrfRouteTable

An LSR creates an entry in this table for every route that is configured, either dynamically or statically, within the context of a specific VRF capable of supporting MPLS VPN.

The mplsVpnVrfRouteTable is indexed by the following:

- mplsVpnVrfName--The VRF name, which provides the VRF routing context
- mplsVpnVrfRouteDest--The IP destination address
- mplsVpnVrfRouteMask--The IP destination mask
- mplsVpnVrfRouteTos--The IP header ToS bits
- mplsVpnVrfRouteNextHop--The IP address of the next hop for each route entry

Note The ToS bits are not supported and, therefore, are always 0.

The table below lists the MIB objects and their functions for the mplsVpnVrfRouteTable. This table represents VRF-specific routes. The global routing table is the ipCidrRouteTable in the IP-FORWARD-MIB.

Table 54: PPVPN-MPLS-VPN MIB Objects for the mplsVpnVrfRouteTable

MIB Object	Function
mplsVpnVrfRouteDest	The destination IP address defined for this route.

MIB Object	Function
mplsVpnVrfRouteDestAddrType	The address type of the IP destination address (mplsVpnVrfRouteDest). This MIB implementation supports only IPv4 (1). Therefore, this object has a value of "ipv4 (1)."
mplsVpnVrfRouteMask	The destination IP address mask defined for this route.
mplsVpnVrfRouteMaskAddrType	The address type of the destination IP address mask. This MIB implementation supports only IPv4 (1). Therefore, this object has a value of "ipv4 (1)."
mplsVpnVrfRouteTos	The ToS bits from the IP header for this route. Cisco software supports only ToS bits of zero. Therefore, the object is always 0.
mplsVpnVrfRouteNextHop	The next hop IP address defined for this route.
mplsVpnVrfRouteNextHopAddrType	The address type of the next hop IP address. This MIB implementation only supports only IPv4 (1). Therefore, this object has a value of "ipv4 (1)."
mplsVpnVrfRouteIfIndex	The interface MIB ifIndex for the interface through which this route is forwarded. The object is 0 if no interface is defined for the route.
mplsVpnVrfRouteType	Defines if this route is a local or remotely defined route.
mplsVpnVrfRouteProto	The routing protocol that was responsible for adding this route to the VRF.
mplsVpnVrfRouteAge	The number of seconds since this route was last updated.
mplsVpnVrfRouteInfo	A pointer to more information from other MIBs. This object is not supported and always returns "nullOID (0.0)."
mplsVpnVrfRouteNextHopAS	The autonomous system number of the next hop for this route. This object is not supported and is always 0.
mplsVpnVrfRouteMetric1	The primary routing metric used for this route.
mplsVpnVrfRouteMetric2 mplsVpnVrfRouteMetric3 mplsVpnVrfRouteMetric4 mplsVpnVrfRouteMetric5	Alternate routing metrics used for this route. These objects are supported only for Cisco Interior Gateway Routing Protocol (IGRP) and Cisco Enhanced Interior Gateway Routing Protocol (EIGRP). These objects display the bandwidth metrics used for the route. Otherwise, these values are set to -1.
mplsVpnVrfRouteRowStatus	Read-only implementation. This object normally reads "active (1)," but may read "notInService (2)," if a VRF was recently deleted.
mplsVpnVrfRouteStorageType	Read-only implementation. This object always reads "volatile (2)."

PPVPN-MPLS-VPN MIB Notifications

This section provides the following information about supported PPVPN-MPLS-VPN MIB notifications:

PPVPN-MPLS-VPN MIB Notification Events

The following notifications of the PPVPN-MPLS-VPN MIB are supported:

- mplsVrfIfUp--Sent to an NMS when an interface comes up and is assigned a VRF instance.

- mplsVrfIfDown--Generated and sent to the NMS when a VRF is removed from an interface or the interface transitions from an operationally "up" state to a "down" state.
- mplsNumVrfRouteMidThreshExceeded--Generated and sent when the middle (warning) threshold is crossed. You can configure this threshold in the CLI by using the following commands:

```
Router(config)# ip vrf vrf-name
Router(config-vrf)#  maximum routes limit warn-threshold (% of max)
```

The *warn-threshold* argument is a percentage of the maximum routes specified by the *limit* argument. You can also configure a middle threshold with the following command, in which the *limit* argument represents the warning threshold:

```
Router(config-vrf)# maximum routes limit warn-threshold (% of max)
```

This notification is sent to the NMS only at the time the threshold is exceeded. (See the figure below for a comparison of the warning and maximum thresholds.) Whenever the number of routes falls below this threshold and exceeds the threshold again, a notification is sent to the NMS.

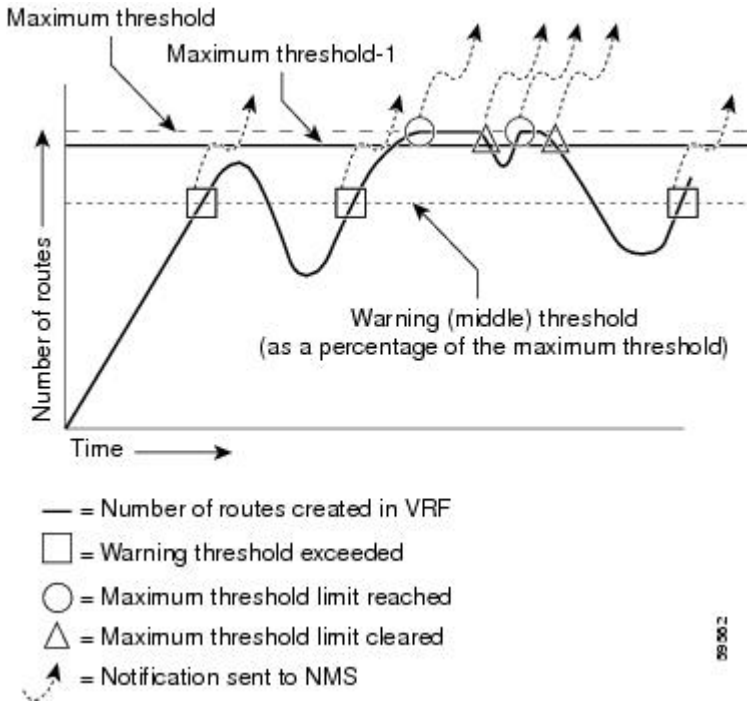
- MplsNumVrfRouteMaxThreshExceeded--Generated and sent when you attempt to create a route on a VRF that already contains the maximum number of routes as defined by the *limit* argument of the **maximum routes**c ommands:

```
Router(config)# ip vrf vrf-name
Router(config-vrfmaximum routes limit warn-threshold (% of max)
```

A trap notification is sent to the NMS when you attempt to exceed the maximum threshold. Another MplsNumVrfRouteMaxThreshExceeded notification is not sent until the number of routes falls below the maximum threshold and reaches the maximum threshold again. (See the figure below for an example of how this notification works and for a comparison of the maximum and warning thresholds.)

Note The **maximum routes** command sets the number of routes for a VRF. You *cannot* exceed the number of routes in the VRF that you set with the **maximum routes** *limit warn-threshold* command. Prior to implementation of the PPVPN-MPLS-VPN MIB, you were not notified when this threshold (or the warning threshold) was reached.

- mplsNumVrfSecIllegalLabelThreshExceeded--Generated and sent when the number of illegal labels received on a VRF interface exceeds the threshold *mplsVpnVrfSecIllegalLabelRcvThresh* . This threshold is defined with a value of 0. Therefore, a notification is sent when the first illegal label is received on a VRF. Labels are considered illegal if they are outside of the valid label range, do not have a Label Forwarding Information Base (LFIB) entry, or the table ID of the message does not match the table ID for the label in the LFIB.



CISCO-IETF-PPVPN-MPLS-VPN MIB Notification Events

The following notification of the CISCO-IETF-PPVPN-MPLS-VPN MIB is supported in Cisco software:

- cMplsNumVrfRouteMaxThreshCleared--Generated and sent when the number of routes on a VRF attempts to exceed the maximum number of routes and then drops below the maximum number of routes. If you attempt to create a route on a VRF that already contains the maximum number of routes, the mplsNumVrfRouteMaxThreshExceeded notification is sent (if enabled). When you remove routes from

the VRF so that the number of routes falls below the set limit, the cMplsNumVrfRouteMaxThreshCleared notification is sent. You can clear all routes from the VRF by using the **clear ip route vrf** command. (See the figure below to see when the cMplsNumVrfRouteMaxThreshCleared notification is sent.)

Figure 37: Comparison of Warning and Maximum Thresholds

Notification Specification

In an SNMPv1 notification, each VPN notification has a generic type identifier and an enterprise-specific type identifier for identifying the notification type.

- The generic type for all VPN notifications is “enterpriseSpecific” because this is not one of the generic notification types defined for SNMP.
- The enterprise-specific type is identified as follows:
  - 1 for *mplsVrfIfUp*
  - 2 for *mplsVrfIfDown*
  - 3 for *mplsNumVrfRouteMidThreshExceeded*
  - 4 for *mplsNumVrfRouteMaxThreshExceeded*
  - 5 for *mplsNumVrfSecIllegalLabelThreshExceeded*
  - 6 for cMplsNumVrfRouteMaxThreshCleared

In SNMPv2, the notification type is identified by an SnmpTrapOID varbind (variable binding consisting of an object identifier [OID] type and value) included within the notification message.

Each notification also contains two additional objects from the PPVPN-MPLS-VPN MIB. These objects provide additional information about the event, as follows:

- The VRF interface up/down notifications provide additional variables--*mplsVpnInterfaceConfIndex* and *mplsVpnVrfName*-- in the notification. These variables describe the SNMP interface index and the VRF name, respectively.
- The mid and max threshold notifications include the *mplsVpnVrfName* variable (VRF name) and the *mplsVpnVrfPerfCurrNumRoutes* variable that indicates the current number of routes within the VRF.
- The illegal label notification includes the *mplsVpnVrfName* variable (VRF name) and the *mplsVpnVrfSecIllegalLabelViolations* variable that maintains the current count of illegal labels on a VPN.

Monitoring the PPVPN-MPLS-VPN MIB Notifications

When PPVPN-MPLS-VPN MIB notifications are enabled (see the **snmp-server enable traps mpls vpn** command in the Cisco IOS Multiprotocol Label Switching Command Reference), notification messages relating to specific MPLS VPN events within Cisco software are generated and sent to a specified NMS in the network. Any utility that supports SNMPv1 or SNMPv2 notifications can receive notification messages.

To monitor PPVPN-MPLS-VPN MIB notification messages, log in to an NMS that supports a utility that displays SNMP notifications, and start the display utility.

Unsupported Objects in PPVPN-MPLS-VPN MIB

The following objects from the mplsVpnVrfBgpPathAttrTable are not supported with SNMP management for MPLS VPN features in Cisco software:

- mplsVpnVrfBgpPathAttrPeer
- mplsVpnVrfBgpPathAttrIpAddrPrefixLen
- mplsVpnVrfBgpPathAttrIpAddrPrefix
- mplsVpnVrfBgpPathAttrOrigin
- mplsVpnVrfBgpPathAttrASPathSegment
- mplsVpnVrfBgpPathAttrNextHop
- mplsVpnVrfBgpPathAttrMultiExitDisc
- mplsVpnVrfBgpPathAttrLocalPref
- mplsVpnVrfBgpPathAttrAtomicAggregate
- mplsVpnVrfBgpPathAttrAggregatorAS
- mplsVpnVrfBgpPathAttrAggregatorAddr
- mplsVpnVrfBgpPathAttrCalcLocalPref
- mplsVpnVrfBgpPathAttrBest
- mplsVpnVrfBgpPathAttrUnknown

How to Configure MPLS VPN--MIB Support

Configuring the SNMP Community

An SNMP community string defines the relationship between the SNMP manager and the agent. The community string acts like a password to regulate access to the agent on the router.

Perform this task to configure an SNMP community.

SUMMARY STEPS

1. **enable**
2. **show running-config** [*options*]
3. **configure terminal**
4. **snmp-server community** *string* [**view** *view-name*] [**ro** | **rw**] [*acl-number*]
5. **do copy running-config startup-config**
6. **exit**
7. **show running-config** [*options*]

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**show running-config** [*options*] **Example:** `Router# show running-config`	Displays the running configuration to determine if an SNMP agent is already running. • If no SNMP information is displayed, continue with the next step. If any SNMP information is displayed, you can modify the information or change it as needed.
Step 3	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 4	**snmp-server community** *string* [**view** *view-name*] [**ro** | **rw**] [*acl-number*] **Example:** `Router(config)# snmp-server community comaccess ro`	Sets up the community access string to permit access to the SNMP protocol. • The *string* argument acts like a password and permits access to the SNMP protocol.

	Command or Action	Purpose
		• The **view** *view-nameview-name* keyword argument pair specifies the name of a previously defined view. The view defines the objects available to the community. • The **ro** keyword specifies read-only access. Authorized management stations are only able to retrieve MIB objects. • The **rw** keyword specifies read/write access. Authorized management stations are able to both retrieve and modify MIB objects. • The *acl-number* argument is an integer from 1 to 99 that specifies an access list of IP addresses that are allowed to use the community string to gain access to the SNMP agent.
Step 5	**do copy running-config startup-config** **Example:** `Router(config)# do copy running-config startup-config`	Saves the modified configuration to NVRAM as the startup configuration file. • The **do** command allows you to perform EXEC level commands in configuration mode.
Step 6	**exit** **Example:** `Router(config)# exit`	Returns to privileged EXEC mode.
Step 7	**show running-config** [*options*] **Example:** `Router# show-running config | include smnp-server`	(Optional) Displays the configuration information currently on the router, the configuration for a specific interface, or map-class information. • Use the **show running-config** command to check that the **snmp-server** statements appear in the output.

Configuring the Router to Send SNMP Traps

Perform this task to configure the router to sendm SNMP traps to a host.

The **snmp-server host** command specifies which hosts receive traps. The **snmp-server enable traps** command globally enables the trap production mechanism for the specified traps.

For a host to receive a trap, an **snmp-server host** command must be configured for that host, and, generally, the trap must be enabled globally through the **snmp-server enable traps** command.

Note Although you can set the *community-string* argument using the **snmp-server host** command by itself, we recommend you define this string using the **snmp-server community** command before using the **snmp-server host** command.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server host** *host-addr* [**traps** | **informs**] [**version** {**1** | **2c** | **3** [**auth** | **noauth** | **priv**]}] *community-string* [**udp-port** *port*] [*notification-type*] [**vrf** *vrf-name*]
4. **snmp-server enable traps mpls vpn** [**illegal-label**] [**max-thresh-cleared**] [**max-threshold**] [**mid-threshold**] [**vrf-down**] [**vrf-up**]
5. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**snmp-server host** *host-addr* [**traps** | **informs**] [**version** {**1** | **2c** | **3** [**auth** | **noauth** | **priv**]}] *community-string* [**udp-port** *port*] [*notification-type*] [**vrf** *vrf-name*] **Example:** `Router(config)# snmp-server host 172.20.2.160 traps comaccess mpls-vpn`	Specifies the recipient of an SNMP notification operation. • The*host-addr* argument specifies the name or Internet address of the host (the targeted recipient). • The **traps** keyword sends SNMP traps to this host. This is the default. • The **informs** keyword sends SNMP informs to this host. • The **version** keyword specifies the version of the SNMP used to send the traps. Version 3 is the most secure model, because it allows packet encryption with the **priv** keyword. If you use the **version** keyword, you must specify one of the following: • **1**--SNMPv1. This option is not available with informs.

	Command or Action	Purpose
		• **2c** --SNMPv2C. • **3**--SNMPv3. The following three optional keywords can follow the **version 3**keyword (**auth**, **noauth**, **priv**). • The *community-string* argument is a password-like community string sent with the notification operation. • The **udp-port** *port* keyword and argument pair names the User Datagram Protocol (UDP) port of the host to use. The default is 162. • The *notification-type* argument specifies the type of notification to be sent to the host. If no type is specified, all notifications are sent. • The **vrf** *vrf-name* keyword and argument pair specifies the VRF table that should be used to send SNMP notifications.
Step 4	**snmp-server enable traps mpls vpn** [**illegal-label**] [**max-thresh-cleared**] [**max-threshold**] [**mid-threshold**] [**vrf-down**] [**vrf-up**] **Example:** `Router(config)# snmp-server enable traps mpls vpn vrf-down vrf-up`	Enables the router to send MPLS VPN-specific SNMP notifications (traps and informs). • The **illegal-label** keyword enables a notification for any illegal labels received on a VRF interface. Labels are illegal if they are outside the legal range, do not have an LFIB entry, or do not match table IDs for the label. • The **max-thresh-cleared** keyword enables a notification when the number of routes falls below the limit after the maximum route limit was attempted. • The **max-threshold** keyword enables a notification that a route creation attempt was unsuccessful because the maximum route limit was reached. Another MplsNumVrfRouteMaxThreshExceeded notification is not sent until the number of routes falls below the maximum threshold and reaches the maximum threshold again. The max-threshold value is determined by the **maximum routes** command in VRF configuration mode. • The **mid-threshold** keyword enables a notification of a warning that the number of routes created has crossed the warning threshold. This warning is sent only at the time the warning threshold is exceeded. • The **vrf-down** keyword enables a notification for the removal of a VRF from an interface or the transition of an interface to the down state.

	Command or Action	Purpose
		• The **vrf-up** keyword enables a notification for the assignment VRF to an interface that is operational or for the transition of a VRF interface to the operationally up state.
Step 5	**end** **Example:** `Router(config)# end`	(Optional) Exits to privileged EXEC mode.

Configuring Threshold Values for MPLS VPN--SNMP Notifications

Perform this task to configure the following threshold values for MPLS VPN--SNMP notifications:

- The mplsNumVrfRouteMidThreshExceeded notification event is generated and sent when the middle (warning) threshold is crossed. You can configure this threshold in the CLI by using the **maximum routes** command in VRF configuration mode. This notification is sent to the NMS only at the time the threshold is exceeded. Whenever the number of routes falls below this threshold and exceeds the threshold again, a notification is sent to the NMS.
- The mplsNumVrfRouteMaxThreshExceeded notification event is generated and sent when you attempt to create a route on a VRF that already contains the maximum number of routes as defined by the **maximum routes** command in VRF configuration mode. A trap notification is sent to the NMS when you attempt to exceed the maximum threshold. Another MplsNumVrfRouteMaxThreshExceeded notification is not sent until the number of routes falls below the maximum threshold and reaches the maximum threshold again.

See the figure above for an example of how this notification works and for a comparison of the maximum and warning thresholds.

Note The **maximum routes** command sets the number of routes for a VRF. You *cannot* exceed the number of routes in the VRF that you set with the **maximum routes** *limit warn-threshold* command. Prior to the implementation of the PPVPN-MPLS-VPN MIB, you were not notified when this threshold (or the warning threshold) was reached.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip vrf** *vrf-name*
4. **maximum routes** *limit* {*warn-threshold* | **warn-only**}
5. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**ip vrf** *vrf-name* **Example:** `Router(config)# ip vrf vpn1`	Configures a VRF routing table and enters VRF configuration mode. • The *vrf-name* argument specifies the name assigned to a VRF.
Step 4	**maximum routes** *limit* {*warn-threshold* | **warn-only**} **Example:** `Router(config-vrf)# maximum routes 10000 80`	Limits the maximum number of routes in a VRF to prevent a PE router from importing too many routes. • The *limit* argument specifies the maximum number of routes allowed in a VRF. The range is from 1 to 4,294,967,295. • The *warn-threshold* argument generates a warning when the number of routes set by the *warn-threshold* argument is reached and rejects routes that exceed the maximum number set in the *limit* argument. The warning threshold is a percentage from 1 to 100 of the maximum number of routes specified in the *limit* argument. • The **warn-only** keyword specifies that a system logging error message is issued when the maximum number of routes allowed for a VRF exceeds the limit threshold. However, additional routes are still allowed.
Step 5	**end** **Example:** `Router(config-vrf)# end`	(Optional) Exits to privileged EXEC mode.

Configuration Examples for MPLS VPN--MIB Support

Example Configuring the SNMP Community

The following example shows enabling a simple SNMP community group. This configuration permits any SNMP client to access all PPVPN-MPLS-VPN MIB objects with read-only access using the community string comaccess.

```
Router# configure terminal
Router(config)# snmp-server community comaccess ro
```

Verify that the SNMP master agent is enabled for the MPLS VPN--MIB Support feature:

```
Router# show running-config | include snmp-server
Building configuration...
.
snmp-server community comaccess RO
```

Note If you do not see any "snmp-server" statements, SNMP is not enabled on the router.

Example Configuring the Router to Send SNMP Traps

The following example shows you how to enable the router to send MPLS VPN notifications to host 172.20.2.160 using the comaccess community string if a VRF transitions from an up or down state:

```
Router# configure terminal
Router(config)# snmp-server host 172.20.2.160 traps comaccess mpls-vpn
Router(config)# snmp-server enable traps mpls vpn vrf-down vrf-up
```

Example Configuring Threshold Values for MPLS VPN--SNMP Notifications

The following example shows how to set a maximum threshold of 10,000 routes and a warning threshold that is 80 percent of the maximum threshold for a VRF named vpn1 on a router:

```
Router(config)# ip vrf vpn1
Router(config-vrf)# maximum routes 10000 80
```

The following example shows how to set a warning threshold of 10,000 routes for a VRF named vpn2 on a router. An error message is generated; however, additional routes are still allowed because a maximum route threshold is not set with this command.

```
Router(config)# ip vrf vpn2
Router(config-vrf)# maximum routes 10000 warn-only
```

Feature Name	Releases	Feature Information
MPLS VPN--MIB Support	Cisco IOS XE Release 2.1	The following command was introduced or modified: **snmp-server enable traps mpls vpn**

Glossary

6VPE router—Provider edge router that provides BGP-MPLS IPv6 VPN service over an IPv4-based MPLS core. It is a IPv6 VPN PE, dual-stack router that implements 6PE concepts on the core-facing interfaces.

autonomous system—A collection of networks that share the same routing protocol and that are under the same system administration.

ASN.1 —Abstract Syntax Notation One. The data types independent of particular computer structures and representation techniques. Described by ISO International Standard 8824.

BGP —Border Gateway Protocol. The exterior Border Gateway Protocol used to exchange routing information between routers in separate autonomous systems. BGP uses TCP. Because TCP is a reliable protocol, BGP does not experience problems with dropped or fragmented data packets.

BGP prefixes—A route announcement using the BGP. A prefix is composed of a path of autonomous system numbers, indicating which networks the packet must pass through, and the IP block that is being routed. A BGP prefix would look something like: 701 1239 42 206.24.14.0/24. (The /24 part is referred to as a CIDR mask.) The /24 indicates that there are 24 ones in the netmask for this block starting from the left side. A /24 corresponds to the natural mask 255.255.255.0.

CE router—customer edge router. A router on the border between a VPN provider and a VPN customer that belongs to the customer.

CIDR —classless interdomain routing. A technique supported by BGP4 and based on route aggregation. CIDR allows routers to group routes to reduce the quantity of routing information carried by the core routers. With CIDR, several IP networks appear to networks outside the group as a single, larger entity. With CIDR, IP addresses and their subnet masks are written as four octets, separated by periods, followed by a forward slash and a two-digit number that represents the subnet mask.

Cisco Express Forwarding—An advanced Layer 3 IP switching technology. Cisco Express Forwarding optimizes network performance and scalability for networks with large and dynamic traffic patterns.

community —In SNMP, a logical group of managed devices and NMSs in the same administrative domain.

community name—*See* community string.

community string—A text string that acts as a password and is used to authenticate messages sent between a managed station and a router containing an SNMP agent. The community string is sent in every packet between the manager and the client. Also called a community name.

IETF —Internet Engineering Task Force. A task force consisting of over 80 working groups responsible for developing Internet standards. The IETF operates under the auspices of ISOC. *See also* ISOC.

informs —A type of notification message that is more reliable than a conventional trap notification message, because the informs message notification requires acknowledgment, and a trap notification does not.

ISOC —Internet Society. An international nonprofit organization, founded in 1992, that coordinates the evolution and use of the Internet. In addition, ISOC delegates authority to other groups related to the Internet, such as the IAB. ISOC is headquartered in Reston, Virginia (United States).

label —A short, fixed-length data construct that tells switching nodes how to forward data (packets or cells).

LDP —Label Distribution Protocol. A standard protocol between MPLS-enabled routers that is used for the negotiation of the labels (addresses) used to forward packets.

LFIB —Label Forwarding Information Base. In the Cisco Label Switching system, the data structure for storing information about incoming and outgoing tags (labels) and associated equivalent packets suitable for labeling.

LSR —label switch router. A device that forwards MPLS packets based on the value of a fixed-length label encapsulated in each packet.

MIB —Management Information Base. A database of network management information that is used and maintained by a network management protocol such as SNMP or CMIP. The value of a MIB object can be changed or retrieved using SNMP or CMIP commands, usually through a GUI network management system. MIB objects are organized in a tree structure that includes public (standard) and private (proprietary) branches.

MPLS —Multiprotocol Label Switching. A method for forwarding packets (frames) through a network. It enables routers at the edge of a network to apply labels to packets (frames). ATM switches or existing routers in the network core can switch packets according to the labels with minimal lookup overhead.

MPLS interface—An interface on which MPLS traffic is enabled.

MPLS VPN—Multiprotocol Label Switching Virtual Private Network. An IP network infrastructure delivering private network services over a public infrastructure using a Layer 3 backbone. Using MPLS VPNs in a Cisco IOS network provides the capability to deploy and administer scalable Layer 3 VPN backbone services including applications, data hosting network commerce, and telephony services to business customers.

For an MPLS VPN solution, an MPLS VPN is a set of provider edge routers that are connected by means of a common “backbone” network to supply private IP interconnectivity between two or more customer sites for a given customer. Each VPN has a set of provisioning templates and policies and can span multiple provider administrative domains (PADs).

NMS —network management system. A powerful, well-equipped computer (typically an engineering workstation) that is used by a network administrator to communicate with other devices in the network. An NMS is typically used to manage network resources, gather statistics, and perform a variety of network administration and configuration tasks.

notification —A message sent by an SNMP agent to a network management station, console, or terminal to indicate that a significant event within Cisco IOS software has occurred. *See also* trap.

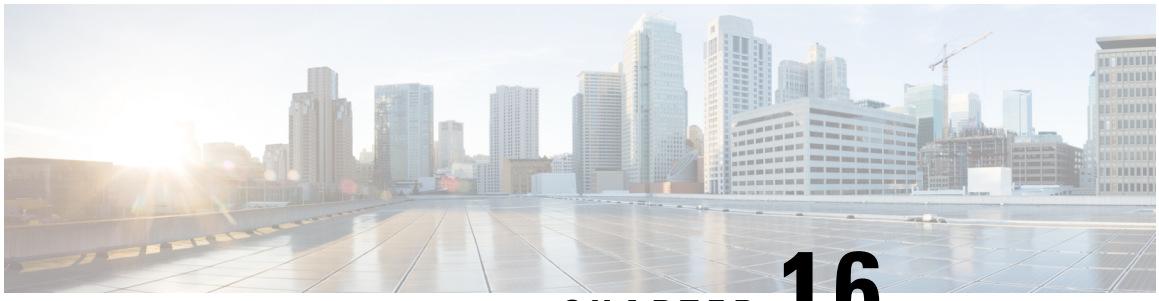
PE router—provider edge router. A router on the border between a VPN provider and a VPN customer that belongs to the provider.

QoS —quality of service. A measure of performance for a transmission system that reflects its transmission quality and service availability.

RIB —Routing Information Base. Also called the routing table.

RT —route target. An extended community attribute that identifies a group of routers and, in each router of that group, a subset of forwarding tables maintained by the router that can be populated with a BGP route carrying that extended community attribute. The RT is a 64-bit value by which Cisco IOS software discriminates routes for route updates in VRFs.

SNMP —Simple Network Management Protocol. The network management protocol used almost exclusively in TCP/IP networks. SNMP provides a means to monitor and control network devices, and to manage configurations, statistics collection, performance, and security. *Seealso* SNMP2.



SNMP2 —SNMP Version 2. Version 2 of the popular network management protocol. SNMP2 supports centralized and distributed network management strategies, and includes improvements in the Structure of Management Information (SMI), protocol operations, management architecture, and security. *See also* SNMP.

trap —A message sent by an SNMP agent to a network management station, console, or terminal, indicating that a significant event occurred. Traps (notifications) are less reliable than inform requests, because the receiver does not send an acknowledgment when it receives a trap. The sender cannot determine if the trap was received. *See also* notification.

VPN —Virtual Private Network. A group of sites that, as the result of a set of administrative policies, are able to communicate with each other over a shared backbone network. A VPN is a secure IP-based network that shares resources on one or more physical networks. A VPN contains geographically dispersed sites that can communicate securely over a shared backbone. *Seealso* MPLS VPN.

VPN ID —A mechanism that identifies a VPN based on RFC 2685. A VPN ID consists of an Organizational Unique Identifier (OUI), a three-octet hex number assigned by the IEEE Registration Authority, and a VPN index, a four-octet hex number, which identifies the VPN within the company.

VRF —VPN routing and forwarding instance. A VRF consists of an IP routing table, a derived forwarding table, a set of interfaces that use the forwarding table, and a set of rules and routing protocols that determine what goes into the forwarding table. In general, a VRF includes the routing information that defines a customer VPN site that is attached to a PE router.

CHAPTER 16

MPLS VPN SNMP Notifications

This document describes the Simple Network Management Protocol (SNMP) agent support in Cisco IOS for Multiprotocol Label Switching (MPLS) Virtual Private Network (VPN) event notifications as implemented in the notifications section of the draft *MPLS/BGP Virtual Private Network Management Information Base Using SMIv2* (*draft-ietf-ppvpn-mpls-vpn-mib-03.txt*).

The MPLS VPN technology allows service providers to offer intranet and extranet VPN services that directly connect their customers' remote offices to a public network with the same security and service levels that a private network offers. The Provider-Provisioned VPN (PPVPN)-MPLS-VPN MIB notifications provide SNMP notification for critical MPLS VPN events.

The MPLS VPN SNMP Notifications feature provides the following benefits:

- A standards-based SNMP interface for retrieving information about critical MPLS VPN events.
- The generation and queuing of notifications that call attention to major changes in the operational status of MPLS VPN enabled interfaces; the forwarding of notification messages to a designated NMS for evaluation and action by network administrators.
- Advanced warning when VPN routing tables are approaching or exceed their capacity.
- Warnings about the reception of illegal labels on a VRF enabled interface. Such receptions may indicate misconfiguration or an attempt to violate security.

- Prerequisites for MPLS VPN SNMP Notifications , on page 329
- Restrictions for MPLS VPN SNMP Notifications , on page 330
- Information About MPLS VPN SNMP Notifications, on page 330
- How to Configure the MPLS VPN SNMP Notifications, on page 333
- Configuration Examples for MPLS VPN SNMP Notifications, on page 338
- Additional References, on page 339
- Feature Information for MPLS VPN SNMP Notifications, on page 340
- Glossary, on page 341

Prerequisites for MPLS VPN SNMP Notifications

The MPLS VPN SNMP Notifications feature requires the following:

- SNMP is installed and enabled on the label switching routers.
- Multiprotocol Label Switching (MPLS) is enabled on the label switching routers.

- Multiprotocol Border Gateway Protocol (BGP) is enabled on the label switching routers.
- Cisco Express Forwarding is enabled on the label switching routers.

Restrictions for MPLS VPN SNMP Notifications

- The MPLS-VPN-MIB agent is not implemented in this release.
- Configuration of the MIB using the SNMP SET command is not supported in this release.
- The retrieval of MPLS-VPN-MIB objects using SNMP GET is not supported in this release.

Information About MPLS VPN SNMP Notifications

Cisco Implementation of MPLS VPN MIB

SNMP agent code operating with the notifications of the MPLS VPN SNMP Notifications feature enables a standardized, SNMP-based approach to monitoring the MPLS VPN MIB notifications that aid in the management of Multiprotocol Label Switching (MPLS) Virtual Private Networks (VPNs) in Cisco software.

The MPLS VPN SNMP Notifications feature is based on the IETF draft specification *draft-ietf-ppvpn-mpls-vpn-mib-02.txt*, which includes notification objects that support MPLS VPN notification events. This IETF draft MIB, which undergoes revisions from time to time, is being evolved toward becoming a standard. Accordingly, the Cisco implementation of features of the MPLS VPN MIB is expected to track the evolution of the IETF draft MIB, and may change accordingly.

Some slight differences between the IETF draft MIB and the actual implementation of MPLS VPNs within Cisco software require some minor translations between the MPLS VPN MIB and the internal data structures of Cisco software. These translations are accomplished by means of the SNMP agent code. Also, while running as a low priority process, the SNMP agent provides a management interface to Cisco software. SNMP adds little overhead on the normal functions of the device.

The SNMP objects defined in the MPLS VPN MIB notifications can be viewed by any standard SNMP utility. The network administrator can retrieve information in the MPLS VPN MIB using standard SNMP **get** and **getnext** operations for SNMP v1, v2, and v3.

All MPLS VPN MIB objects are based on the IETF draft MIB; thus, no specific Cisco SNMP application is required to support the functions and operations pertaining to the MPLS VPN SNMP Notifications feature.

This section contains the following information about the Cisco implementation of the MPLS VPN MIB:

Capabilities Supported by MPLS VPN SNMP Notifications

The following functionality is supported in this release for the MPLS VPN SNMP Notifications feature. This feature provides you with the ability to do the following:

- Create and send notification messages that signal changes when critical Multiprotocol Label Switching (MPLS) Virtual Private Network (VPN) events occur.
- Enable, disable, and configure notification messages for MPLS VPN events by using extensions to existing SNMP CLI commands.

- Specify the IP address of a network management system (NMS) in the operating environment to which notification messages are sent.
- Write notification configurations into nonvolatile memory.

Notification Generation Events for the MPLS VPN MIB

The following notifications of the MPLS VPN MIB are implemented for this release:

- **mplsVrfIfUp**—Sent to an NMS when an interface comes up and is assigned a VPN routing/forwarding table instance (VRF).
- **mplsVrfIfDown**—Generated and sent to the NMS when a VRF is removed from an interface or the interface transitions from an operationally "up" state to a "down" state.

Note For the mplsVrfIfUp or mplsVrfIfDown notifications to be issued on ATM or Frame Relay subinterfaces, you must configure the **snmp-server traps atm subif** command or the **snmp-server traps frame-relay subif** command on the subinterfaces, respectively.

- **mplsNumVrfRouteMidThreshExceeded**—Generated and sent when the middle (warning) threshold is crossed. You can configure this threshold in the CLI by using the following commands:

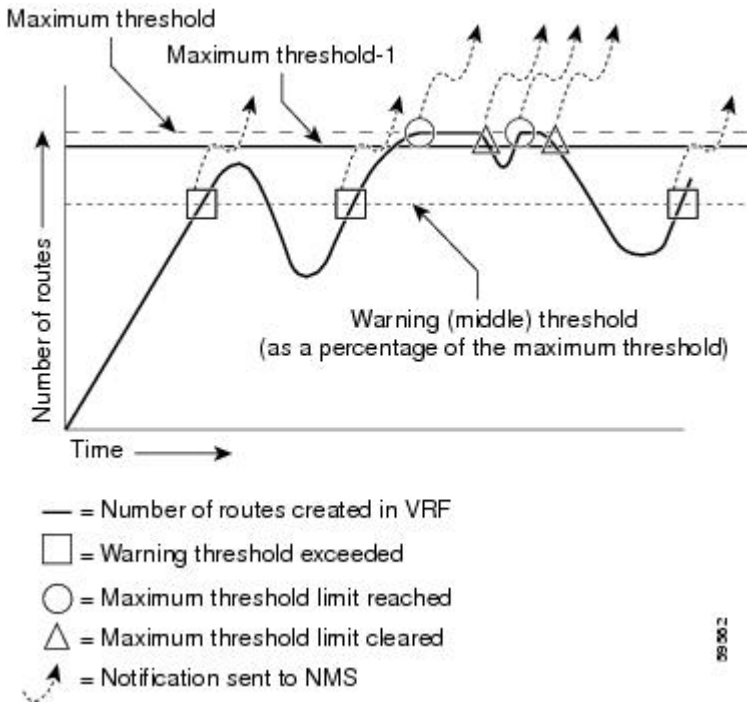
```
Router(config)# ip vrf vrf-name
Router(config-vrf)# maximum routes max-thresh
mid-thresh (% of max)
```

This notification is sent to the NMS only at the time the threshold is exceeded. Whenever the number of routes falls below this threshold and exceeds the threshold again, a notification is sent to the NMS. (See the figure below for a comparison of the warning and maximum thresholds.)

- **mplsNumVrfRouteMaxThreshExceeded**—Generated and sent when you attempt to create a route on a VRF that already contains the maximum number of routes as defined by the following CLI commands:

```
Router(config)# ip vrf vrf-name
Router(config-vrf)# maximum routes max-thresh
mid-thresh (% of max)
```

A trap notification is sent to the NMS when you attempt to exceed the maximum threshold. Another notification is not sent until the number of routes falls below the maximum threshold and reaches the maximum threshold again. (See the figure below for an example of how this notification works and for a comparison of the maximum and warning thresholds.)



Note The **maximum routes** command sets the number of routes for a VRF. You *cannot* exceed the number of routes in the VRF that you set with the **maximum routes** *max-thresh* CLI command. Prior to this implementation of the MPLS-VPN-MIB, you were not notified when this threshold (or the warning threshold) was reached.

- **mplsNumVrfSecIllegalLabelThreshExceeded**—Generated and sent when the amount of illegal labels received on a VRF interface exceeds the threshold *mplsVpnVrfSecIllegalLabelRcvThresh*. This threshold

is defined with a value of 0. Therefore, a notification is sent when the first illegal label is received on a VRF. Labels are considered illegal if they are outside of the valid label range, do not have a Label Forwarding Information Base (LFIB) entry, or the table ID of the message does not match the table ID for the label in the LFIB.

Figure 38: Comparison of Warning and Maximum Thresholds

Notification Specification for MPLS-VPN-MIB

In an SNMPv1 notification, each VPN notification has a generic type identifier and an enterprise-specific type identifier for identifying the notification type.

- The generic type for all VPN notifications is “enterpriseSpecific” as this is not one of the generic notification types defined for SNMP.
- The enterprise-specific type is identified as follows:
  - 1 for *mplsVrfIfUp*
  - 2 for *mplsVrfIfDown*
  - 3 for *mplsNumVrfRouteMidThreshExceeded*
  - 4 for *mplsNumVrfRouteMaxThreshExceeded*
  - 5 for *mplsNumVrfSecIllegalLabelThreshExceeded*

In SNMPv2, the notification type is identified by an **SnmpTrapOID** varbind (variable binding consisting of an object identifier (OID) type and value) included within the notification message.

Each notification also contains two additional objects from the MPLS-VPN-MIB. These objects provide additional information about the event, as follows:

- The VRF interface up/down notifications provide additional variables--*mplsVpnInterfaceConfIndex* and *mplsVpnVrfName*-- in the notification. These variables describe the SNMP interface index and the VRF name, respectively.
- The mid and max threshold notifications include the *mplsVpnVrfName* variable (VRF name) as well as the *mplsVpnVrfPerfCurrNumRoutes* variable that indicates the current number of routes within the VRF.
- The illegal label notification includes the *mplsVpnVrfName* variable (VRF name) and the *mplsVpnVrfSecIllegalLabelViolations* variable that maintains the current count of illegal labels on a VPN.

Monitoring the MPLS VPN SNMP Notifications

When MPLS-VPN-MIB notifications are enabled, notification messages relating to specific Multiprotocol Label Switching (MPLS) Virtual Private Network (VPN) events within Cisco software are generated and sent to a specified network management system (NMS) in the network. Any utility that supports SNMPv1 or SNMPv2 notifications can receive notification messages.

To monitor MPLS-VPN-MIB notification messages, log in to an NMS that supports a utility that displays SNMP notifications, and start the display utility.

How to Configure the MPLS VPN SNMP Notifications

Configuring an SNMP Community

An SNMP community string defines the relationship between the SNMP manager and the agent. The community string acts like a password to regulate access to the agent on the device.

Perform this task to configure an SNMP community.

SUMMARY STEPS

1. **enable**
2. **show running-config**
3. **configure terminal**
4. **snmp-server community** *string* [**view** *view-name*] [**ro** | **rw**] [*acl-number*]
5. **do copy running-config startup-config**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.

	Command or Action	Purpose
Step 2	**show running-config** **Example:** `Device# show running-config`	Displays the running configuration to determine if an SNMP agent is already running. If no SNMP information is displayed, continue with the next step. If any SNMP information is displayed, you can modify the information or change it as needed.
Step 3	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 4	**snmp-server community** *string* [**view** *view-name*] [**ro** | **rw**] [*acl-number*] **Example:** `Device(config)# snmp-server community comaccess ro`	Sets up the community access string to permit access to the Simple Network Management Protocol (SNMP). • The *string* argument acts like a password and permits access to the SNMP protocol. • The **view***view-name* keyword and argument specifies the name of a previously defined view. The view defines the objects available to the community. • The **ro** keyword specifies read-only access. Authorized management stations are only able to retrieve MIB objects. • The **rw** keyword specifies read-write access. Authorized management stations are able to both retrieve and modify MIB objects. • The *acl-number* argument is an integer from 1 to 99 that specifies an access list of IP addresses that are allowed to use the community string to gain access to the SNMP agent.
Step 5	**do copy running-config startup-config** **Example:** `Device(config)# do copy running-config startup-config`	Saves the modified configuration to nonvolatile memory (NVRAM) as the startup configuration file. (The **do** command allows you to perform Exec level commands in configuration mode.)

Configuring the Device to Send SNMP Traps

Perform this task to configure the device to send traps to a host.

The **snmp-server host** command specifies which hosts receive traps. The **snmp-server enable traps** command globally enables the trap production mechanism for the specified traps.

Note Although you can set the *community-string* argument using the **snmp-server host** command by itself, we recommend you define this string using the **snmp-server community** command prior to using the **snmp-server host** command.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server host** *host-addr* [**traps** | **informs**] [**version** {**1** | **2c** | **3** [**auth** | **noauth** | **priv**]}] *community-string* [**udp-port** *port*] [*notification-type*]
4. Do one of the following:
   - **snmp-server enable traps atm** [**pvc** | **subif**]
   - **snmp-server enable traps frame-relay** [**subif**]
5. **snmp-server enable traps mpls vpn**
6. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**snmp-server host** *host-addr* [**traps** | **informs**] [**version** {**1** | **2c** | **3** [**auth** | **noauth** | **priv**]}] *community-string* [**udp-port** *port*] [*notification-type*] **Example:** `Device(config)# snmp-server host 172.20.2.160 traps comaccess mpls-vpn`	Specifies the recipient of an SNMP notification operation. • The *host-addr* argument specifies the name or Internet address of the host (the targeted recipient). • The **traps** keyword sends SNMP traps to this host. This is the default. • The **informs** keyword sends SNMP informs to this host. • The **version** keyword specifies the version of the SNMP used to send the traps. Version 3 is the most secure model, as it allows packet encryption with the

	Command or Action	Purpose
		priv keyword. If you use the **version** keyword, you must specify one of the following: • **1**—SNMPv1. This option is not available with informs. • **2c**—SNMPv2C. • **3**—SNMPv3. The following three optional keywords can follow the **version 3** keyword (**auth**, **noauth**, **priv**). • The *community-string* argument is a password-like community string sent with the notification operation. • The **udp-port** *port* keyword and argument names the UDP port of the host to use. The default is 162. • The *notification-type* argument specifies the type of notification to be sent to the host. If no type is specified, all notifications are sent. MPLS VPN notifications are specified with the **mpls-vpn** keyword.

Step 4	Do one of the following:
	• **snmp-server enable traps atm** [**pvc** | **subif**]
	• **snmp-server enable traps frame-relay** [**subif**]
	Example:
	`Device(config)# snmp-server enable traps atm subif`
	Example:
	`Device(config)# snmp-server enable traps frame-relay subif`
		(For ATM subinterfaces only) Enables the sending of ATM SNMP notifications.
		• The **pvc** keyword enables SNMP ATM permanent virtual circuit (PVC) traps.
		• The **subif** keyword enables SNMP ATM subinterface traps.
		or
		(For Frame Relay subinterfaces only) Enables Frame Relay DLCI link status SNMP notifications.
		• The **subif** keyword enables SNMP Frame Relay subinterface traps.
		Note
		For mplsVrfIfUp or mplsVrfIfDown notifications to be issued on ATM or Frame Relay subinterfaces, you must configure the appropriate **snmp-server enable traps** command with the **subif** keyword.

Step 5	**snmp-server enable traps mpls vpn** **Example:** `Device(config)# snmp-server enable traps mpls vpn vrf-up vrf-down`	Enables the device to send MPLS VPN SNMP notifications.
Step 6	**end** **Example:**	(Optional) Returns to user EXEC mode.

	Command or Action	Purpose
	`Device(config)# end`	

Configuring Threshold Values for MPLS VPN SNMP Notifications

Perform this task to configure threshold values for MPLS VPN SNMP notifications.

The **mplsNumVrfRouteMidThreshExceeded** notification event is generated and sent when the middle (warning) threshold is crossed. You can configure this threshold in the CLI by using the **maximum routes** command in VRF configuration mode. This notification is sent to the NMS only at the time the threshold is exceeded. Whenever the number of routes falls below this threshold and exceeds the threshold again, a notification is sent to the NMS.

The **mplsNumVrfRouteMaxThreshExceeded** notification event is generated and sent when you attempt to create a route on a VRF that already contains the maximum number of routes as defined by the **maximum routes** command in VRF configuration mode. A trap notification is sent to the NMS when you attempt to exceed the maximum threshold. Another notification is not sent until the number of routes falls below the maximum threshold and reaches the maximum threshold again.

(See the figure above for an example of how this notification works and for a comparison of the maximum and warning thresholds.)

Note The **maximum routes** command sets the number of routes for a VRF. You *cannot* exceed the number of routes in the VRF that you set with the **maximum routes** *max-thresh* CLI command. Prior to this implementation of the MPLS-VPN-MIB, you were not notified when this threshold (or the warning threshold) was reached.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip vrf** *vrf-name*
4. **maximum routes** *limit* {*warn-threshold* | **warning-only**}
5. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.

	Command or Action	Purpose
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**ip vrf** *vrf-name* **Example:** `Device(config)# ip vrf vpn1`	Configures a VRF routing table. • The *vrf-name* argument specifies the name assigned to a VRF.
Step 4	**maximum routes** *limit* {*warn-threshold* | **warning-only**} **Example:** `Device(config-vrf)# maximum routes 10000 80`	Limits the maximum number of routes in a VRF to prevent a PE device from importing too many routes. • The *limit* argument specifies the maximum number of routes allowed in a VRF. You may select from 1 to 4,294,967,295 routes to be allowed in a VRF. • The *warn-threshold* argument specifies when the threshold limit is reached and routes are rejected. The threshold limit is a percentage of the *limit* specified, from 1 to 100 percent. • The **warning-only** keyword specifies that a SYSLOG error message is issued when the maximum number of routes allowed for a VRF exceeds the threshold. However, additional routes are still allowed.
Step 5	**end** **Example:** `Device(config-vrf)# end`	(Optional) Returns to privileged EXEC mode.

Configuration Examples for MPLS VPN SNMP Notifications

Example: Configuring the Community

The following example shows enabling a simple SNMP community group. This configuration permits any SNMP client to access all MPLS-VPN-MIB objects with read-only access using the community string comaccess.

```
Device# configure terminal
Device(config)# snmp-server community comaccess ro
```

Verify that the SNMP master agent is enabled for the MPLS VPN SNMP Notifications feature:

```
Device# show running-config | include snmp-server
Building configuration...
```

```
....
snmp-server community comaccess RO
....
```

Note If you do not see any "snmp-server" statements, SNMP has not been enabled on the device.

Example: Configuring the Device to Send SNMP Traps

The following example shows you how to enable the device to send MPLS VPN notifications to host 172.20.2.160 using the comaccess community string if a VRF transitions from a down state to an up state or from an up state to a down state.

```
Device# configure terminal
Device(config)# snmp-server host 172.20.2.160 traps comaccess mpls-vpn
Device(config)# snmp-server enable traps mpls vpn vrf-up vrf-down
```

Example: Configuring Threshold Values for MPLS VPN SNMP Notifications

The following example shows how to set a maximum threshold or 10000 routes and a warning threshold that is 80 percent of the maximum threshold for a VRF named vpn1 on a device:

```
Device(config)# ip vrf vpn1
Device(config)# maximum routes 10000 80
```

Feature Information for MPLS VPN SNMP Notifications

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 56: Feature Information for MPLS VPN SNMP Notifications

Feature Name	Releases	Feature Information
MPLS VPN SNMP Notifications	12.0(21)ST 12.0(22)S 12.2(13)T	The MPLS VPN SNMP Notifications feature provides Simple Network Management Protocol (SNMP) agent support in Cisco software for Multiprotocol Label Switching (MPLS) Virtual Private Network (VPN) event notifications. In Cisco IOS Release 12.0(21)ST, this feature was introduced. In Cisco IOS Release 12.0(22)S, this feature was integrated. In Cisco IOS Release 12.2(13)T, this feature was integrated. Supported platforms: • Cisco IOS 12.0 S and ST Releases: Cisco 7500 series, Cisco 12000 series. • Cisco IOS 12.2 T Releases: Cisco 3620, Cisco 3640, Cisco 7200 series, Cisco 7500 series, Cisco MGX 8850-RPM. **Note** In Cisco IOS Releases 12.0(21)ST and 12.0(22)S, the PPVPN MPLS-VPN-MIB notifications are described in the *MPLS VPN--SNMP MIB Support* feature module. The following commands were introduced or modified: **snmp-server enable traps mpls vpn**, **snmp-server host**.

Glossary

ASN.1—Abstract Syntax Notation One. OSI language for describing data types independent of particular computer structures and representation techniques. Described by ISO International Standard 8824.

BGP—Border Gateway Protocol. The exterior Border Gateway Protocol used to exchange routing information between routers in separate autonomous systems. BGP uses Transmission Control Protocol (TCP). Because TCP is a reliable protocol, BGP does not experience problems with dropped or fragmented data packets.

CEF—Cisco Express Forwarding. An advanced Layer 3 IP switching technology. CEF optimizes network performance and scalability for networks with large and dynamic traffic patterns.

CE device—customer edge router. A router on the border between a VPN provider and a VPN customer that belongs to the customer.

community—In SNMP, a logical group of managed devices and NMSs in the same administrative domain.

community name—*See* community string.

community string—Text string that acts as a password and is used to authenticate messages sent between a managed station and a router containing an SNMP agent. The community string is sent in every packet between the manager and the client. Also called a community name.

IETF—Internet Engineering Task Force. Task force consisting of over 80 working groups responsible for developing Internet standards. The IETF operates under the auspices of ISOC. *See also* ISOC.

informs—A type of notification message that is more reliable than a conventional trap notification message, because the informs message notification requires acknowledgment, and a trap notification does not.

ISOC—Internet Society. International nonprofit organization, founded in 1992, that coordinates the evolution and use of the Internet. In addition, ISOC delegates authority to other groups related to the Internet, such as the IAB. ISOC is headquartered in Reston, Virginia (United States).

label—A short, fixed-length data construct that tells switching nodes how to forward data (packets or cells).

label distribution protocol—*See* LDP.

label forwarding information base—*See* LFIB.

label switch router—*See* LSR.

LDP —label distribution protocol. A standard protocol between MPLS-enabled routers that is used for the negotiation of the labels (addresses) used to forward packets.

LFIB —label forwarding information base. In the Cisco Label Switching system, the data structure for storing information about incoming and outgoing tags (labels) and associated equivalent packets suitable for labeling.

LSR —label switch router. A device that forwards MPLS packets based on the value of a fixed-length label encapsulated in each packet.

MIB —Management Information Base. Database of network management information that is used and maintained by a network management protocol such as SNMP or CMIP. The value of a MIB object can be changed or retrieved using SNMP or CMIP commands, usually through a GUI network management system. MIB objects are organized in a tree structure that includes public (standard) and private (proprietary) branches.

MPLS —Multiprotocol Label Switching. A method for forwarding packets (frames) through a network. It enables routers at the edge of a network to apply labels to packets (frames). ATM switches or existing routers in the network core can switch packets according to the labels with minimal lookup overhead.

MPLS interface—An interface on which MPLS traffic is enabled.

MPLS VPN—Multiprotocol Label Switching Virtual Private Network. Using MPLS VPNs in a Cisco network provide the capability to deploy and administer scalable Layer 3 VPN backbone services including applications, data hosting network commerce, and telephony services, to business customers. A VPN is a secure IP-based network that shares resources on one or more physical networks. A VPN contains geographically dispersed sites that can communicate securely over a shared backbone.

For an MPLS VPN Solution, an MPLS VPN is a set of PEs that are connected by means of a common "backbone" network to supply private IP interconnectivity between two or more customer sites for a given customer. Each VPN has a set of provisioning templates and policies and can span multiple provider administrative domains (PADs).

Multiprotocol label Switching—*See* MPLS.

notification —A message sent by an SNMP agent to a network management station, console, or terminal to indicate that a significant event within Cisco software has occurred. *See also* trap.

NMS —network management system. A powerful, well-equipped computer (typically an engineering workstation) that is used by a network administrator to communicate with other devices in the network. An NMS is typically used to manage network resources, gather statistics, and perform a variety of network administration and configuration tasks.

PE device—provider edge router. A router on the border between a VPN provider and a VPN customer that belongs to the provider.

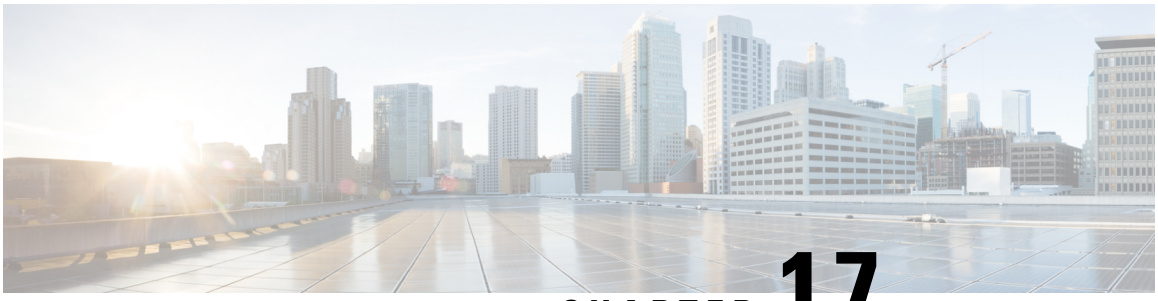
PPVPN —Provider-Provisioned VPN. The name of the IETF working group that is developing the PPVPN-MPLS-VPN MIB (MPLS-VPN-MIB).

QoS —quality of service. Measure of performance for a transmission system that reflects its transmission quality and service availability.

RSVP —Resource Reservation Protocol. Protocol for reserving network resources to provide Quality of Service guarantees to application flows.

Simple Network Management Protocol—*See* SNMP.

SNMP —Simple Network Management Protocol. Network management protocol used almost exclusively in TCP/IP networks. SNMP provides a means to monitor and control network devices, and to manage configurations, statistics collection, performance, and security. See *also* SNMP2.



SNMP2 —SNMP Version 2. Version 2 of the popular network management protocol. SNMP2 supports centralized as well as distributed network management strategies, and includes improvements in the SMI, protocol operations, management architecture, and security. *See also* SNMP.

traffic engineering—The techniques and processes used to cause routed traffic to travel through the network on a path other than the one that would have been chosen if standard routing methods had been used.

trap —A message sent by an SNMP agent to a network management station, console, or terminal, indicating that a significant event occurred. Traps (notifications) are less reliable than inform requests, because the receiver does not send an acknowledgment when it receives a trap. The sender cannot determine if the trap was received. *See also* notification.

VPN —Virtual Private Network. A group of sites that, as the result of a set of administrative policies, are able to communicate with each other over a shared backbone network. *See* MPLS VPN.

VRF —VPN routing/forwarding instance. A VRF consists of an IP routing table, a derived forwarding table, a set of interfaces that use the forwarding table, and a set of rules and routing protocols that determine what goes into the forwarding table. In general, a VRF includes the routing information that defines a customer VPN site that is attached to a PE device.

CHAPTER 17

Pseudowire Emulation Edge-to-Edge MIBs

The Pseudowire Emulation Edge-to-Edge MIBs for Ethernet, Frame Relay, and ATM Services feature provides Simple Network Management Protocol (SNMP) support within an Any Transport over Multiprotocol Label Switching (AToM) infrastructure emulating Ethernet, Frame Relay, and ATM services over packet switched networks (PSNs). The Pseudowire Emulation Edge-to-Edge (PWE3) MIBs are the following:

- CISCO-IETF-PW-MIB (PW-MIB)
- CISCO-IETF-PW-MPLS-MIB (PW-MPLS-MIB)
- CISCO-IETF-PW-ENET-MIB (PW-ENET-MIB)
- CISCO-IETF-PW-FR-MIB (PW-FR-MIB)
- CISCO-IETF-PW-ATM-MIB (PW-ATM-MIB)

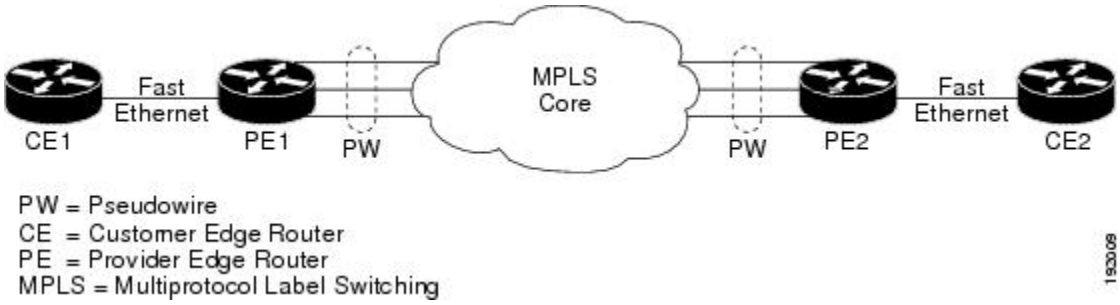
- Prerequisites for Pseudowire Emulation Edge-to-Edge MIBs, on page 345
- Restrictions for Pseudowire Emulation Edge-to-Edge MIBs, on page 346
- Information About Pseudowire Emulation Edge-to-Edge MIBs, on page 346
- How to Configure Pseudowire Emulation Edge-to-Edge MIBs, on page 363
- Configuration Examples for the Pseudowire Emulation Edge-to-Edge MIBs, on page 366
- Additional References, on page 367
- Feature Information for Pseudowire Emulation Edge-to-Edge MIBs, on page 368
- Glossary, on page 369

Prerequisites for Pseudowire Emulation Edge-to-Edge MIBs

- SNMP must be enabled on the label switch routers (LSRs).
- MPLS must be enabled on the LSRs.
- Pseudowires must be configured with Ethernet, Frame Relay, or ATM access circuits. (For more detailed information, see the “Any Transport over MPLS” module.

Restrictions for Pseudowire Emulation Edge-to-Edge MIBs

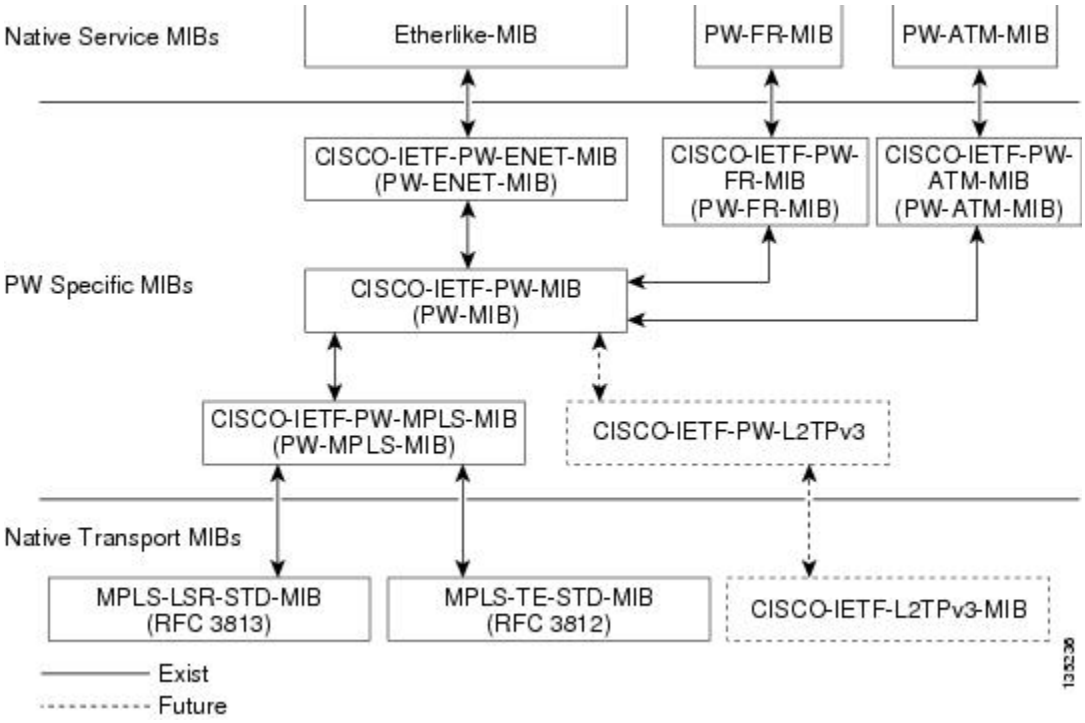
The PWE3 MIBs are limited to read-only (RO) permission for MIB objects except for the cpwVcUp and cpwVcDown notification enable object, cpwVcUpDownNotifEnable, which has been extended to be writable by the SNMP agent.



- The following tables in the PW-MIB are not supported:
  - cpwVcPerfCurrentTable
  - cpwVcPerfIntervalTable
- The following objects in the PW-MPLS-MIB are not supported:
  - cpwVcMplsOutboundIndexNext
  - cpwVcMplsInboundIndexNext
- The following tables in the PW-ENET-MIB are not supported:
  - cpwVcEnetMplsPriMappingTable
  - cpwVcEnetStatsTable
- The following table in the PW-FR-MIB is not supported:
  - cpwVcFrPMTable
- The PW-ATM-MIB does not support a high-capacity cell counter per virtual path (VP) or cells per port.
- The PW-ATM-MIB virtual path identifier (VPI)/virtual channel identifier (VCI) value for port mode cell relay is 0.
- The PW-ATM-MIB VP cell relay VCI value is 0.
- The PW-ATM-MIB VP does not support ATM adaptation layer 5 (AAL5); therefore, all packet counters are invalid.

Note This feature is not supported over Ethernet, Frame Relay, and ATM in all releases. For more detailed information, see the "Feature Information for Pseudowire Emulation Edge-to-Edge MIBs for Ethernet Frame Relay and ATM Services" section.

Information About Pseudowire Emulation Edge-to-Edge MIBs



The Function of a Pseudowire in the PWE3 MIBs

A pseudowire is a point-to-point connection between pairs of provider edge (PE) routers (as shown in the figure below). Its primary function is to emulate services like Ethernet over an underlying core MPLS network through encapsulation into a common MPLS format. By encapsulating services into a common MPLS format, a pseudowire allows carriers to converge their services to an MPLS network.

PWE3 MIBs Architecture

The PWE3 MIBs architecture shown in the figure below categorizes three groups of MIBs that, when used together, provide the complete emulated service; the native transport, which carries the service across the core network; and the relationship between the two.

The architecture is modular in that once deployed, new emulated service MIB modules or additional transport MIB modules "plug in" to or extend the existing infrastructure rather than require a new and unique one. This allows you to build management applications without the concern of a new service requiring the deployment of a completely different management strategy. Because the architecture is a generalized association mechanism between existing service and transport MIB modules, native MIB modules work in the absence of the associated PWE3-specific MIBs. The advantage is that if a PWE3-specific MIB has not yet been deployed in Cisco software, which associates a service or transport with pseudowires, these MIB modules can still be queried. However, the only drawback is that the associations with the pseudowires are absent.

Components and Functions of the PWE3 MIBs

The PWE3 MIBs have the following components and functions:

- PW-MIB (the pseudowire MIB)

This MIB binds the PW-MPLS-MIB and the PW-ENET-MIB together, and provides status of the pseudowire emulation and statistics and configuration information. The PW-MIB also defines the notifications for pseudowire fault and event monitoring.

- PW-MPLS-MIB (the pseudowire MPLS-MIB)

This MIB contains managed objects that can be used by a network manager to monitor pseudowire emulation MPLS services, such as MPLS-traffic engineering (TE)-PSN and MPLS-non-TE-PSN.

This MIB shows the following:

-
  - Cross-connect (XC) indexes for virtual circuits (VCs) that are Label Distribution Protocol (LDP)-signaled and have a preferred path that is not set to an MPLS TE tunnel.
  - Tunnel indexes for VCs with a preferred path set to a TE tunnel and an output interface that is a TE tunnel.

- PW-ENET-MIB (the pseudowire Ethernet services MIB)

This MIB contains managed objects that can be used by a network manager to monitor pseudowire emulation Ethernet services.

- PW-FR-MIB (the pseudowire Frame Relay services MIB)

This MIB contains managed objects that can be used by a network manager to monitor pseudowire emulation Frame Relay services.

This MIB uses a Frame Relay over pseudowire (FRoPW) connection that consists of two segments: the Frame Relay segment and the pseudowire segment. The PW-FR-MIB provides hooks to those segments. The PW MIB contains information about the pseudowire segment, and the PW-FR-MIB contains information about the Frame Relay segment.

The PW-FR-MIB is defined at the Pseudowire Service Emulation Layer and resides on top of the generic PW-MIB as shown in the figure above. Therefore, the PW-FR-MIB is highly dependent on the existence and the service provided by the PW-MIB. In addition, an existing PW-FR connection entry must associate with an existing VC entry in the PW-MIB.

The PW-FR-MIB and the generic PW-MIB are logically tied by the PW VC Index, which is an internal index defined to support the PW-MIB. Each PW VC index uniquely maps into an existing VC entry in the PW-MIB and the PW-FR-MIB.

- PW-ATM-MIB (the pseudowire ATM services MIB)

This MIB contains managed objects that can be used by a network manager to monitor pseudowire emulation ATM services.

This MIB uses an ATM over pseudowire (ATMoPW) connection that consists of two segments: the ATM segment and the pseudowire segment. The PW-ATM-MIB provides hooks to those segments. The PW MIB contains information about the pseudowire segment, and the PW-ATM-MIB contains information about the ATM segment called the attachment circuit.

The PW-ATM-MIB is defined at the Pseudowire Service Emulation Layer and resides on top of the generic PW-MIB as shown in the figure above. Therefore, the PW-ATM-MIB is highly dependent on the existence and the service provided by the PW-MIB. In addition, an existing PW-ATM connection entry must associate with an existing VC entry in the PW-MIB.

The PW-ATM-MIB and the generic PW-MIB are logically tied by the PW VC Index, which is an internal index defined to support the PW-MIB. Each PW VC index uniquely maps into an existing VC entry in the PW-MIB and the PW-ATM-MIB.

Tables in the PW-MIB

The PW-MIB consists of the following tables:

- cpwVcTable -- Contains high-level generic parameters related to VC creation. This table is implemented as read only and is indexed by the cpwVcIndex, which uniquely identifies a singular connection. A row in this table represents an emulated virtual connection. This table is used for all VC types.
- cpwVcPerfTotalTable -- Provides per-VC performance information from the VC start time. This table is indexed by the cpwVcIndex.
- cpwVcIdMappingTable -- Provides reverse mapping of the existing VCs based on VC type and VC ID ordering. This table is typically useful for element manager software (EMS) ordered query of existing VCs. This table is indexed by cpwVcIdMappingVcType, cpwVcIdMappingVcID, cpwVcIdMappingPeerAddrType, and cpwVcIdMappingPeerAddr. This table is implemented as read only.
- cpwVcPeerMappingTable -- Provides reverse mapping of the existing VCs based on VC type and VC ID ordering. This table is typically useful for EMS ordered query of existing VCs. This table is indexed by cpwVcPeerMappingPeerAddrType, cpwVcPeerMappingPeerAddr, cpwVcPeerMappingVcType, and cpwVcPeerMappingVcID. This table is implemented as read only.

cpwVcTable

The table below lists the cpwVcTable objects and their descriptions.

Table 57: cpwVcTable Objects and Descriptions

Objects	Description
cpwVcType	Indicates the service to be carried over this VC. This is circuit type information.
cpwVcOwner	Set by the operator to indicate the protocol responsible for establishing this VC. Values are the following: • manual(1)--Used when no maintenance protocol (PW signaling) is needed to set up the VC, such as configuration of entries in the VC tables including VC labels, and so forth. • maintenanceProtocol(2)--Used for standard signaling of the VC for the specific PSN; for example, LDP for MPLS PSN as specified in draft-martini-l2circuit-trans-mpls or the Layer 2 Tunneling Protocol (L2TP). • other(3)--Used for all other types of signaling.

Objects	Description
cpwVcPsnType	Set by the operator to indicate the PSN type on which this VC is carried. Based on this object, the relevant PSN table entries are created in the PSN-specific MIB modules. For example, if mpls(1) is defined, the agent creates an entry in the cpwVcMplsTable, which further defines the MPLS PSN configuration.
cpwVcSetUpPriority	Defines the relative setup priority of the VC in a lowest-to-highest manner, where 0 is the highest priority. This value is significant if there are competing resources between VCs and the implementation supports this feature. Because this is not implemented in AToM, the value of 0 is used.
cpwVcHoldingPriority	Defines the relative holding priority of the VC in a lowest-to-highest manner, where 0 is the highest priority. This value is significant if there are competing resources between VCs and the implementation supports this feature. Because this is not implemented in AToM, the value of 0 is used.
cpwVcInboundMode	Enables greater security for implementations that use per-platform VC label space. Modes are the following: • strict(1) • loose(2) In strict mode, packets coming from the PSN are accepted only from tunnels that are associated to the same VC via the inbound tunnel table in the case of MPLS, or as identified by the source IP address in the case of L2TP or IP PSN. The entries in the inbound tunnel table are either explicitly configured or implicitly known by the maintenance protocol used for VC setup. If such association is not known, not configured, or not desired, loose mode should be configured, and the node should accept the packet based on the VC label only, regardless of the outer tunnel used to carry the VC.
cpwVcPeerAddrType	Denotes the address type of the peer node maintenance protocol (signaling) address if the PW maintenance protocol is used for the VC creation. It should be set to unknown if the PW maintenance protocol is not used; for example, cpwVcOwner is set to manual.
cpwVcPeerAddr	Contains the value of the peer node address of the PW maintenance protocol entity. This object should contain a value of 0 if not relevant (manual configuration of the VC).
cpwVcID	Use in the outgoing VC ID field within the VC forward equivalence class (FEC) element with LDP signaling or the PW ID attribute-value (AV) pair for the L2TP.
cpwVcLocalGroupID	Use in the Group ID field sent to the peer PW within the maintenance protocol for VC setup; 0 if not used.
cpwVcControlWord	Defines if the control word is sent with each packet by the local node.

Objects	Description
cpwVcLocalIfMtu	If not = 0, the optional IfMtu object in the maintenance protocol is sent with this value, representing the locally supported maximum transmission unit (MTU) size over the interface (or the virtual interface) associated with the VC.
cpwVcLocalIfString	Each VC is associated to an interface (or a virtual interface) in the ifTable of the node as part of the service configuration. This object defines if the maintenance protocol sends the interface's name as it appears in the ifTable in the name object as part of the maintenance protocol. If this object is set to false, the optional element is not sent.
cpwVcRemoteGroupID	Obtained from the Group ID field as received via the maintenance protocol used for VC setup; 0 if not used. The value of 0xFFFF is used if the object is not defined by the VC maintenance protocol.
cpwVcRemoteControlWord	If the maintenance protocol is used for VC establishment, this parameter indicates the received status of the control word usage; that is, if packets are received with the control word or not. The value of notYetKnown is used while the maintenance protocol has not yet received the indication from the remote node. In a manual configuration of the VC, this parameter indicates to the local node the expected encapsulation for the received packets.
cpwVcRemoteIfMtu	The remote interface MTU as received from the remote node via the maintenance protocol. This object should be 0 if this parameter is not available or not used.
cpwVcRemoteIfString	Indicates the interface description string as received by the maintenance protocol; it must be a NULL string if not applicable or not known yet.
cpwVcOutboundVcLabel	The VC label used in the outbound direction toward the PSN. This object may be set up manually if the owner is manual; otherwise, it is automatic. Examples; for MPLS PSN, the label represents the 20 bits of the VC tag; for L2TP, it represents the 32 bits of the session ID. If the label is not yet known (signaling in process), the object should return a value of 0xFFFF.
cpwVcInboundVcLabel	The VC label used in the inbound direction for packets received from the PSN. This object may be set up manually if the owner is manual; otherwise, it is automatic. Examples; for MPLS PSN, the label represents the 20 bits of VC tag; for L2TP, the label represents the 32 bits of the session ID. If the label is not yet known (signaling in process), the object should return a value of 0xFFFF.
cpwVcName	The canonical name assigned to the VC.
cpwVcDescr	A textual string containing information about the VC. If there is no description, this object contains a 0 length string.
cpwVcCreateTime	System time when this VC was created.
cpwVcUpTime	Number of consecutive ticks that this VC has been up in both directions together. (Up is observed in cpwVcOperStatus.)
cpwVcAdminStatus	The desired operational status of this VC.

Objects	Description
cpwVcOperStatus	Indicates the actual combined operational status of this VC. This object is up if both cpwVcInboundOperStatus and cpwVcOutboundOperStatus are in the up state. For all other values, if the VCs in both directions are of the same value, this object reflects that value; otherwise, it is set to the more severe status of the two. The order of severity from most severe to less severe is as follows: unknown, notPresent, down, lowerLayerDown, dormant, testing, and up. The operator can consult the direction of OperStatus for fault isolation.
cpwVcInboundOperStatus	Indicates the actual operational status of this VC in the inbound direction. Values are the following: • up--The VC is established and ready to pass packets. • down--PW signaling has not yet finished or indications available at the service level show that the VC is not passing packets. • testing--AdminStatus at the VC level is set to test. • dormant--The VC is not available because the required resources are occupied by higher priority VCs. • notPresent--Some component needed for the setup of the VC is missing. • lowerLayerDown--The underlying PSN is not in OperStatus up.
cpwVcOutboundOperStatus	Indicates the actual operational status of this VC in the outbound direction. Values are the following: • up--The VC is established and ready to pass packets. • down--PW signaling has not yet finished or indications available at the service level show that the VC is not passing packets. • testing--AdminStatus at the VC level is set to test. • dormant--The VC is not available because the required resources are occupied by higher priority VCs. • notPresent--Some component needed for the setup of the VC is missing. • lowerLayerDown--The underlying PSN is not in OperStatus up.
cpwVcTimeElapsed	The number of seconds, including partial seconds, that have elapsed since the beginning of the current measurement period. If, for some reason, such as an adjustment in the system's time-of-day clock, and the current interval exceeds the maximum value, the agent returns the maximum value. Because cpwVcPerfIntervalTable is not implemented, this is 0.

Objects	Description
cpwVcValidIntervals	The number of previous 15-minute intervals for which data was collected. An agent with PW capability must be capable of supporting at least *x*intervals. The minimum value of *x*is 4; the default of *x*is 32, and the maximum value of *x*is 96. The value is *x*unless the measurement was (re)started within the last *x**15 minutes, in which case the value will be the number of complete 15-minute intervals; for example, in the case where the agent is a proxy, some intervals may be unavailable. In this case, this interval is the maximum interval number for which data is available. This interval is set to 0.
cpwVcRowStatus	A read-only implementation that is always active(1). It is used for creating, modifying, and deleting.
cpwVcStorageType	The storage type for this object is a read-only implementation that is always volatile(2).

cpwVcPerfTotalTable

The table below lists the cpwVcPerfTotalTable objects and their descriptions.

Table 58: cpwVcPerfTotalTable Objects and Descriptions

Objects	Description
cpwVcPerfTotalInHCPackets	High-capacity counter for the number of packets received by the VC from the PSN.
cpwVcPerfTotalInHCBytes	High-capacity counter for the number of bytes received by the VC from the PSN.
cpwVcPerfTotalOutHCPackets	High-capacity counter for the number of packets forwarded by the VC to the PSN.
cpwVcPerfTotalOutHCBytes	High-capacity counter for the number of bytes forwarded by the VC (to the PSN).
cpwVcPerfTotalDiscontinuityTime	The value of sysUpTime on the most recent occasion when one or more of this object's counters suffered a discontinuity. The relevant counters are the specific instances of any Counter32 or Counter64. If no such discontinuities have occurred since the last reinitialization of the local management subsystem, this object contains a 0 value.

cpwVcIdMappingTable

The table below lists the cpwVcIdMappingTable objects and their descriptions.

Table 59: cpwVcIdMappingTable Objects and Descriptions

Objects	Description
cpwVcIdMappingVcType	The VC type (indicates the service) of this VC.

Objects	Description
cpwVcIdMappingVcID	The VC ID of this VC; 0 if the VC is configured manually.
cpwVcIdMappingPeerAddrType	IP address type of the peer node.
cpwVcIdMappingPeerAddr	IP address of the peer node.
cpwVcIdMappingVcIndex	The value that represents the VC in the cpwVcTable.

cpwVcPeerMappingTable

The table below lists the cpwVcPeerMappingTable objects and their descriptions.

Table 60: cpwVcPeerMappingTable Objects and Descriptions

Objects	Description
cpwVcPeerMappingPeerAddrType	IP address type of the peer node.
cpwVcPeerMappingPeerAddr	IP address of the peer node.
cpwVcPeerMappingVcType	The VC type (indicates the service) of this VC.
cpwVcPeerMappingVcID	The VC ID of this VC; 0 if the VC is configured manually.
cpwVcPeerMappingVcIndex	The value that represents the VC in the cpwVcTable.

Tables in the PW-MPLS-MIB

The PW-MPLS-MIB consists of the following tables:

- cpwVcMplsTable -- Specifies information for the VC to be carried over an MPLS PSN. This table is indexed on cpwVcIndex.
- cpwVcMplsOutboundTable -- Associates VCs using an MPLS PSN with the outbound MPLS tunnels toward the PSN or the physical interface in the case of the VC only. A row in this table represents a link between PW VCs that require MPLS tunnels and an MPLS tunnel toward the PSN. This table is indexed by the cpwVcIndex and an additional index that is not supported; consequently, its value is 1. The operator creates at least one entry in this table for each PW VC that requires an MPLS PSN. The VC-only case and the cpwVcMplsOutboundIndex is not supported.
- cpwVcMplsInboundTable -- Associates VCs using an MPLS PSN with the inbound MPLS tunnels for packets coming from the PSN, if such association is desired mainly for security reasons. A row in this table represents a link between PW VCs that require MPLS tunnels and an MPLS tunnel for packets arriving from the PSN. This table is indexed by the set of indexes used to identify the VC, cpwVcIndex, and an additional index that is not supported; consequently, its value is 1. An entry is created in this table either automatically by the local agent or manually by the operator when strict mode is required. This table points to the appropriate MPLS MIB. For MPLS-TE, the four variables relevant to the indexing of an MPLS TE tunnel are set. The VC-only case and the cpwVcMplsInboundIndex are not supported.
- cpwVcMplsNonTeMappingTable -- Maps an inbound or outbound tunnel to a VC in non-TE applications. A row in this table represents the association between a PW VC and its non-TE MPLS outer tunnel. An

application can use this table to retrieve the PW carried over a specific non-TE MPLS outer tunnel quickly. This table is indexed by the xconnect index for the MPLS non-TE tunnel and the direction of the VC in the specific entry. The same table is used in both inbound and outbound directions, but in a different row for each direction. If the inbound association is not known, no rows should exist for it. Rows are created by the local agent when all the association data is available for display.

- cpwVcMplsTeMappingTable -- Maps an inbound or outbound tunnel to a VC in MPLS-TE applications. A row in this table represents the association between a PW VC and its MPLS-TE outer tunnel. An application can use this table to retrieve the PW carried over a specific TE MPLS outer tunnel quickly. This table is indexed by the four indexes of a TE tunnel, the direction of the VC specific entry, and the VcIndex. The same table is used in both inbound and outbound directions, but a different row for each direction. If the inbound association is not known, no rows should exist for it. Rows are created by the local agent when all the association data is available for display. This table shows mappings between pseudowires and the xconnect index for non-TE outer tunnel or index.

cpwVcMplsTable

The table below lists the cpwVcMplsTable objects and their descriptions.

Table 61: cpwVcMplsTable Objects and Descriptions

Objects	Description
cpwVcMplsMplsType	Set by the operator to indicate the outer tunnel types, if they exist. Values are the following: • mplsTe(0)--Used when the outer tunnel is set up by MPLS-TE. • mplsNonTe(1)--Used when the outer tunnel is set up by LDP or manually.
cpwVcMplsExpBitsMode	Set by the operator to indicate the way the VC shim label EXP bits are to be determined. The value is the following: • outerTunnel(1)--Used when there is an outer tunnel and cpwVcMplsMplsType is mplsTe or mplsNonTe.
cpwVcMplsExpBits	Set by the operator to indicate the MPLS EXP bits to be used on the VC shim label if cpwVcMplsExpBitsMode is specified; value = 0.
cpwVcMplsTtl	Set by the operator to indicate the VC time-to-live (TTL) bits to be used on the VC shim label; value = 0.
cpwVcMplsLocalLdpID	The local LDP identifier of the LDP entity creating this VC in the local node. Because the VC labels are always set from the per-platform label space, the last two octets in the LDP ID must be 0s.
cpwVcMplsLocalLdpEntityID	The local LDP entity index of the LDP entity to be used for this VC on the local node; this should be set to all 0s when this object is not used.
cpwVcMplsPeerLdpID	The peer LDP identifier as identified by the LDP session; this should be zero if not relevant or not known yet.

Objects	Description
cpwVcMplsStorageType	The storage type for this object is a read-only implementation that is always volatile(2).

cpwVcMplsOutboundTable

The table below lists the cpwVcMplsOutboundTable objects and their descriptions.

Table 62: cpwVcMplsOutboundTable Objects and Descriptions

Objects	Description
cpwVcMplsOutboundIndex	An arbitrary index for enabling multiple rows per VC in this table. The next available free index can be retrieved using cpwVcMplsOutboundIndexNext. The value = 1, because this object is not supported.
cpwVcMplsOutboundLsrXcIndex	Set by the operator. If the outer label is defined in the MPL-LSR-MIB, that is, set by LDP or manually, this object points to the xconnect index of the outer tunnel. Otherwise, this object is set to 0.
cpwVcMplsOutboundTunnelIndex	Part of the set of indexes for an outbound tunnel, specifically an MPLS-TE outer tunnel; otherwise, this object is set to 0.
cpwVcMplsOutboundTunnelInstance	Part of the set of indexes for an outbound tunnel, specifically an MPLS-TE outer tunnel; otherwise, this object is set to 0.
cpwVcMplsOutboundTunnelLclLSR	Part of the set of indexes for an outbound tunnel, specifically an MPLS-TE outer tunnel; otherwise, this object is set to NULL.
cpwVcMplsOutboundTunnelPeerLSR	Part of the set of indexes for an outbound tunnel, specifically an MPLS-TE outer tunnel; otherwise, this object is set to NULL.
cpwVcMplsOutboundIfIndex	For a VC only with no outer tunnel, this object holds the ifIndex of the outbound port. The value = 0.
cpwVcMplsOutboundRowStatus	A read-only implementation that is always active(1). It is used for creating, modifying, and deleting.
cpwVcMplsOutboundStorageType	The storage type for this object is a read-only implementation that is always volatile(2).

cpwVcMplsInboundTable

The table below lists the cpwVcMplsInboundTable objects and their descriptions.

Table 63: cpwVcMplsInboundTable Objects and Descriptions

Objects	Description
cpwVcMplsInboundIndex	An arbitrary index for enabling multiple rows per VC in this table. The next available free index can be retrieved using cpwVcMplsInboundIndexNext. the value = 1, because this object is not supported.
cpwVcMplsInboundLsrXcIndex	If the outer label is defined in the MPL-LSR-MIB; that is, set by LDP or manually, this object points to the xconnect index of the outer tunnel. The xconnect index represents the pseudowire in the inbound direction retrieving 0 if information for this object is not known.
cpwVcMplsInboundTunnelIndex	Part of the set of indexes for an inbound tunnel, specifically an MPLS-TE outer tunnel; value = 0. This object does not support TE tunnels at the ingress router.
cpwVcMplsInboundTunnelInstance	Part of the set of indexes for an inbound tunnel, specifically an MPLS-TE outer tunnel; value = 0. This object does not support TE tunnels at the ingress router.
cpwVcMplsInboundTunnelLclLSR	Part of the set of indexes for an inbound tunnel, specifically an MPLS-TE outer tunnel; otherwise, set to NULL. This object does not support TE tunnels at the ingress router.
cpwVcMplsInboundTunnelPeerLSR	Part of the set of indexes for an inbound tunnel, specifically an MPLS-TE outer tunnel; otherwise, this object is set to NULL. This object does not support TE tunnels at the ingress router.
cpwVcMplsInboundIfIndex	In the case of a VC only (no outer tunnel), this object holds the ifIndex of the inbound port. The value = 0.
cpwVcMplsInboundRowStatus	A read-only implementation that is always active(1). It is used for creating, modifying, and deleting.
cpwVcMplsInboundStorageType	The storage type for this object is a read-only implementation that is always volatile(2).

cpwVcMplsNonTeMappingTable

The table below lists the cpwVcMplsNonTeMappingTable objects and their descriptions.

Table 64: cpwVcMplsNonTeMappingTable Objects and Descriptions

Objects	Description
cpwVcMplsNonTeMappingTunnelDirection	Identifies if the row represents an outbound or inbound mapping.
cpwVcMplsNonTeMappingXcTunnelIndex	XC index in the MPLS-LSR-MIB of the pseudowire LDP-generated XC entry.

Objects	Description
cpwVcMplsNonTeMappingIfIndex	Identifies the port on which the VC is carried for VC only; the value = 0.
cpwVcMplsNonTeMappingVcIndex	Represents the VC in the cpwVcTable.

cpwVcMplsTeMappingTable

The table below lists the cpwVcMplsTeMappingTable objects and their descriptions.

Table 65: cpwVcMplsTeMappingTable Objects and Descriptions

Objects	Description
cpwVcMplsTeMappingTunnelDirection	Identifies if the row represents an outbound mapping.
cpwVcMplsTeMappingTunnelIndex	Index for the conceptual row identifying an MPLS-TE tunnel.
cpwVcMplsTeMappingTunnelInstance	Identifies an instance of an MPLS-TE tunnel.
cpwVcMplsTeMappingTunnelPeerLsrID	Identifies a peer LSR when the outer tunnel is MPLS-TE based.
cpwVcMplsTeMappingTunnelLocalLsrID	Identifies the local LSR.
cpwVcMplsTeMappingVcIndex	Represents the VC in the cpwVcTable.

Tables in the PW-ENET-MIB

The PW-ENET-MIB consists of the following table:

- cpwVcEnetTable -- Provides Ethernet port mapping and VLAN configuration for each Ethernet emulated virtual connection. This table is indexed on cpwVcIndex, which uniquely identifies a singular connection. The second level index for this table is cpwVcEnetPwVlan, which indicates VLANs on this VC. This table is used only for Ethernet VC types--ethernetVLAN, ethernet, or ethernet virtual private LAN service (VPLS), and is implemented as read-only.

cpwVcEnetTable

The table below lists the cpwVcEnetTable objects and their descriptions.

Table 66: cpwVcEnetTable Objects and Descriptions

Objects	Description
cpwVcEnetPwVlan	The VLAN value for frames on a VC. This is one of the indexes to the table so multiple VLAN values can be configured for a PW VC. This value is 4096 to indicate untagged frames; that is, if the cpwVcEnetVlanMode value is removeVlan. This value is the VLAN value of the access circuit if the cpwVcEnetVlanMode value is noChange. The value of 4097 is used if the object is not applicable; for example, when mapping all packets from an Ethernet port to the VC.

Objects	Description
cpwVcEnetVlanMode	Indicates the way the VLAN field is handled between the access circuit and the PW VC. The possible values for this field are as follows: • noChange--Indicates that the VC contains the original user VLAN, as specified in cpwVcEnetPortVlan. • changeVlan--Indicates that the VLAN field on the VC may be different from the VLAN field on the user's port. • removeVlan--Indicates that the encapsulation on the VC does not include the original VLAN field.
cpwVcEnetPortVlan	Defines the VLAN value on the physical port (or VPLS virtual port) if a change is required to the VLAN value between the VC and the physical or virtual port. It is equal to cpwVcEnetPwVlan if the cpwVcEnetVlanMode value is noChange. A value of 4096 indicates that no VLAN is associated with the VC; that is, assigning Default VLAN to untagged frames. If all traffic from the VC is being forwarded to the port, then this value is 4097 indicating it is not relevant.
cpwVcEnetPortIfIndex	The ifIndex value of the Ethernet port associated with this PW VC for point-to-point Ethernet service. For VPLS, this value is an ifIndex value for a virtual interface for the VPLS instance.
cpwVcEnetVcIfIndex	Models the VC as a virtual interface in the ifTable. This value is always 0 to indicate no virtual interface is created.
cpwVcEnetRowStatus	A read-only implementation that is always active(1). It is used for creating, modifying, and deleting.
cpwVcEnetStorageType	The storage type for this object is a read-only implementation that is always volatile(2).

Tables in the PW-FR-MIB

The PW-FR-MIB consists of the following table:

- cpwVcFrTable -- Contains entries that represent an FRoPW connection operating in one-to-one mapping mode in which there is a one-to-one correspondence between a Frame Relay VC and a pair of unidirectional pseudowires.

cpwVcFrTable

The table below lists the cpwVcFrTable objects and their descriptions.

Table 67: cpwVcFrTable Objects and Descriptions

Objects	Description
cpwVcFrIfIndex	Returns the interface ifIndex of the Frame Relay (FR) segment of the FRoPW connection.

Objects	Description
cpwVcFrDlci	Returns the data-link connection identifier (DLCI) of the Frame Relay segment of an FRoPW connection.
cpwVcFrAdminStatus	Returns the administrative status of an FRoPW connection.
cpwVcFrOperStatus	Returns the combined operational status of an FRoPW connection.
cpwVcFrPw2FrOperStatus	Returns the operational status of the PW-to-FR direction in an FRoPW connection.
cpwVcFrRowStatus	A read-only implementation that is always active(1). It is used for creating, modifying, and deleting.
cpwVcFrStorageType	The storage type for this object is a read-only implementation that is always volatile(2).

Tables in the PW-ATM-MIB

The PW-ATM-MIB consists of the following tables:

- cpwVcAtmTable -- Specifies information for an ATM VC to be carried over the PSN.
- cpwVcAtmPerfTable -- Specifies performance-related attributes for an ATM VC.

cpwVcAtmTable

The table below lists the cpwVcAtmTable objects and their descriptions.

Table 68: cpwVcAtmTable Objects and Descriptions

Objects	Description
cpwAtmIf	Specifies the ATM interface that sends and receives cells from the ATM network.
cpwAtmVpi	Specifies the VPI value of the ATM VC.
cpwAtmVci	Specifies the VCI value of the ATM VC.
cpwAtmClpQosMapping	Indicates the presence of cell loss priority (CLP) bits determining the value in quality of service (QoS) fields of the encapsulating protocol. The value could be used only for outbound traffic, which means traffic going out to the PSN.
cpwAtmRowStatus	A read-only implementation that is always active(1). It is used for creating, modifying, and deleting.
cpwAtmOamCellSupported	Indicates whether operation, administration, and maintenance (OAM) cells are transported on this VC.
cpwAtmQosScalingFactor	Represents the scaling factor to be applied to ATM QoS rates when calculating QoS rates for the PSN domain.

Objects	Description
cpwAtmCellPacking	Identifies if the VC is configured to do cell packing.
cpwAtmMncp	Identifies the number of cells that need to be packed.
cpwAtmEncap	Provides information on whether MPLS or Layer 2 Tunneling Protocol Version 3 (L2TPv3) is used as the transport.
cpwAtmPeerMncp	Represents the maximum number of cells that can be packed in one packet for a peer interface.
cpwAtmMcptTimeout	Represents the maximum cell packing timeout (MCPT) value used.

cpwVcAtmPerfTable

The table below lists the cpwVcAtmPerfTable objects and their descriptions.

Table 69: cpwVcAtmPerfTable Objects and Descriptions

Objects	Description
cpwAtmCellsReceived	Obtains information on the number of cells that were received and sent to the PSN.
cpwAtmCellsSent	Provides information on the number of cells sent to the ATM network.
cpwAtmCellsRejected	Indicates the number of cells that were rejected by this VC because of policing.
cpwAtmCellsTagged	Indicates the number of cells that were tagged.
cpwAtmHCCellsReceived	Provides the high-capacity counter for the number of cells received by this VC.
cpwAtmHCCellsRejected	Provides the high-capacity counter for the number of cells rejected by this VC.
cpwAtmHCCellsTagged	Provides the high-capacity counter for number of cells that were tagged.
cpwAtmAvgCellsPacked	Provides the average number of cells that were packed.
cpwAtmPktsReceived	Indicates the number of ATM AAL5 packets that are actually sent into the ATM network as packets when the VC is configured to do AAL5 over PW.
cpwAtmPktsSent	Gets the number of packets that are reconstructed from the cells, assigns a VC label, and sends the packets into the PSN.
cpwAtmPktsRejected	Indicates the number of packets that were rejected because of policing.

Objects in the PWE3 MIBs

The PWE3 MIBs represent an ASN.1 notation reflecting specific components of the pseudowire services. The MIBs enable a network management application using SNMP to get this information for display. The MIBs support the standard GETNEXT and GETBULK functionality, but do not support configuration capabilities (via SET) in the current implementation.

Scalar Objects in the PWE3 MIBs

The PWE3 MIBs contain the following supported scalar object:

- cpwVcUpDownNotifEnable--This object reflects the configuration of the cpwVcUp and cpwVcDown notifications. If either of the notifications is configured via the command-line interface (CLI), then this object has a value of true(1). If this object is set via SNMP to true(1), then it enables the emission of both the cpwVcUp and cpwVcDown notifications; if the object is set via SNMP to false(2), these notifications are not emitted.

Note cpwVcUpDownNotifEnable can be set only if RW is configured for the **snmp-server community** *string* [**view** *view-name*] [**ro** | **rw**] [**ipv6** *nacl*] [*access-list-number*] command.

The PWE3 MIBs contain the following unsupported scalar objects:

- cpwVcIndexNext--Indicates the next cpwVcIndex value to use when you add rows to the cpwVcTable.
- cpwVcNotifRate--Indicates the rate at which cpwVcUp/Down notifications can be issued from the device.
- cpwVcMplsOutboundIndexNext--Contains an appropriate value to be used for cpwVcMplsOutboundIndex when you create entries in the cpwVcMplsOutboundTable. The value 0 indicates that no unassigned entries are available. To obtain the cpwVcMplsOutboundIndex value for a new entry, the manager issues a management protocol retrieval operation to obtain the current value of this object. After each retrieval, the software agent should modify the value to the next unassigned index; however, the software agent *must not* assume such retrieval will be done for each row created.
- cpwVcMplsInboundIndexNext--Contains an appropriate value to be used for cpwVcMplsInboundIndex when you create entries in the cpwVcMplsInboundTable. The value 0 indicates that no unassigned entries are available. To obtain the cpwVcMplsInboundIndex value for a new entry, the manager issues a management protocol retrieval operation to obtain the current value of this object. After each retrieval, the software agent should modify the value to the next unassigned index; however, the agent *must not* assume such retrieval will be done for each row created.

Notifications in the PWE3 MIBs

The cpwVcUp and cpwVcDown notifications in the PW-MIB indicate when the operStatus values for a range of PW VCs have changed state.

The definition of these objects in the PW-MIB indicates that events of the same type, either up or down, must be able to be correlated into ranges. The implementation of these notifications does not do any of this correlation. A notification is generated for each individual VC that has an operational state change if that notification is enabled. A notification does not signal an operational state change for a group of VCs as described in the MIB.

Benefits of the PWE3 MIBs

The PWE3 MIBs provide the ability to manage pseudowire emulation edge-to-edge by providing MPLS-related information about the service and a mechanism to monitor the Ethernet, Frame Relay, or ATM access circuits.

How to Configure Pseudowire Emulation Edge-to-Edge MIBs

Enabling the SNMP Agent for the PWE3 MIBs

SUMMARY STEPS

1. **enable**
2. **show running-config** [**interface** | **map-class**]
3. **configure terminal**
4. **snmp-server community** *string* [**view** *view-name*] [**ro** | **rw**] [**ipv6** *nacl*] [*access-list-number*]
5. **end**
6. **write memory**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**show running-config** [**interface**	**map-class**] **Example:** `Router# show running-config`	Displays the running configuration of the router so that you can determine if an SNMP agent is already running on the device. If no SNMP information is displayed, continue with the next step. If any SNMP information is displayed, you can modify the information or change it as desired. • The optional **interface** keyword displays interface-specific configuration information. • The optional **map-class** keyword displays dialer or Frame Relay map-class information.
Step 3	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 4	**snmp-server community** *string* [**view** *view-name*] [**ro**	**rw**] [**ipv6** *nacl*] [*access-list-number*] **Example:**	Sets up the community access string to permit access to SNMP for the MIBs.

	Command or Action	Purpose
	`Router(config)# snmp-server community public ro`	• The *string* argument consists of 1 to 32 alphanumeric characters and functions much like a password, permitting access to SNMP. Blank spaces are not permitted in the community string. • The optional **view** *view-name* keyword argument combination specifies a previously defined view. The view defines the objects available to the SNMP community. • The optional **ro** keyword configures read-only (ro) access to the objects in the MIBs. • The optional **rw** keyword specifies read-write access. Authorized management stations can both retrieve and modify MIB objects. • The optional **ipv6** *nacl* keyword argument combination specifies an IPv6 named access list. • The optional *access-list-number* argument is an integer from 1 to 99 that specifies a standard access list of IP addresses or a string (not to exceed 64 characters) that is the name of a standard access list of IP addresses allowed access to the SNMP agent. Alternatively, it is an integer from 1300 to 1999 that specifies a list of IP addresses in the expanded range of standard access list numbers that are allowed to use the community string to gain access to the SNMP agent.
Step 5	**end** **Example:** `Router(config)# end`	Exits to privileged EXEC mode.
Step 6	**write memory** **Example:** `Router# write memory`	Writes the modified SNMP configuration into NVRAM of the router, permanently saving the SNMP settings.

Configuring the Pseudowire Class

The successful transmission of the Layer 2 frames between PE routers is due to the configuration of the PE routers. You configure the connection, called a pseudowire, between the routers.

Note In simple configurations, this task is optional. You do not need to specify a pseudowire class if you specify the tunneling method as part of the **xconnect**command.

The pseudowire-class configuration group specifies the following characteristics of the tunneling mechanism:

- Encapsulation type
- Control protocol
- Payload-specific options

You must specify the **encapsulation mpls** command as part of the pseudowire class or as part of the **xconnect** command for the AToM VCs to work properly. If you omit the **encapsulation mpls** command as part of the **xconnect**command, you receive the following error:

```
% Incomplete command.
```

Once you specify the **encapsulation mpls** command, you cannot remove it using the **no encapsulation mpls**command. Nor can you change the command's setting using the **encapsulation l2tpv3** command. Those methods result in the following error message:

```
Encapsulation changes are not allowed on an existing pw-class.
```

To remove the command, you must delete the pseudowire with the **no pseudowire-class** command. To change the type of encapsulation, remove the pseudowire with the **no pseudowire-class** command and reestablish the pseudowire and specify the new encapsulation type.

Note There are many options that you can configure. For detailed information, see the "Any Transport over MPLS" module.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **pseudowire-class** *name*
4. **encapsulation mpls**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.

	Command or Action	Purpose
Step 3	**pseudowire-class** *name* **Example:** `Router(config)# pseudowire-class atom`	Establishes a pseudowire class with a name that you specify and enters pseudowire class configuration mode.
Step 4	**encapsulation mpls** **Example:** `Router(config-pw)# encapsulation mpls`	Specifies the tunneling encapsulation. For AToM, the encapsulation type is mpls.

What to Do Next

Perform a MIB walk using your SNMP management tool on cpwVcMIB, cpwVcMplsMIB, cpwVcEnetMIB, cpwVcFrMIB, and cpwVcAtmMIB to verify that the PW-MIB, the PW-MPLS-MIB, the PW-ENET-MIB, the PW-FR-MIB, and the PW-ATM-MIB objects, respectively, are populated correctly.

Note SNMPv1 and SNMPv2c are supported.

Configuration Examples for the Pseudowire Emulation Edge-to-Edge MIBs

PWE3 MIBs Example

In the following example, the configuration permits any SNMP manager to access all objects with read-only permissions using the community string *public* .

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# snmp-server community public ro
```

Note There is no explicit way to configure the PWE3 MIBs. However, for information on AToM configuration tasks and examples, see the "Any Transport over MPLS" module.

There are notifications specific to the PWE3 MIBs. For detailed information on the commands used to configure them, see the "Additional References" section.

Feature Information for Pseudowire Emulation Edge-to-Edge MIBs

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 70: Feature Information for Pseudowire Emulation Edge-to-Edge MIBs for Ethernet, Frame Relay, and ATM Services

Feature Name	Releases	Feature Information
Pseudowire Emulation Edge-to-Edge MIBs for Ethernet, Frame Relay, and ATM Services	Cisco IOS Release XE 2.3	The Pseudowire Emulation Edge-to-Edge MIBs for Ethernet, Frame Relay, and ATM Services feature provides Simple Network Management Protocol (SNMP) support within an Any Transport over Multiprotocol Label Switching (AToM) infrastructure emulating Ethernet, Frame Relay, and ATM services over packet switched networks (PSNs). In Cisco IOS Release XE 2.3, this feature was integrated into the releases as the Pseudowire Emulation Edge-to-Edge (PWE3) MIBs providing SNMP support within an Any Transport over Multiprotocol Label Switching (AToM) infrastructure emulating Ethernet, Frame Relay, and ATM services over packet switched networks (PSNs).

Glossary

AAL —ATM adaptation layer. AAL defines the conversion of user information into cells. AAL1 and AAL2 handle isochronous traffic, such as voice and video; AAL3/4 and AAL5 pertain to data communications through the segmentation and reassembly of packets.

ATM —asynchronous transfer mode. A cell-based data transfer technique in which channel demand determines packet allocation. This is an international standard for cell relay in which multiple service types (such as voice, video, or data) are conveyed in fixed-length (53-byte) cells. Fixed-length cells allow cell processing to occur in hardware, thereby reducing transit delays. ATM is designed to take advantage of high-speed transmission media such as E3, SONET, and T3.

CE router—customer edge router. A router that is part of a customer network and that interfaces to a provider edge (PE) router.

DLCI —data-link connection identifier. A unique number assigned to a PVC endpoint in a Frame Relay network. Identifies a particular PVC endpoint within an access channel in a Frame Relay network and has local significance only to that channel.

encapsulation —Wrapping of data in a particular protocol header. For example, Ethernet data is wrapped in a specific Ethernet header before network transit. Also, when bridging occurs in dissimilar networks, the entire frame from one network is simply placed in the header used by the data link layer protocol of the other network.

EoMPLS —Ethernet over multiprotocol label switching (MPLS). A tunneling mechanism that allows a service provider to tunnel customer Layer 2 traffic through a Layer 3 MPLS network. EoMPLS is a point-to-point solution only. EoMPLS is also known as Layer 2 tunneling.

Frame Relay—The industry standard, switched data link layer protocol that handles multiple virtual circuits using High-Level Data Link Control (HDLC) encapsulation between connected devices. Frame Relay is more efficient than X.25, the protocol for which it is generally considered a replacement.

IETF —internet engineering task force. A task force (consisting of more than 80 working groups) that is developing standards for the Internet and the IP suite of protocols.

LDP —label distribution protocol. The protocol that supports MPLS hop-by-hop forwarding and the distribution of bindings between labels and network prefixes. The Cisco proprietary version of this protocol is the Tag Distribution Protocol (TDP).

LSP —label switched path. A configured connection between two label switch routers (LSRs) in which label-switching techniques are used for packet forwarding; also a specific path through an MPLS network.

LSR —label switch router. A Multiprotocol Label Switching (MPLS) node that can forward native Layer 3 packets. The LSR forwards a packet based on the value of a label attached to the packet.

MIB—management information base. A database of network management information that is used and maintained by a network management protocol such as simple network management protocol (SNMP). The value of a MIB object can be changed or retrieved by using SNMP commands, usually through a network management system. MIB objects are organized in a tree structure that includes public (standard) and private (proprietary) branches.

MPLS—multiprotocol label switching. A switching method for the forwarding of IP traffic through the use of a label. This label instructs the routers and the switches in the network where to forward the packets based on preestablished IP routing information.

MTU —maximum transmission unit. Maximum packet size, in bytes, that a particular interface can handle.

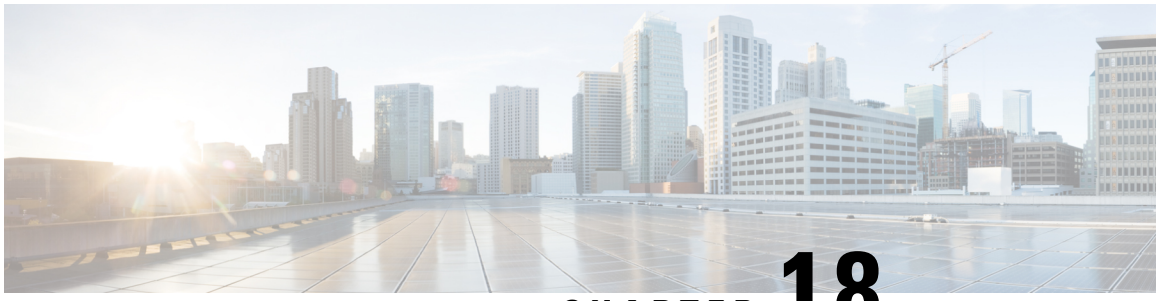
NMS—network management system. System responsible for managing at least part of a network. An NMS is generally a reasonably powerful and well-equipped computer, such as an engineering workstation. An NMS communicates with agents to help keep track of network statistics and resources.

notification —A message sent by a Simple Network Management Protocol (SNMP) agent to a network management station, console, or terminal to indicate that a significant network event has occurred. See also trap.

OSPF —Open Shortest Path First. A link-state hierarchical Interior Gateway Protocol routing algorithm, derived from the IS-IS protocol. OSPF features include least-cost routing, multipath routing, and load balancing.

PE router—provider edge router. A router that is part of a service provider's network and is connected to a customer edge (CE) router.

primary tunnel—A tunnel whose label-switched path (LSP) may be fast rerouted if there is a failure. Backup tunnels cannot be primary tunnels.



pseudowire —PW. A mechanism that carries the elements of an emulated service from one provider edge (PE) to one or more PEs over a packet switched network (PSN).

SNMP—simple network management protocol. A management protocol used almost exclusively in TCP/IP networks. SNMP provides a means for monitoring and controlling network devices, and for managing configurations, statistics collection, performance, and security.

trap—A message sent by an SNMP agent to a network management station, console, or terminal, indicating that a significant event occurred. Traps are less reliable than notification requests because the receiver does not send an acknowledgment when it receives a trap. The sender cannot determine if the trap was received.

tunnel —A secure communication path between two peers, such as routers.

VC —virtual circuit. A logical circuit created to ensure reliable communication between two network devices. A virtual circuit can be either permanent (PVC) or switched (SVC).

CHAPTER 18

MPLS Traffic Engineering--Fast Reroute MIB

The MPLS Traffic Engineering--Fast Reroute MIB provides Simple Network Management Protocol (SNMP)-based network management of the Multiprotocol Label Switching (MPLS) Fast Reroute (FRR) feature in Cisco software.

The Fast Reroute MIB has the following features:

- Notifications can be created and queued.
- Command-line interface (CLI) commands enable notifications, and specify the IP address to where the notifications will be sent.
- The configuration of the notifications can be written into nonvolatile memory.

The MIB includes objects describing features within MPLS FRR, and it includes the following tables:

- cmplsFrrConstTable
- cmplsFrrLogTable
- cmplsFrrFacRouteDBTable

The MIB also includes scalar objects (that is, objects that are not in a table). For more information, see theMPLS Traffic Engineering--Fast Reroute MIB, on page 371 .

- Prerequisites for the MPLS Traffic Engineering--Fast Reroute MIB, on page 371
- Restrictions for the MPLS Traffic Engineering--Fast Reroute MIB, on page 372
- Information About the MPLS Traffic Engineering--Fast Reroute MIB, on page 372
- How to Configure the MPLS Traffic Engineering--Fast Reroute MIB, on page 378
- Configuration Examples for the MPLS Traffic Engineering--Fast Reroute MIB, on page 383
- Additional References, on page 384
- Feature Information for MPLS Traffic Engineering--Fast Reroute MIB, on page 385
- Glossary, on page 385

Prerequisites for the MPLS Traffic Engineering--Fast Reroute MIB

- The network must support the Intermediate System-to-Intermediate System (IS-IS) or Open Shortest Path First (OSPF) protocol.

- The SNMP is installed and enabled on the label switch routers (LSRs).
- MPLS is enabled globally on each LSR.
- Cisco Express Forwarding is enabled on the LSRs.
- Traffic engineering (TE) tunnels are enabled.
- MPLS FRR is enabled on one of the TE tunnels.
- The Resource Reservation Protocol (RSVP) is enabled.

Restrictions for the MPLS Traffic Engineering--Fast Reroute MIB

- The implementation of the FRR MIB is limited to read-only (RO) permission for MIB objects.
- The following tables are not implemented:
  - mplsFrrOne2OnePlrTable
  - mplsFrrDetourTable.

Information About the MPLS Traffic Engineering--Fast Reroute MIB

Feature Design of the MPLS Traffic Engineering--Fast Reroute MIB

The FRR MIB enables standard, SNMP-based network management of FRR in Cisco software. This capability requires that SNMP agent code executes on a designated network management station (NMS) in the network. The NMS serves as the medium for user interaction with the network management objects in the MIB.

The FRR MIB is based on the Internet Engineering Task Force (IETF) draft MIB specification *draft-ietf-mpls-fastreroute-mib-02.txt* . The IETF draft MIB, which undergoes revisions periodically, is evolving toward becoming a standard. The Cisco implementation of the FRR MIB is expected to track the evolution of the IETF draft MIB, and may change accordingly.

Slight differences between the IETF draft MIB and the implementation of FRR within Cisco software require some minor translations between the FRR MIB objects and the internal data structures of Cisco software. These translations are accomplished by the SNMP agent, which runs in the background on the NMS workstation as a low priority process and provides a management interface to Cisco software.

You can use an SNMP agent to access FRR MIB objects using standard SNMP GET operations. All the objects in the FRR MIB follow the conventions defined in the IETF draft MIB.

Functional Structure of the MPLS Traffic Engineering--Fast Reroute MIB

The SNMP agent code supporting the FRR MIB follows the existing model for such code in Cisco software and is, in part, generated by the Cisco tool set, based on the MIB source code. The basis for the generated code is the Cisco version of the FRR MIB CISCO-ietf-frr-mib.

The SNMP agent code, which has a layered structure that is common to MIB support code in Cisco software, consists of the following layers:

- Platform-independent layer--This layer is generated primarily by the MIB development Cisco tool set and incorporates platform- and implementation-independent functions. These functions handle SNMP standard functionality in the context of the specific MIB. This layer handles indexes and range or enumeration value checks for GET, GET-NEXT, and SET SNMP operations. A function is generated for each SNMP table or group of objects. This layer calls into the next layer.
- Application interface layer--The Cisco tool set generates the function names and template code for MIB objects.
- Application-specific layer--This layer provides the mechanism for retrieving relevant data from the managed application layer. It includes an entry point function for each table. This function calls two other functions; one that searches the TE tunnel database that RSVP maintains for the relevant data according to the indexes, and another function that fills the data into the structure.
- Managed application layer--This layer includes all the structures and mechanisms, and is managed by the MIB.

System Flow of SNMP Protocol Requests and Response Messages

All SNMP protocol requests and response messages are ultimately handled by the SNMP master agent. When such a message is received on a router, the master agent parses the requests and identifies the MIB to which the request refers. The master agent then queries the subagent responsible for the MIB with a GET, GET-NEXT, or SET request. The FRR MIB subagent retrieves the appropriate data, and returns it to the master agent. The master agent is then responsible for returning an SNMP response to the NMS. All queries occur within the IP SNMP Cisco software process, which runs as a low priority task.

FRR MIB Scalar Objects

Scalar objects are objects that are not in tables. A scalar object has one instance (that is, one occurrence).

The table below describes the FRR MIB scalar objects.

Table 71: Scalar Objects

MIB Object	Function
cmplsFrrDetourIncoming	Number of detour link-state packets (LSPs) entering the device. This object returns 0 because cmplsFrrConstProtectionMethod is set to facilityBackup(1).
cmplsFrrDetourOutgoing	Number of detour LSPs leaving the device. This object returns 0 because cmplsFrrConstProtectionMethod is set to facilityBackup(1).
cmplsFrrDetourOriginating	Number of detour LSPs originating from the device. This object returns 0 because cmplsFrrConstProtectionMethod is set to facilityBackup(1).

MIB Object	Function
cmplsFrrSwitchover	Number of tunnels that are being backed up because cmplsFrrConstProtectionMethod is set to facilityBackup(1).
cmplsFrrNumOfConfIfs	Number of MPLS interfaces FRR configured for protection; 0 indicates that LSPs traversing any interface can be protected.
cmplsFrrActProtectedIfs	Number of interfaces FRR is protecting because cmplsFrrConstProtectionMethod is set to facilityBackup(1).
cmplsFrrConfProtectingTuns	Number of backup Fast Reroute-protected tunnels configured because cmplsFrrConstProtectionMethod is set to facilityBackup(1).
cmplsFrrActProtectedTuns	Number of tunnels protected by the Fast Reroute feature. This object returns 0 because cmplsFrrConstProtectionMethod is set to facilityBackup(1).
cmplsFrrActProtectedLSPs	Number of LSPs that FRR is protecting. If cmplsFrrConstProtectionMethod is set to facilityBackup(1), this object returns 0.
cmplsFrrConstProtectionMethod	This object always returns facilityBackup(1) because Cisco software supports only the facility backup protection method.
cmplsFrrNotifsEnabled	A value that indicates whether FRR notifications defined in this MIB are enabled or disabled. This object returns True(1) for enabled, or False(2) for disabled. The default is that notifications are disabled.
cmplsFrrLogTableMaxEntries	Maximum number of entries allowed in the FRR log table.
cmplsFrrLogTableCurrEntries	Current number of entries in the FRR log table. This object always returns 0.
cmplsFrrNotifMaxRate	Maximum interval rate between FRR MIB notifications. This object always returns 0.

FRR MIB Notification Generation Events

Notifications are issued after particular FRR events occur.

When you enable FRR MIB notification functionality by issuing the **snmp-server enable traps mpls fast-reroute** command, FRR events generate notification messages that are sent to a designated NMS in the network to signal the occurrence of specific events in Cisco software.

The FRR MIB objects involved in FRR status transitions and event notifications include cmplsFrrProtected. This message is sent to an NMS if there is a major TE tunnel change (that is, fast rerouting of TE tunnels).

FRR MIB Notification Specification

Notifications are issued after particular FRR events occur.

Each FRR notification has a generic type identifier and an enterprise-specific type identifier for identifying the notification type. The generic type for all FRR notifications is “enterprise Specific” because this is not one of the generic notification types defined for SNMP. The enterprise-specific type is 1 for cmplsFrrProtected.

Each notification contains the following objects from the FRR MIB so that the FRR tunnel can be easily identified:

- cmplsFrrConstNumProtectingTunOnIf
- cmplsFrrConstNumProtectedTunOnIf
- cmplsFrrConstBandwidth

Upon being invoked, the appropriate FRR interface indexes have already been retrieved by existing FRR code. The FRR interfaces are then used to fill in data for the three objects included in the notification.

FRR MIB Notification Monitoring

Notifications are issued after particular FRR events occur.

When FRR MIB notifications are enabled (see the **snmp-server enable traps** command), notification messages relating to specific FRR events within Cisco software are generated and sent to a specified NMS in the network. Any utility that supports SNMPv1 or SNPv2 notifications can receive notification messages.

To monitor FRR MIB notifications, log in to an NMS that supports a utility that displays SNMP notifications, and start the display utility.

MIB Tables in the MPLS Traffic Engineering--Fast Reroute MIB

The FRR MIB consists of the following tables:

The tables access various data structures to obtain information regarding detours, the FRR database, and logging.

cmplsFrrConstTable

cmplsFrrConstTable displays the configuration of an FRR-enabled tunnel and the characteristics of its accompanying backup tunnels. For each protected tunnel, there can be multiple backup tunnels.

The table is indexed by the following:

- cmplsFrrConstIfIndex
- cmplsFrrConstTunnelIndex
- cmplsFrrConstTunnelInstance

The table below describes the MIB objects for cmplsFrrConstTable.

Table 72: cmplsFrrConstTable Objects

MIB Object	Function
cmplsFrrConstIfIndex	Uniquely identifies an interface on which FRR is configured. If an index has a value of 0, the configuration applies to all interfaces on the device on which the FRR feature can operate.
cmplsFrrConstTunnelIndex	Tunnel for which FRR is requested.
cmplsFrrConstTunnelInstance	Tunnel for which FRR is requested. The value always is 0 because only tunnel heads are represented, and tunnel heads have an instance value of 0.

MIB Object	Function
cmplsFrrConstSetupPrio	Setup priority of the backup tunnel.
cmplsFrrConstHoldingPrio	Holding priority of the backup tunnel.
cmplsFrrConstInclAnyAffinity	Attribute bits that must be set for the tunnel to traverse a link.
cmplsFrrConstInclAllAffinity	Attribute bits that must not be set for the tunnel to traverse a link.
cmplsFrrConstExclAllAffinity	A link satisfies the exclude-all constraint only if the link contains none of the administrative groups specified in the constraint.
cmplsFrrConstHopLimit	The maximum number of hops that the backup tunnel can traverse.
cmplsFrrConstBandwidth	The bandwidth of the backup tunnels for this tunnel, in thousands of bits per second (kbps).
cmplsFrrConstRowStatus	Creates, modifies, and deletes a row in this table.

cmplsFrrLogTable

cmplsFrrLogTable is indexed by the object cmplsFrrLogIndex. The index corresponds to a log entry in the FRR feature's **show mpls traffic-eng fast-reroute log reroutes** command. That **show** command stores up to 32 entries at a time. If entries are added, the oldest entry is overwritten with new log information.

cmplsFrrLogTable can store up to 32 entries at a time, overwriting older entries as newer ones are added. The index cmplsFrrLogIndex is incremented to give each log table entry of the MIB a unique index value. Therefore, it is possible to have indexes greater than 32 even though only 32 entries are displaying.

The table below describes the MIB objects for cmplsFrrLogTable.

Table 73: cmplsFrrLogTable Objects

MIB Object	Function
cmplsFrrLogIndex	Number of the FRR event.
cmplsFrrLogEventTime	Number of milliseconds that elapsed from bootstrap time to the time that the event occurred.
cmplsFrrLogInterface	Identifies the interface that was affected by this FRR event. The value can be set to 0 if mplsFrrConstProtectionMethod is set to oneToOneBackup(0).
cmplsFrrLogEventType	The type of FRR event that occurred. The object returns Protected or Other.
cmplsFrrLogEventDuration	Duration of the event, in milliseconds.
cmplsFrrLogEventReasonString	Implementation-specific explanation of the event. The object returns interface down event or interface other event.

cmplsFrrFacRouteDBTable

The following indexes specify which interface and tunnel are being protected by the FRR feature:

- cmplsFrrFacRouteProtectedIfIndex

- cmplsFrrFacRouteProtectedTunIndex

The following indexes specify the backup tunnel that provides protection to the protected tunnel:

- cmplsFrrFacRouteProtectedIfIndex
- cmplsFrrFacRouteProtectingTunIndex
- cmplsFrrFacRouteProtectedTunIndex
- cmplsFrrFacRouteProtectedTunInstance
- cmplsFrrFacRouteProtectedTunIngressLSRId
- cmplsFrrFacRouteProtectedTunEgressLSRId

This version of the MIB will attempt to leverage the work already done for the MPLS TE MIB because it contains similar lookup functions for TE tunnels.

The table below describes the MIB objects for cmplsFrrFacRouteDBTable.

Table 74: cmplsFrrFacRouteDBTable Objects

MIB Object	Function
cmplsFrrFacRouteProtectedIfIndex	Interface configured for FRR protection.
cmplsFrrFacRouteProtectingTunIndex	The tunnel number of the protecting (backup) tunnel.
cmplsFrrFacRouteProtectedTunIndex	The mplsTunnelEntry primary index for the tunnel head interface designated to protect the interface specified in mplsFrrFacRouteIfProtIdx (and all the tunnels using this interface).
cmplsFrrFacRouteProtectedTunInstance	An mplsTunnelEntry that is being protected by FRR. An instance uniquely identifies a tunnel.
cmplsFrrFacRouteProtectedTunIngressLSRId	Inbound label for the backup LSR.
cmplsFrrFacRouteProtectedTunEgressLSRId	Outbound label for the backup LSR.
cmplsFrrFacRouteProtectedTunStatus	State of the protected tunnel. Valid values are: • active--Tunnel label has been placed in the Label Forwarding Information Base (LFIB) and is ready to be applied to incoming packets. • ready--Tunnel's label entry has been created, but is not in the LFIB. • partial--Tunnel's label entry has not been fully created.
cmplsFrrFacRouteProtectingTunResvBw	Amount of bandwidth, in megabytes per second, that is reserved by the backup tunnel.
cmplsFrrFacRouteProtectingTunProtectionType	Type of protection: 0 designates link protection; 1 designates node protection.

How to Configure the MPLS Traffic Engineering--Fast Reroute MIB

Enabling the SNMP Agent for FRR MIB Notifications

SUMMARY STEPS

1. **enable**
2. **show running-config**
3. **configure terminal**
4. **snmp-server community** *string* [**view** *view-name*] [**ro**] [*access-list-number*]
5. **snmp-server enable traps mpls fast-reroute protected**
6. **end**
7. **write memory**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**show running-config** **Example:** `Router# show running-config`	Displays the running configuration of the router to determine if an SNMP agent is already running on the device. If no SNMP information is displayed, continue with the next step. If any SNMP information is displayed, you can modify or change the information.
Step 3	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 4	**snmp-server community** *string* [**view** *view-name*] [**ro**] [*access-list-number*] **Example:** `Router(config)# snmp-server community public ro`	Configures read-only (ro) SNMP community strings for the FRR MIB.

	Command or Action	Purpose
Step 5	**snmp-server enable traps mpls fast-reroute protected** **Example:** `Router(config)# snmp-server enable traps mpls fast-reroute protected`	Enables Fast Reroute traps.
Step 6	**end** **Example:** `Router(config)# end`	Exits to privileged EXEC mode.
Step 7	**write memory** **Example:** `Router# write memory`	Writes the modified SNMP configuration into NVRAM of the router, permanently saving the SNMP settings.

Enabling Cisco Express Forwarding

SUMMARY STEPS

1. **enable**
2. **configure teminal**
3. **ip cef distributed**
4. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure teminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**ip cef distributed** **Example:** `Router(config)# ip cef distributed`	Enables distributed Cisco Express Forwarding.

	Command or Action	Purpose
Step 4	**end** **Example:** `Router(config)# end`	Exits to privileged EXEC mode.

Enabling TE Tunnels

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip cef**
4. **mpls traffic-eng tunnels**
5. **interface** *type slot/subslot/port*[**.***subinterface*]
6. **mpls traffic-eng tunnels**
7. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**ip cef** **Example:** `Router(config)# ip cef`	Enables standard Cisco Express Forwarding operations.
Step 4	**mpls traffic-eng tunnels** **Example:** `Router(config)# mpls traffic-eng tunnels`	Enables the MPLS TE tunnel feature on a device.
Step 5	**interface** *type slot/subslot/port*[**.***subinterface*] **Example:**	Specifies the interface and enters interface configuration mode.

	Command or Action	Purpose
	`Router(config)# interface POS1/0/0`	
Step 6	**mpls traffic-eng tunnels** **Example:** `Router(config-if)# mpls traffic-eng tunnels`	Enables the MPLS TE tunnel feature on an interface.
Step 7	**end** **Example:** `Router(config-if)# end`	Returns to privileged EXEC mode.

Enabling MPLS FRR on Each TE Tunnel

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type slot/subslot/port*[**.***subinterface*]
4. **tunnel mode mpls traffic-eng**
5. **tunnel mpls traffic-eng fast-reroute**
6. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**interface** *type slot/subslot/port*[**.***subinterface*] **Example:** `Router(config)# interface POS1/0/0`	Specifies the interface and enters interface configuration mode.

	Command or Action	Purpose
Step 4	**tunnel mode mpls traffic-eng** **Example:** `Router(config-if)# tunnel mode mpls traffic-eng`	Sets the mode of a tunnel to MPLS for traffic engineering.
Step 5	**tunnel mpls traffic-eng fast-reroute** **Example:** `Router(config-if)# tunnel mpls traffic-eng fast-reroute`	Enables Fast Reroute on the TE tunnel being protected.
Step 6	**end** **Example:** `Router(config-if)# end`	Exits to privileged EXEC mode.

Enabling a Backup Tunnel on an Interface

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *typeslot/subslot/port*[**.***subinterface*]
4. **mpls traffic-eng backup-path tunnel** *interface*
5. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**interface** *typeslot/subslot/port*[**.***subinterface*] **Example:**	Specifies the interface and enters interface configuration mode.

	Command or Action	Purpose
	`Router(config)# interface POS1/0/0`	
Step 4	**mpls traffic-eng backup-path tunnel** *interface* **Example:** `Router(config-if)# mpls traffic-eng backup-path tunnel1`	Enables a backup tunnel on a specified interface.
Step 5	**end** **Example:** `Router(config-if)# end`	Exits to privileged EXEC mode.

Configuration Examples for the MPLS Traffic Engineering--Fast Reroute MIB

Example Enabling an SNMP Agent on a Host NMS

```
enable
 show running-config
 configure terminal
 snmp-server community public ro
 snmp-server enable traps mpls fast-reroute protected
 end
 write memory
```

Example Enabling Cisco Express Forwarding

```
enable
 configure terminal
 ip cef
 end
```

Example Enabling TE Tunnels

```
enable
 configure terminal
 ip cef
 mpls traffic-eng tunnels
 interface FastEthernet1/0/0
 mpls traffic-eng tunnels
 end
```

Example Enabling MPLS FRR on Each TE Tunnel

```
enable
 configure terminal
 interface POS1/0/0
 tunnel mode mpls traffic-eng
 tunnel mpls traffic-eng fast-reroute
 end
```

Example Enabling a Backup Tunnel on an Interface

```
enable
 configure terminal
 interface POS1/0/0
 mpls traffic-eng backup-path tunnel1
 end
```

Feature Information for MPLS Traffic Engineering--Fast Reroute MIB

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Glossary

FEC—Forwarding Equivalence Class. A set of packets that can be handled equivalently for forwarding purposes and are thus suitable for binding to a single label. Examples include the set of packets destined for one address prefix and any flow.

flow—Generally, a set of packets traveling between a pair of hosts, or a pair of transport protocol ports on a pair of hosts. For example, packets with the same source address, source port, destination address, and destination port might be considered a flow.

A flow is also a stream of data traveling between two endpoints across a network (for example, from one LAN station to another). Multiple flows can be transmitted on a single circuit.

fragmentation—Process of breaking a packet into smaller units when transmitting over a network medium that cannot support the original size of the packet.

ICMP— Internet Control Message Protocol. A network layer Internet protocol that reports errors and provides other information relevant to IP packet processing. It is documented in RFC 792.

LFIB—label forwarding information base. A data structure and way of managing forwarding in which destinations and incoming labels are associated with outgoing interfaces and labels.

localhost—A name that represents the host name of a device. The localhost uses the reserved loopback IP address 127.0.0.1.

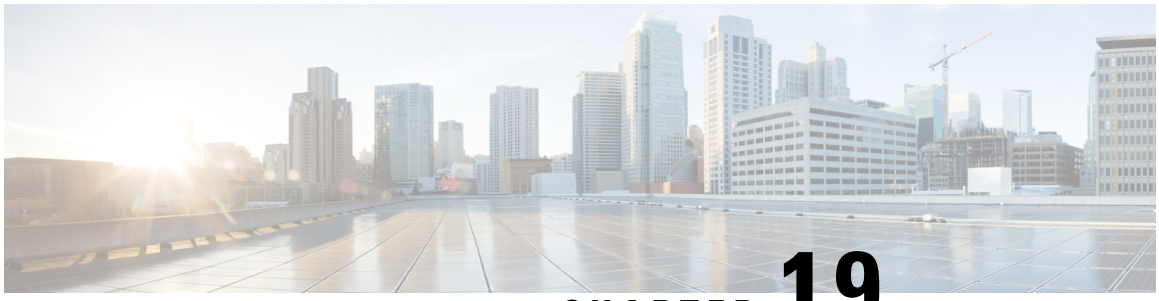
LSP—label switched path. A connection between two devices that uses MPLS to carry the packets.

LSPV—Label Switched Path Verification. An LSP Ping subprocess that encodes and decodes MPLS echo requests and replies; interfaces with IP, MPLS, and AToM switching for sending and receiving MPLS echo requests and replies; and, at the MPLS echo request originator device, maintains a database of outstanding echo requests for which echo responses have not been received.

MPLS router alert label—An MPLS label of 1. An MPLS packet with a router alert label is redirected by the device to the Route Processor (PR) processing level for handling. This allows these packets to bypass any forwarding failures in hardware routing tables.

MRU—maximum receive unit. Maximum size, in bytes, of a labeled packet that can be forwarded through an LSP.

MTU—maximum transmission unit. Maximum packet size, in bytes, that a particular interface can handle.



punt—Redirect packets with a router alert from the line card or interface to Route Processor (RP) level processing for handling.

PW—pseudowire. A mechanism that carries the essential elements of an emulated circuit from one provider edge (PE) device to another PE device over a packet-switched network.

RP—Route Processor. Processor module in the Cisco 7000 series routers that contains the CPU, system software, and most of the memory components that are used in the device. It is sometimes called a supervisory processor.

RSVP—Resource Reservation Protocol. A protocol that supports the reservation of resources across an IP network. Applications running on IP end systems can use RSVP to indicate to other nodes the nature (bandwidth, jitter, maximum burst, and so on) of the packet streams they want to receive. RSVP depends on IPv6. Is is also known as Resource Reservation Setup Protocol.

UDP—User Datagram Protocol. Connectionless transport layer protocol in the TCP/IP protocol stack. UDP is a simple protocol that exchanges datagrams without acknowledgments or guaranteed delivery, requiring that error processing and retransmission be handled by other protocols. UDP is defined in RFC 768.

CHAPTER 19

MPLS Traffic Engineering MIB

The MPLS Traffic Engineering MIB enables Simple Network Management Protocol (SNMP) agent support in Cisco software for Multiprotocol Label Switching (MPLS) traffic engineering (TE) management, as implemented in the MPLS Traffic Engineering MIB (MPLS TE MIB). The SNMP agent code operating with the MPLS TE MIB enables a standardized, SNMP-based approach to be used in managing the MPLS TE features in Cisco software.

- Restrictions for the MPLS Traffic Engineering MIB, on page 387
- Information About the MPLS Traffic Engineering MIB, on page 387
- How to Configure the MPLS Traffic Engineering MIB, on page 395
- Configuration Examples for the MPLS Traffic Engineering MIB, on page 397
- Additional References, on page 398
- Feature Information for the MPLS Traffic Engineering MIB, on page 399
- Glossary, on page 399

Restrictions for the MPLS Traffic Engineering MIB

- Supports read-only (RO) permission for MIB objects.
- Contains no configuration support by means of SET functions, except for the mplsTunnelTrapEnable object (which has been made writable). Accordingly, the MPLS TE MIB contains indexing support for the Interfaces MIB.
- Supports only SNMP GET, GETNEXT, and GETBULK retrieval functions, except in the case of the mplsTunnelTrapEnable object (which has been made writable by means of SET functions).
- Contains no support for Guaranteed Bandwidth Traffic Engineering (GBTE) or Auto Bandwidth features.

Information About the MPLS Traffic Engineering MIB

MPLS Traffic Engineering MIB Cisco Implementation

The MPLS TE MIB is based on the Internet Engineering Task Force (IETF) draft MIB entitled *draft-ietf-mpls-te-mib-05.txt* which includes objects describing features that support MPLS TE.

Slight differences between the IETF draft MIB and the implementation of the TE capabilities within Cisco software require some minor translations between the MPLS TE MIB and the internal data structures of Cisco software. These translations are made by the SNMP agent code that is installed and operating on various hosts within the network. This SNMP agent code, running in the background as a low priority process, provides a management interface to Cisco software.

The SNMP objects defined in the MPLS TE MIB can be displayed by any standard SNMP utility. All MPLS TE MIB objects are based on the IETF draft MIB; thus, no specific Cisco SNMP application is required to support the functions and operations pertaining to the MPLS TE MIB.

MPLS Traffic Engineering Overview

MPLS TE capabilities in Cisco software enable an MPLS backbone to replicate and expand upon the TE capabilities of Layer 2 ATM and Frame Relay networks.

TE capabilities are essential to effective management of service provider and Internet service provider (ISP) backbones. Such backbones must support high transmission capacities, and the networks incorporating backbones must be extremely resilient to link or node failures.

The MPLS TE facilities built into Cisco software provide a feature-rich, integrated approach to managing the large volumes of traffic that typically flow through WANs. The MPLS TE facilities are integrated into Layer 3 network services, thereby optimizing the routing of IP traffic in the face of constraints imposed by existing backbone transmission capacities and network topologies.

Capabilities Supported by the MPLS Traffic Engineering MIB

- The ability to generate and queue notification messages that signal changes in the operational status of MPLS TE tunnels.
- Extensions to existing SNMP commands that provide the ability to enable, disable, and configure notification messages for MPLS TE tunnels.
- The ability to specify the name or the IP address of a network management station (NMS) in the operating environment to which notification messages are to be sent.
- The ability to write notification configurations into nonvolatile memory.

Notification Generation Events

When MPLS TE notifications are enabled (see the **snmp-server enable traps mpls** command), notification messages relating to specific events within Cisco software are generated and sent to a specified NMS in the network.

For example, an mplsTunnelUp notification is sent to an NMS when an MPLS TE tunnel is configured and the tunnel transitions from an operationally “down” state to an “up” state.

Conversely, an mplsTunnelDown notification is generated and sent to an NMS when an MPLS TE tunnel transitions from an operationally “up” state to a “down” state.

An mplstunnelRerouted notification is sent to the NMS under the following conditions:

- The signaling path of an existing MPLS TE tunnel fails for some reason and a new path option is signaled and placed into effect (that is, the tunnel is rerouted).

- The signaling path of an existing MPLS TE tunnel is fully operational, but a better path option can be signaled and placed into effect (that is, the tunnel can be reoptimized). This reoptimazation can be triggered by:
  - A timer
  - The issuance of an **mpls traffic-eng reoptimize** command
  - A configuration change that requires the resignaling of a tunnel

The mplsTunnelReoptimized notification is not generated when an MPLS traffic engineering tunnel is reoptimized. However, an mplsTunnelReroute notification is generated. Thus, at the NMS, you cannot distinguish between a tunnel reoptimization event and tunnel reroute event.

Path options are configurable parameters that you can use to specify the order of priority for establishing a new tunnel path. For example, you can create a tunnel head configuration and define any one of many path options numbered 1 through n, with "1" being the highest priority option and "n" being an unlimited number of lower priority path options. Thus, there is no limit to the number of path options that you can specify in this manner.

Notification Implementation

When an MPLS TE tunnel interface (or any other device interface, such as an FastEthernet or Packet over SONET (POS) interface) transitions between an up and down state, an Interfaces MIB (ifMIB) link notification is generated. When such a notification occurs in an MPLS TE MIB environment, the interface is checked by software to determine if the notification is associated with an MPLS TE tunnel. If so, the interfaces MIB link notification is interlinked with the appropriate mplsTunnelUp or mplsTunnelDown notification to provide notification to the NMS regarding the operational event occurring on the tunnel interface. Hence, the generation of an Interfaces MIB link notification pertaining to an MPLS traffic engineering tunnel interface begets an appropriate mplsTunnelUp or mplsTunnelDown notification that is transmitted to the specified NMS.

An mplsTunnelRerouted notification is generated whenever the signaling path for an MPLS TE tunnel changes. However, software intelligence in the MPLS TE MIB prevents the reroute notification from being sent to the NMS when a TE tunnel transitions between an up or down state during an administrative or operational status check of the tunnel. Either an up or down notification or a reroute notification can be sent in this instance, but not both. This action prevents unnecessary traffic on the network.

Benefits of the MPLS Traffic Engineering MIB

- Provides a standards-based SNMP interface for retrieving information about MPLS TE.
- Provides information about the traffic flows on MPLS TE tunnels.
- Presents MPLS TE tunnel routes, including the configured route, the Interior Gateway Protocol (IGP) calculated route, and the actual route traversed.
- Provides information, in conjunction with the Interfaces MIB, about how a tunnel was rerouted in the event of a link failure.
- Provides information about the configured resources used for an MPLS TE tunnel.
- Supports the generation and queueing of notifications that call attention to major changes in the operational status of MPLS TE tunnels;
- Forwards notification messages to a designated NMS for evaluation or action by network administrators.

MPLS Traffic Engineering MIB Layer Structure

The SNMP agent code supporting the MPLS TE MIB follows the existing model for such code in Cisco software and is, in part, generated by the Cisco tool set, based on the MIB source code.

The SNMP agent code, which has a layered structure similar to that of the MIB support code in Cisco software, consists of four layers:

- Platform independent layer--This layer is generated primarily by the Cisco MIB development tool set and incorporates platform and implementation independent functions. The Cisco MIB development tool set creates a standard set of files associated with a MIB.
- Application interface layer--The functions, names, and template code for MIB objects in this layer are also generated by the Cisco MIB development tool set.
- Application specific layer--This layer provides an interface between the application interface layer and the application program interface (API) and data structures layer and performs tasks needed to retrieve required information from Cisco software, such as searching through data structures.
- API and data structures layer--This layer contains the data structures or APIs within Cisco software that are retrieved or called in order to set or retrieve SNMP management information.

Features and Technologies Related to the MPLS Traffic Engineering MIB

The MPLS TE MIB feature is used with the following features and technologies:

- Standards-based SNMP network management application
- MPLS
- MPLS TE

Supported Objects in the MPLS Traffic Engineering MIB

The MPLS TE MIB contains numerous tables and object definitions that provide read-only SNMP management support for the MPLS TE features in Cisco software. The MPLS TE MIB conforms to Abstract Syntax Notation One (ASN.1), thus reflecting an idealized MPLS TE database.

Using any standard SNMP network management application, you can retrieve and display information from the MPLS TE MIB by using GET operations; similarly, you can traverse information in the MIB database for display by using GETNEXT operations.

The MPLS TE MIB tables and objects supported in Cisco software follow. Important MIB tables (those highlighted in bold type) are described briefly in accompanying text.

- mplsTunnelConfigured--Total number of tunnel configurations that are defined on this node.
- mplsTunnelActive--Total number of label switched paths (LSPs) that are defined on this node.
- mplsTunnelTEDistProto--The IGP distribution protocol in use.
- mplsTunnelMaxHops--The maximum number of hops any given tunnel can utilize.
- mplsTunnelIndexNext--Unsupported; set to 0.

- mplsTunnelTable--Entries in this table with an instance of 0 and a source address of 0 represent tunnel head configurations. All other entries in this table represent instances of LSPs, both signaled and standby. If a tunnel instance is signaled, its operating status (operStatus) is set to “up” (1) and its instance corresponds to an active LSP.

Tunnel configurations exist only on the tunnel head where the tunnel interface is defined. LSPs traverse the network and involve tunnel heads, tunnel midpoints, and tunnel tails.

Pointers in the tunnel table refer to corresponding entries in other MIB tables. By using these pointers, you can find an entry in the mplsTunnelTable and follow a pointer to other tables for additional information. The pointers are the following: mplsTunnelResourcePointer, mplsTunnelHopTableIndex, mplsTunnelARHopTableIndex, and mplsTunnelCHopTableIndex.

The tunnel table is indexed by tunnel ID, tunnel instance, tunnel source address, and tunnel destination address. The description of each entry has an alphabetic suffix (a) for tunnel head configurations only, (b) for LSPs only, or (c) for both tunnel head configurations and LSPs , if appropriate, to indicate the applicability of the entry.

Following is a list and description of each entry.

-
  - mplsTunnelIndex--Same as tunnel ID (c).
  - mplsTunnelInstance--Tunnel instance of the LSP; 0 for head configurations (b).
  - mplsTunnelIngressLSRId--Source IP address of the LSP; 0 for head configurations (b).
  - mplsTunnelEgressLSRId--Destination IP address of the tunnel (c).
  - mplsTunnelName--Command name for the tunnel interfaces (a).
  - mplsTunnelDescr--Descriptive name for tunnel configurations and LSPs (c).
  - mplsTunnelIsIf--Indicator of whether the entry represents an interface (c).
  - mplsTunnelIfIndex--Index of the tunnel interface within the ifMIB (a).
  - mplsTunnelXCPointer--(For midpoints only - no tails) Pointer for the LSP within the mplsXCTable of the MPLS LSR MIB (b).
  - mplsTunnelSignallingProto--Signaling protocol used by tunnels (c).
  - mplsTunnelSetupPrio--Setup priority of the tunnel (c).
  - mplsTunnelHoldingPrio--Holding priority of the tunnel (c).
  - mplsTunnelSessionAttributes--Session attributes (c).
  - mplsTunnelOwner--Tunnel owner (c).
  - mplsTunnelLocalProtectInUse-- Not supported on midpoint node (c).
  - mplsTunnelResourcePointer--Pointer into the Resource Table (b).
  - mplsTunnelInstancePriority--Not implemented (b).
  - mplsTunnelHopTableIndex--Index into the Hop Table (a).
  - mplsTunnelARHopTableIndex--Index into the AR Hop Table (b).
  - mplsTunnelCHopTableIndex--Index into the C Hop Table (b).
  - mplsTunnelPrimaryTimeUp--Amount of time, in seconds, that the current path has been up (a).
  - mplsTunnelPathChanges--Number of times a tunnel has been resignalled (a).
  - mplsTunnelLastPathChange--Amount of time, in seconds, since the last path resignaling occurred (a).
  - mplsTunnelCreationTime--Time stamp when the tunnel was created (a).
  - mplsTunnelStateTransitions--Number of times the tunnel has changed state (a).
  - mplsTunnelIncludeAnyAffinity--Not implemented (a).
  - mplsTunnelIncludeAllAffinity--Attribute bits that must be set for the tunnel to traverse a link (a).

- mplsTunnelExcludeAllAffinity--Attribute bits that must *not* be set for the tunnel to traverse a link (a).
- mplsTunnelPathInUse--Path option number being used for the tunnel's path. If no path option is active, this object will be 0 (a).
- mplsTunnelRole--Role of the tunnel on the router; that is, head, midpoint, or tail (c).
- mplsTunneltotalUptime--Amount of time, in seconds, that the tunnel has been operationally up (a).
- mplsTunnelInstanceUptime--Not implemented (b).
- mplsTunnelAdminStatus--Administrative status of a tunnel (c).
- mplsTunnelOperStatus--Actual operating status of a tunnel (c).
- mplsTunnelRowStatus--This object is used in conjunction with configuring a new tunnel. This object will always be seen as "active" (a).
- mplsTunnelStorageType--Storage type of a tunnel entry (c).

- mplsTunnelHopListIndexNext--Next valid index to use as an index in the mplsTunnelHopTable.
- **mplsTunnelHopTable** --Entries in this table exist only for tunnel configurations and correspond to the path options defined for the tunnel. Two types of path options exist: *explicit* and *dynamic* . This table shows all hops listed in the explicit path options, while showing only the destination hop for dynamic path options. The tunnel hop table is indexed by tunnel ID, path option, and hop number.

Following is a list and description of each table entry.

- - mplsTunnelHopListIndex--Primary index into the table.
  - mplsTunnelHopIndex--Secondary index into the table.
  - mplsTunnelHopAddrType--Indicates if the address of this hop is the type IPv4 or IPv6.
  - mplsTunnelHopIpv4Addr--The IPv4 address of this hop.
  - mplsTunnelHopIpv4PrefixLen--The prefix length of the IPv4 address.
  - mplsTunnelHopIpv6Addr--The IPv6 address of this hop.
  - mplsTunnelHopIpv6PrefixLen--The prefix length of the IPv6 address.
  - mplsTunnelHopAsNumber--This object will contain 0 or the autonomous system number of the hop, depending on the value of mplsTunnelHopAddrType.
  - mplsTunnelHopLspId--This object will contain 0 or the LSPID of the tunnel, depending on the value of mplsTunnelHopAddrType.
  - mplsTunnelHopType--Denotes whether this tunnel hop is routed in a strict or loose fashion.
  - mplsTunnelHopRowStatus--This object is used in conjunction with the configuring of a new row in the table.
  - mplsTunnelHopStorageType--The storage type of this MIB object.

- mplsTunnelResourceIndexNext--This object contains the next appropriate value to be used for mplsTunnelResourceIndex when creating entries in the mplsTunnelResourceTable
- **mplsTunnelResourceTable** --Entries in this table correspond to the "Tspec" information displayed when you execute the **show mpls traff9c-eng tunnels** command. These entries exist only for LSPs.

The tunnel resource table is indexed by address and hop number. Following the mplsTunnelResourcePointer pointer from the tunnel table is the best way to retrieve information from this table.

Following is a list and description of each table entry.

- - mplsTunnelResourceIndex--The primary index into this table.
  - mplsTunnelResourceMaxRate--The maximum rate, in bits per second, supported by this tunnel.
  - mplsTunnelResourceMeanRate--The mean rate, in bits per second, supported by this tunnel.

- mplsTunnelResourceMaxBurstSize--The maximum burst size, in bytes, allowed by this tunnel.
- mplsTunnelResourceRowStatus--This object is used in conjunction with the configuration of a new row in the table.
- mplsTunnelResourceStorageType--The storage type of this MIB object.

- **mplsTunnelARHopTable** --Entries in this table correspond to the actual route taken by the tunnel, and whose route was successfully signaled by the network. The hops present in this table correspond to those present in the record route object (RRO) in Resource Reservation Protocol (RSVP). You can also display the information in this table by executing the **show mpls traff9c-eng tunnels** command.

The actual route hop table is indexed by address and hop number. Following the mplsTunnelARHopTableIndex pointer from the tunnel table is the best way to retrieve information from this table.

Following is a list and description of each table entry:

- • mplsTunnelARHopListIndex--The primary index into this table.
  - mplsTunnelARHopIndex--The secondary index into this table.
  - mplsTunnelARHopIpv4Addr--The IPv4 address of this hop.
  - mplsTunnelARHopIpv4PrefixLen--The prefix length of the IPv4 address.
  - mplsTunnelARHopIpv6Addr--The IPv6 address of this hop.
  - mplsTunnelARHopIpv6PrefixLen--The prefix length of the IPv6 address.
  - mplsTunnelARHopAsNumber--This object will contain 0 or the AS number of the hop, depending on the value of mplsTunnelARHopAddrType.
  - mplsTunnelARHopAddrType--The type of address for this MIB entry, either IPv4 or IPv6.
  - mplsTunnelARHopType--Denotes whether this tunnel hop is routed in a strict or loose manner.

- **mplsTunnelCHopTable** --Entries in this table correspond to the explicit route object (ERO) in RSVP, which is used to signal the LSP. The list of hops in this table will contain those hops that are computed by the constraint-based shortest path first (SPF) algorithm. In those cases where "loose" hops are specified for the tunnel, this table will contain the hops that are "filled-in" between the loose hops to complete the path. If you specify a complete explicit path, the computed hop table matches your specified path.

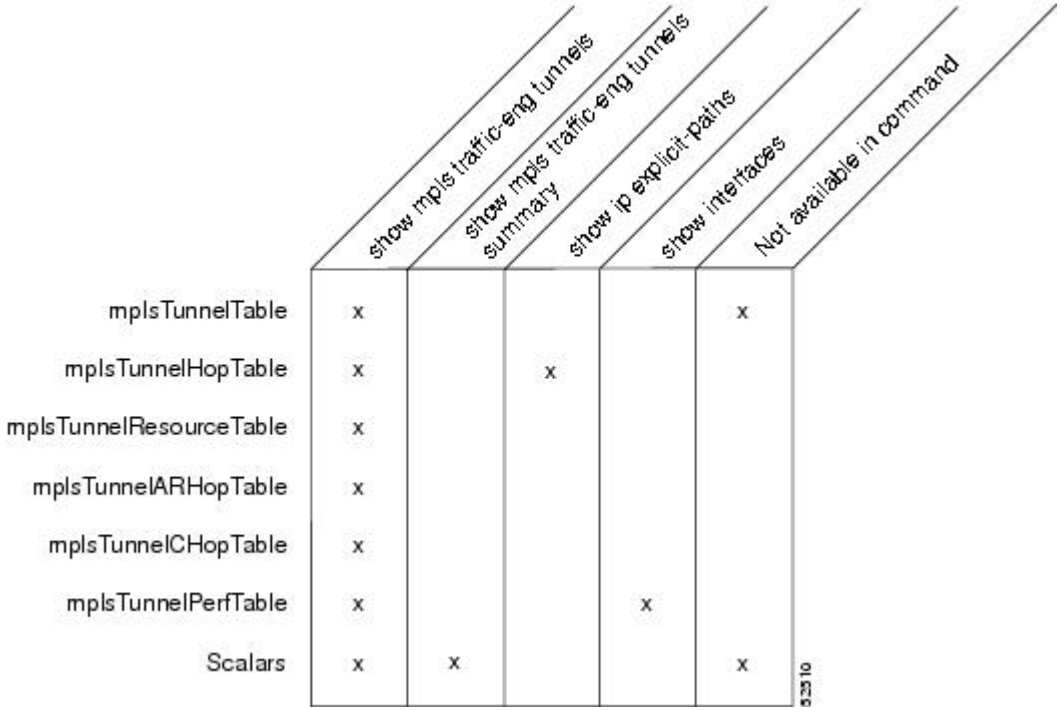
The computed hop table is indexed by address and hop number. Following the mplsTunnelCHopTableIndex pointer from the tunnel table is the best way to retrieve information from this table.

Following is a list and description of each table entry:

- • mplsTunnelCHopListIndex--The primary index into this table.
  - mplsTunnelCHopIndex--The secondary index into this table.
  - mplsTunnelCHopAddrType--Indicates if the address of this hop is the type IPv4 or IPv6.
  - mplsTunnelCHopIpv4Addr--The IPv4 address of this hop.
  - mplsTunnelCHopIpv4PrefixLen--The prefix length of the IPv4 address.
  - mplsTunnelCHopIpv6Addr--The IPv6 address of this hop.
  - mplsTunnelCHopIpv6PrefixLen--The prefix length of the IPv6 address.
  - mplsTunnelCHopAsNumber--This object will contain 0 or the autonomous system number of the hop, depending on the value of mplsTunnelHopAddrType.
  - mplsTunnelCHopType--Denotes whether this tunnel hop is routed in a strict or loose way.

- **mplsTunnelPerfTable** --The tunnel performance table, which augments the **mplsTunnelTable**, provides packet and byte counters for each tunnel. This table contains the following packet and byte counters:
  - mplsTunnelPerfPackets--This packet counter works only for tunnel heads.
  - mplsTunnelPerfHCPackets--This packet counter works only for tunnel heads.

- mplsTunnelPerfErrors--This packet counter works only for tunnel heads.
- mplsTunnelPerfBytes--This byte counter works for tunnel heads and tunnel midpoints, but not for tunnel tails.
- mplsTunnelPerfHCBytes--This byte counter works for tunnel heads and tunnel midpoints, but not for tunnel tails.



- mplsTunnelTrapEnable--The object type *mplsTunnelTrapEnable* is enhanced to be writable. Accordingly, if this object type is set to "TRUE," the following notifications are enabled, thus giving you the ability to monitor changes in the operational status of MPLS TE tunnels:
  - mplsTunnelUp
  - mplsTunnelDown
  - mplsTunnelRerouted

If the *mplsTunnelTrapEnable* object is set to "FALSE," such operational status notifications are not generated. These notification functions are based on the definitions (mplsTeNotifications) contained in the IETF draft document entitled *draft-ietf-mpls-te-mib-05.txt* .

CLI Access to MPLS Traffic Engineering MIB Information

The figure below shows commands that you can use to retrieve information from specific tables in the MPLS TE MIB. As noted in this figure, some information in the MPLS TE MIB is not retrievable by commands.

Figure 39: Commands for Retrieving MPLS TE MIB Information

Retrieving Information from the MPLS Traffic Engineering MIB

This section describes how to efficiently retrieve information about TE tunnels. Such information can be useful in large networks that contain many TE tunnels.

Traverse across a single column of the mplsTunnelTable, such as mplsTunnelName. This action provides the indexes of every tunnel configuration, and any LSPs involving the host router. Using these indexes, you can perform a GET operation to retrieve information from any column and row of the mplsTunnelTable.

The mplsTunnelTable provides pointers to other tables for each tunnel. The column mplsTunnelResourcePointer, for example, provides an object ID (OID) that you can use to access resource allocation information in the mplsTunnelResourceTable. The columns mplsTunnelHopTableIndex, mplsTunnelARHopTableIndex, and mplsTunnelCHopTableIndex provide the primary index into the mplsTunnelHopTable, mplsTunnelARHopTable, and mplsTunnelCHopTable, respectively. By traversing the MPLS TE MIB in this manner using a hop table column and primary index, you can retrieve information pertaining to the hops of that tunnel configuration.

Because tunnels are treated as interfaces, the tunnel table column (mplsTunnelIfIndex) provides an index into the Interfaces MIB that you can use to retrieve interface-specific information about a tunnel.

How to Configure the MPLS Traffic Engineering MIB

Enabling the SNMP Agent to Help Manage Various MPLS TE Tunnel Characteristics of Tunnels on the Local Router

The SNMP agent for the MPLS TE MIB is disabled by default. To enable the SNMP agent for the MPLS TE MIB, perform the following task.

SUMMARY STEPS

1. **telnet** *host*
2. **enable**
3. **show running-config**
4. **configure terminal**
5. **snmp-server community** *string* [**view** *view-name*] [**ro** | **rw**] [**ipv6** *nacl*] [*access-list-number*]
6. **snmp-server enable traps** [*identification-type*] [*notification-option*]
7. **exit**
8. **write memory**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**telnet** *host* **Example:** `Router> telnet 192.172.172.172`	Telnets to the router identified by the specified IP address (represented as *xxx.xxx.xxx.xxx*).
Step 2	**enable** **Example:**	Enables privileged EXEC mode. • Enter your password if prompted.

	Command or Action	Purpose
	`Router# enable`	
Step 3	**show running-config** **Example:** `Router# show running-config`	Displays the running configuration to determine if an SNMP agent is already running. • If no SNMP information is displayed, go to Step 4 . If any SNMP information is displayed, you can modify the information or change it as needed.
Step 4	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 5	**snmp-server community** *string* [**view** *view-name*] [**ro** | **rw**] [**ipv6** *nacl*] [*access-list-number*] **Example:** `Router(config)# snmp-server community comaccess ro 4`	Enables the read-only (RO) community string.
Step 6	**snmp-server enable traps** [*identification-type*] [*notification-option*] **Example:** `Router(config)# snmp-server enable traps`	Enables an LSR to send SNMP notifications or informs to an SNMP host. **Note** This command is optional. After SNMP is enabled, all MIBs (not just the TE MIB) are available for the user to query.
Step 7	**exit** **Example:** `Router(config)# exit`	Exits global configuration mode and returns to privileged EXEC mode.
Step 8	**write memory** **Example:** `Router# write memory`	Writes the modified configuration to NVRAM, permanently saving the settings.

Verifying the Status of the SNMP Agent

To verify that the SNMP agent has been enabled on a host network device, perform the following steps.

SUMMARY STEPS

1. **telnet** *host*
2. **enable**
3. **show running-config**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**telnet** *host* **Example:** `Router# telnet 192.172.172.172`	Telnets to the target device identified by the specified IP address (represented as *xxx.xxx.xxx.xxx*).
Step 2	**enable** **Example:** `Router# enable`	Enables SNMP on the target device.
Step 3	**show running-config** **Example:** `Router# show running-config`	Displays the running configuration on the target device and is used to examine the output for displayed SNMP information.

Examples

The follows example displays the running configuration on the target device and its SNMP information.

```
Router# show running-config
.
.
.
snmp-server community public ro
snmp-server community private ro
```

Any **snmp-server** statement that appears in the output and takes the form shown here verifies that SNMP has been enabled on that device.

Configuration Examples for the MPLS Traffic Engineering MIB

Example Enabling the SNMP Agent to Help Manage MPLS TE Characteristics of Tunnels on the Local Router

The following example shows how to enable an SNMP agent on a host network device:

```
Router# configure terminal
Router(config)# snmp-server community private
```

The following example shows how to enable SNMPv1 and SNMPv2C. The configuration permits any SNMP agent to access all MPLS TE MIB objects with read-only permissions using the community string public.

```
Router(config)# snmp-server community public
```

The following example shows how to allow read-only access to all MPLS TE MIB objects relating to members of access list 4 that specify the comaccess community string. No other SNMP agents will have access to any MPLS TE MIB objects.

```
Router(config)# snmp-server community comaccess ro 4
```

Feature Information for the MPLS Traffic Engineering MIB

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 76: Feature Information for the MPLS Traffic Engineering MIB

Feature Name	Releases	Feature Information
MPLS Traffic Engineering MIB	Cisco IOS XE Release 2.3	The MPLS Traffic Engineering MIB feature enables the SNMP agent support in Cisco software for MPLS TE management, as implemented in the MPLS TE MIB. In Cisco IOS XE Release 2.3, this feature was introduced on the Cisco ASR 1000 Series Aggregation Services Routers. The following commands were introduced or modified: **snmp-server community**, **snmp-server enable traps** , **snmp-server hpst**.

Glossary

affinity bits—An MPLS traffic engineering tunnel's requirements on the attributes of the links it will cross. The tunnel's affinity bits and affinity mask must match with the attributes of the various links carrying the tunnel.

call admission precedence—An MPLS traffic engineering tunnel with a higher priority will, if necessary, preempt an MPLS traffic engineering tunnel with a lower priority. An expected use is that tunnels that are more difficult to route will have a higher priority, and can preempt tunnels that are less difficult to route, on the assumption that those lower priority tunnels can find another path.

constraint-based routing—Procedures and protocols used to determine a route across a backbone taking into account resource requirements and resource availability, instead of simply using the shortest path.

flow —A traffic load entering the backbone at one point—point of presence (POP)—and leaving it from another that must be traffic engineered across the backbone. The traffic load will be carried across one or more LSP tunnels running from the entry POP to the exit POP.

headend —The LSR at which the tunnel originates. The tunnel's "head" or tunnel interface will reside at this LSR as well.

informs —A type of notification message that is more reliable than a conventional trap notification message because an informs message requires acknowledgment.

label —A short, fixed-length data construct that tells switching nodes how to forward data (packets or cells).

label switched path (LSP) tunnel—A configured connection between two routers, using label switching to carry the packets.

LSP —label switched path. A path that is followed by a labeled packet over several hops, starting at an ingress LSR and ending at an egress LSR.

LSR —label switch router. A Layer 3 router that forwards a packet based on the value of a label encapsulated in the packet.

MIB —Management Information Base. A database of network management information (consisting of MIB objects) that is used and maintained by a network management protocol such as SNMP. The value of a MIB object can be changed or retrieved using SNMP commands, usually by a GUI-based network management system. MIB objects are organized in a tree structure that includes public (standard) and private (proprietary) branches.

MPLS —Multiprotocol Label Switching. Switching method that forwards IP traffic using a label. This label instructs the routers and the switches in the network where to forward the packets based on preestablished IP routing information.

NMS —network management station. An NMS is a powerful, well-equipped computer (typically an engineering workstation) that is used by a network administrator to communicate with other devices in the network. An NMS is typically used to manage network resources, gather statistics, and perform a variety of network administration and configuration tasks.

notification —A message sent by an SNMP agent to a network management station, console, or terminal to indicate that a significant event within Cisco IOS software has occurred (see traps).

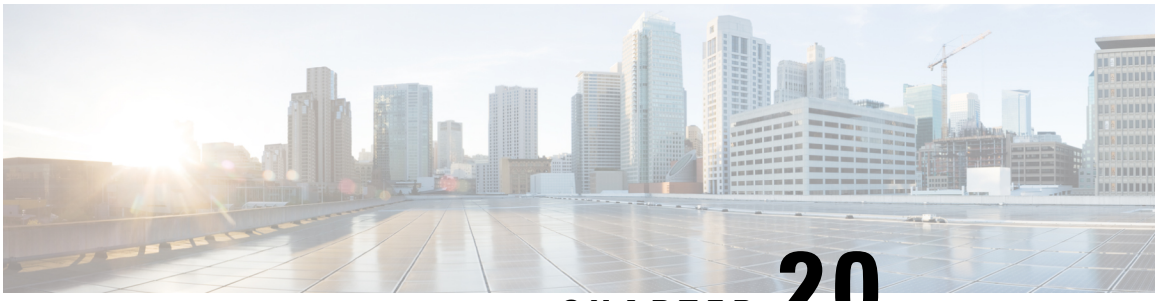
OSPF —Open Shortest Path First. A link-state routing protocol used for routing IP.

RSVP —Resource Reservation Protocol. Protocol for reserving network resources to provide quality of service (QoS) guarantees to application flows.

SNMP —Simple Network Management Protocol. A network management protocol used almost exclusively in TCP/IP networks. SNMP provides a means to monitor and control network devices, manage configurations, collect statistics, monitor performance, and ensure network security.

tailend —The downstream, receive end of a tunnel.

traffic engineering—Techniques and processes that cause routed traffic to travel through the network on a path other than the one that would have been chosen if standard routing methods were used.



trap —A message sent by an SNMP agent to a network management station, console, or terminal to indicate that a significant event within Cisco IOS software has occurred. Traps (notifications) are less reliable than inform requests, because the receiver of the trap does not send an acknowledgment of receipt; furthermore, the sender of the trap cannot determine if the trap was received (see notification).

VCC —virtual channel connection. A VCC is a logical circuit consisting of VCLs that carries data between two endpoints in an ATM network. Sometimes called a virtual circuit connection.

VCI —virtual channel identifier. A 16-bit field in the header of an ATM cell. The VCI, together with the VPI, is used to identify the next network VCL as the cell passes through a series of ATM switches on its way to its final destination.

VCL —virtual channel link. A VCL is the logical connection that exists between two adjacent switches in an ATM network.

VPI —virtual path identifier. An 8-bit field in the header of an ATM cell. The VPI, together with the VCI, is used to identify the next network VCL as the cell passes through a series of ATM switches on its way to its final destination.

CHAPTER 20

Point-to-Multipoint MPLS-TE MIB

The point-to-multipoint (P2MP) Multiprotocol Label Switching (MPLS)-traffic engineering (TE) MIB describes the Label Switched Path (LSP) in an IP MPLS network. An administrator can use the P2MP MPLS-TE MIB to determine optimal branch points in the network so that optimal links are used.

The P2MP MPLS-TE MIB has the following benefits:

- Provides a standards-based Simple Network Management Protocol (SNMP) interface for retrieving information about P2MP MPLS-TE tunnels.
- Shows traffic flow information for P2MP MPLS-TE tunnels.
- Shows P2MP MPLS-TE tunnel routes, including the configured route, the Interior Gateway Protocol (IGP) calculated route, and the actual route traversed.
- Shows tunnel reroute information in the event of a link failure in accordance with the Interfaces MIB.
- Shows information about the configured resources used for an P2MP MPLS-TE tunnel.
- Supports the generation of notifications. These notifications call attention to major changes in the operational status of P2MP MPLS-TE tunnels.
- Forwards notification messages to a designated network management server (NMS) for evaluation or action by administrators.

Restrictions for Point-to-Multipoint MPLS-TE MIB

The P2MP MPLS-TE MIB supports read-only access to the objects.

Information About the Point-to-Multipoint MPLS-TE MIB

Point-to-Multipoint MPLS-TE MIB Cisco Implementation

The P2MP MPLS-TE MIB is based on the Internet Engineering Task Force (IETF) draft MIB entitled *draft-ietf-mpls-p2mp-te-mib-09* , which includes objects describing features that support P2MP MPLS-TE.

The SNMP objects defined in the P2MP MPLS-TE MIB can be displayed by any standard SNMP utility. All supported P2MP MPLS-TE MIB objects are based on the IETF draft MIB; thus, no specific Cisco SNMP application is required to support the functions and operations pertaining to the P2MP MPLS-TE MIB.

The P2MP MPLS-TE LSP determines optimal branch points in the IP and MPLS network and must be managed using SNMP.

MPLS was defined in RFC 3031, and a signaling protocol for P2MP MPLS-TE, that is, TE extensions to the Resource Reservation Protocol (RSVP-TE) was defined in RFC 3209. RSVP-TE is extended for use in a P2MP MPLS-TE environment by RFC 4875 following the requirements set out in RFC 4461.

RFC 3812 provides a MIB module for modeling and controlling P2MP MPLS-TE in conjunction with Textual Conventions defined in RFC 3811. In addition, RFC 3813 defines a MIB module for modeling and controlling an MPLS Label Switching Router (LSR) that may support MPLS-TE. An overview of MPLS MIB modules can be found in RFC 4221.

In addition, there is a description for how to use the LSR MIB module RFC 3813 to model and control an LSR that supports P2MP MPLS-TE.

Functionality Supported by the Point-to-Multipoint MPLS-TE MIB

- The ability to generate and queue notification messages that signal changes in the operational status of P2MP MPLS-TE tunnels.
- The ability to enable, disable, and configure notification messages for P2MP MPLS-TE tunnels through extensions to existing SNMP commands. .
- The ability to specify the name or the IP address of a network management station (NMS) in the operating environment to which notification messages are to be sent.
- The ability to write notification configurations into nonvolatile memory.

Notification Generation Events for the Point-to-Multipoint MPLS-TE MIB

When P2MP MPLS-TE notifications are enabled (see the **snmp-server enable traps mpls p2mp-traffic-eng** command), notification messages relating to specific events within Cisco software are generated and sent to a specified NMS in the network. For example, an mplsTeP2mpTunnelDestUp notification is sent to an NMS when an P2MP MPLS-TE tunnel is configured and the tunnel transitions from an operationally “down” state to an “up” state. Conversely, an mplsTeP2mpTunnelDestDown notification is generated and sent to an NMS when an MPLS-TE tunnel transitions from an operationally “up” state to a “down” state.

An up or down trap is generated per sub-LSP when a sub-LSP up or down event is triggered. The traps have two Varbinds:

- cmplsTeP2mpTunnelDestAdminStatus
- cmplsTeP2mpTunnelDestOperStatus

Each trap object is indexed by 12 indices:

- mplsTunnelIndex
- mplsTunnelInstance
- mplsTunnelIngressLsrId
- mplsTunnelEgressLsrId
- mplsTeP2mpTunnelDestSrcSubGroupOriginType
- mplsTeP2mpTunnelDestSrcSubGroupOrigin
- mplsTeP2mpTunnelDestSrcSubGroupID
- mplsTeP2mpTunnelDestSubGroupOriginType
- mplsTeP2mpTunnelDestSubGroupOrigin
- mplsTeP2mpTunnelDestSubGroupID
- mplsTeP2mpTunnelDestDestinationType
- mplsTeP2mpTunnelDestDestination

Supported Objects in the Point-to-Multipoint MPLS-TE MIB

Using any standard SNMP network management application, you can retrieve and display information from the P2MP MPLS-TE MIB (CISCO-IETF-MPLS-TE-P2MP-MIB) by using GET operations; similarly, you can traverse information in the MIB database for display by using GETNEXT operations.

Note The **show mpls traffic-eng tunnels** command can be used to see the value of various objects discussed in this section through the CLI.

The point-to-multipoint MIB tables and objects supported in Cisco IOS releases follow. Important MIB tables (those highlighted in bold type) are described briefly in accompanying text.

Following is a list and description of each entry for the supported P2MP MPLS-TE MIB Scalar objects:

- mplsTeP2mpTunnelConfigured—Total number of P2MP MPLS-TE tunnels configured on this device. A tunnel is considered configured if the mplsTunnelRowStatus in MPLS-TE-STD-MIB is active.
- mplsTeP2mpTunnelActive—Total number of P2MP MPLS-TE tunnels active on this device.

mplsTeP2mpTunnelTable

The mplsTeP2mpTunnelTable allows new P2MP MPLS-TE tunnels to be created between an LSR and one or more remote endpoints, and existing P2MP MPLS-TE tunnels to be reconfigured or removed. This table augments the mplsTunnelTable in the MPLS-TE-STD-MIB so that the entries in that table can be flagged as

point-to-multipoint, and can be configured and monitored appropriately. The mplsTeP2mpTunnelTable is indexed by four indices similar to the mplsTunnelTable:

- mplsTunnelIndex
- mplsTunnelInstance
- mplsTunnelIngressLSRId
- mplsTunnelEgressLSRId

The mplsTunnelEgressLSRId maps to the P2MP MPLS-TE subgroup-id of the sub-lsp. The subgroup-id is zero for the P2MP MPLS-TE LSP virtual interface (VIF). Therefore, the mplsTunnelEgressLSRId has a zero value for the P2MP MPLS-TE LSP VIF. The mapping of the remainder of the indices is similar to those found in the MPLS-TE MIB.

The following is a list and description of each supported mplsTeP2mpTunnelTable object:

- mplsTeP2mpTunnelBranchRole—Supplements the value in the object mplsTunnelRole in MPLS-TE-STD-MIB that indicates the role of this LSR in the tunnel represented by this entry in mplsTeP2mpTunnelTable. This object supports the head, transit, and tail in order to describe the role of LSR for the tunnel. The following objects describe the mplsTunnelRole:
  - RRR_MGMT_TUN_ROLE_HEAD–Contains the value D_cmplsTeP2mpTunnelBranchRole_notBranch.
  - RRR_MGMT_TUN_ROLE_MID–Contains the value D_cmplsTeP2mpTunnelBranchRole_branch.
  - RRR_MGMT_TUN_ROLE_TAIL–Contains the value D_cmplsTeP2mpTunnelBranchRole_notBranch.
- mplsTeP2mpTunnelP2mpXcIndex– Contains the value of mplsXCIndex, the primary index of the mplsXCTable for all cross-connect entries for this P2MP MPLS-TE LSP.
- mplsTeP2mpTunnelRowStatus– Contains the variable used to create, modify, and delete a row in this table. The row in this table is in the active state only and no objects in that row can be modified by the agent except for the mplsTeP2mpTunnelRowStatus and mplsTeP2mpTunnelStorageType.
- mplsTeP2mpTunnelStorageType– Contains the storage type for this tunnel entry that may or may not be marked “volitile” because this value may or may not be persisted.

mplsTeP2mpTunnelDestTable

An entry in this table represents a destination of a P2MP MPLS-TE tunnel. Entries in this table share some index fields with the mplsTeP2mpTunnelTable and the mplsTunnelTable in MPLS-TE-STD-MIB. Entries in this table have no meaning unless there is a corresponding entry in mplsTeP2mpTunnelTable (which, itself, depends on a corresponding entry in mplsTunnelTable). This table shows information about sub-LSPs (one entry per destination of the tunnel). An entry to a destination is considered as sub-lsp.

The first three mplsTeP2mpTunnelDestTable indices are the same as the MPLS-TE MIB:

- mplsTunnelIndex
- mplsTunnelInstance
- mplsTunnelIngressLSRId

The fourth index entry, mplsTunnelEgressLSRId maps to the P2MP MPLS-TE ID. The remainder of the indices are as follows:

- mplsTeP2mpTunnelDestSrcSubGroupOriginType
- mplsTeP2mpTunnelDestSrcSubGroupOrigin
- mplsTeP2mpTunnelDestSrcSubGroupID
- mplsTeP2mpTunnelDestSubGroupOriginType
- mplsTeP2mpTunnelDestSubGroupOrigin
- mplsTeP2mpTunnelDestSubGroupID
- mplsTeP2mpTunnelDestDestinationType
- mplsTeP2mpTunnelDestDestination

The following is a list and description of each supported mplsTeP2mpTunnelDestTable object:

- mplsTeP2mpTunnelDestSrcSubGroupOriginType—Identifies the IPv4 address carried in mplsTeP2mpTunnelDestSrcSubGroupOrigin object at a transit or egress LSR and has a value unknown (0) for an ingress LSR.
- mplsTeP2mpTunnelDestSrcSubGroupOrigin—Contains the TE Router ID (reachable and stable IP address) of the originator of the P2MP MPLS-TE subgroup as received on a Path message by a transit or egress LSR. This object maps to the ingress LSR ID for a egress and transit LSR and unknown (0) for ingress LSR.
- mplsTeP2mpTunnelDestSrcSubGroupID—Contains the unique identifier assigned by the subgroup originator for this subgroup of this P2MP MPLS-TE tunnel as received on a Path message by a transit or egress LSR. This object maps to the subgroup ID for the sub-LSP to this destination for an egress and transit LSR ID and 0 for Ingress. The rrr_get_lsp_id_p2mp_subgroup_id (lsp_id) is used to fetch the value at egress or transit.
- mplsTeP2mpTunnelDestSubGroupOriginType—Identifies the IPv4 address carried in the mplsTeP2mpTunnelDestSubGroupOrigin object.
- mplsTeP2mpTunnelDestSubGroupOrigin—Contains the TE Router ID (reachable and stable IP address) of the originator of the P2MP MPLS-TE subgroup. In many cases, this is the ingress LSR of the P2MP MPLS-TE tunnel and is the received signaled value as available in mplsTeP2mpTunnelDestSrcSubGroupOrigin object. This object maps to Ingress LSR ID.

Note The **show mpls traffic-eng tunnels** command can be used to list the source address for tunnel that maps to this object's value.

- mplsTeP2mpTunnelDestSubGroupOrigin—Contains the unique identifier assigned by the subgroup originator for this subgroup of this P2MP MPLS-TE tunnel. This object has the value of subgroup ID of the sub-LSP. At egress, this contains the value of mplsTeP2mpTunnelDestSrcSubGroupID.
- mplsTeP2mpTunnelDestDestinationType—Identifies the IPv4 address carried in the mplsTeP2mpTunnelDestDestination object.
- mplsTeP2mpTunnelDestDestination—Identifies the single destination of this P2MP MPLS-TE tunnel that is the TE address of a leaf that can be routed. This is often the TE Router ID of the leaf, but can be any interface address. When a signaling protocol is used, this object corresponds to the S2L sub-LSP

destination address field in the S2L_SUB_LSP object. This object maps to the destination address of the sub-LSP.

- mplsTeP2mpTunnelDestBranchOutSegment—Identifies the outgoing branch from this LSR towards the destination represented by this table entry. It must be a unique identifier within the scope of this tunnel. This object contains an index into mplsOutSegmentTable object. This value maps to mplsOutSegmentIndex of the MPLS-LSR-STD-MIB. The LSR MIB shows the outgoing branches at a bud node. This outsegmentindex value (for each outsegment) is mapped to each sub-LSP.
- mplsTeP2mpTunnelDestHopTableIndex—Provides the index into the mplsTunnelHopListIndex of mplsTunnelHopTable of RFC TE MIB entry that specifies the explicit route hops for this destination of the P2MP MPLS-TE tunnel. This index is only valid for head entries. For nonhead entries the value is zero.
- mplsTeP2mpTunnelDestPathInUse—Contains the value that denotes the configured path that was chosen as the explicit path to this destination of this P2MP MPLS-TE tunnel. This value reflects the secondary index into mplsTunnelHopTable where the primary index comes from mplsTeP2mpTunnelDestHopTableIndex. This object maps to mplsTunnelPathOptionIndex of RFC TE MIB. TE only supports one path-option to be configured per sub-LSP, so the mplsTeP2mpTunnelDestPathInUse object is always 1.
- mplsTeP2mpTunnelDestCHopTableIndex—Provides the index into the mplsTunnelCHopTable that identifies the explicit path for this destination of the P2MP MPLS-TE tunnel. This object maps to mplsTunnelCHopListIndex of RFC TE MIB.
- mplsTeP2mpTunnelDestARHopTableIndex—Provides the index into the mplsTunnelARHopTable that identifies the actual hops traversed to this destination of the P2MP MPLS-TE tunnel. This is automatically updated by the agent when the actual hops become available. This object maps to mplsTunnelARHopTableIndex of RFC TE MIB.
- mplsTeP2mpTunnelDestAdminStatus—Indicates the desired operational status of this destination of this P2MP MPLS-TE tunnel. Status can be up or down.
- mplsTeP2mpTunnelDestOperStatus—Indicates the actual operational status of this destination of this P2MP MPLS-TE tunnel.
- mplsTeP2mpTunnelDestRowStatus—Creates, modifies, and/or deletes a row in this table. When a row in this table is in the active (1) state, no objects in that row can be modified by SET operations except mplsTeP2mpTunnelDestAdminStatus and mplsTeP2mpTunnelDestStorageType.
- mplsTeP2mpTunnelDestStorageType—Indicates the storage type for this table entry which is permanent. Conceptual rows having the value “permanent” do not allow write-access to any columnar objects in the row.

mplsTeP2mpTunnelBranchPerfBranch

An entry in this table provides information about P2MP MPLS-TE Tunnel. The mapping of the first four indices is similar to mplsTeP2mpTunnelTable. The table shows the outsegment information for head and transit entries. For tail entries, the entries are shown to display that tails are configured but values for objects are not provided.

This table has five indices:

- mplsTunnelIndex
- mplsTunnelInstance

- mplsTunnelIngressLSRId
- mplsTunnelEgressLSRId
- mplsTunnelBranchPerfBranch

The following is a list and description of each supported mplsTeP2mpTunnelBranchPerfBranch object:

- mplsTeP2mpTunnelBranchPerfBranch—Identifies an outgoing branch from this LSR for this tunnel. Its value is unique within the context of the tunnel. If MPLS-LSR-STD-MIB is implemented, this object should contain an index into mplsOutSegmentTable. Under all circumstances, this object should contain the same value as mplsTeP2mpTunnelDestBranchOutSegment for destinations reached on this branch. This value maps to mplsOutSegmentIndex of MPLS-LSR-STD-MIB.
- mplsTeP2mpTunnelBranchPerfPackets—Displays the number of packets forwarded by the tunnel onto this branch. This object should represents the 32-bit value of the least significant part of the 64-bit value if both mplsTeP2mpTunnelBranchPerfHCPackets is returned. This object should be read in conjunction with mplsTeP2mpTunnelBranchDiscontinuityTime object.

Note The **show interface tunnel** command can be used to see the value of packets.

- mplsTeP2mpTunnelBranchPerfHCPackets—Displays the High Capacity counter for number of packets forwarded by the tunnel onto this branch.
- mplsTeP2mpTunnelBranchPerfErrors—Displays the number of packets dropped because of errors or for other reasons, that were supposed to be forwarded onto this branch for this tunnel. This object should be read in conjunction with mplsTeP2mpTunnelBranchDiscontinuityTime object.
- mplsTeP2mpTunnelBranchPerfBytes—Displays the number of bytes forwarded by the tunnel onto this branch. This object should represent the 32-bit value of the least significant part of the 64-bit value if both mplsTeP2mpTunnelBranchPerfHCBytes is returned. This object should be read in conjunction with mplsTeP2mpTunnelBranchDiscontinuityTime object.

Note The **show mpls forwarding-table** command can be used to verify the values.

- cmplsTeP2mpTunnelBranchLocalLabel—Displays the local MPLS label for this branch.

Note Use the **show mpls traffic-eng forwarding path-set** and **show cef path set detail** commands can also be used to view label information.

- cmplsTeP2mpTunnelBranchOutIfIndex—Displays the index of outgoing TE link physical interface for the P2MP MPLS-TE egress tunnel branch. It is nonzero when the P2MP MPLS-TE tunnel's outgoing branch has been signaled.
- cmplsTeP2mpTunnelBranchOutLabel—Displays the outgoing MPLS label for this branch.

Note Use the **show mpls traffic-eng forwarding path-set** and **show cef path set detail** commands can also be used to view label information.

- cmplsTeP2mpTunnelBranchInIfIndex—Displays the index of incoming TE link physical interface for the P2MP MPLS-TE ingress tunnel branch. It is nonzero when the P2MP MPLS-TE tunnel's incoming branch has been signaled and it is applicable only on midpoint routers for tunnels having out-segment up and running.

How to Configure the Point-to-Multipoint MPLS-TE MIB

Configuring the Router to Send SNMP Notifications to a Host for Monitoring Point-to-Multipoint MPLS-TE

Although you can set the *community-string* argument using the **snmp-server host** command by itself, we recommend that you define this string using the **snmp-server community** command prior to using the **snmp-server host** command.

Perform this task to configure the router to send SNMP notifications to a host to monitor P2MP MPLS-TE. The ability to display SNMP notifications helps in managing P2MP MPLS-TE sessions by determining if any P2MP MPLS-TE sessions between peers are up or down.

The **snmp-server host** command specifies which hosts receive notifications or traps. The **snmp-server enable traps** command globally enables the trap production mechanism for the specified traps.

For a host to receive a trap, an **snmp-server host** command must be configured for that host, and, generally, the trap must be enabled globally through the **snmp-server enable traps** command.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server host** *host-address community-string* **udp-port** *port* **p2mp-traffic-eng**
4. **snmp-server enable traps mpls p2mp-traffic-eng** [**down** | **up**]
5. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.

	Command or Action	Purpose
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**snmp-server host** *host-address community-string* **udp-port** *port* **p2mp-traffic-eng** **Example:** `Router(config)# snmp-server host 172.20.2.160 comp2mppublic udp-port 162 p2mp-traffic-eng`	Specifies the recipient of an SNMP notification operation. • The *host-address* argument specifies the name or Internet address of the host (the targeted recipient). • The *community-string* argument is a password-like community string sent with the notification operation. • The **udp-port** *port* keyword-argument pair names the UDP port of the host to use. The default is 162. • The **p2mp-traffic-eng** keyword specifies that P2MP MPLS-TE SNMP traps are allowed to be sent to the host.
Step 4	**snmp-server enable traps mpls p2mp-traffic-eng** [**down** | **up**] **Example:** `Router(config)# snmp-server enable traps mpls p2mp-traffic-eng`	Enables the router to send P2MP MPLS-TE SNMP traps. • (Optional) The **down** keyword enables or disables P2MP MPLS-TE tunnel down trap notifications (mplsTeP2mpTunnelDestDown). This message is generated when a P2MP MPLS-TE tunnel between the router and its destination is terminated. • (Optional) The **up** keyword enables or disables P2MP MPLS-TE tunnel up trap notifications (mplsTeP2mpTunnelDestUp). This notification is generated when the router establishes a P2MP MPLS-TE tunnel between the router and its destination is established.
Step 5	**end** **Example:** `Router(config)# end`	(Optional) Exits to privileged EXEC mode.

Feature Information for Point-to-Multipoint MPLS-TE MIB

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 77: Feature Information for Point-to-Multipoint MPLS-TE MIB

Feature Name	Releases	Feature Information
Point-to-Multipoint MPLS-TE MIB	15.2(1)S	The point-to-multipoint (P2MP) Multiprotocol Label Switching (MPLS)-traffic engineering (TE) MIB describes the Label Switched Path (LSP) in the IP and MPLS network. An administrator can use the P2MP MPLS-TE MIB to determine optimal branch points in the network so that optimal links are used. This feature was introduced in Cisco IOS Release 15.2(1)S. The following commands were introduced or modified: **snmp-server enable traps mpls p2mp-traffic-eng**, **snmp-server host udp-port p2mp-traffic-eng**

CHAPTER 21

MPLS-TP MIB

The Multiprotocol Label Switching Transport Profile (MPLS-TP) allows you to meet your transport requirements as those requirements evolve from Synchronous Optical Networking (SONET) and Synchronous Digital Hierarchy (SDH) time-division multiplexing (TDM) technologies to MPLS and Ethernet technologies. Currently, a strong momentum for MPLS-TP in terms of both rapid standards development and increasing market demand exists. MPLS-TP technologies have been recently requested by multiple service providers for packet transport primarily in the aggregation networks and access networks while the core network remains MPLS (MPLS-TP is being considered for core transport as well by one or two providers). Service providers aim at using MPLS-TP to support the following deployment scenarios: Ethernet services, mobile backhaul, Asynchronous Transfer Mode (ATM) aggregation replacement, video transport, and long haul transport.

MPLS TP MIB allows you to poll MPLS-TP configured nodes via Simple Network Management Protocol (SNMP) and monitor and manage the MPLS-TP network.

- Prerequisites for MPLS-TP MIB, on page 415
- Restrictions for MPLS-TP MIB, on page 415
- Information about MPLS-TP MIB, on page 416
- How to Configure MPLS-TP MIB, on page 426
- Configuration Examples for MPLS-TP MIB, on page 428
- Additional References, on page 429
- Feature Information for MPLS-TP MIB, on page 430

Prerequisites for MPLS-TP MIB

- General knowledge of SNMP
- Software used to query Cisco devices via SNMP

Restrictions for MPLS-TP MIB

- MPLS-TP MIB doesn't specify any traps for TP and thus no trap support is provided.
- The MPLS-TP MIB module supports point-to-point, co-routed bi-directional tunnels.

Information about MPLS-TP MIB

Overview of MPLS-TP MIB

MPLS-TP MIB is part of the SNMP process. The MIB interacts with MPLS-TP functions to get the data required for objects and indices.

The following MIBs are implemented:

- CISCO-MPLS-TC-EXT-STD-MIB
- CISCO-MPLS-ID-STD-MIB
- CISCO-MPLS-LSR-EXT-STD-MIB
- CISCO-MPLS-TE-EXT-STD-MIB

CISCO-MPLS-TC-EXT-STD-MIB

This MIB module contains textual conventions for MPLS-based transport networks.

Textual Convention	Description (from IETF draft)
MplsGlobalId	This object contains the textual convention of the operator unique identifier (Global_ID). The Global_ID can contain the 2-octet or 4-octet value of the operator's Autonomous System Number (ASN). When the Global_ID is derived from a 2-octet AS number, the two high-order octets of this 4-octet identifier MUST be set to zero. ASN 0 is reserved. A Global_ID of zero means that no Global_ID is present.
MplsNodeId	The Node_ID is assigned within the scope of the Global_ID. The value 0 (or 0.0.0.0 in dotted decimal notation) is reserved and MUST NOT be used. When IPv4 addresses are in use, the value of this object can be derived from the LSR's /32 IPv4 loop back address.

MplsLocalId	This textual convention is used in accommodating the bigger size Global_Node_ID and/or ICC with lower size LSR identifier in order to index mplsTunnelTable. The Local Identifier is configured between 1 and 16777215, as the valid IP address range starts from 16777216 (01.00.00.00). This range is chosen to identify the mplsTunnelTable's Ingress/Egress. LSR-id is the IP address or local identifier. If the configured range is not an IP address, the administrator is expected to retrieve the complete information (Global_Node_ID) from mplsNodeConfigTable. This way, the existing mplsTunnelTable is reused for bidirectional tunnel extensions for MPLS-based transport networks.

CISCO-MPLS-ID-EXT-STD-MIB

This MIB module contains generic object definitions for MPLS Traffic Engineering in transport networks.

Object	Description (from IETF draft)
mplsGlobalId	This object allows the administrator to assign a unique operator identifier also called MPLS-TP Global_ID.
mplsNodeId	This object allows the operator or service provider to assign a unique MPLS-TP Node_ID. The Node_ID is assigned within the scope of the Global_ID.

MPLS LSR STD MIB

Existing Label Switch Router (LSR) MIB functions are used to fetch values for the tables below. For TP, an FPI type of FPI_IF4 is used for IPv4. Only IPv4 is supported in this release.

- **At the endpoints.** For each tunnel, there is one entry for mplsOutSegmentTable [RFC 3813] showing the outsegment label and one entry for mplsInSegmentTable [RFC 3813] for the working LSP. Similarly, an entry is shown to the protected LSP. The assumption is that both working and protected LSPs are configured. If only one working LSP and one protected LSP is configured, the entries are displayed accordingly. There are 2 entries per tunnel for mplsXCTable [RFC 3813] for a working LSP and similarly to a protected LSP.

- **At the midpoints.** For a co-routed bidirectional tunnel, a midpoint has forward and reverse LSPs configured. Thus, there are a pair of mplsInSegmentTable and mplsOutSegmentTable entries for the forward LSP and a pair of mplsInSegmentTable and mplsOutSegmentTable entries for the reverse LSP. If the working and protected LSPs are configured then the above listed entries are shown for both protected and working LSPs. For mplsXCTable, there are two entries—one for the forward LSP and one for the reverse LSP. If the config has working and protected LSPs configured, then the above listed mplsXCTable entries are shown for both protected and working LSPs.

- **Indexing for mplsOutSegmentTable, mplsInSegmentTable and mplsXCTable.** mplsXCTable is indexed by mplsXCIndex [RFC3813], mplsXCInSegmentIndex [RFC3813], and mplsXCOutSegmentIndex [RFC3813]. The mplsXCInSegmentIndex, which is the same as mplsInSegmentIndex, is a 4-byte octet string containing the local label. The mplsXCIndex for TP is represented in the octet string format. The FPI value of FPI_IF4 is taken from file lsd_common_issu_sensitive.enum. The FPI value of 3 is used for TP.
  - At the endpoint, mplsXCIndex is represented as an octet string that contains fpi_type, tunnel index, and the LSP identifier. The LSP identifier specifies if the LSP is working or protected. The LSP identifier can be of either two types: CFC_MPLS_CP_LSP_TYPE_WORKING - working LSP (integer value 2) or CFC_MPLS_CP_LSP_TYPE_PROTECT - protected LSP (integer value 3).

```
|----|          |----||----||----||----|         |----|
FPI = 3         Tunnel-id                    LSP_ident
```

Note Internally, Tunnel-id is used to get if_number (outgoing interface) and if_number is used to poll MFI where

```
|----|
```

equals 1 byte.

  - At the midpoint, mplsXCIndex is represented by an octet string that contains fpi_type and in-label. The Fpi_type value is 0 for label.

```
|----|          |----||----||----||----|
FPI = 0         Label
```

mplsXCOutSegmentIndex is the same as mplsOutSegmentIndex, which is the same as mplsXCIndex plus moi_index. The last two bytes in mplsOutSegmentIndex contain the MOI list index.

A new cfc_mpls_cp_lsrmib_rfc_get_tp_label_id MIB function will be created for the MIB team to fetch TP-related data.

Object	Value and function used to get the value
mplsOutSegmentTable	
mplsOutSegmentIndex	This object contains the outsegment index as explained above. The cfc_mpls_cp_lsrmib_rfc_get_outseg_entry function is used to get this value.
mplsOutSegmentInterface	This object contains the outsegment interface that comes from the IDB. The cfc_mpls_cp_lsrmib_rfc_get_outseg_entry function is used to get this value.
mplsOutSegmentPushTopLabel	This object is set to D_mplsOutSegmentPushTopLabel_true.
mplsOutSegmentTopLabel	The lsrmib_get_top_label function is used to get this value.

mplsOutSegmentTopLabelPtr	Set to 0.0.
mplsOutSegmentNextHopAddrType	The value of mfi_out_info.nh.type provides the value of this object.
mplsOutSegmentNextHopAddr	The value of mfi_out_info.nh.ip_addr provides the value of this object.
mplsOutSegmentXCIndex	This object contains mplsXCIndex from mplsXCTable. The cfc_mpls_cp_lsrmib_rfc_get_xc_search_indices function is used to get this value.
mplsOutSegmentOwner	Will add a new a macro: LSRMIB_MPLS_FPI_IF4 and this will map to D_mplsOutSegmentOwner_tp.
mplsOutSegmentTrafficParamPtr	Always set to 0.0.
mplsOutSegmentRowStatus	D_mplsOutSegmentRowStatus_active
mplsOutSegmentStorageType	D_mplsInSegmentStorageType_volatile
mplsOutSegmentPerfTable	
mplsOutSegmentPerfOctets	mfi_out_info.bytes
mplsOutSegmentPerfPackets	mfi_out_info.packets
mplsOutSegmentPerfErrors	mfi_out_info.errors
mplsOutSegmentPerfDiscards	mfi_out_info.discards
mplsOutSegmentPerfHCOctets	Get from MFI.
mplsOutSegmentPerfDiscontinuityTime	lsrmib_get_discontinuity_time()
mplsInSegmentTable	
mplsInSegmentIndex	This object contains the insegmen index as explained above. The lsrmib_get_in_label_id function is used to get the value.
mplsInSegmentInterface	This is set to 0.
mplsInSegmentLabel	lsrmib_get_in_label_id function is used.
mplsInSegmentLabelPtr	Always set to 0.0.
mplsInSegmentNPop	Set to default value 1.
mplsInSegmentAddrFamily	Set to D_mplsInSegmentAddrFamily_ipV4.
mplsInSegmentXCIndex	This object contains mplsXCIndex. The cfc_mpls_cp_lsrmib_rfc_mfi_info_to_xc function is used to get this value.

mplsInSegmentOwner	D_mplsInSegmentOwner_other
mplsInSegmentTrafficParamPtr	0.0
mplsInSegmentRowStatus	D_mplsInSegmentRowStatus_active
mplsInSegmentStorageType	D_mplsInSegmentStorageType_volatile
mplsInSegmentPerfTable	
mplsInSegmentPerfOctets	mfi_out_info.bytes
mplsInSegmentPerfPackets	mfi_out_info.packets
mplsInSegmentPerfErrors	mfi_out_info.errors
mplsInSegmentPerfDiscards	mfi_out_info.discards
mplsInSegmentPerfHCOctets	Get from MFI.
mplsInSegmentPerfDiscontinuityTime	lsrmib_get_discontinuity_time()
mplsXCTable	
mplsXCIndex	cfc_mpls_cp_lsrmib_rfc_get_xc_search_indices function is used to get this value.
mplsXCInSegmentIndex	cfc_mpls_cp_lsrmib_rfc_get_xc_search_indices function is used to get this value.
mplsXCOutSegmentIndex	cfc_mpls_cp_lsrmib_rfc_get_xc_search_indices function is used to get this value.
mplsXCLSPId	cfc_mpls_cp_lsrmib_rfc_get_xc_search_indices is used to get this value.
mplsXCLabelStackIndex	This object contains the octet string 0.0. which indicates that no labels are to be stacked beneath the top label.
mplsXCOwner	RFC LSR MIB doesn't provide a specific value for TP. Thus, D_mplsXCOwner_other is used to fetch this value.
mplsXCRowStatus	Set to D_mplsXCRowStatus_active.
mplsXCStorageType	Set to D_mplsXCStorageType_volatile.
mplsXCAdminStatus	Set to D_mplsXCAdminStatus_up.
mplsXCOperStatus	Set to D_mplsXCOperStatus_up.

CISCO-MPLS-LSR-EXT-STD-MIB

mplsXCExtEntry: An entry in this table extends the cross connect information represented by an entry in the mplsXCTable through a sparse augmentation. The indices for this table are mplsXCIndex, mplsXCInSegmentIndex, and mplsXCOutSegmentIndex.

- **Midpoint.** At the midpoint there are 2 entries, one for the forward LSP and one for the reverse LSP. If both working and protected LSPs are configured, then there will be 2 entries for each of the LSPs.
- **Endpoint.** At the endpoint there are two entries in mplsXCExtTunnelPointer. If both working and protected LSPs are configured, then there will be 2 entries for each LSP.

Object	Description	Value and function used to get the value
mplsXCExtTunnelPointer	This object indicates the back pointer to the tunnel entry segment. This object cannot be modified if mplsXCRowStatus for the corresponding entry in the mplsXCTable is active(1).	Both the entries (per tunnel) point to the same tunnel entry. A new function to fetch this information from TP will be created. At the endpoint, the MIB code provides the tunnel number and the LSP identifier (working/protected) and expects in return from the TP the other two tunnel indices—the local ID for the source and the local ID for the destination of this tunnel. At midpoint, the MIB code provides the incoming label and expects the TP to return the unique tunnel entry that provides the tunnel index, LSP instance, source-local-id, and destination-local-id.

mplsXCOppositeDirXCPtr	This object indicates the pointer to the opposite direction XC entry. This object cannot be modified if mplsXCRowStatus for the corresponding entry in the mplsXCTable is active(1).	For the endpoint, there are two entries for this object. At the endpoint, the entry that represents the outgoing segment contains the mplsXCLspId entry that corresponds to the reverse direction in-label. The entry that corresponds to the in-label contains the mplsXCLspId representing the outgoing segment (so, in essence, contains the indices with FPI type 3 for the TP tunnel). For the midpoint, there are two entries for this object. Each entry contains the mplsXCLspId representing the reverse direction in-label.

MPLS-TE-STD-MIB and MPLS Draft TE MIB

mplsTunnelTable from MPLS-TE-STD-MIB shows TP tunnel entries. For details on object description, refer to RFC 3812. Protected LSP is assumed to be configured for every working LSP.

TP configuration allows partial configuration. If an LSP is partially configured where destination node-id/global ID is not specified, then the local-id is set to 0.

- **Endpoint.** mplsTunnelTable has one entry per LSP.
- **Midpoint.** For the working LSP, mplsTunnelTable has one entry for the forward LSP and one entry for the reverse LSP. Similarly, if the protected LSP is configured, entries for the protected LSP are shown.

Object	Value and function used to get the value
mplsTunnelIndex	At an endpoint, mplsTunnelIndex contains the source tunnel number. At a midpoint, the mplsTunnelIndex contains the source tunnel number for the forward LSP and the destination tunnel number for the reverse LSP.
mplsTunnelInstance	This contains the LSP number. The tp_get_tunnel_detail function is used to get this value.
mplsTunnelIngressLSRId	At an endpoint, this contains the value of mplsNodeConfigLocalId for the source of the tunnel. At a midpoint, it stores the mplsNodeConfigLocalId for the source of the tunnel for the forward LSP and mplsNodeConfigLocalId for the destination of the reverse LSP. This value ranges between 1 and 16777215. The tp_get_tunnel_detail function is used to get this value.

mplsTunnelEgressLSRId	At an endpoint, this contains the value of mplsNodeConfigLocalId for the destination node of the tunnel. At a midpoint, it stores the mplsNodeConfigLocalId for the destination of the tunnel for the forward LSP and mplsNodeConfigLocalId for the source of the tunnel for the reverse LSP. This value ranges between 1 and 16777215. The tp_get_tunnel_detail function is used to get this value.
mplsTunnelName	This contains the tunnel name, applicable at both endpoint and midpoint. The tp_get_tunnel_detail function is used to get this value.
mplsTunnelDescr	This contains the tunnel description. The tp_get_tunnel_detail function is used to get this value.
mplsTunnelIsIf	This is always true because the TP tunnel is always an interface.
mplsTunnelIfIndex	This contains the tunnel ifindex. The tp_get_tunnel_detail function provides the IF number. The interface number can be used to get the interface index.
mplsTunnelOwner	This is set to D_mplsTunnelOwner_other.
mplsTunnelRole	The tp_get_tunnel_detail function is used to get this value.
mplsTunnelXCPointer	The cfc_mpls_cp_lsrmib_rfc_make_XC_pointer function is used.
mplsTunnelSignallingProto	None(1). The MPLS TP implementation on Cisco IOS does not have a control plane and there is no signaling protocol.
mplsTunnelSetupPrio	0. By default, MPLS TP LSPs have 0 priority.
mplsTunnelHoldingPrio	0. By default, MPLS TP LSPs have 0 priority.
mplsTunnelSessionAttributes	N/A. 0.
mplsTunnelLocalProtectInUse	This object indicates whether a protected LSP is being used. The tp_get_tunnel_detail function is used to get this value.
mplsTunnelResourcePointer	0.0. Not supported.
mplsTunnelPrimaryInstance	This is used to indicate the LSP number of the working LSP. If the working LSP is not configured, then this shows a default value of 0.

mplsTunnelInstancePriority	N/A. 0.
mplsTunnelHopTableIndex	N/A. 0.
mplsTunnelPathInUse	N/A. 0.
mplsTunnelARHopTableIndex	N/A. 0.
mplsTunnelCHopTableIndex	N/A. 0.
mplsTunnelIncludeAnyAffinity	N/A. 0.
mplsTunnelIncludeAllAffinity	N/A. 0.
mplsTunnelTotalUpTime	The tp_get_tunnel_detail function is used to get this value.
mplsTunnelInstanceUpTime	The tp_get_tunnel_detail function is used to get this value.
mplsTunnelPrimaryUpTime	The tp_get_tunnel_detail function is used to get this value.
mplsTunnelPathChanges	N/A. 0.
mplsTunnelLastPathChange	N/A.
mplsTunnelCreationTime	The tp_get_tunnel_detail function is used to get this value.
mplsTunnelStateTransitions	N/A. 0.
mplsTunnelAdminStatus	At endpoint, the tp_get_tunnel_detail function is used to get this value. At midpoint, this is set to "testing(3)" as the TP does not maintain admin status at the midpoint.
mplsTunnelOperStatus	At endpoint, the tp_get_tunnel_detail function is used to get this value. At midpoint, this is set to "testing(3)" as the TP does not maintain oper status at the midpoint.
mplsTunnelRowStatus	D_mplsTunnelRowStatus_active
mplsTunnelStorageType	D_mplsTunnelStorageType_readOnly
mplsTunnelPerfTable: This counter is not supported.	

CISCO-MPLS-TE-EXT-STD-MIB

This MIB module contains generic object definitions for MPLS Traffic Engineering in transport networks.

Object	Description (as IETF draft defines it)	Value and function used to get the value
mplsNodeConfigTable		
mplsNodeConfigLocalId	This object allows the administrator to assign a unique local identifier to map Global_Node_ID.	This table is used to represent a node in a TP network. This object provides a unique local value for the node. The value of this object lies between 1 and 16777215. The TP provides a new tp_get_node_detail function. This is used to get this object's value.
mplsNodeConfigGlobalId	This object indicates the Global Operator Identifier.	This maps to the mpls_tp_global_id_t global_id field of the TP data structure. tp_get_node_detail is used to get this object's value.
mplsNodeConfigNodeId	This object indicates the Node_ID within the operator. This object value should be zero when mplsNodeConfigIccId is configured with non-null value.	This object maps to mpls_tp_node_id_t node_id field of TP data structure. The tp_get_node_detail function is used to get this object's value.
mplsNodeConfigIccId	This object allows the operator or service provider to configure a unique MPLS-TP ITU-T Carrier Code (ICC) either for Ingress ID or Egress ID. This object value should be zero when mplsNodeConfigGlobalId and mplsNodeConfigNodeId are assigned with a non-zero value.	This object is set to 0. Cisco IOS implementation only supports IP-compatible implementation.
mplsNodeConfigRowStatus	This object allows the administrator to create, modify, and/or delete a row in this table.	This is set to 'active'.
mplsNodeConfigStorageType	This variable indicates the storage type for this object. Conceptual rows having the value 'permanent' need not allow write-access to any columnar objects in the row.	This is set to 'readonly' because write access to any object is not allowed.
mplsNodeIpMapTable: This table is indexed by mplsNodeIpMapNodeId and mplsNodeIpMapLocalId		
mplsNodeIpMapGlobalId	This object indicates the Global_ID.	The tp_get_node_detail function is used to get this object's value.

mplsNodeIpMapNodeId	This object indicates the Node_ID within the operator.	The tp_get_node_detail function is used to get this object's value.
mplsNodeIpMapLocalId	This object contains an IP compatible local identifier that is defined in mplsNodeConfigTable.	The tp_get_node_detail function is used to get this object's value.
mplsTunnelExtTable : The indices of this table are the same as mplsTunnelTable (RFC 3812)		
mplsTunnelOppositeDirPtr	This object is applicable only for the bidirectional tunnel that has the forward and reverse LSPs in the same tunnel or in different tunnels. This object holds the opposite direction tunnel entry if the bidirectional tunnel is set up by configuring two tunnel entries in mplsTunnelTable. The value of zeroDotZero indicates single tunnel entry is used for bidirectional tunnel setup.	Because only one entry per tunnel per LSP for mplsTunnelTable is shown, this object will contain the value 0.0.
mplsTunnelReversePerfTable: This counter is not supported.		
mplsNodeIccMapTable: Because only IP-compatible implementation of the TP is supported, this table is not supported.		

How to Configure MPLS-TP MIB

Configuring MPLS-TP MIB

A generic SNMP configuration automatically enables MPLS-TP MIB. However, the MPLS TP feature must be configured. See the MPLS Transport Profile document for more information.

You should perform the following generic SNMP configuration tasks:

- Enabling the SNMP agent (required)
- Verifying the status of the SNMP agent (optional)

Enabling the SNMP Agent

SUMMARY STEPS

1. **enable**
2. **show running-config**
3. **configure terminal**
4. **snmp-server community** *string* [**view** *view-name*] [**ro** | **rw**][*number*]

5. **end**
6. **write memory**
7. **show running-config**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**show running-config** **Example:** `Router# show running-config`	Displays the running configuration of the router so that you can determine if an SNMP agent is already running on the device. If no SNMP information is displayed, continue with the next step. If any SNMP information is displayed, you can modify the information or change it as desired.
Step 3	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 4	**snmp-server community** *string* [**view** *view-name*] [**ro** | **rw**][*number*] **Example:** `Router(config)# snmp-server community public ro`	Configures read-only (ro) community strings for the MPLS-TP MIB. • The *string* argument functions like a password, permitting access to SNMP functionality on label switch routers (LSRs) in an MPLS network. • The optional **ro** keyword configures read-only (ro) access to the objects in the MPLS-TP MIB.
Step 5	**end** **Example:** `Router(config)# end`	Exits to privileged EXEC mode.
Step 6	**write memory** **Example:** `Router# write memory`	Writes the modified SNMP configuration into NVRAM of the router, permanently saving the SNMP settings.

	Command or Action	Purpose
Step 7	**show running-config** **Example:** `Router# show running-config`	Displays the running configuration of the router so that you can determine if an SNMP agent is already running on the device. If you see any snmp-server statements, SNMP has been enabled on the router. If any SNMP information is displayed, you can modify the information or change it as desired.

Verifying the Status of the SNMP Agent

To verify that the SNMP agent has been enabled on a host network device, perform the steps shown in the following table:

SUMMARY STEPS

1. **enable**
2. **show running-config**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**show running-config** **Example:** `Device# show running-config`	Displays the running configuration on the target device.

Configuration Examples for MPLS-TP MIB

Example Enabling the SNMP Agent

The following example shows how to enable an SNMP agent on a host network device.

```
Device# config terminal
Device(config)# snmp-server community
```

The following example shows how to enable SNMPv1 and SNMPv2C. The configuration permits any SNMP agent to access all MPLS TP MIB objects with read-only permissions using the community string *public*.

```
Device(config)#  snmp-server community public
```

The following example shows how to allow read-only access to all MPLS TP MIB objects relating to members of access list 4 that specify the *comaccess* community string. No other SNMP agents will have access to any MPLS TP MIB objects.

```
Device(config)#  snmp-server community comaccess ro 4
```

Example Verifying the Status of the SNMP Agent

The following example shows how to verify the status of the SNMP agent.

```
Device# show running-config
...

...

snmp-server community public RO

snmp-server community private RO
```

Any snmp-server statement that appears in the output and which takes the form shown above verifies that SNMP has been enabled on that device.

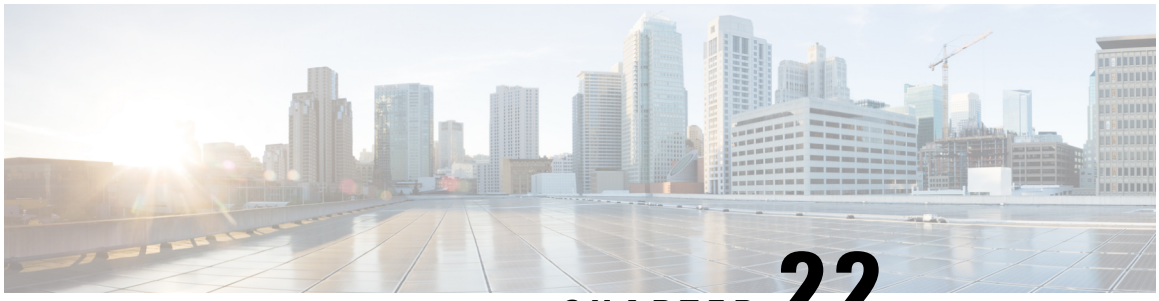
Feature Information for MPLS-TP MIB

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 78: Feature Information for MPLS-TP MIB



Feature Name	Releases	Feature Information
MPLS-TP MIB	15.3(1)S XE 3S	Allows you to meet your transport requirements as those requirements evolve from Synchronous Optical Networking (SONET) and Synchronous Digital Hierarchy (SDH) time-division multiplexing (TDM) technologies to MPLS and Ethernet technologies.

CHAPTER 22

MPLS LDP Graceful Restart

When a router is configured with Multiprotocol Label Switching (MPLS) Label Distribution Protocol (LDP) Graceful Restart (GR), it assists a neighboring router that has MPLS LDP Stateful Switchover/Nonstop Forwarding (SSO/NSF) Support and Graceful Restart to recover gracefully from an interruption in service. MPLS LDP GR functions strictly in helper mode, which means it can only help other routers that are enabled with MPLS SSO/NSF and GR to recover. If the router with LDP GR fails, its peer routers cannot help the router recover.

For brevity, the following are used in this document:

- MPLS LDP SSO/NSF Support and Graceful Restart is called LDP SSO/NSF.
- The MPLS LDP GR feature described in this document refers to helper mode.

When you enable MPLS LDP GR on a router that peers with an MPLS LDP SSO/NSF-enabled router, the SSO/NSF-enabled router can maintain its forwarding state when the LDP session between them is interrupted. While the SSO/NSF-enabled router recovers, the peer router forwards packets using stale information. This enables the SSO/NSF-enabled router to become operational more quickly.

- Prerequisites for MPLS LDP Graceful Restart, on page 433
- Restrictions for MPLS LDP Graceful Restart, on page 433
- Information About MPLS LDP Graceful Restart, on page 434
- How to Configure MPLS LDP Graceful Restart, on page 435
- Configuration Examples for MPLS LDP Graceful Restart, on page 438
- Additional References, on page 441
- Feature Information for MPLS LDP Graceful Restart, on page 442

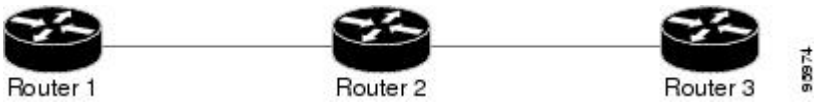
Prerequisites for MPLS LDP Graceful Restart

You must enable MPLS LDP GR on all route processors for an LDP session to be preserved during an interruption in service.

Restrictions for MPLS LDP Graceful Restart

- MPLS LDP GR is supported in strict helper mode.
- MPLS LDP GR cannot be configured on label-controlled ATM (LC-ATM) interfaces.

Information About MPLS LDP Graceful Restart



How MPLS LDP Graceful Restart Works

MPLS LDP GR works in strict helper mode, which means it helps a neighboring route processor that has MPLS LDP SSO/NSF to recover from disruption in service without losing its MPLS forwarding state. The disruption in service could be the result of a TCP or UDP event or the stateful switchover of a route processor. When the neighboring router establishes a new session, the LDP bindings and MPLS forwarding states are recovered.

In the topology shown in the figure below, the following elements have been configured:

- LDP sessions are established between Router 1 and Router 2, as well as between Router 2 and Router 3.
- Router 2 has been configured with MPLS LDP SSO/NSF. Routers 1 and 3 have been configured with MPLS LDP GR.
- A label switched path (LSP) has been established between Router 1 and Router 3.

Figure 40: Example of a Network Using LDP Graceful Restart

The following process shows how Routers 1 and 3, which have been configured with MPLS LDP GR, help Router 2, which has been configured with LDP SSO/NSF, recover from a disruption in service:

1. Router 1 notices an interruption in service with Router 2. (Router 3 also performs the same actions in this process.)
2. Router 1 marks all the label bindings from Router 2 as stale, but it continues to use the bindings for MPLS forwarding.

Router 1 reestablishes an LDP session with Router 2, but keeps its stale label bindings. If you issue a **showmplsldpneighbor** command with the **graceful-restart** keyword, the command output displays the recovering LDP sessions.

1. Both routers readvertise their label binding information. If Router 1 relearns a label from Router 2 after the session has been established, the stale flags are removed. The **showmplsforwarding-table**command displays the information in the MPLS forwarding table, including the local label, outgoing label or VC, prefix, label-switched bytes, outgoing interface, and next hop.

You can set various graceful restart timers. See the following commands for more information:

- **mpls ldp graceful-restart timers neighbor-liveness**
- **mpls ldp graceful-restart timers max-recovery**

How a Route Processor Advertises That It Supports MPLS LDP Graceful Restart

A Route Processor (RP) that is configured to perform MPLS LDP GR includes the Fault Tolerant (FT) Type Length Value (TLV) in the LDP initialization message. The RP sends the LDP initialization message to a neighbor to establish an LDP session.

The FT session TLV includes the following information:

- The Learn from Network (L) flag is set to 1, which indicates that the route processor is configured to perform MPLS LDP GR.
- The Reconnect Timeout field shows the time (in milliseconds) that the neighbor should wait for a reconnection if the LDP session is lost. In this release, the timer is set to 0, which indicates that if the local router fails, its peers should not wait for it to recover. The timer setting indicates that the local router is working in helper mode.
- The Recovery Time field shows the time (in milliseconds) that the neighbor should retain the MPLS forwarding state during a recovery. If a neighbor did not preserve the MPLS forwarding state before the restart of the control plane, the neighbor sets the recovery time to 0.

What Happens If a Route Processor Does Not Have MPLS LDP Graceful Restart

If two route processors establish an LDP session and one route processor is not configured for MPLS LDP GR, the two route processors create a normal LDP session but do not have the ability to perform MPLS LDP GR. Both route processors must be configured for MPLS LDP GR.

How to Configure MPLS LDP Graceful Restart

Configuring MPLS LDP Graceful Restart

To configure MPLS LDP Graceful Restart, perform the following task.

You must enable MPLS LDP GR on all route processors for an LDP session to be preserved during an interruption in service.

MPLS LDP GR is enabled globally. When you enable MPLS LDP GR, it has no effect on existing LDP sessions. New LDP sessions that are established can perform MPLS LDP GR.

Note You can also issue the **mpls label protocol ldp** command in global configuration mode, which enables LDP on all interfaces configured for MPLS.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip cef distributed**
4. **mpls ldp graceful-restart**

5. **interface** *type slot* / *subslot* / *port* [**.** *subinterface-number*]
6. **mpls ip**
7. **mpls label protocol ldp**
8. **exit**
9. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**ip cef distributed** **Example:** `Router(config)# ip cef distributed`	Enables distributed Cisco Express Forwarding.
Step 4	**mpls ldp graceful-restart** **Example:** `Router(config)# mpls ldp graceful-restart`	Enables the router to protect the LDP bindings and MPLS forwarding state during a disruption in service.
Step 5	**interface** *type slot* / *subslot* / *port* [**.** *subinterface-number*] **Example:** `Router(config)# interface pos 0/3/0`	Specifies an interface and enters interface configuration mode.
Step 6	**mpls ip** **Example:** `Router(config-if)# mpls ip`	Configures MPLS hop-by-hop forwarding for an interface.
Step 7	**mpls label protocol ldp** **Example:** `Router(config-if)# mpls label protocol ldp`	Configures the use of LDP for an interface.

	Command or Action	Purpose
Step 8	**exit** **Example:** `Router(config-if)# exit`	Exits interface configuration mode and returns to global configuration mode.
Step 9	**exit** **Example:** `Router(config)# exit`	Exits global configuration mode and returns to privileged EXEC mode.

Verifying the MPLS LDP Graceful Restart Configuration

To verify that MPLS LDP Graceful Restart is configured correctly, perform the following task.

SUMMARY STEPS

1. **enable**
2. **show mpls ldp neighbor graceful restart**
3. **show mpls ldp graceful-restart**
4. **exit**

DETAILED STEPS

Procedure

Step 1 **enable**

Use this command to enable privileged ECEC mode. Enter your password if prompted. For example:

Example:

```
Router>? enable
Router#
```

Step 2 **show mpls ldp neighbor graceful restart**

Use this command to display graceful restart information for LDP sessions. For example:

Example:

```
Router# show mpls ldp neighbor graceful restart
Peer LDP Ident: 10.20.20.20:0; Local LDP Ident 10.17.17.17:0
   TCP connection: 10.20.20.20.16510 - 10.17.17.17.646
    State: Oper; Msgs sent/rcvd: 8/18; Downstream
    Up time: 00:04:39
    Graceful Restart enabled; Peer reconnect time (msecs): 120000
Peer LDP Ident: 10.19.19.19:0; Local LDP Ident 10.17.17.17:0
    TCP connection: 10.19.19.19.11007 - 10.17.17.17.646
    State: Oper; Msgs sent/rcvd: 8/38; Downstream
```

```
    Up time: 00:04:30
    Graceful Restart enabled; Peer reconnect time (msecs): 120000
```

Step 3 **show mpls ldp graceful-restart**

Use this command to display graceful restart sessions and session parameters. For example:

Example:

```
Router# show mpls ldp graceful-restart
LDP Graceful Restart is enabled
Neighbor Liveness Timer: 5 seconds
Max Recovery Time: 200 seconds
Down Neighbor Database (0 records):

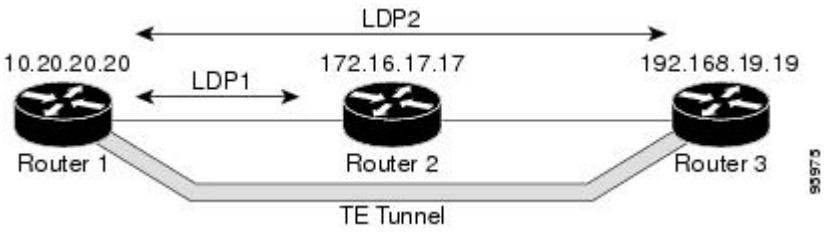
```

Step 4 **exit**

Use this command to exit to user EXEC mode. For example:

Example:



```
Router# exit
Router>
```

Configuration Examples for MPLS LDP Graceful Restart

Configuring MPLS LDP Graceful Restart Example

The figure below shows a configuration where MPLS LDP GR is enabled on Router 1 and MPLS LDP SSO/NSF is enabled on Routers 2 and 3. In this configuration example, Router 1 creates an LDP session with Router 2. Router 1 also creates a targeted session with Router 3 through a traffic engineering tunnel using Router 2.

Figure 41: MPLS LDP Graceful Restart Configuration Example

Router 1 configured with LDP GR:

```
!
ip subnet-zero
ip cef
```

```
mpls label range 16 10000 static 10001 1048575

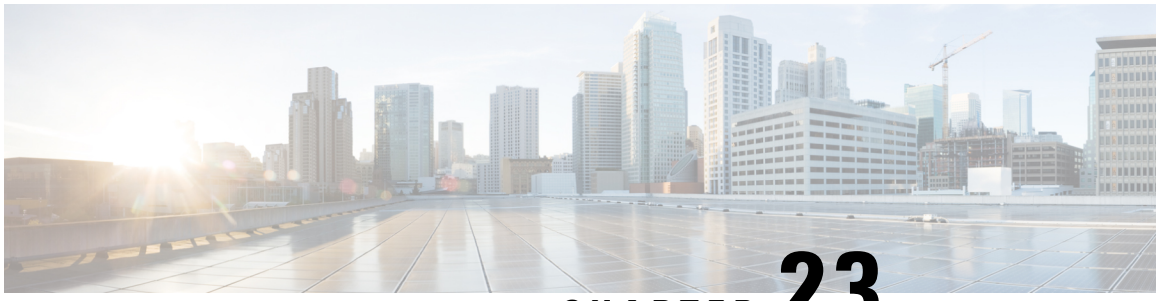
The Cisco Support website provides extensive online resources, including documentation and tools for troubleshooting and resolving technical issues with Cisco products and technologies. To receive security and technical information about your products, you can subscribe to various services, such as the Product Alert Tool (accessed from Field Notices), the Cisco Technical Services Newsletter, and Really Simple Syndication (RSS) Feeds. Access to most tools on the Cisco Support website requires a Cisco.com user ID and password.	http://www.cisco.com/techsupport



Feature Information for MPLS LDP Graceful Restart

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 79: Feature Information for MPLS LDP Graceful Restart

Feature Name	Releases	Feature Information
MPLS LDP Graceful Restart	Cisco IOS XE Release 2.1	When a router is configured with Multiprotocol Label Switching (MPLS) Label Distribution Protocol (LDP) Graceful Restart (GR), it assists a neighboring router that has MPLS LDP Stateful Switchover/Nonstop Forwarding (SSO/NSF) Support and Graceful Restart to recover gracefully from an interruption in service. MPLS LDP GR functions strictly in helper mode, which means it can only help other routers that are enabled with MPLS SSO/NSF and GR to recover. If the router with LDP GR fails, its peer routers cannot help the router recover. In Cisco IOS XE Release 2.1, this feature was introduced on the Cisco ASR 1000 Series Aggregation Services Routers. The following commands were introduced or modified: **debugmplsldpgraceful-restart**, **mplsldpgraceful-restart**, **mplsldpgraceful-restarttimersmax-recovery**, **mplsldpgraceful-restarttimersneighbor-liveness**, **showmplsipbinding**, **showmplsldpbindings**, **showmplsldpgraceful-restart**, **showmplsldpneighbor**.

CHAPTER 23

Configuring NSF SSO--MPLS VPN

The NSF/SSO--MPLS VPN feature allows a provider edge (PE) router to preserve data forwarding information in a Multiprotocol Label Switching (MPLS) Virtual Private Network (VPN) when the primary Route Processor (RP) restarts. This module describes how to enable nonstop forwarding (NSF) in a basic MPLS VPN network.

- Restrictions for NSF SSO--MPLS VPN, on page 445
- Information About NSF SSO--MPLS VPN, on page 445
- How to Configure NSF SSO--MPLS VPN, on page 446
- Configuration Examples for NSF SSO--MPLS VPN, on page 449
- Additional References, on page 452
- Feature Information for NSF SSO--MPLS VPN, on page 454

Restrictions for NSF SSO--MPLS VPN

- Tag Distribution Protocol (TDP) sessions are not supported. Only Label Distribution Protocol (LDP) sessions are supported.
- The NSF/SSO--MPLS VPN feature cannot be configured on label-controlled ATM (LC-ATM) interfaces.

Information About NSF SSO--MPLS VPN

Elements That Enable NSF SSO--MPLS VPN

VPN NSF requires several elements in order to work:

- VPN NSF uses the BGP Graceful Restart mechanisms to create MPLS forwarding entries for VPNv4 prefixes in NSF mode. The forwarding entries are preserved during a restart. BGP also saves prefix and corresponding label information and recovers the information after a restart.
- The NSF/SSO--MPLS VPN feature also uses NSF for the label distribution protocol in the core network (either MPLS Label Distribution Protocol, traffic engineering, or static labeling).
- The NSF/SSO--MPLS VPN feature uses NSF for the Interior Gateway Protocol (IGP) used in the core (OSPF or IS-IS).
- The NSF/SSO--MPLS VPN feature uses NSF for the routing protocols between the PE and CE routers.

How VPN Prefix Information Is Checkpointed to the Backup Route Processor

When BGP allocates local labels for prefixes, it checkpoints the local label binding in the backup RP. The checkpointing function copies state information from the active RP to the backup RP, thereby ensuring that the backup RP has an identical copy of the latest information. If the active RP fails, the backup RP can take over with no interruption in service. Checkpointing begins when the active RP does a bulk synchronization, which copies all of the local label bindings to the backup RP. After that, the active RP dynamically checkpoints individual prefix label bindings when a label is allocated or freed. This allows forwarding of labeled packets to continue before BGP reconverges.

How BGP Graceful Restart Preserves Prefix Information During a Restart

When a BGP Graceful Restart-capable router loses connectivity, it performs the following actions as the restarting router:

1. The restarting router establishes BGP sessions with other routers and relearns the BGP routes from other routers that are also capable of Graceful Restart. The restarting router waits to receive updates from the neighboring routers. When the neighboring routers send end-of-Routing Information Base (RIB) markers to indicate that they are done sending updates, the restarting router starts sending its own updates.
2. The restarting router accesses the checkpoint database to find the label that was assigned for each prefix. If it finds the label, it advertises it to the neighboring router. If it does not find the label, it allocates a new label and advertises it.
3. The restarting router removes any stale prefixes after a timer for stale entries expires.

A BGP Graceful Restart-capable peer router performs the following actions when it encounters a restarting router:

1. The peer router sends all the routing updates to the restarting router. When it has finished sending updates, the peer router sends an end-of-RIB marker to the restarting router.
2. The peer router does not immediately remove the BGP routes learned from the restarting router from its BGP routing table. As it learns the prefixes from the restarting router, the peer refreshes the stale routes if the new prefix and label information matches the old information.

If a router is not configured for the NSF/SSO--MPLS VPN feature and it attempts to establish a BGP session with a router that is configured with the NSF/SSO--MPLS VPN feature, the two routers create a normal BGP session but do not have the ability to perform the NSF/SSO--MPLS VPN feature.

How to Configure NSF SSO--MPLS VPN

Configuring NSF Support for Basic VPNs

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip cef** [**distributed**]

4. **router bgp** *autonomous-system-number*
5. **bgp graceful-restart**
6. **bgp graceful-restart restart-time** *seconds*
7. **bgp graceful-restart stalepath-time** *seconds*
8. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**ip cef** [**distributed**] **Example:** `Router(config)# ip cef distributed`	Enables Cisco Express Forwarding. • Use this command if Cisco Express Forwarding is not enabled by default on the router.
Step 4	**router bgp** *autonomous-system-number* **Example:** `Router(config)# router bgp 1`	Configures a BGP routing process and enters router configuration mode.
Step 5	**bgp graceful-restart** **Example:** `Router(config-router)# bgp graceful-restart`	Enables BGP Graceful Restart on the router.
Step 6	**bgp graceful-restart restart-time** *seconds* **Example:** `Router(config-router)# bgp graceful-restart restart-time 200`	(Optional) Specifies the maximum time to wait for a graceful-restart-capable neighbor to come back up after a restart.
Step 7	**bgp graceful-restart stalepath-time** *seconds* **Example:** `Router(config-router)# bgp graceful-restart stalepath-time 400`	(Optional) Specifies the maximum time to hold on to the stale paths of a gracefully restarted peer. All stale paths are deleted after the expiration of this timer.

	Command or Action	Purpose
Step 8	**end** **Example:** `Router(config-router)# end`	Exits to privileged EXEC mode.

Verifying the Configuration

SUMMARY STEPS

1. **show ip bgp vpnv4 all labels**
2. **show ip bgp vpnv4 all neighbors**
3. **show ip bgp labels**
4. **show ip bgp neighbors**

DETAILED STEPS

Procedure

Step 1 **show ip bgp vpnv4 all labels**

This command displays incoming and outgoing BGP labels for each route distinguisher. The following is sample output from the command:

Example:

```
Router# show ip bgp vpnv4 all labels

Network          Next Hop      In label/Out label
Route Distinguisher: 100:1 (vpn1)
   10.3.0.0/16      10.0.0.5        25/20
                    10.0.0.1        25/23
                    10.0.0.2        25/imp-null
   10.0.0.9/32      10.0.0.1        24/22
                    10.0.0.2        24/imp-null
```

Step 2 **show ip bgp vpnv4 all neighbors**

This command displays whether the BGP peers are capable of Graceful Restart. The following is sample output from the command:

Example:

```
Router# show ip bgp vpnv4 all neighbors
BGP neighbor is 10.0.0.1,  remote AS 100, internal link
  BGP version 4, remote router ID 10.0.0.1
  BGP state = Established, up for 02:49:47
  Last read 00:00:47, hold time is 180, keepalive interval is 60 seconds
  Neighbor capabilities:
    Route refresh: advertised and received(new)
    Address family VPNv4 Unicast: advertised and received
    Graceful Restart Capabilty: advertised and received
```

```
      Remote Restart timer is 120 seconds
      Address families preserved by peer:
        VPNv4 Unicast
.
.
.
```

Step 3 **show ip bgp labels**

This command displays information about MPLS labels in the Exterior Border Gateway Protocol (EBGP) route table. The following is sample output from the command:

Example:

```
Router# show ip bgp labels
   Network          Next Hop      In label/Out label
   10.3.0.0/16      10.0.0.1        imp-null/imp-null
                    0.0.0.0         imp-null/nolabel
   10.0.0.9/32      10.0.0.1        21/29
   10.0.0.11/32     10.0.0.1        24/38
   10.0.0.13/32     0.0.0.0         imp-null/nolabel
   10.0.0.15/32     10.0.0.1        29/nolabel
                    10.0.0.1        29/21
```

Step 4 **show ip bgp neighbors**

This command displays whether the BGP peers are capable of Graceful Restart. The following is sample output from the command:

Example:

```
Router# show ip bgp neighbors
BGP neighbor is 10.0.0.1,  remote AS 100, external link
  BGP version 4, remote router ID 10.0.0.5
  BGP state = Established, up for 02:54:19
  Last read 00:00:18, hold time is 180, keepalive interval is 60 seconds
  Neighbor capabilities:
    Route refresh: advertised and received(new)
    Address family IPv4 Unicast: advertised and received
    ipv4 MPLS Label capability: advertised and received
    Graceful Restart Capabilty: advertised and received
      Remote Restart timer is 120 seconds
      Address families preserved by peer:
        IPv4 Unicast
.
.
.
```

Configuration Examples for NSF SSO--MPLS VPN

Example NSF SSO--MPLS VPN for a Basic MPLS VPN

The following sample output shows the configuration of the NSF/SSO--MPLS VPN feature on the CE and PE routers. SSO is enabled by default, and LDP is the default MPLS label protocol.

CE1 Router

Feature Name	Releases	Feature Information
NSF/SSO--MPLS VPN	Cisco IOS XE Release 2.1	This feature allows a provider edge router to preserve data forwarding information in a Multiprotocol Label Switching (MPLS) Virtual Private Network (VPN) when the primary Route Processor restarts.

CHAPTER 24

ISSU MPLS Clients

MPLS applications can be upgraded using the In Service Software Upgrade (ISSU) process. Thus, MPLS applications are considered ISSU's MPLS clients. The ISSU process allows Cisco IOS XE software to be updated or otherwise modified while packet forwarding continues.

- Prerequisites for ISSU MPLS Clients, on page 455
- Information About ISSU MPLS Clients, on page 456
- How to Verify that an MPLS Client Can Support an In Service Software Upgrade, on page 457
- Configuration Examples for ISSU MPLS Clients, on page 459
- Additional References, on page 467
- Feature Information for ISSU MPLS Clients, on page 468
- Glossary, on page 469

Prerequisites for ISSU MPLS Clients

Before you perform an upgrade, you need to verify that the clients you are concerned about are compatible with the intended switchover. Use the commands listed in the Verifying the ISSU Process for an MPLS Client, on page 457 to determine compatibility.

The success performance of some clients in the upgraded network will depend upon their compatibility with other clients as described in the table below.

Table 81: MPLS Client Interdependencies

This client . . .	...can only work when this client is shown to be compatible
MPLS VPN	LSD Label Manager High Availability
LDP	LSD Label Manager High Availability
VRF ("Table ID")	LSD Label Manager High Availability
LSD Label Manager High Availability	Base clients: Checkpointing and Redundancy Facility
MFI Pull	XDR
MFI Push	XDR
LSPV Push within OAM	XDR

This client . . .	...can only work when this client is shown to be compatible
TE	Base clients: • Checkpointing and Redundancy Facility • MPLS TE High Availability

Information About ISSU MPLS Clients

Before examining ISSU coordination of MPLS clients, you should understand the following concepts:

This section provides information about upgrading MPLS-related applications through ISSU. Those MPLS applications are considered ISSU's MPLS "clients."

For more information on the ISSU procedure, see Cisco IOS XE In Service Software Upgrade Process document and see the Cisco ASR 1000 Series Aggregation Services Routers Software Configuration Guide .

ISSU-Capable Protocols and Applications Clients

Protocols and applications that can be upgraded through the ISSU process are considered clients of ISSU. These include at least the following:

- Address Resolution Protocol (ARP)
- Asynchronous Transfer Mode (ATM)
- Cisco Express Forwarding
- Dynamic Host Configuration Protocol (DHCP)
- EtherChannel--port aggregration protocol (PagP) and Link Aggregration Control Protocol (LACP)
- Frame Relay (FR)
- Gateway Load Balancing Protocol (GLBP)
- High-Level Data Link Control (HDLC)
- Hot Standby Router Protocol (HSRP)
- IEEE 802.1x and 802.3af
- Internet Group Management Protocol (IGMP) snooping
- IP host
- Intermediate System-to-Intermediate System (IS-IS)
- Multiprotocol Label Switching (MPLS)
- PPP and Multilink PPP
- Port security
- Quality of service (QoS)

- Remote File System (RFS) versioning
- Simple Network Management Protocol (SNMP)
- Spanning Tree Protocol (STP)

Note For a complete list of ISSU- compliant protocols and applications that are supported for the Cisco ASR Series Routers for your release, see the Release Notes for Cisco ASR Series Aggregation Services Routers .

ISSU-Capable MPLS Feature Sets

Within the MPLS technology, ISSU supports the following feature sets as clients:

- Label Distribution Protocol (LDP)
- MPLS Virtual Private Network (MPLS VPN)
- VPN routing and forwarding (VRF), also called the "Table ID" client
- Label Switching Database Label Manager for high availability, usually called "LSD Label Manager for HA"
- MPLS Forwarding Infrastructure Pull, called "MFI Pull"
- MPLS Forwarding Infrastructure Push, called "MFI Push"
- Label Switched Path Verification Push within Operation, Administration, and Management (OAM), called "LSPV Push"
- TE

How to Verify that an MPLS Client Can Support an In Service Software Upgrade

Note For the complete task sequence that accomplishes ISSU see theCisco ASR 1000 Series Aggregation Services Routers Software Configuration Guide .

Verifying the ISSU Process for an MPLS Client

Perform this task to verify that a particular MPLS client can be upgraded successfully during a particular ISSU session. The commands in this task also can be used to display other details about the ISSU MPLS clients, and should be entered in the order described.

Before you begin

Ensure that you have successfully loaded new Cisco IOS XE software onto the standby processor as described in the Cisco ASR 1000 Series Aggregation Services Routers Software Configuration Guide.

SUMMARY STEPS

1. **enable**
2. **show issu clients**
3. **show issu sessions** *clientID*
4. **show issu negotiated version** *sessionID*
5. **show issu negotiated capability** *sessionID*
6. **show issu message types** *clientID*

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**show issu clients** **Example:** `Router# show issu clients`	Lists network applications and protocols currently supported by ISSU. • You can use this command to discover the client ID that you will need to enter in Steps 3 and 6.
Step 3	**show issu sessions** *clientID* **Example:** `Router# show issu sessions 2002`	Displays detailed information about a particular ISSU client that includes whether a particular client is compatible with the intended upgrade. • You can use this command to discover the session ID that you will need to enter in Steps 4 and 5.

Step 4	**show issu negotiated version** *sessionID*
	Example:
	`Router#`
	`show issu negotiated version 33`
		Displays details of the session's negotiated message version.

Step 5	**show issu negotiated capability** *sessionID*
	Example:
	`Router#`
	`show issu negotiated capability 33`
		Displays results of a negotiation about the client application's capabilities.

	Command or Action	Purpose
Step 6	**show issu message types** *clientID* **Example:** `Router# show issu message types 2002`	Displays the message formats ("types") and versions supported by the specified client.

Configuration Examples for ISSU MPLS Clients

To examine any ISSU client, you must specify its unique client ID when entering the **show issu sessions** command. If you do not already know that client ID, enter the **show issu clients**command in user EXEC or privileged EXEC mode. Each ISSU client on the network will then be listed, with its client ID and client name on the same line, as shown in the following example:

```
Router# show issu clients
Client_ID = 2,  Client_Name = ISSU Proto client,  Entity_Count = 1
Client_ID = 3,  Client_Name = ISSU RF,  Entity_Count = 1
Client_ID = 4,  Client_Name = ISSU CF client,  Entity_Count = 1
Client_ID = 5,  Client_Name = ISSU Network RF client,  Entity_Count = 1
Client_ID = 7,  Client_Name = ISSU CONFIG SYNC,  Entity_Count = 1
Client_ID = 8,  Client_Name = ISSU ifIndex sync,  Entity_Count = 1
Client_ID = 9,  Client_Name = ISSU IPC client,  Entity_Count = 1
Client_ID = 10,  Client_Name = ISSU IPC Server client,  Entity_Count = 1
Client_ID = 11,  Client_Name = ISSU Red Mode Client,  Entity_Count = 1
Client_ID = 12,  Client_Name = ISSU EHSA services client,  Entity_Count = 1
Client_ID = 100,  Client_Name = ISSU rfs client,  Entity_Count = 1
Client_ID = 110,  Client_Name = ISSU ifs client,  Entity_Count = 1
Client_ID = 1001,  Client_Name = OC3POS-6,  Entity_Count = 4
Client_ID = 1002,  Client_Name = C10K ATM,  Entity_Count = 1
Client_ID = 1003,  Client_Name = C10K CHSTM1,  Entity_Count = 1
Client_ID = 1004,  Client_Name = C10K CT3,  Entity_Count = 1
Client_ID = 1005,  Client_Name = C10K GE,  Entity_Count = 1
Client_ID = 1006,  Client_Name = C10K ET,  Entity_Count = 1
Client_ID = 1007,  Client_Name = C10K CHE1T1,  Entity_Count = 1
Client_ID = 1009,  Client_Name = C10K MFE,  Entity_Count = 1
Client_ID = 1010,  Client_Name = C10K APS,  Entity_Count = 1
Client_ID = 1013,  Client_Name = C10K CARD OIR,  Entity_Count = 1
Client_ID = 2002,  Client_Name = CEF Push ISSU client,  Entity_Count = 1
Client_ID = 2003,  Client_Name = ISSU XDR client,  Entity_Count = 1
Client_ID = 2004,  Client_Name = ISSU SNMP client,  Entity_Count = 1
Client_ID = 2005,  Client_Name = ISSU HDLC Client,  Entity_Count = 1
Client_ID = 2006,  Client_Name = ISSU QoS client,  Entity_Count = 1
Client_ID = 2007,  Client_Name = ISSU LSD Label Mgr HA Client,  Entity_Count = 1
Client_ID = 2008,  Client_Name = ISSU Tableid Client,  Entity_Count = 1
Client_ID = 2009,  Client_Name = ISSU MPLS VPN Client,  Entity_Count = 1
Client_ID = 2010,  Client_Name = ARP HA,  Entity_Count = 1
Client_ID = 2011,  Client_Name = ISSU LDP Client,  Entity_Count = 1
Client_ID = 2012,  Client_Name = ISSU HSRP Client,  Entity_Count = 1
Client_ID = 2013,  Client_Name = ISSU ATM Client,  Entity_Count = 1
Client_ID = 2014,  Client_Name = ISSU FR Client,  Entity_Count = 1
Client_ID = 2015,  Client_Name = ISSU REDSSOC client,  Entity_Count = 1
Client_ID = 2019,  Client_Name = ISSU TCP client,  Entity_Count = 1
Client_ID = 2020,  Client_Name = ISSU BGP client,  Entity_Count = 1
Client_ID = 2021,  Client_Name = XDR Int Priority ISSU client,  Entity_Count = 1
Client_ID = 2022,  Client_Name = XDR Proc Priority ISSU client,  Entity_Count = 1
Client_ID = 2023,  Client_Name = FIB HWIDB ISSU client,  Entity_Count = 1
Client_ID = 2024,  Client_Name = FIB IDB ISSU client,  Entity_Count = 1
Client_ID = 2025,  Client_Name = FIB HW subblock ISSU client,  Entity_Count = 1
```

```
Client_ID = 2026,  Client_Name = FIB SW subblock ISSU client,  Entity_Count = 1
Client_ID = 2027,  Client_Name = Adjacency ISSU client,  Entity_Count = 1
Client_ID = 2028,  Client_Name = FIB IPV4 ISSU client,  Entity_Count = 1
Client_ID = 2030,  Client_Name = MFI Pull ISSU client,  Entity_Count = 1
Client_ID = 2031,  Client_Name = MFI Push ISSU client,  Entity_Count = 1
Client_ID = 2051,  Client_Name = ISSU CCM Client,  Entity_Count = 1
Client_ID = 2052,  Client_Name = ISSU PPP SIP CCM Client,  Entity_Count = 1
Client_ID = 2053,  Client_Name = ISSU MPLS TE Client,  Entity_Count = 1
Client_ID = 2054,  Client_Name = ISSU process client,  Entity_Count = 1
Client_ID = 2089,  Client_Name = MPLS LSPV Push client,  Entity_Count = 1
.
.
.
.
Base Clients:
 Client_Name = ISSU Proto client
 Client_Name = ISSU RF
 Client_Name = ISSU CF client
 Client_Name = ISSU Network RF client
 Client_Name = ISSU CONFIG SYNC
 Client_Name = ISSU ifIndex sync
 Client_Name = ISSU IPC client
 Client_Name = ISSU IPC Server client
 Client_Name = ISSU Red Mode Client
 Client_Name = ISSU EHSA services client
 Client_Name = ISSU rfs client
 Client_Name = ISSU ifs client
 Client_Name = ISSU EM client
 Client_Name = ISSU Platform Medialayer Client
 Client_Name = ISSU FM Client
 Client_Name = ISSU TCAM Manager Client
 Client_Name = ISSU L2 Cmn Client
 Client_Name = ISSU L3 Manager HA Client
 Client_Name = ISSU L3 Manager Client
 Client_Name = ISSU CFIB BASE Client
 Client_Name = ISSU PF CONFIG SYNC Client
 Client_Name = ISSU MLS CEF Client
 Client_Name = ISSU Cat6k Logger Client
```

Verifying the ISSU Process for an MPLS LDP Client Example

This example shows how to verify the ISSU process for an LDP client.

The first command shows you whether the LDP client's old and new software versions are compatible, and therefore are able to make use of the ISSU opportunity:

```
Router# show issu sessions 2011
------------------------------------------------------------------------
 Client_ID = 2011,  Entity_ID = 1 :
 *** Session_ID = 46,  Session_Name = LDP Session :
    Peer   Peer  Negotiate  Negotiated   Cap      Msg     Session
  UniqueID  Sid    Role       Result   GroupID  GroupID  Signature
     4       34   PRIMARY   COMPATIBLE    1        1         0
                          (no policy)
    Negotiation Session Info for This Message Session:
         Nego_Session_ID = 46
         Nego_Session_Name = LDP Session
         Transport_Mtu = 3948
```

Now you can take the session ID displayed in the previous command's output and enter it into the next command, to see the negotiated message version:

```
Router# show issu negotiated version 46
 Session_ID = 46 :
     Message_Type = 1,  Negotiated_Version = 2,  Message_MTU = 20
     Message_Type = 2,  Negotiated_Version = 2,  Message_MTU = 20
     Message_Type = 3,  Negotiated_Version = 2,  Message_MTU = 4
```

Next you can enter the same session ID into the following command to display the capability negotiation result:

```
Router# show issu negotiated capability 46
 Session_ID = 46 :
     Negotiated_Cap_Entry = 1
```

Finally, to see which message types and versions are supported by this particular client, you enter the client ID into the following command:

```
Router# show issu message types 2011
------------------------------------------------------------------------
 Client_ID = 2011,  Entity_ID = 1 :
    Message_Type = 1,  Version_Range = 2 ~ 2
          Message_Ver = 2,    Message_Mtu = 20
    Message_Type = 2,  Version_Range = 2 ~ 2
          Message_Ver = 2,    Message_Mtu = 20
    Message_Type = 3,  Version_Range = 2 ~ 2
          Message_Ver = 2,    Message_Mtu = 4
```

Verifying the ISSU Process for an MPLS VPN Client Example

This example shows how to verify the ISSU process for an MPLS VPN client.

The first command shows you whether the VPN client's old and new software versions are compatible, and therefore are able to make use of the ISSU opportunity:

```
Router# show issu sessions 2009
------------------------------------------------------------------------
Client_ID = 2009,  Entity_ID = 1 :
*** Session_ID = 39,  Session_Name = MPLS VPN ISSU Session :
   Peer    Peer  Negotiate  Negotiated   Cap      Msg     Session
 UniqueID  Sid    Role       Result   GroupID  GroupID  Signature
    3       33   PASSIVE   COMPATIBLE    1        1         0
                          (no policy)
   Negotiation Session Info for This Message Session:
        Nego_Session_ID = 39
        Nego_Session_Name = MPLS VPN ISSU Session
        Transport_Mtu = 3980
```

Now you can take the session ID displayed in the previous command's output and enter it into the next command, in order to see the negotiated message version:

```
Router# show issu negotiated version 39
Session_ID = 39 :
    Message_Type = 1,  Negotiated_Version = 1,  Message_MTU = 32
```

Next you can enter the same session ID into the following command to display the capability negotiation result:

```
Router# show issu negotiated capability 39
```

```
Session_ID = 39 :
Negotiated_Cap_Entry = 1
```

Finally,= to see which message types and versions are supported by this particular client, you enter the client ID into the following command:

```
Router# show issu message types 2009
------------------------------------------------------------------------
Client_ID = 2009,  Entity_ID = 1 :
   Message_Type = 1,  Version_Range = 1 ~ 1
         Message_Ver = 1,    Message_Mtu = 32
```

Verifying the ISSU Process for an MPLS VRF ("Table ID") Client Example

This example shows how to verify the ISSU process for an MPLS VRF ("Table ID") client.

The first command shows you whether the VRF client's old and new software versions are compatible, and therefore are able to make use of the ISSU opportunity:

```
Router# show issu sessions 2008
------------------------------------------------------------------------
 Client_ID = 2008,  Entity_ID = 1 :
 *** Session_ID = 19,  Session_Name = TABLEID ISSU CF :
    Peer   Peer  Negotiate  Negotiated   Cap      Msg     Session
  UniqueID  Sid    Role       Result   GroupID  GroupID  Signature
     4       13   PRIMARY   COMPATIBLE    1        1         0
                          (no policy)
    Negotiation Session Info for This Message Session:
         Nego_Session_ID = 19
         Nego_Session_Name = TABLEID ISSU CF
         Transport_Mtu = 3948
```

```
Router# show issu sessions 2008
------------------------------------------------------------------------
 Client_ID = 2008,  Entity_ID = 1 :
 *** Session_ID = 19,  Session_Name = TABLEID ISSU CF :
    Peer   Peer  Negotiate  Negotiated   Cap      Msg     Session
  UniqueID  Sid    Role       Result   GroupID  GroupID  Signature
     4       13   PRIMARY   COMPATIBLE    1        1         0
                          (no policy)
    Negotiation Session Info for This Message Session:
         Nego_Session_ID = 19
         Nego_Session_Name = TABLEID ISSU CF
         Transport_Mtu = 3948
```

Now you can take the session ID displayed in the previous command's output and enter it into the next command, in order to see the negotiated message version:

```
Router# show issu negotiated version 19
 Session_ID = 19 :
     Message_Type = 1,  Negotiated_Version = 1,  Message_MTU = 44
     Message_Type = 2,  Negotiated_Version = 1,  Message_MTU = 4
```

Next you can enter the same session ID into the following command to display the capability negotiation result:

```
Router# show issu negotiated capability 19
Session_ID = 19 :
Negotiated_Cap_Entry = 1
```

Finally, to see which message types and versions are supported by this particular client, you enter the client ID into the following command:

```
Router# show issu message types 2008
------------------------------------------------------------------------
 Client_ID = 2008,  Entity_ID = 1 :
    Message_Type = 1,  Version_Range = 1 ~ 1
          Message_Ver = 1,    Message_Mtu = 44
    Message_Type = 2,  Version_Range = 1 ~ 1
          Message_Ver = 1,    Message_Mtu = 4
```

Verifying the ISSU Process for an MPLS LSD Label Manager HA Client Example

This example shows how to verify the ISSU process for an MPLS LSD Label Manager HA client.

The first command shows you whether the LSD client's old and new software versions are compatible, and therefore are able to make use of the ISSU opportunity:

```
Router# show issu sessions 2007
------------------------------------------------------------------------
 Client_ID = 2007,  Entity_ID = 1 :
 *** Session_ID = 40,  Session_Name = lsd_ha :
    Peer    Peer  Negotiate  Negotiated   Cap      Msg     Session
  UniqueID  Sid    Role       Result   GroupID  GroupID  Signature
     4       30   PRIMARY   COMPATIBLE    1        1         0
                              (policy)
    Negotiation Session Info for This Message Session:
         Nego_Session_ID = 40
         Nego_Session_Name = lsd_ha
         Transport_Mtu = 3948
         Compat_Result: raw_result = COMPATIBLE,  policy_result = COMPATIBLE
```

Now you can take the session ID displayed in the previous command's output and enter it into the next command, in order to see the negotiated message version:

```
Router# show issu negotiated version 40
Session_ID = 40 :
     Message_Type = 1,  Negotiated_Version = 2,  Message_MTU = 8
```

Next you can enter the same session ID into the following command to display the capability negotiation result:

```
Router# show issu negotiated capability 40
------------------------------------------------
  Client_ID = 2007,  Entity_ID = 1,  Session_ID = 40 :
      Negotiated_Cap_Entry = 1
```

Finally, to see which message types and versions are supported by this particular client, you enter the client ID into the following command:

```
Router# show issu message types 2007
------------------------------------------------------------------------
 Client_ID = 2007,  Entity_ID = 1 :
    Message_Type = 1,  Version_Range = 1 ~ 2
          Message_Ver = 1,    Message_Mtu = 12
          Message_Ver = 2,    Message_Mtu = 8
```

Verifying the ISSU Process for an MPLS MFI Pull Client Example

This example shows how to verify the ISSU process for an MPLS MFI Pull client.

The first command shows you whether the MFI Pull client's old and new software versions are compatible, and therefore are able to make use of the ISSU opportunity:

```
Router# show issu sessions 2030
------------------------------------------------------------------------
Client_ID = 2030,  Entity_ID = 1 :
*** Session_ID = 131073,  Session_Name = MFI Pull         (6):
    Peer   Peer  Negotiate  Negotiated   Cap      Msg     Session
  UniqueID  Sid    Role       Result   GroupID  GroupID  Signature
     7      35   PRIMARY    COMPATIBLE    1        1         0
                             (no policy)
    Negotiation Session Info for This Message Session:
         Nego_Session_ID = 131073
         Nego_Session_Name = MFI Pull                       (6)
         Transport_Mtu = 4056
```

Now you can take the session ID displayed in the previous command's output and enter it into the next command, in order to see the negotiated message version:

```
Router# show issu negotiated version 131073
 Session_ID = 131073:
     Message_Type = 1006,  Negotiated_Version = 1,  Message_MTU = 4
 Message_Type = 3003,  Negotiated_Version = 1,  Message_MTU = 12
```

Next you can enter the same session ID into the following command to display the capability negotiation result:

```
Router# show issu negotiated capability 131073
 Session_ID = 131073 :
      Negotiated_Cap_Entry = 1
```

Finally to see which message types and versions are supported by this particular client, you enter the client ID into the following command:

```
Router# show issu message types 2030
------------------------------------------------------------------------
 Client_ID = 2030,  Entity_ID = 1 :
 Message_Type = 1006,  Version_Range = 1 ~ 1
          Message_Ver = 1,    Message_Mtu = 4
 Message_Type = 2004,  Version_Range = 1 ~ 1
          Message_Ver = 1,    Message_Mtu = 12
```

Verifying the ISSU Process for an MPLS MFI Push Client Example

This example shows how to verify the ISSU process for an MPLS MFI Push client.

The first command shows you whether the MFI Push client's old and new software versions are compatible, and therefore are able to make use of the ISSU opportunity:

```
Router# show issu sessions 2031
------------------------------------------------------------------------
Client_ID = 2031,  Entity_ID = 1 :
*** Session_ID = 196646,  Session_Name = MFI Push         (6):
    Peer   Peer  Negotiate  Negotiated   Cap      Msg     Session
```

```
  UniqueID  Sid    Role       Result   GroupID  GroupID  Signature
     7      36   PRIMARY    COMPATIBLE    1        1        0
                            (no policy)
    Negotiation Session Info for This Message Session:
         Nego_Session_ID = 196646
         Nego_Session_Name = MFI Push                      (6)
         Transport_Mtu = 4056
```

Now you can take the session ID displayed in the previous command's output and enter it into the next command, in order to see the negotiated message version:

```
Router# show issu negotiated version 196646
Session_ID = 196646:
     Message_Type = 101,  Negotiated_Version = 1,  Message_MTU = 17
     Message_Type = 105,  Negotiated_Version = 1,  Message_MTU = 31
```

Next you can enter the same session ID into the following command to display the capability negotiation result:

```
Router# show issu negotiated capability 196646
Session_ID = 196646 :
      Negotiated_Cap_Entry = 1
```

Finally to see which message types and versions are supported by this particular client, you enter the client ID into the following command:

```
Router# show issu message types 2031
------------------------------------------------------------------------
Client_ID = 2031,  Entity_ID = 1 :
        Message_Type = 5002,  Version_Range = 1 ~ 2
              Message_Ver = 1,    Message_Mtu = 10
        Message_Type = 5018,  Version_Range = 1 ~ 1
              Message_Ver = 1,    Message_Mtu = 39
```

Verifying the ISSU Process for an MPLS LSPV Push Client Example

This example shows how to verify the ISSU process for an MPLS LSVP Push client.

The first command shows you whether the LSPV Push client's old and new software versions are compatible, and therefore are able to make use of the ISSU opportunity:

```
Router# show issu sessions 2089
------------------------------------------------------------------------
Client_ID = 2089,  Entity_ID = 1 :
 *** Session_ID = 45,  Session_Name = MPLS LSPV Push (6 ):
    Peer    Peer  Negotiate  Negotiated   Cap      Msg     Session
  UniqueID  Sid    Role       Result   GroupID  GroupID  Signature
      7     36   PRIMARY    COMPATIBLE    1        1         0
                           (no policy)
    Negotiation Session Info for This Message Session:
         Nego_Session_ID = 45
         Nego_Session_Name = MPLS LSPV Push (6 )
         Transport_Mtu = 1438
```

Now you can take the session ID displayed in the previous command's output and enter it into the next command, in order to see the negotiated message version:

```
Router# show issu negotiated version 45
 Session_ID = 45:
```

```
 Message_Type = 0,  Negotiated_Version = 1,  Message_MTU = 74
 Message_Type = 1,  Negotiated_Version = 1,  Message_MTU = 120
 Message_Type = 2,  Negotiated_Version = 1,  Message_MTU = 120
 Message_Type = 3,  Negotiated_Version = 1,  Message_MTU = 5122
 Message_Type = 4,  Negotiated_Version = 1,  Message_MTU = 6
```

Next you can enter the same session ID into the following command to display the capability negotiation result:

```
Router# show issu negotiated capability 45
Session_ID = 45:
Cap_Type = 0    Cap_Result = 1     No cap value assigned
```

Finally to see which message types and versions are supported by this particular client, you enter the client ID into the following command:

```
Router# show issu message types 2089
------------------------------------------------------------------------
 Client_ID = 2089,  Entity_ID = 1 :
    Message_Type = 0,  Version_Range = 1 ~ 1
          Message_Ver = 1,    Message_Mtu = 74
    Message_Type = 1,  Version_Range = 1 ~ 1
          Message_Ver = 1,    Message_Mtu = 120
 Message_Type = 2,  Version_Range = 1 ~ 1
          Message_Ver = 1,    Message_Mtu = 120
    Message_Type = 3,  Version_Range = 1 ~ 1
          Message_Ver = 1,    Message_Mtu = 5122
 Message_Type = 4,  Version_Range = 1 ~ 1
          Message_Ver = 1,    Message_Mtu = 6
```

Verifying the ISSU Process for an MPLS TE Client Example

This example shows how to verify the ISSU process for an MPLS TE client.

The first command shows you whether the TE client's old and new software versions are compatible, and therefore are able to make use of the ISSU opportunity:

```
Router# show issu sessions 2053
------------------------------------------------------------------------
 Client_ID = 2053,  Entity_ID = 1 :
 *** Session_ID = 84,  Session_Name = RSVP HA Session :
    Peer    Peer  Negotiate  Negotiated   Cap      Msg     Session
  UniqueID  Sid    Role       Result   GroupID  GroupID  Signature
    22       94   PRIMARY   COMPATIBLE    1        1         0
                          (no policy)
    Negotiation Session Info for This Message Session:
         Nego_Session_ID = 84
         Nego_Session_Name = RSVP HA Session
         Transport_Mtu = 1392
```

Now you can take the session ID displayed in the previous command's output and enter it into the next command, in order to see the negotiated message version:

```
Router# show issu negotiated version 84
Session_ID = 84 :
     Message_Type = 1,  Negotiated_Version = 2,  Message_MTU = 1024
```

Next you can enter the same session ID into the following command to display the capability negotiation result:

```
Router# show issu negotiated capability 84
Session_ID = 84 :
     Cap_Type = 0,     Cap_Result = 1     No cap value assigned
```

Finally to see which message types and versions are supported by this particular client, you enter the client ID into the following command:

```
Router# show issu message types 2053
------------------------------------------------------------------------
 Client_ID = 2053,  Entity_ID = 1 :
    Message_Type = 1,  Version_Range = 1 ~ 2
          Message_Ver = 1,    Message_Mtu = 1024
          Message_Ver = 2,    Message_Mtu = 1024
```

The Cisco Support website provides extensive online resources, including documentation and tools for troubleshooting and resolving technical issues with Cisco products and technologies. To receive security and technical information about your products, you can subscribe to various services, such as the Product Alert Tool (accessed from Field Notices), the Cisco Technical Services Newsletter, and Really Simple Syndication (RSS) Feeds. Access to most tools on the Cisco Support website requires a Cisco.com user ID and password.	http://www.cisco.com/techsupport

Feature Information for ISSU MPLS Clients

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 82: Feature Information for ISSU MPLS Clients

Feature Name	Releases	Feature Information
ISSU MPLS--LDP	Cisco IOS XE Release 2.1	This feature allows In Service Software Upgrade (ISSU) support for the Label Distribution Protocol (LDP) and Multiprotocol Label Switching (MPLS) Forwarding. MPLS applications can be upgraded using the In Service Software Upgrade (ISSU) process. Thus, MPLS applications are considered ISSU's MPLS clients. The ISSU process allows Cisco IOS XE software to be updated or otherwise modified while packet forwarding continues. In Cisco IOS XE Release 2.1, this feature was introduced on Cisco ASR 1000 Series Aggregation Services Routers.
		The following commands were introduced or modified: **show issu clients, show issu entities, show issu message types, show issu negotiated, show issu outage, show issu sessions.**

Feature Name	Releases	Feature Information
ISSU--MPLS VPN (Support for IPv4 VPNs)	Cisco IOS XE Release 2.1	This feature supports In Service Software Upgrade (ISSU) for Multiprotocol Label Switching (MPLS) Virtual Private networks (VPNs) for IPv4 address families only. In Cisco IOS XE Release 2.1, this feature was introduced on Cisco ASR 1000 Series Aggregation Services Routers. No commands were introduced or modified for this feature.
ISSU--MPLS TE	Cisco IOS XE Release 2.3	This feature allows upgrade or downgrade of compatible Cisco IOS XE software images on the back up Route Processor (RP) while the device is operational and passing traffic on Multiprotocol Label Switching (MPLS) traffic engineering (TE) tunnels. In Cisco IOS XE Release 2.3, this feature was introduced on Cisco ASR 1000 Series Aggregation Services Routers. No commands were introduced or modified for this feature.

CHAPTER 25

MPLS Traffic Engineering--RSVP Graceful Restart

The MPLS Traffic Engineering--RSVP Graceful Restart feature allows a neighboring Route Processor (RP) to recover from disruption in control plane service (specifically, the Label Distribution Protocol [LDP] component) without losing its Multiprotocol Label Switching (MPLS) forwarding state.

- Prerequisites for MPLS TE--RSVP Graceful Restart, on page 471
- Restrictions for MPLS TE--RSVP Graceful Restart, on page 472

- Additional References, on page 479
- Feature Information for MPLS Traffic Engineering--RSVP Graceful Restart, on page 480
- Glossary, on page 481

Prerequisites for MPLS TE--RSVP Graceful Restart

Perform the following tasks on routers before configuring the MPLS Traffic Engineering--RSVP Graceful Restart feature:

- Configure the Resource Reservation Protocol (RSVP).
- Enable MPLS.
- Configure traffic engineering (TE).
- Enable graceful restart.

If you have many tunnels/LSPs (100 or more) or if you have a large-scale network, the following configuration is recommended:

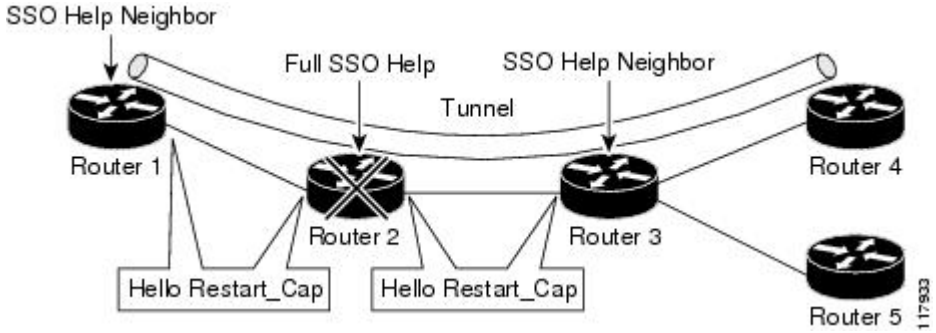
```
ip rsvp signalling refresh reduction
ip rsvp signalling rate-limit period 50 burst 16 maxsize 3000 limit 37
ip rsvp signalling patherr state-removal
ip rsvp signalling initial-retransmit-delay 15000
```

Additional info about these RSVP commands can be found in the *Cisco IOS Quality of Service Command Reference*.

Restrictions for MPLS TE--RSVP Graceful Restart

- Graceful restart supports node failure only.
- Graceful restart does not support restart or recovery on Cisco nodes, but helps in recovering a neighbor that is restart capable. Cisco routers advertise a restart time of 5 milliseconds (ms) and a recovery time of 0 in hello messages.
- Unnumbered interfaces are not supported.

Information About MPLS TE--RSVP Graceful Restart



Graceful Restart

Graceful restart allows RSVP TE enabled nodes to start gracefully following a node failure in the network such that the RSVP state after the failure is restored as quickly as possible. The node failure may be completely transparent to other nodes in the network as far as the RSVP state is concerned.

Graceful restart preserves the label values and forwarding information and works with third-party or Cisco routers seamlessly.

Graceful restart depends on RSVP hello messages that include Hello Request or Hello Acknowledgment (ACK) objects between two neighbors.

The figure below shows the graceful restart extension to these messages that an object called Restart_Cap, which tells neighbors that a node, may be capable of restarting if a failure occurs. The time-to-live (TTL) in these messages is set to 255 so that adjacencies can be maintained through alternate paths even if the link between two neighbors goes down.

The Restart_Cap object has two values--the restart time, which is the sender's time to restart the RSVP_TE component and exchange hello messages after a failure; and the recovery time, which is the desired time that the sender wants the receiver to synchronize the RSVP and MPLS databases.

In the figure above, graceful restart is enabled on Router 1, Router 2, Router 3, and Router 4. For simplicity, assume that all routers are restart capable. A TE label switched path (LSP) is signaled from Router 1 to Router 4.

Router 2 and Router 3 exchange periodic graceful restart hello messages every 10,000 ms (10 seconds), and so do Router 2 and Router 1 and Router 3 and Router 4. Assume that Router 2 advertises its restart time as 60,000 ms (60 seconds) and its recovery time as 60,000 ms (60 seconds) as shown in the following example:

```
23:33:36: Outgoing Hello:
23:33:36:   version:1 flags:0000 cksum:883C ttl:255 reserved:0 length:32
23:33:36:   HELLO               type HELLO REQUEST length 12:
23:33:36:   Src_Instance: 0x6EDA8BD7, Dst_Instance: 0x00000000
23:33:36:   RESTART_CAP         type 1 length 12:
23:33:36:   Restart_Time: 0x0000EA60
, Recovery_Time: 0x0000EA60
```

Note The restart and recovery time are shown in **bold** in the last entry.

Router 3 records this into its database. Also, both neighbors maintain the neighbor status as UP. However, Router 3's control plane fails at some point (for example, a Primary Route Processor failure). As a result, RSVP and TE lose their signaling information and states although data packets continue to be forwarded by the line cards.

When four ACK messages are missed from Router 2 (40 seconds), Router 3 declares communication with Router 2 lost "indicated by LOST" and starts the restart time to wait for the duration advertised in Router 2's restart time previously and recorded (60 seconds). Router 1 and Router 2 suppress all RSVP messages to Router 3 except hellos. Router 3 keeps sending the RSVP Path and Resv refresh messages to Router 4 and Router 5 so that they do not expire the state for the LSP; however, Router 3 suppresses these messages for Router 2.

Note A node restarts if it misses four ACKs or its hello src_instance (last source instance sent to its neighbor) changes so that its restart time = 0.

Before the restart time expires, Router 2 restarts and loads its configuration and graceful restart makes the configuration of router 2 send the hello messages with a new source instance to all the data links attached. However, because Router 2 has lost the neighbor states, it does not know what destination instance it should use in those messages; therefore, all destination instances are set to 0.

When Router 3 sees the hello from Router 2, Router 3 stops the restart time for Router 2 and sends an ACK message back. When Router 3 sees a new source instance value in Router 2's hello message, Router 3 knows that Router 2 had a control plane failure. Router 2 gets Router 3's source instance value and uses it as the destination instance going forward.

Router 3 also checks the recovery time value in the hello message from Router 2. If the recovery time is 0, Router 3 knows that Router 2 was not able to preserve its forwarding information and Router 3 deletes all RSVP state that it had with Router 2.

If the recovery time is greater than 0, Router 1 sends Router 2 Path messages for each LSP that it had previously sent through Router 2. If these messages were previously refreshed in summary messages, they are sent individually during the recovery time. Each of these Path messages includes a Recovery_Label object containing the label value received from Router 2 before the failure.

When Router 3 receives a Path message from Router 2, Router 3 sends a Resv message upstream. However, Router 3 suppresses the Resv message until it receives a Path message.

Graceful Restart Benefits

- Graceful restart allows a node to recover state information from its neighbor when there is an RP failure or the device has undergone a stateful switchover (SSO).
- Graceful restart allows session information recovery with minimal disruption to the network.
- A node can perform a graceful restart to help a neighbor recover its state by keeping the label bindings and state information to provide a quick recovery of the failed node and not affect the traffic that is currently forwarded.

How to Configure MPLS TE--RSVP Graceful Restart

Enabling Graceful Restart

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip rsvp signalling hello graceful-restart mode help-neighbor**
4. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**ip rsvp signalling hello graceful-restart mode help-neighbor** **Example:** `Router(config)# ip rsvp signalling hello graceful-restart mode help-neighbor`	Sets the number of DSCP hello messages on a neighboring router with restart capability.
Step 4	**exit** **Example:**	Exits to privileged EXEC mode.

	Command or Action	Purpose
	`Router(config)# exit`	

What to do next

Note

If you have many tunnels/LSPs (100 or more) or if you have a large-scale network, the following configuration is recommended:

```
ip rsvp signalling refresh reduction
ip rsvp signalling rate-limit period 50 burst 16 maxsize 3000 limit 37
ip rsvp signalling patherr state-removal
ip rsvp signalling initial-retransmit-delay 15000
```

Additional info about these RSVP commands can be found in the Cisco IOS Quality of Service Command Reference.

Setting a DSCP Value on a Router for MPLS TE Graceful Restart

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip rsvp signalling hello graceful-restart dscp** *num*
4. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**ip rsvp signalling hello graceful-restart dscp** *num* **Example:** `Router(config)# ip rsvp signalling hello graceful-restart dscp 30`	Sets the number of DSCP hello messages on a graceful restart-enabled router.

	Command or Action	Purpose
Step 4	**exit** **Example:** `Router(config)# exit`	Exits to privileged EXEC mode.

Setting a Hello Refresh Interval for MPLS TE Graceful Restart

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip rsvp signalling hello graceful-restart refresh interval** *interval-value*
4. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**ip rsvp signalling hello graceful-restart refresh interval** *interval-value* **Example:** `Router(config)# ip rsvp signalling hello graceful-restart refresh interval 5000`	Sets a hello refresh interval on a router with graceful restart enabled.
Step 4	**exit** **Example:** `Router(config)# end`	Exits to privileged EXEC mode.

Setting a Missed Refresh Limit for MPLS TE Graceful Restart

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip rsvp signalling hello graceful-restart refresh misses** *msg-count*
4. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**ip rsvp signalling hello graceful-restart refresh misses** *msg-count* **Example:** `Router(config)# ip rsvp signalling hello graceful-restart refresh misses 5`	Sets a refresh limit on a router with graceful restart enabled.
Step 4	**exit** **Example:** `Router(config)# end`	Exits to privileged EXEC mode.

Verifying Graceful Restart Configuration

SUMMARY STEPS

1. **enable**
2. **show ip rsvp hello graceful-restart**
3. **exit**

DETAILED STEPS

Procedure

Step 1 **enable**

Use this command to enable privileged EXEC mode. Enter your password if prompted. For example:

Example:

```
Router> enable
Router#
```

Step 2 **show ip rsvp hello graceful-restart**

Use this command to display information about the status of graceful restart and related parameters. For example:

Example:

```
Router# show ip rsvp hello graceful-restart
Graceful Restart:Enabled (help-neighbor only)
  Refresh interval:10000 msecs
  Refresh misses:4
  DSCP:0x30
  Advertised restart time:0 secs
  Advertised recovery time:0 secs
  Maximum wait for recovery:3600000 secs
```

Step 3 **exit**

Use this command to exit to user EXEC mode. For example:

Example:

```
Router# exit
Router>
```

Configuration Examples for MPLS TE--RSVP Graceful Restart

Example MPLS TE--RSVP Graceful Restart

In the following example, graceful restart is enabled, and related parameters, including a DSCP value, a refresh interval, and a missed refresh limit are set:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# ip rsvp signalling hello graceful-restart mode help-neighbor
Router(config)# ip rsvp signalling hello graceful-restart dscp 30
Router(config)# ip rsvp signalling hello graceful-restart refresh interval 10000
Router(config)# ip rsvp signalling hello graceful-restart refresh misses 4
Router(config)# end
```

Feature Information for MPLS Traffic Engineering--RSVP Graceful Restart

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 83: Feature Information for MPLS Traffic Engineering--RSVP Graceful Restart

Feature Name	Releases	Feature Information
MPLS Traffic Engineering--RSVP Graceful Restart	Cisco IOS XE Release 2.3	The MPLS TE--RSVP Graceful Restart feature allows a neighboring Route Processor (RP) to recover from disruption in control plane service (specifically, the Label Distribution Protocol (LDP) component) without losing its MPLS forwarding state. In Cisco IOS XE Release 2.3, this feature was introduced on the Cisco ASR 1000 Series Aggregation Services Routers. The following commands were introduced or modified: **ip rsvp signalling hello graceful-restart dscp**, **ip rsvp signalling hello graceful-restart mode help-neighbor**, **ip rsvp signalling hello graceful-restart refresh interval**, **ip rsvp signalling hello graceful-restart refresh misses**, **show ip rsvp counters**, **show ip rsvp counters state teardown**, **show ip rsvp hello**, **show ip rsvp hello client lsp detail**, **show ip rsvp hello client lsp summary**, **show ip rsvp hello client neighbor detail**, **show ip rsvp hello client neighbor summary**, **show ip rsvp hello graceful-restart**, **show ip rsvp hello instance detail**, **show ip rsvp hello instance summary**.

Glossary

autonomous system --A collection of networks that share the same routing protocol and that are under the same system administration.

ASBR --**Autonomous System Boundary Router**. A router that connects and exchanges information between two or more autonomous systems.

backup tunnel --A Multiprotocol Label Switching (MPLS) traffic engineering (TE) tunnel used to protect other (primary) tunnels' traffic when a link or node failure occurs.

DSCP --differentiated services code point. Six bits in the IP header, as defined by the Internet Engineering Task Force (IETF). These bits determine the class of service provided to the IP packet.

Fast Reroute --A mechanism for protecting Multiprotocol Label Switching (MPLS) traffic engineering (TE) label switched paths (LSPs) from link and node failure by locally repairing the LSPs at the point of failure, allowing data to continue to flow on them while their headend routers attempt to establish end-to-end LSPs to replace them. Fast Reroute (FRR) locally repairs the protected LSPs by rerouting them over backup tunnels that bypass failed links or nodes.

graceful restart --A process for helping a neighboring Route Processor (RP) restart after a node failure has occurred.

headend --The router that originates and maintains a given label switched path (LSP). This is the first router in the LSP's path.

IGP --Interior Gateway Protocol. Internet protocol used to exchange routing information within an autonomous system. Examples of common Internet IGPs include Interior Gateway Routing Protocol (IGRP), Open Shortest Path First (OSPF), and Routing Information Protocol (RIP).

instance --A mechanism that implements the Resource Reservation Protocol. (RSVP) hello extensions for a given router interface address and remote IP address. Active hello instances periodically send Hello Request messages, expecting Hello ACK messages in response. If the expected ACK message is not received, the active hello instance declares that the neighbor (remote IP address) is unreachable (that is, it is lost). This can cause label switched paths (LSPs) crossing this neighbor to be fast rerouted.

label --A short, fixed-length data identifier that tells switching nodes how to forward data (packets or cells).

LDP --Label Distribution Protocol. The protocol that supports Multiprotocol Label Switching (MPLS) hop-by-hop forwarding by distributing bindings between labels and network prefixes.

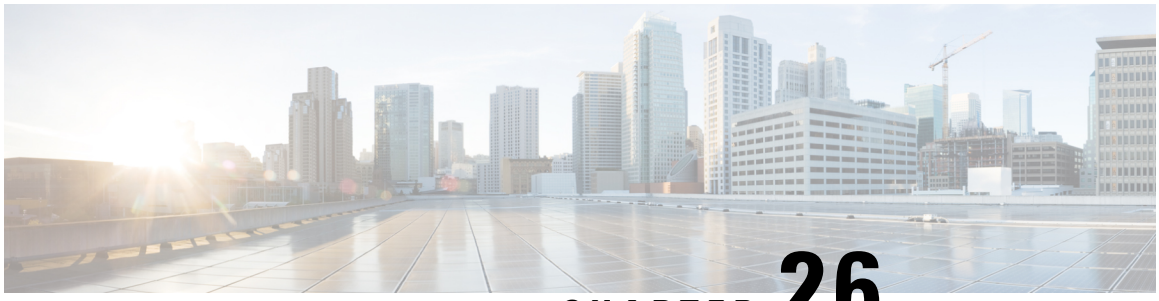
LSP --label switched path. A configured connection between two routers, in which Multiprotocol Label Switching (MPLS) is used to carry packets. A path created by the concatenation of one or more label switched hops, allowing a packet to be forwarded by swapping labels from an MPLS node to another MPLS node.

merge point --The tail of the backup tunnel.

MPLS --Multiprotocol Label Switching. A method for forwarding packets (frames) through a network. MPLS enables routers at the edge of a network to apply labels to packets (frames). ATM switches or existing routers in the network core can switch packets according to the labels.

PLR --point of local repair. The headend of the backup tunnel.

RSVP --Resource Reservation Protocol. A protocol that supports the reservation of resources across an IP network. Applications running on IP end systems can use RSVP to indicate to other nodes the nature (bandwidth, jitter, maximum burst, and so on) of the packet streams they want to receive.



state --Information that a router must maintain about each label switched path (LSP). The information is used for rerouting tunnels.

tailend --The router upon which an label switched path (LSP) is terminated. This is the last router in the LSP's path.

TE --traffic engineering. The techniques and processes used to cause routed traffic to travel through the network on a path other than the one that would have been chosen if standard routing methods had been used.

topology --The physical arrangement of network nodes and media within an enterprise networking structure.

tunnel --Secure communications path between two peers, such as two routers.

CHAPTER 26

NSF SSO--MPLS TE and RSVP Graceful Restart

The NSF/SSO--MPLS TE and RSVP Graceful Restart feature allows a Route Processor (RP) to recover from disruption in control plane service without losing its Multiprotocol Label Switching (MPLS) forwarding state.

Cisco nonstop forwarding (NSF) with stateful switchover (SSO) provides continuous packet forwarding, even during a network processor hardware or software failure. In a redundant system, the secondary processor recovers control plane service during a critical failure in the primary processor. SSO synchronizes the network state information between the primary and the secondary processor.

- Prerequisites for NSF SSO--MPLS TE and RSVP Graceful Restart, on page 483
- Restrictions for NSF SSO--MPLS TE and RSVP Graceful Restart, on page 484
- Information About NSF SSO--MPLS TE and RSVP Graceful Restart, on page 484
- How to Configure NSF SSO--MPLS TE and RSVP Graceful Restart, on page 486
- Configuration Examples for NSF SSO--MPLS TE and RSVP Graceful Restart, on page 491
- Additional References, on page 492
- Feature Information for NSF SSO--MPLS TE and RSVP Graceful Restart, on page 493
- Glossary, on page 494

Prerequisites for NSF SSO--MPLS TE and RSVP Graceful Restart

- Configure Resource Reservation Protocol (RSVP) graceful restart in full mode.
- Configure RSVP graceful restart on all interfaces of the neighbor that you want to be restart-capable.
- Configure the redundancy mode as SSO. See the Stateful Switchover feature module for more information.
- Enable NSF on the routing protocols running among the provider routers (P), provider edge (PE) routers, and customer edge (CE) routers. The routing protocols are as follows:
  - Border Gateway Protocol (BGP)
  - Open Shortest Path First (OSPF)
  - Intermediate System-to-Intermediate System (IS-IS)

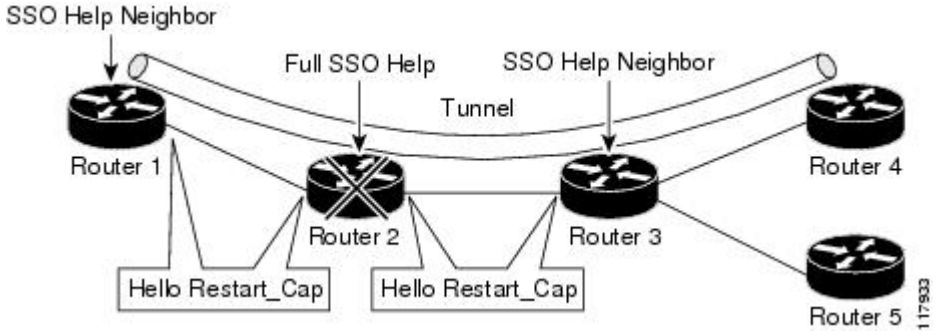
See the Cisco Nonstop Forwarding feature module for more information.

- Enable MPLS.
- Configure traffic engineering (TE).

Restrictions for NSF SSO--MPLS TE and RSVP Graceful Restart

- RSVP graceful restart supports node failure only.
- Unnumbered interfaces are not supported.
- You cannot enable RSVP fast reroute (FRR) hello messages and RSVP graceful restart on the same router.
- You cannot enable primary one-hop autotunnels, backup autotunnels, or autotunnel mesh groups on a router that is also configured with SSO and Route Processor Redundancy Plus (RPR+). This restriction does not prevent an MPLS TE tunnel that is automatically configured by TE autotunnel from being successfully recovered if any midpoint router along the label-switched path (LSP) of the router experiences an SSO.
- MPLS TE LSPs that are fast reroutable cannot be successfully recovered if the LSPs are FRR active and the Point of Local Repair (PLR) router experiences an SSO.
- When you configure RSVP graceful restart, you must use the neighbor's interface IP address.

Information About NSF SSO--MPLS TE and RSVP Graceful Restart



Overview of MPLS TE and RSVP Graceful Restart

RSVP graceful restart allows RSVP TE-enabled nodes to recover gracefully following a node failure in the network such that the RSVP state after the failure is restored as quickly as possible. The node failure may be completely transparent to other nodes in the network.

RSVP graceful restart preserves the label values and forwarding information and works with third-party or Cisco routers seamlessly.

RSVP graceful restart depends on RSVP hello messages to detect that a neighbor went down. Hello messages include Hello Request or Hello Acknowledgment (ACK) objects between two neighbors.

As shown in the figure below, the RSVP graceful restart extension to these messages adds an object called Hello Restart_Cap, which tells neighbors that a node may be capable of recovering if a failure occurs.

The Hello Restart_Cap object has two values: the restart time, which is the sender's time to restart the RSVP_TE component and exchange hello messages after a failure; and the recovery time, which is the desired time that the sender wants the receiver to synchronize the RSVP and MPLS databases.

In the figure above, RSVP graceful restart help neighbor support is enabled on Routers 1 and 3 so that they can help a neighbor recover after a failure, but they cannot perform self recovery. Router 2 has full SSO help support enabled, meaning it can perform self recovery after a failure or help its neighbor to recover. Router 2 has two RPs, one that is active and one that is standby (backup). A TE LSP is signaled from Router 1 to Router 4.

Router 2 performs checkpointing; that is, it copies state information from the active RP to the standby RP, thereby ensuring that the standby RP has the latest information. If an active RP fails, the standby RP can take over.

Routers 2 and 3 exchange periodic graceful restart hello messages every 10,000 milliseconds (ms) (10 seconds), and so do Routers 2 and 1 and Routers 3 and 4. Assume that Router 2 advertises its restart time = 60,000 ms (60 seconds) and its recovery time = 60,000 ms (60 seconds) as shown in the following example:

```
23:33:36: Outgoing Hello:
23:33:36:   version:1 flags:0000 cksum:883C ttl:255 reserved:0 length:32
23:33:36:  HELLO               type HELLO REQUEST length 12:
23:33:36:   Src_Instance: 0x6EDA8BD7, Dst_Instance: 0x00000000
23:33:36:  RESTART_CAP         type 1 length 12:
23:33:36:   Restart_Time: 0x0000EA60, Recovery_Time: 0x0000EA60
```

Router 3 records this into its database. Also, both neighbors maintain the neighbor status as UP. However, Router 3's control plane fails at some point (for example, a primary RP failure). As a result, RSVP and TE lose their signaling information and states although data packets continue to be forwarded by the line cards.

When Router 3 declares communication with Router 2 lost, Router 3 starts the restart time to wait for the duration advertised in Router 2's restart time previously recorded (60 seconds). Routers 1 and 2 suppress all RSVP messages to Router 3 except hellos. Router 3 keeps sending the RSVP PATH and RESV refresh messages to Routers 4 and 5 so that they do not expire the state for the LSP; however, Routers 1 and 3 suppress these messages for Router 2.

When Routers 1 and 3 receive the hello message from Router 2, Routers 1 and 3 check the recovery time value in the message. If the recovery time is 0, Router 3 knows that Router 2 was not able to preserve its forwarding information, and Routers 1 and 3 delete all RSVP state that they had with Router 2.

If the recovery time is greater than 0, Router 1 sends Router 2 PATH messages for each LSP that it had previously sent through Router 2. If these messages were previously refreshed in summary messages, they are sent individually during the recovery time. Each of these PATH messages includes a Recovery_Label object containing the label value received from Router 2 before the failure.

When Router 3 receives a PATH message from Router 2, Router 3 sends a RESV message upstream. However, Router 3 suppresses the RESV message until it receives a PATH message. When Router 2 receives the RESV message, it installs the RSVP state and reprograms the forwarding entry for the LSP.

Benefits of MPLS TE and RSVP Graceful Restart

State Information Recovery

RSVP graceful restart allows a node to perform self recovery or to help its neighbor recover state information when there is an RP failure or the device has undergone an SSO.

Session Information Recovery

RSVP graceful restart allows session information recovery with minimal disruption to the network.

Increased Availability of Network Services

A node can perform a graceful restart to help itself or a neighbor recover its state by keeping the label bindings and state information, thereby providing a faster recovery of the failed node and not affecting currently forwarded traffic.

How to Configure NSF SSO--MPLS TE and RSVP Graceful Restart

Enabling RSVP Graceful Restart Globally

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip rsvp signalling hello graceful-restart mode** (**help-neighbor**| **full**)
4. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**ip rsvp signalling hello graceful-restart mode** (**help-neighbor**| **full**) **Example:** `Router(config)# ip rsvp signalling hello graceful-restart mode full`	Enables RSVP TE graceful restart capability on an RP. • Enter the **help-neighbor** keyword to enable a neighboring router to restart after a failure. • Enter the **full**keyword to enable a router to perform self recovery or to help a neighbor recover after a failure.
Step 4	**exit** **Example:**	(Optional) Returns to privileged EXEC mode.

	Command or Action	Purpose
	`Router(config)# exit`	

Enabling RSVP Graceful Restart on an Interface

You must repeat this procedure for each of the neighbor router's interfaces.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type slot* / *subslot* / *port* [**.** *subinterface-number*]
4. Repeat Step 3 as needed to configure additional interfaces.
5. **ip rsvp signalling hello graceful-restart neighbor** *ip-address*
6. Repeat Step 5 as needed to configure additional IP addresses on a neighbor router's interfaces.
7. **exit**
8. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**interface** *type slot* / *subslot* / *port* [**.** *subinterface-number*] **Example:** `Router(config)# interface POS 1/0/0`	Configures the interface type and number and enters interface configuration mode.
Step 4	Repeat Step 3 as needed to configure additional interfaces.	(Optional) Configures additional interfaces.
Step 5	**ip rsvp signalling hello graceful-restart neighbor** *ip-address* **Example:**	Enables support for RSVP graceful restart on routers helping their neighbors recover TE tunnels following SSO. **Note** The IP address must be that of the neighbor's interface.

	Command or Action	Purpose
	`Router(config-if)# ip rsvp signalling hello graceful-restart neighbor 10.0.0.0`	
Step 6	Repeat Step 5 as needed to configure additional IP addresses on a neighbor router's interfaces.	(Optional) Configures additional IP addresses on a neighbor router's interfaces.
Step 7	**exit** **Example:** `Router(config-if)# exit`	Exits interface configuration mode and returns to global configuration mode.
Step 8	**exit** **Example:** `Router(config)# exit`	(Optional) Exits global configuration mode and returns to privileged EXEC mode.

Setting a DSCP Value for RSVP Graceful Restart

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip rsvp signalling hello graceful-restart dscp num**
4. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**ip rsvp signalling hello graceful-restart dscp num** **Example:** `Router(config)# ip rsvp signalling hello graceful-restart dscp 30`	Sets a DSCP value on a router with RSVP graceful restart enabled.

	Command or Action	Purpose
Step 4	**exit** **Example:** `Router(config)# exit`	(Optional) Returns to privileged EXEC mode.

Setting a Value to Control the Refresh Interval for RSVP Hello Messages

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip rsvp signalling hello graceful-restart refresh interval** *interval-value*
4. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**ip rsvp signalling hello graceful-restart refresh interval** *interval-value* **Example:** `Router(config)# ip rsvp signalling hello graceful-restart refresh interval 5000`	Sets the value to control the request interval in graceful restart hello messages. This interval represents the frequency at which RSVP hello messages are sent to a neighbor; for example, one hello message is sent per each interval. **Note** If you change the default value for this command and you also changed the RSVP refresh interval using the **ip rsvp signalling refresh interval** command, ensure that the value for the **ip rsvp signalling hello graceful-restart refresh interval**command **is less than the value for the ip rsvp signalling hello refresh interval** command. Otherwise, some or all of the label-switched paths (LSPs) may not be recovered after an SSO has occurred.

	Command or Action	Purpose
Step 4	**exit** **Example:** `Router(config)# exit`	(Optional) Returns to privileged EXEC mode.

Setting a Value to Control the Missed Refresh Limit for RSVP Graceful Restart Hello Acknowledgements

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip rsvp signalling hello graceful-restart refresh misses** *msg-count*
4. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**ip rsvp signalling hello graceful-restart refresh misses** *msg-count* **Example:** `Router(config)# ip rsvp signalling hello graceful-restart refresh misses 5`	Specifies how many sequential RSVP TE graceful restart hello acknowledgments (ACKs) a node can miss before the node considers communication with its neighbor lost. **Note** If you change the default value for this command and you are also using the **ip rsvp signalling hello refresh misses**command, ensure that the value for the **ip rsvp signalling hello graceful-restart refresh misses**command **is less than the value for the ip rsvp signalling hello refresh misses** command. Otherwise, some or all of the LSPs may not be recovered after an SSO has occurred.

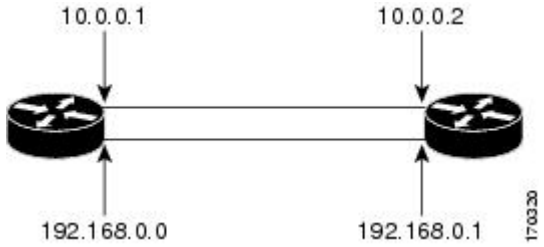
	Command or Action	Purpose
Step 4	**exit** **Example:** `Router(config)# exit`	(Optional) Returns to privileged EXEC mode.

Verifying the RSVP Graceful Restart Configuration

SUMMARY STEPS

1. **enable**
2. **show ip rsvp hello graceful-restart**
3. **exit**

DETAILED STEPS



Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	(Optional) Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**show ip rsvp hello graceful-restart** **Example:** `Router# show ip rsvp hello graceful-restart`	Displays information about the status of RSVP graceful restart and related parameters.
Step 3	**exit** **Example:** `Router# exit`	(Optional) Returns to user EXEC mode.

Configuration Examples for NSF SSO--MPLS TE and RSVP Graceful Restart

Example Configuring NSF SSO--MPLS TE and RSVP Graceful Restart

In the following example, RSVP graceful restart is enabled globally and on a neighbor router's interfaces as shown in the figure below. Related parameters, including a DSCP value, a refresh interval, and a missed refresh limit are set.

```
enable
configure terminal
ip rsvp signalling hello graceful-restart mode full
interface POS 1/0/0
 ip rsvp signalling hello graceful-restart neighbor 10.0.0.1
 ip rsvp signalling hello graceful-restart neighbor 10.0.0.2
 exit
ip rsvp signalling hello graceful-restart dscp 30
ip rsvp signalling hello graceful-restart refresh interval 50000
ip rsvp signalling hello graceful-restart refresh misses 5
exit
```

Example Verifying the NSF SSO--MPLS TE and RSVP Graceful Restart Configuration

```
Router# show ip rsvp hello graceful-restart
Graceful Restart: Enabled (full mode)
  Refresh interval: 10000 msecs
  Refresh misses: 4
  DSCP:0x30
  Advertised restart time: 30000 msecs
  Advertised recovery time: 120000 msecs
  Maximum wait for recovery: 3600000 msecs
```

Feature Information for NSF SSO--MPLS TE and RSVP Graceful Restart

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 84: Feature Information for NSF/SSO--MPLS TE and RSVP Graceful Restart

Feature Name	Releases	Feature Information
NSF/SSO--MPLS TE and RSVP Graceful Restart	Cisco IOS XE Release 3.1S Cisco IOS XE Release 3.5S	The NSF/SSO--MPLS TE and RSVP Graceful Restart feature allows a Route Processor (RP) to recover from disruption in control plane service without losing its Multiprotocol Label Switching (MPLS) forwarding state. Cisco nonstop forwarding (NSF) with stateful switchover (SSO) provides continuous packet forwarding, even during a network processor hardware or software failure. In a redundant system, the secondary processor recovers control plane service during a critical failure in the primary processor. SSO synchronizes the network state information between the primary and the secondary processor. In Cisco IOS XE Release 3.1S, this feature was implemented on the Cisco ASR 1000 Series Aggregation Services Routers.
		The following commands were introduced or modified: **clear ip rsvp high-availability counters**, **debug ip rsvp high-availability**, **debug ip rsvp sso**, **debug mpls traffic-eng ha sso**, **ip rsvp signalling hello graceful-restart dscp**, **ip rsvp signalling hello graceful-restart mode**, **ip rsvp signalling hello graceful-restart mode help-neighbor**, **ip rsvp signalling hello graceful-restart neighbor**, **ip rsvp signalling hello graceful-restart refresh interval**, **ip rsvp signalling hello graceful-restart refresh misses**, **show ip rsvp counters**, **show ip rsvp counters state teardown**, **show ip rsvp hello**, **show ip rsvp hello client lsp detail**, **show ip rsvp hello client lsp summary**, **show ip rsvp hello client neighbor detail**, **show ip rsvp hello client neighbor summary**, **show ip rsvp hello graceful-restart**, **show ip rsvp hello instance detail**, **show ip rsvp hello instance summary**, **show ip rsvp high-availability counters**, **show ip rsvp high-availability database**, **show ip rsvp high-availability summary**.

Glossary

DSCP --differentiated services code point. Six bits in the IP header, as defined by the Internet Engineering Task Force (IETF). These bits determine the class of service provided to the IP packet.

Fast Reroute --A mechanism for protecting Multiprotocol Label Switching (MPLS) traffic engineering (TE) label switched paths (LSPs) from link and node failure by locally repairing the LSPs at the point of failure, allowing data to continue to flow on them while their headend routers attempt to establish end-to-end LSPs

to replace them. Fast reroute (FRR) locally repairs the protected LSPs by rerouting them over backup tunnels that bypass failed links or nodes.

graceful restart --A process for helping a Route Processor (RP) restart after a node failure has occurred.

headend --The router that originates and maintains a given label switched path (LSP). This is the first router in the LSP's path.

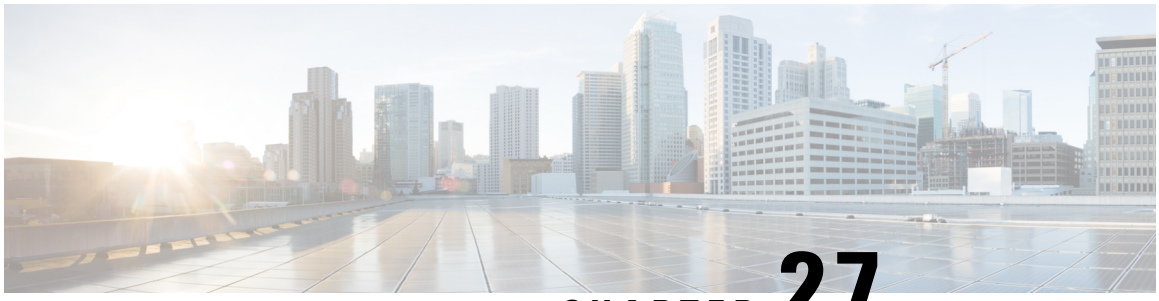
hello instance --A mechanism that implements the Resource Reservation Protocol (RSVP) hello extensions for a given router interface address and remote IP address. Active hello instances periodically send hello request messages, expecting Hello ACK messages in response. If the expected ACK message is not received, the active hello instance declares that the neighbor (remote IP address) is unreachable (that is, it is lost). This can cause LSPs crossing this neighbor to be fast rerouted.

IGP --Interior Gateway Protocol. Internet protocol used to exchange routing information within an autonomous system. Examples of common Internet IGPs include Interior Gateway Routing Protocol (IGRP), Open Shortest Path First (OSPF), and Routing Information Protocol (RIP).

ISSU --In Service Software Upgrade. Software upgrade without service interruption.

label --A short, fixed-length data identifier that tells switching nodes how to forward data (packets or cells).

LSP --label switched path. A configured connection between two routers, in which Multiprotocol Label Switching (MPLS) is used to carry packets.



MPLS --Multiprotocol Label Switching. A method for forwarding packets (frames) through a network. MPLS enables routers at the edge of a network to apply labels to packets (frames). ATM switches or existing routers in the network core can switch packets according to the labels.

RSVP --Resource Reservation Protocol. A protocol that supports the reservation of resources across an IP network. Applications running on IP end systems can use RSVP to indicate to other nodes the nature (bandwidth, jitter, maximum burst, and so on) of the packet streams they want to receive.

state --Information that a router must maintain about each label switched path (LSP). The information is used for rerouting tunnels.

tailend --The router upon which a label switched path (LSP) is terminated. This is the last router in the LSP's path.

TE --traffic engineering. The techniques and processes used to cause routed traffic to travel through the network on a path other than the one that would have been chosen if standard routing methods had been used.

CHAPTER 27

AToM Graceful Restart

The AToM Graceful Restart feature assists neighboring devices that have nonstop forwarding (NSF), stateful switchover (SSO), and graceful restart (GR) for Any Transport over Multiprotocol Label Switching (AToM) to recover gracefully from an interruption in service. AToM GR functions strictly in helper mode, which means it helps other devices that are enabled with the NSF/SSO—Any Transport over MPLS and AToM Graceful Restart feature to recover. If the device with AToM GR fails, its peers cannot help it recover. AToM GR is based on the MPLS Label Distribution Protocol (LDP) Graceful Restart feature.

Keep the following points in mind when reading this document:

- The AToM GR feature described in this document refers to helper mode.
- For brevity, the NSF/SSO—Any Transport over MPLS and AToM Graceful Restart feature is called AToM SSO/NSF in this document.

- Prerequisites for AToM Graceful Restart, on page 497
- Restrictions for AToM Graceful Restart, on page 497
- Information About AToM Graceful Restart, on page 498
- How to Configure AToM Graceful Restart, on page 498
- Configuration Examples for AToM Graceful Restart, on page 499
- Additional References, on page 502
- Feature Information for AToM Graceful Restart, on page 503

Prerequisites for AToM Graceful Restart

Any Transport over Multiprotocol Label Switching (AToM) must be configured.

Restrictions for AToM Graceful Restart

- Any Transport over Multiprotocol Label Switching (AToM) graceful restart (GR) is supported in strict helper mode.
- MPLS Label Distribution Protocol (LDP) GR cannot be configured on label-controlled ATM (LC-ATM) interfaces.
- On some hardware platforms, Tag Distribution Protocol (TDP) sessions are not supported. Only LDP sessions are supported.

Information About AToM Graceful Restart

How AToM Graceful Restart Works

Any Transport over Multiprotocol Label Switching Graceful Restart (AToM GR) works in strict helper mode, which means it helps a neighboring Route Processor (RP) that has AToM nonstop forwarding (NSF) and stateful switchover (SSO) to recover from a disruption in service without losing its MPLS forwarding state. The disruption in service could result from a TCP or User Datagram Protocol (UDP) event or the SSO of an RP. AToM GR is based on the MPLS Label Distribution Protocol (LDP) Graceful Restart feature, which preserves forwarding information for AToM circuits during an LDP session interruption. When the neighboring device establishes a new session, the LDP bindings and MPLS forwarding state are recovered.

How to Configure AToM Graceful Restart

Configuring AToM Graceful Restart

There is no Any Transport over Multiprotocol Label Switching (AToM)-specific configuration for AToM Graceful Restart (GR). You enable the Label Distribution Protocol (LDP) GR to assist a neighboring device configured with AToM nonstop forwarding (NSF) and stateful switchover (SSO) to maintain its forwarding state while the LDP session is disrupted.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip cef distributed**
4. **mpls ldp graceful-restart**
5. **exit**
6. **show mpls l2transport vc detail**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:**	Enters global configuration mode.

	Command or Action	Purpose
	`Device# configure terminal`	
Step 3	**ip cef distributed** **Example:** `Device(config)# ip cef distributed`	Enables distributed Cisco Express Forwarding.
Step 4	**mpls ldp graceful-restart** **Example:** `Device(config)# mpls ldp graceful-restart`	Enables the device to protect the LDP bindings and MPLS forwarding state during a disruption in service. • AToM GR is enabled globally. When you enable AToM GR, it has no effect on existing LDP sessions. New LDP sessions that are established can perform AToM GR.
Step 5	**exit** **Example:** `Device(config)# exit`	Exits to privileged EXEC mode.
Step 6	**show mpls l2transport vc detail** **Example:** `Device# show mpls l2transport vc detail`	Displays detailed information about AToM virtual circuits (VCs).

Configuration Examples for AToM Graceful Restart

Example: Configuring AToM Graceful Restart

The following example shows a Fast Ethernet VLAN over Multiprotocol Label Switching (MPLS) configuration. PE1 is configured with Any Transport over MPLS Graceful Restart (AToM GR). PE2 is configured with AToM nonstop forwarding (NSF) and stateful switchover (SSO). The commands for configuring AToM GR and NSF/SSO are shown in bold.

PE1 with AToM GR	PE2 with AToM NSF/SSO

Examples: Verifying AToM Graceful Restart Recovery from an LDP Session Disruption

The following examples show the output of the **show mpls l2transport vc** command during normal operation and when a Label Distribution Protocol (LDP) session is recovering from a disruption.

The following example shows the status of the virtual circuit (VC) on PE1 with Any Transport over Multiprotocol Label Switching Graceful Restart (AToM GR) during normal operation:

```
Device# show mpls l2transport vc

Local intf     Local circuit        Dest address    VC ID      Status
-------------  -------------------- --------------- ---------- ----------
Fa2/1/1.2      Eth VLAN 2           10.2.2.2         1002       UP
```

The following example shows the status of the VC on PE1 with AToM GR while the VC is recovering from an LDP session disruption. The forwarding state for the circuit remains as it was before the disruption.

```
Device# show mpls l2transport vc

Local intf     Local circuit        Dest address    VC ID      Status
-------------  -------------------- --------------- ---------- ----------
Fa2/1/1.2      Eth VLAN 2           10.2.2.2         1002       RECOVERING
```

The following example shows the status of the VC on PE1 with AToM GR after the LDP session disruption was cleared. The AToM label bindings were advertised within the allotted time and the status returned to UP.

```
Device# show mpls l2transport vc

Local intf     Local circuit        Dest address    VC ID      Status
-------------  -------------------- --------------- ---------- ----------
Fa2/1/1.2      Eth VLAN 2           10.2.2.2         1002       UP
```

The following example shows the detailed status of the VC on PE1 with AToM GR during normal operation:

```
Device# show mpls l2transport vc detail

Local interface: Fa2/1/1.2 up, line protocol up, Eth VLAN 2 up
  Destination address: 10.2.2.2, VC ID: 1002, VC status: up
    Preferred path: not configured
    Default path: active
    Tunnel label: imp-null, next hop point2point
    Output interface: Se2/0/2, imposed label stack {16}
  Create time: 1d00h, last status change time: 1d00h
  Signaling protocol: LDP, peer 10.2.2.2:0 up
    MPLS VC labels: local 21, remote 16
    Group ID: local 0, remote 0
    MTU: local 1500, remote 1500
    Remote interface description: "xconnect to PE2"
  Sequencing: receive disabled, send disabled
  VC statistics:
    packet totals: receive 3466, send 12286
    byte totals:   receive 4322368, send 5040220
    packet drops:  receive 0, send 0
```

The following example shows the detailed status of the VC on PE1 with AToM GR while the VC is recovering.

```
Device# show mpls l2transport vc detail

Local interface: Fa2/1/1.2 up, line protocol up, Eth VLAN 2 up
  Destination address: 10.2.2.2, VC ID: 1002, VC status: recovering
    Preferred path: not configured
    Default path: active
    Tunnel label: imp-null, next hop point2point
    Output interface: Se2/0/2, imposed label stack {16}
  Create time: 1d00h, last status change time: 00:00:03
  Signaling protocol: LDP, peer 10.2.2.2:0 down
    MPLS VC labels: local 21, remote 16
    Group ID: local 0, remote 0
    MTU: local 1500, remote 1500
    Remote interface description: "xconnect to PE2"
  Sequencing: receive disabled, send disabled
  VC statistics:
    packet totals: receive 20040, send 28879
    byte totals:   receive 25073016, send 25992388
    packet drops:  receive 0, send 0
```

Feature Information for AToM Graceful Restart

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 85: Feature Information for AToM Graceful Restart

Feature Name	Releases	Feature Information
AToM Graceful Restart	12.0(29)S 12.2(33)SRA 12.2(33)SXH 12.4(11)T Cisco IOS XE Release 2.3	The AToM Graceful Restart feature assists neighboring devices that have nonstop forwarding (NSF), stateful switchover (SSO), and graceful restart (GR) for Any Transport over Multiprotocol Label Switching (AToM) to recover gracefully from an interruption in service. AToM GR functions strictly in helper mode, which means it helps other devices that are enabled with the NSF/SSO—Any Transport over MPLS and AToM Graceful Restart feature to recover. If the device with AToM GR fails, its peers cannot help it recover. AToM GR is based on the MPLS Label Distribution Protocol (LDP) Graceful Restart feature. In Cisco IOS Release 12.0(29)S, this feature was introduced. In Cisco IOS Release 12.2(33)SRA, support was added for the Cisco 7600 series routers. In Cisco IOS Release 12.2(33)SXH, this feature was integrated into the release. In Cisco IOS Release 12.4(11)T, this feature was integrated into the release. In Cisco IOS Release XE 2.3, this feature was implemented on the Cisco ASR 1000 Series Aggregation Services Routers. This feature uses no new or modified commands.

CHAPTER 28

NSF SSO--Any Transport over MPLS and AToM Graceful Restart

The NSF/SSO--Any Transport over MPLS and AToM Graceful Restart feature allows Any Transport over MPLS (AToM) to use Cisco nonstop forwarding (NSF), stateful switchover (SSO), and Graceful Restart (GR) to allow a Route Processor (RP) to recover from a disruption in control plane service without losing its Multiprotocol Label Switching (MPLS) forwarding state.

NSF with SSO is effective at increasing availability of network services. Cisco NSF with SSO provides continuous packet forwarding, even during a network processor hardware or software failure. In a redundant system, the secondary processor recovers control plane service during a critical failure in the primary processor. SSO synchronizes the network state information between the primary and the secondary processor.

Note In this document, the NSF/SSO--Any Transport over MPLS and AToM Graceful Restart feature is referred to as AToM NSF for brevity.

In Cisco IOS XE software, AToM NSF supports the following attachment circuits:

- ATM
- Ethernet to Ethernet VLAN interworking

- Prerequisites for AToM NSF, on page 505
- Restrictions for AToM NSF, on page 506
- Information About AToM NSF, on page 506
- How to Configure AToM NSF, on page 507
- Configuration Examples for AToM NSF, on page 509
- Additional References, on page 511
- Feature Information for AToM NSF, on page 512

Prerequisites for AToM NSF

Before you can configure AToM NSF, make sure the following tasks have been completed:

- AToM virtual circuits (VCs) have been configured on the router. See the Any Transport over MPLS for information on configuring AToM. For configuring L2VPN Interworking, see the L2VPN Interworking feature module.
- SSO has been configured on the RPs. See the Stateful Switchover feature module for configuration information.
- Nonstop forwarding has been configured on the routers. You must enable nonstop forwarding on the routing protocols running between the P routers, PE routers, and CE routers. The routing protocols are the following:
  - Open Shortest Path First (OSPF),
  - Intermediate System-to-Intermediate System (IS-IS), and
  - Border Gateway Protocol (BGP).

See the Cisco Nonstop Forwarding feature module for configuration information.

- AToM NSF requires that neighbor networking devices be able to perform AToM GR.

Restrictions for AToM NSF

- AToM NSF cannot be configured on label-controlled ATM (LC-ATM) interfaces.
- AToM NSF supports AToM Layer 2 Virtual Private Network (L2VPN) Interworking. However, Layer 2 Tunnel Protocol Version 3 (L2TPv3) Interworking is not supported.
- AToM NSF interoperates with Layer 2 local switching. However, AToM NSF has no effect on interfaces configured for local switching.
- To allow distributed Cisco Express Forwarding to work on the interfaces, disable fair queueing on serial interfaces.

Information About AToM NSF

How AToM NSF Works

AToM NSF improves the availability of a service provider's network that uses AToM to provide Layer 2 VPN services to its customers. HA provides the ability to detect failures and handle them with minimal disruption to the service being provided. AToM NSF is achieved by SSO and NSF mechanisms. A standby RP provides control-plane redundancy. The control plane state and data plane provisioning information for the attachment circuits (ACs) and AToM pseudowires (PWs) are checkpointed to the standby RP to provide NSF for AToM L2VPNs.

AToM Information Checkpointing

Checkpointing is a function that copies state information from the active RP to the backup RP, thereby ensuring that the backup RP has the latest information. If the active RP fails, the backup RP can take over.

For the AToM NSF feature, the checkpointing function copies the active RP's information bindings to the backup RP. The active RP sends updates to the backup RP when information is modified.

To display checkpointing data, issue the **show acircuit checkpoint** command on the active and backup RPs. The active and backup RPs have identical copies of the information.

Checkpointing Troubleshooting Tips for AToM NSF

To help troubleshoot checkpointing errors, use the following commands:

- Use the **debug acircuit checkpoint** command to enable checkpointing debug messages for ACs.
- Use the **debug mpls l2transport checkpoint** command to enable checkpointing debug messages for AToM.
- Use the **show acircuit checkpoint** command to display the AC checkpoint information.
- Use the **show mpls l2transport checkpoint** command to display whether checkpointing is allowed, how many AToM VCs were bulk-synchronized (on the active RP), and how many AToM VCs have checkpoint data (on the standby RP).
- Use the **show mpls l2transport vc detail** command to display details of VC checkpointed information.

NSF SSO Support for Ethernet to Ethernet VLAN Interworking

The NSF/SS0--Ethernet to Ethernet VLAN Interworking features enables SSO and NSF capabilities for Ethernet to VLAN attachment circuits. Changes in the learned MAC address for interworking are reflected on the standby RP so that identical values exist on the active and standby RPs.

ISSU Support for AToM NSF

AToM NSF supports In Service Software Upgrade (ISSU) capability. Virtual Private LAN Services (VPLS) NSF/SSO and HA with ISSU work together to enable upgrades or downgrades of a Cisco IOS XE image without control and data plane outages. With ISSU, all message data structures that are used for checkpointing and exchanges between the active RP and standby RP are versioned.

How to Configure AToM NSF

There is no AToM-specific configuration for AToM NSF. Before you configure AToM NSF, you need to configure MPLS LDP Graceful Restart. You enable MPLS LDP Graceful Restart to assist a neighboring router configured with AToM NSF to maintain its forwarding state while the LDP session is disrupted. See the LDP Graceful Restart document for information about how MPLS LDP Graceful Restart works and how you can customize it for your network.

MPLS LDP Graceful Restart is enabled globally. When you enable MPLS LDP Graceful Restart, it has no effect on existing LDP sessions. MPLS LDP Graceful Restart is enabled for new sessions that are established after the feature has been globally enabled.

This section contains the following task:

Configuring MPLS LDP Graceful Restart

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip cef distributed**
4. **mpls ldp graceful-restart**
5. **interface** *type slot / subslot / port* [**.** *subinterface-number*]
6. **mpls ip**
7. **mpls label protocol ldp**
8. **exit**
9. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**ip cef distributed** **Example:** `Router(config)# ip cef distributed`	Enables distributed Cisco Express Forwarding. **Note** In Cisco ASR 1000 Series Aggregation Services Routers, the **distributed** keyword is mandatory.
Step 4	**mpls ldp graceful-restart** **Example:** `Router (config)# mpls ldp graceful-restart`	Enables the router to protect the LDP bindings and MPLS forwarding state during a disruption in service.
Step 5	**interface** *type slot / subslot / port* [**.** *subinterface-number*] **Example:** `Router(config)# interface pos 0/3/0`	Specifies an interface and enters interface configuration mode.

	Command or Action	Purpose
Step 6	**mpls ip** **Example:** `Router(config-if)# mpls ip`	Configures MPLS hop-by-hop forwarding for an interface.
Step 7	**mpls label protocol ldp** **Example:** `Router(config-if)# mpls label protocol ldp`	Configures the use of LDP for an interface. • You can also issue the **mpls label protocol ldp** command in global configuration mode, which enables LDP on all interfaces configured for MPLS.
Step 8	**exit** **Example:** `Router(config-if)# exit`	Exits interface configuration mode and returns to global configuration mode.
Step 9	**exit** **Example:** `Router(config)# exit`	Exits global configuration mode and returns to privileged EXEC mode.

Configuration Examples for AToM NSF

Example Ethernet to VLAN Interworking with AToM NSF

The following example shows how to configure AToM NSF on two PE routers:

PE1

```
ip cef distributed
!
redundancy

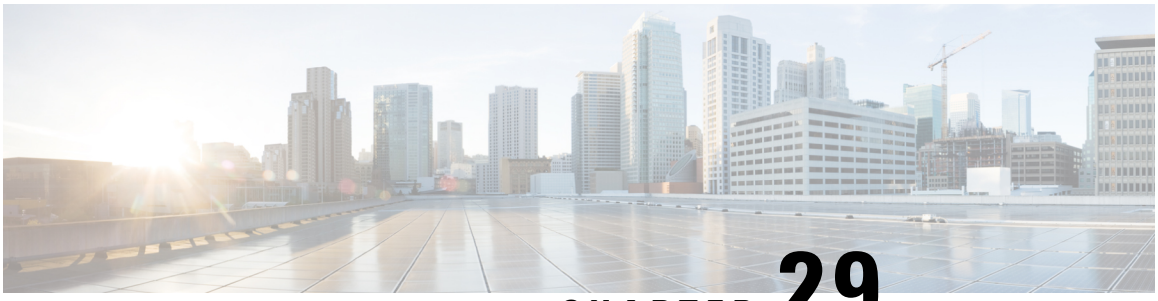
Feature Information for AToM NSF



The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 86: Feature Information for AToM NSF Any Transport over MPLS and AToM Graceful Restart

Feature Name	Releases	Feature Information
NSF/SSO--AToM ATM Attachment Circuit	Cisco IOS XE Release 2.3	This feature provides support for AToM NSF/SSO support for ATM over MPLS (ATMoMPLS), which allows ATMoMPLS to use Cisco nonstop forwarding (NSF), stateful switchover (SSO), and Graceful Restart (GR) to allow a Route Processor (RP) to recover from a disruption in control plane service without losing its Multiprotocol Label Switching (MPLS) forwarding state. In Cisco IOS XE Release 2.3, this feature was implemented on the Cisco ASR 1000 Series Aggregation Services Routers. The following commands were introduced or modified: **debug acircuit checkpoint**, **debug mpls l2transport checkpoint**, **show acircuit checkpoint**, **show mpls l2transport checkpoint**, **show mpls l2transport vc**.
ISSU--AToM ATM Attachment Circuit	Cisco IOS XE Release 2.3	This feature supports In Service Software Upgrade (ISSU) capability. Virtual Private LAN Services (VPLS) NSF/SSO and HA with ISSU work together to enable upgrades or downgrades of a Cisco IOS XE image without control and data plane outages. With ISSU, all message data structures that are used for checkpointing and exchanges between the active RP and standby RP are versioned. In Cisco IOS XE Release 2.3, this feature was implemented on the Cisco ASR 1000 Series Aggregation Services Routers. No commands were introduced or modified for this feature.

Feature Name	Releases	Feature Information
NSF/SSO--Ethernet to Ethernet VLAN Interworking	Cisco IOS XE Release 2.4	The NSF/SS0--Ethernet to Ethernet VLAN Interworking features enables stateful switchover (SSO) and nonstop forwarding (NSF) capabilities for Ethernet to VLAN attachment circuits. Changes in the learned MAC address for interworking are reflected on the standby RP so that identical values exist on the Active and Standby RPs. In Cisco IOS XE Release 2.4, this feature was introduced on the Cisco ASR 1000 Series Aggregation Routers. No commands were introduced or modified for this feature.

CHAPTER 29

Prerequisites for NSF SSO--MPLS VPN

- You must have a supported MPLS VPN network configuration. See Configuring MPLS VPNs for more information.
- The networking device that is to be configured for NSF must first be configured for stateful switchover (SSO). See Stateful Switchover for more information
- You must enable NSF on the routing protocols running between the provider (P) routers, provider edge (PE) routers, and customer edge (CE) routers. The supported routing protocols are Border Gateway Protocol (BGP), Open Shortest Path First (OSPF), and Intermediate System-to-Intermediate System (IS-IS). See Configuring Nonstop Forwarding for more information.
- You must configure Cisco NSF support on the routers for Cisco Express Forwarding. See Configuring Nonstop Forwarding for more information.
- All neighbor networking devices must be NSF-aware. Peer routers must support the graceful restart of the protocol used to communicate with the NSF/SSO--MPLS VPN-capable router.

- Restrictions for NSF SSO--MPLS VPN, on page 515
- Information About NSF SSO--MPLS VPN, on page 516
- How to Configure NSF SSO--MPLS VPN, on page 517
- Configuration Examples for NSF SSO--MPLS VPN, on page 520
- Additional References, on page 523
- Feature Information for NSF SSO--MPLS VPN, on page 524

Restrictions for NSF SSO--MPLS VPN

- Tag Distribution Protocol (TDP) sessions are not supported. Only Label Distribution Protocol (LDP) sessions are supported.
- The NSF/SSO--MPLS VPN feature cannot be configured on label-controlled ATM (LC-ATM) interfaces.

Information About NSF SSO--MPLS VPN

Elements That Enable NSF SSO--MPLS VPN

VPN NSF requires several elements in order to work:

- VPN NSF uses the BGP Graceful Restart mechanisms to create MPLS forwarding entries for VPNv4 prefixes in NSF mode. The forwarding entries are preserved during a restart. BGP also saves prefix and corresponding label information and recovers the information after a restart.
- The NSF/SSO--MPLS VPN feature also uses NSF for the label distribution protocol in the core network (either MPLS Label Distribution Protocol, traffic engineering, or static labeling).
- The NSF/SSO--MPLS VPN feature uses NSF for the Interior Gateway Protocol (IGP) used in the core (OSPF or IS-IS).
- The NSF/SSO--MPLS VPN feature uses NSF for the routing protocols between the PE and CE routers.

How VPN Prefix Information Is Checkpointed to the Backup Route Processor

When BGP allocates local labels for prefixes, it checkpoints the local label binding in the backup RP. The checkpointing function copies state information from the active RP to the backup RP, thereby ensuring that the backup RP has an identical copy of the latest information. If the active RP fails, the backup RP can take over with no interruption in service. Checkpointing begins when the active RP does a bulk synchronization, which copies all of the local label bindings to the backup RP. After that, the active RP dynamically checkpoints individual prefix label bindings when a label is allocated or freed. This allows forwarding of labeled packets to continue before BGP reconverges.

How BGP Graceful Restart Preserves Prefix Information During a Restart

When a BGP Graceful Restart-capable router loses connectivity, it performs the following actions as the restarting router:

1. The restarting router establishes BGP sessions with other routers and relearns the BGP routes from other routers that are also capable of Graceful Restart. The restarting router waits to receive updates from the neighboring routers. When the neighboring routers send end-of-Routing Information Base (RIB) markers to indicate that they are done sending updates, the restarting router starts sending its own updates.
2. The restarting router accesses the checkpoint database to find the label that was assigned for each prefix. If it finds the label, it advertises it to the neighboring router. If it does not find the label, it allocates a new label and advertises it.
3. The restarting router removes any stale prefixes after a timer for stale entries expires.

A BGP Graceful Restart-capable peer router performs the following actions when it encounters a restarting router:

1. The peer router sends all the routing updates to the restarting router. When it has finished sending updates, the peer router sends an end-of-RIB marker to the restarting router.

2. The peer router does not immediately remove the BGP routes learned from the restarting router from its BGP routing table. As it learns the prefixes from the restarting router, the peer refreshes the stale routes if the new prefix and label information matches the old information.

If a router is not configured for the NSF/SSO--MPLS VPN feature and it attempts to establish a BGP session with a router that is configured with the NSF/SSO--MPLS VPN feature, the two routers create a normal BGP session but do not have the ability to perform the NSF/SSO--MPLS VPN feature.

How to Configure NSF SSO--MPLS VPN

Configuring NSF Support for Basic VPNs

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip cef** [**distributed**]
4. **router bgp** *autonomous-system-number*
5. **bgp graceful-restart**
6. **bgp graceful-restart restart-time** *seconds*
7. **bgp graceful-restart stalepath-time** *seconds*
8. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**ip cef** [**distributed**] **Example:** `Router(config)# ip cef distributed`	Enables Cisco Express Forwarding. • Use this command if Cisco Express Forwarding is not enabled by default on the router.
Step 4	**router bgp** *autonomous-system-number* **Example:**	Configures a BGP routing process and enters router configuration mode.

	Command or Action	Purpose
	`Router(config)# router bgp 1`	
Step 5	**bgp graceful-restart** **Example:** `Router(config-router)# bgp graceful-restart`	Enables BGP Graceful Restart on the router.
Step 6	**bgp graceful-restart restart-time** *seconds* **Example:** `Router(config-router)# bgp graceful-restart restart-time 200`	(Optional) Specifies the maximum time to wait for a graceful-restart-capable neighbor to come back up after a restart.
Step 7	**bgp graceful-restart stalepath-time** *seconds* **Example:** `Router(config-router)# bgp graceful-restart stalepath-time 400`	(Optional) Specifies the maximum time to hold on to the stale paths of a gracefully restarted peer. All stale paths are deleted after the expiration of this timer.
Step 8	**end** **Example:** `Router(config-router)# end`	Exits to privileged EXEC mode.

Verifying the Configuration

SUMMARY STEPS

1. **show ip bgp vpnv4 all labels**
2. **show ip bgp vpnv4 all neighbors**
3. **show ip bgp labels**
4. **show ip bgp neighbors**

DETAILED STEPS

Procedure

Step 1 **show ip bgp vpnv4 all labels**

This command displays incoming and outgoing BGP labels for each route distinguisher. The following is sample output from the command:

Example:

```
Router# show ip bgp vpnv4 all labels
```

```
Network          Next Hop      In label/Out label
Route Distinguisher: 100:1 (vpn1)
   10.3.0.0/16      10.0.0.5        25/20
                    10.0.0.1        25/23
                    10.0.0.2        25/imp-null
   10.0.0.9/32      10.0.0.1        24/22
                    10.0.0.2        24/imp-null
```

Step 2 **show ip bgp vpnv4 all neighbors**

This command displays whether the BGP peers are capable of Graceful Restart. The following is sample output from the command:

Example:

```
Router# show ip bgp vpnv4 all neighbors
BGP neighbor is 10.0.0.1,  remote AS 100, internal link
  BGP version 4, remote router ID 10.0.0.1
  BGP state = Established, up for 02:49:47
  Last read 00:00:47, hold time is 180, keepalive interval is 60 seconds
  Neighbor capabilities:
    Route refresh: advertised and received(new)
    Address family VPNv4 Unicast: advertised and received
    Graceful Restart Capabilty: advertised and received
      Remote Restart timer is 120 seconds
      Address families preserved by peer:
        VPNv4 Unicast
.
.
.
```

Step 3 **show ip bgp labels**

This command displays information about MPLS labels in the Exterior Border Gateway Protocol (EBGP) route table. The following is sample output from the command:

Example:

```
Router# show ip bgp labels
   Network          Next Hop      In label/Out label
   10.3.0.0/16      10.0.0.1        imp-null/imp-null
                    0.0.0.0         imp-null/nolabel
   10.0.0.9/32      10.0.0.1        21/29
   10.0.0.11/32     10.0.0.1        24/38
   10.0.0.13/32     0.0.0.0         imp-null/nolabel
   10.0.0.15/32     10.0.0.1        29/nolabel
                    10.0.0.1        29/21
```

Step 4 **show ip bgp neighbors**

This command displays whether the BGP peers are capable of Graceful Restart. The following is sample output from the command:

Example:

```
Router# show ip bgp neighbors
BGP neighbor is 10.0.0.1,  remote AS 100, external link
  BGP version 4, remote router ID 10.0.0.5
  BGP state = Established, up for 02:54:19
  Last read 00:00:18, hold time is 180, keepalive interval is 60 seconds
  Neighbor capabilities:
    Route refresh: advertised and received(new)
```

```
    Address family IPv4 Unicast: advertised and received
    ipv4 MPLS Label capability: advertised and received
    Graceful Restart Capabilty: advertised and received
      Remote Restart timer is 120 seconds
      Address families preserved by peer:
        IPv4 Unicast
.
.
.
```

Configuration Examples for NSF SSO--MPLS VPN

Example NSF SSO--MPLS VPN for a Basic MPLS VPN

The following sample output shows the configuration of the NSF/SSO--MPLS VPN feature on the CE and PE routers. SSO is enabled by default, and LDP is the default MPLS label protocol.

CE1 Router

```
ip cef

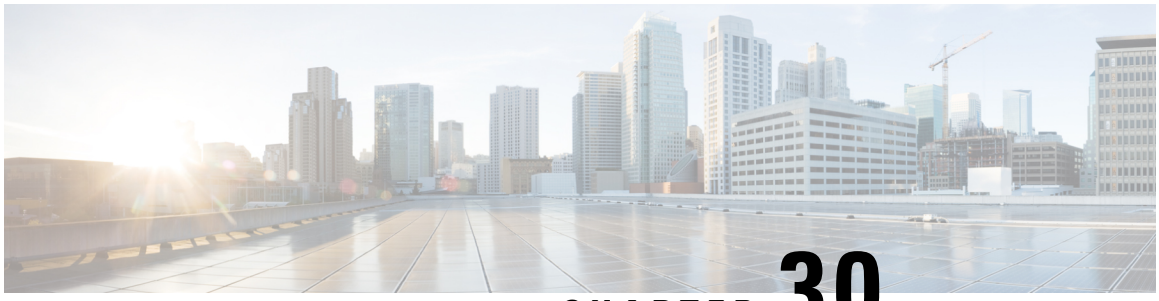
If you have a valid service contract but do not have a user ID or password, you can register on Cisco.com.	http://www.cisco.com/techsupport



Feature Information for NSF SSO--MPLS VPN

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 87: Feature Information for NSF/SSO--MPLS VPN

Feature Name	Releases	Feature Information
NSF/SSO--MPLS VPN	Cisco IOS XE Release 2.1	This feature allows a provider edge router to preserve data forwarding information in a Multiprotocol Label Switching (MPLS) Virtual Private Network (VPN) when the primary Route Processor restarts.

CHAPTER 30

SSO and ISSU--MPLS VPN 6VPE and 6PE Support

This document provides information about configuring stateful switchover (SSO) and In Service Software Upgrade (ISSU) support for Cisco IOS XE VPN IPv6 provider edge (6VPE) and Cisco IOS XE IPv6 provider edge (6PE) routers over Multiprotocol Label Switching (MPLS).

- Prerequisites for SSO and ISSU--MPLS VPN 6VPE and 6PE Support, on page 525

- Configuration Examples for Configuring SSO and ISSU--MPLS VPN 6VPE and 6PE Support, on page 534
- Additional References, on page 537
- Feature Information for SSO and ISSU--MPLS VPN 6VPE and 6PE Support, on page 539
- Glossary, on page 539

Prerequisites for SSO and ISSU--MPLS VPN 6VPE and 6PE Support

- Your networking device must be running Cisco IOS XE 3.2S or a later release.
- Your network must be configured for a supported MPLS VPN. For information, see Configuring MPLS Layer 3 VPNs and Implementing IPv6 VPN over MPLS.
- SSO must be configured on the Route Processor (RP). For information, see Stateful Switchover.
- Your networking device must support the following:
  - IPv6 Cisco Express Forwarding (CEF)
  - IPv6 nonstop forwarding (NSF)
  - Label Distribution Protocol (LDP) Graceful Restart
- NSF must be enabled on the Border Gateway Protocol (BGP) and static routes that run between the provider (P), PE, and the customer edge (CE) routers. For configuration information, see Cisco Nonstop Forwarding.
- LDP Graceful Restart must be enabled if LDP is the protocol used in the MPLS core. For configuration information, see NSF/SSO-MPLS LDP and MPLS LDP Graceful Restart.

Restrictions for SSO and ISSU--MPLS VPN 6VPE and 6PE Support

- Only LDP sessions are supported.
- MPLS VPN 6VPE and 6PE Carrier Supporting Carrier (CSC) VPNs support only BGP. CSC configurations that use LDP are not supported.
- Only BGP and static routes are supported for 6VPE and 6PE.

Information About SSO and ISSU--MPLS VPN 6VPE and 6PE Support

Elements Supporting SSO and ISSU--MPLS VPN 6VPE and 6PE Support Features

The major elements supporting the functionality of the SSO and ISSU for Cisco IOS XE VPN 6vPE and 6PE features are the following:

- MPLS VPN--Forwards IP traffic using a VPN label that instructs the routers and switches in the network where to forward the packets based on preestablished IP routing information.
- BGP Graceful Restart--The BGP Graceful Restart feature is responsible for negotiating graceful restart capabilities, exchanging forwarding preservation states, and coordinating advertisements after session restarts. MPLS VPNs interact with BGP to exchange VPN routing and forwarding (VRF) routes and labels.
- IPv6 NSF--IPv6 NSF support enables IPv6 cache rebuilds during switchover using checkpointed Cisco Express Forwarding adjacencies.
- CEF/MFI--CEF and the MPLS Forwarding Infrastructure (MFI) are responsible for preserving forwarding entries and local labels across RP switchover.

Note If a router does not support the SSO and ISSU--MPLS VPN 6VPE and 6PE Support feature, prefix and label information is not preserved. After a switchover, BGP has to restart, relearn all routes, and install labels in the forwarding database. This can cause the loss of some network traffic.

How BGP Graceful Restart Works for MPLS VPN 6vPE and 6PE

BGP Graceful Restart behavior for IPv6 and VPNv6 is essentially the same as Graceful Restart behavior for IPv4 and VPNv4; the only difference is the addition of support for IPv6 and VPNv6 address families.

When you configure BGP Graceful Restart, BGP includes the Graceful Restart capability and negotiates the preservation states of address families, such as IPv4/VPNv4 and IPv6/VPNv6 address families.

Both BGP peers must agree on a Graceful Restart timer. After a BGP session comes up and finishes sending initial updates, each BGP peer sends an end-of-Routing Information Base (RIB) marker.

The SSO and ISSU--MPLS VPN 6VPE and 6PE Support features use the mechanisms defined in RFC 4724, *Graceful Restart Mechanism for BGP*.

How BGP Graceful Restart Preserves Prefix Information During a Restart

When a router that is capable of BGP Graceful Restart loses connectivity, the following happens to the restarting router:

1. The router establishes BGP sessions with other routers and relearns the BGP routes from other routers that are also capable of Graceful Restart. The restarting router waits to receive updates from the neighboring routers. When the neighboring routers send end-of-RIB markers to indicate that they are done sending updates, the restarting router starts sending its own updates.
2. The restarting router recovers labels from the MFI database for each prefix. If the router finds the label, it advertises the label to the neighboring router. If the router does not find the label, it allocates a new label from the database and advertises it.
3. The restarting router removes any stale prefixes after a timer for stale entries expires.

When a peer router that is capable of BGP Graceful Restart encounters a restarting router, it does the following:

1. The peer router sends all of the routing updates to the restarting router. When it has finished sending updates, the peer router sends an end-of RIB marker to the restarting router.
2. The peer router does not immediately remove the BGP routes learned from the restarting router from its BGP routing table. As it learns the prefixes from the restarting router, the peer refreshes the stale routes if the new prefix and label information matches the old information.

ISSU Support for MPLS VPN 6vPE and 6PE

The ISSU process allows Cisco IOS XE software to be updated or otherwise modified while packet forwarding continues. In most networks, planned software upgrades are a significant cause of downtime. ISSU allows Cisco IOS XE software to be modified while packet forwarding continues, which increases network availability and reduces downtime caused by planned software upgrades.

ISSU support for MPLS 6vPE and 6PE relies on 6vPE and 6PE NFS/SSO capability on the platform to minimize disruption on the forwarding plane.

SSO Support for MPLS VPN 6VPE and 6PE

SSO for 6VPE and 6PE supports the following configurations:

- NSF/SSO for IPv4 and VPNv4 coexistence
- Basic 6VPE and 6PE over MPLS core technology
- BGP multipath configuration

SSO for 6VPE supports the following configurations:

- Per-VRF label configuration
- Interautonomous systems (Inter-AS) topologies, including options B and C

- CSC when IPv6 + labels is configured on the PE-CE link

Because the SSO feature maintains stateful protocol and application information, user session information is maintained during a switchover and line cards continue to forward network traffic with no loss of sessions, providing improved network availability. SSO initializes and configures the standby RP and synchronizes state information, which can reduce the time required for routing protocols to converge. Network stability may be improved with the reduction in the number of route flaps created when routers in the network fail and lose their routing tables.

When RP switchover happens, forwarding information is preserved by MFI and Cisco Express Forwarding on both line cards and the standby RP. VPNv6 prefix and local label mapping is preserved in the forwarding database. When the standby RP becomes the new active RP, 6PE and 6vPE traffic continues to be forwarded with minimal interruption.

When a BGP session restarts on the new active RP, the new active RP does not have any prior state information about prefixes or labels. The new active RP must relearn VPNv6 prefixes from its peers. As the new active RP learns the VPNv6 prefixes, it tries to get new local labels the same way it does when it first comes up. If the MFI database has the preserved copy of the local label for a prefix, the MFI database gives the local label to BGP and BGP then maintains the same local label. If the MFI database does not have a preserved local label for the prefix, MFI allocates a new one.

BGP Graceful Restart Support for MPLS VPN Configurations

Graceful Restart Support for a Basic 6VPE Setup

For PE- to-CE external BGP (eBGP), Graceful Restart capability is supported for IPv6 address families. For PE-to-PE interior BGP (iBGP) sessions with or without a route reflector (RR) in the core, BGP Graceful Restart capability supports VPNv6 address families.

When the PE router resets, the connected CE router retains IPv6 prefixes that it received from the PE router and marks the prefixes as stale. If the eBGP session does not reestablish within the specified restart time or the session reestablishes but does not set the restart or forwarding state bit, the CE router removes the stale IPv6 routes. If the eBGP session reestablishes within the specified restart time and has both the forwarding and restart bits set, the CE router removes the stale state from the IPv6 routes when it receives the updates from PE router. After the CE router receives the end-of-RIB marker, it removes or withdraws the rest of the stale information, if any exists.

The restarting PE router waits for an end-of-RIB marker from all BGP-capable peers including iBGP peers and eBGP peers. The PE router begins to calculate the best path and send out initial updates only after receiving an end-of-RIB marker from all BGP capable peers.

Graceful Restart for 6VPE in Carrier Supporting Carrier and Interautonomous System Setups

The same Graceful Restart capabilities for route preservation that apply to a basic 6VPE setup apply to a CSC and Inter-AS setup. IPv6 or VPNv6 routes and labels are preserved during switchover.

In a CSC configuration, when send-labels are configured between a CSC-PE and CSC-CE eBGP connection, labels are preserved along with IPv6 BGP routes when one of the peers restarts.

In Inter-AS option B and options C setups, VPNv6 routes and labels are preserved on an Autonomous System Border Router (ASBR) or route reflector when the VPNv6 peer restarts.

How to Configure SSO and ISSU--MPLS VPN 6VPE and 6PE Support

Note Unlike SSO, which is a mode of operation for the device and a prerequisite for performing ISSU, the ISSU process is a series of steps performed while the router or switch is in operation. For information on performing ISSU upgrades on the Cisco ASR 1000 Series Aggregation Services Router, see the "In Service Software Upgrade (ISSU)" module in the *Cisco ASR 1000 Series Aggregation Services Routers Software Configuration Guide*.

Configuring SSO for a Basic MPLS 6VPE and 6PE Setup

Perform this task to configure SSO for a basic MPLS 6VPE and 6PE setup.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip cef distributed**
4. **ipv6 unicast-routing**
5. **ipv6 cef distributed**
6. **redundancy**
7. **mode sso**
8. **exit**
9. **router bgp** *autonomous-system-number*
10. **bgp graceful-restart restart-time** *seconds*
11. **bgp graceful-restart stalepath-time** *seconds*
12. **bgp graceful-restart**
13. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:**	Enters global configuration mode.

	Command or Action	Purpose
	`Router# configure terminal`	
Step 3	**ip cef distributed** **Example:** `Router(config)# ip cef distributed`	Enables distributed Cisco Express Forwarding.
Step 4	**ipv6 unicast-routing** **Example:** `Router(config)# ipv6 unicast-routing`	Enables the forwarding of IPv6 unicast datagrams.
Step 5	**ipv6 cef distributed** **Example:** `Router(config)# ipv6 cef distributed`	Enables distributed Cisco Express Forwarding for IPv6.
Step 6	**redundancy** **Example:** `Router(config)# redundancy`	Enters redundancy configuration mode.
Step 7	**mode sso** **Example:** `Router(red-config)# mode sso`	Sets the redundancy configuration mode to SSO.
Step 8	**exit** **Example:** `Router(red-config)# exit`	Exits to global configuration mode.
Step 9	**router bgp** *autonomous-system-number* **Example:** `Router(config)# router bgp 1000`	Enters router configuration mode and configures the BGP routing process.
Step 10	**bgp graceful-restart restart-time** *seconds* **Example:** `Router(config-router)# bgp graceful-restart restart-time 180`	Enables the BGP graceful restart timer capability globally for all BGP neighbors and sets the maximum time period that the local router will wait for a graceful-restart-capable neighbor to return to normal operation after a restart event occurs.
Step 11	**bgp graceful-restart stalepath-time** *seconds* **Example:**	Enables the BGP graceful restart stale path timer capability globally for all BGP neighbors and sets the maximum time period that the local router will hold stale paths for a restarting peer.

	Command or Action	Purpose
	`Router(config-router)# bgp graceful-restart stalepath-time 420`	
Step 12	**bgp graceful-restart** **Example:** `Router(config-router)# bgp graceful-restart`	Enables the BGP graceful restart capability globally for all BGP neighbors.
Step 13	**end** **Example:** `Router(config-router)# end`	Exits to privileged EXEC mode.

Verifying SSO and ISSU Support for 6VPE and 6PE

Perform this task to verify SSO and ISSU support for 6VPE and 6PE routers.

SUMMARY STEPS

1. **enable**
2. **show ip bgp neighbor**
3. **show ip bgp vpnv6 unicast vrf** *vrf-name*
4. **show ip bgp ipv6 unicast**
5. **show mpls forwarding**
6. **show ipv6 cef vrf** *vrf-name*

DETAILED STEPS

Procedure

Step 1 **enable**

Use this command to enable privileged EXEC mode. Enter your password if prompted. For example:

Example:

```
Router> enable
Router#
```

Step 2 **show ip bgp neighbor**

Use this command to verify that the IPv6 address family and VPNv6 address family entries are preserved. For example:

Example:

```
Router# show ip bgp neighbor
BGP neighbor is 10.2.2.2, remote AS 100, internal link
  BGP version 4, remote router ID 10.2.2.2
```

```
  BGP state = Established, up for 00:02:42
  Last read 00:00:36, last write 00:00:36, hold time is 180, keepalive
.
.
.
  Neighbor capabilities:
.
.
.
    Graceful Restart Capability: advertised and received
      Remote Restart timer is 120 seconds
      Address families advertised by peer:
        IPv6 Unicast (was preserved), VPNv6 Unicast (was preserved)
```

IPv6 Unicast (was preserved), VPNv6 Unicast (was preserved) is displayed in the Graceful Restart Capability section of the output only after the peer restarts.

Step 3 **show ip bgp vpnv6 unicast vrf** *vrf-name*

Use this command to verify that VPNv6 entries are marked as stale during switchover. For example:

Example:

```
Router# show ip bgp vpnv6 unicast vrf vpn1
BGP table version is 10, local router ID is 10.4.4.4
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
              r RIB-failure, S Stale
Origin codes: i - IGP, e - EGP, ? - incomplete
Network          Next Hop            Metric LocPrf Weight Path
Route Distinguisher: 1:1 (default for vrf vpn1)
S>iA::1/128         ::FFFF:10.2.2.2          0    100      0 200 ?
*> A::5/128         A::4:5:5                 0             0 200 ?
S>iA::1:2:0/112     ::FFFF:10.2.2.2          0    100      0 ?
*  A::4:5:0/112     A::4:5:5                 0             0 200 ?
```

Step 4 **show ip bgp ipv6 unicast**

Use this command to verify that VPNv6 entries are marked as stale during switchover. For example:

Example:

```
Router# show ip bgp ipv6 unicast
BGP table version is 9, local router ID is 10.1.1.1
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
              r RIB-failure, S Stale
Origin codes: i - IGP, e - EGP, ? - incomplete
   Network          Next Hop            Metric LocPrf Weight Path
*> A::1/128         ::                       0         32768 ?
S  A::1:2:0/112     A::1:2:2                 0             0 100 ?
*>                  ::                       0         32768 ?
S> A::4:5:0/112     A::1:2:2                               0 100 ?
Router#
```

Step 5 **show mpls forwarding**

Use this command to show preserved forwarding entries for IPv6 and VPNv6 prefixes. The sample output is from a PE router in a CSC configuration. Enter the command on the active and the standby router. Compare the sample output from the active router with the sample output from the standby router. Following is sample output from the active router;

Example:

```
Router# show mpls forwarding
```

```
Local      Outgoing   Prefix           Bytes Label   Outgoing   Next Hop
Label      Label      or Tunnel Id     Switched      interface
18         Pop Label      10.3.3.3/32      0             FEt1/0/0      10.2.3.3
19         Pop Label      10.3.4.0/24      0             FEt1/0/0      10.2.3.3
20         17             10.4.4.4/32      0             FEt1/0/0      10.2.3.3
21         Pop Label      10.1.2.1/32[V]   0             FEt0/0/0      10.1.2.1
22         Pop Label      A::1:2:0/112[V]  0             aggregate/vpn1
23         Pop Label      A::1:2:1/128[V]  0             FEt0/0/0      A::1:2:1
24         Pop Label      10.1.2.0/24[V]   0             aggregate/vpn1
25         Pop Label      A::1:2:2/128[V]  0             aggregate/vpn1
26         18             A::1/128[V]      0             FEt0/0/0
FE80::A8BB:CCFF:FE03:2101
27         26             10.4.5.5/32[V]   0             FEt1/0/0      10.2.3.3
28         25             10.4.5.0/24[V]   0             FEt1/0/0      10.2.3.3
29         22             A::4:5:5/128[V]  0             FEt1/0/0      10.2.3.3
30         21             A::4:5:0/112[V]  0             FEt1/0/0      10.2.3.3
31         23             A::4:5:4/128[V]  0             FEt1/0/0      10.2.3.3
32         24             A::5/128[V]      0             FEt1/0/0      10.2.3.3
33         Pop Label      10.1.2.2/32[V]   0             aggregate/vpn1
34         Pop Label      10.1.1.1/32[V]   0             FEt0/0/0      10.1.2.1
35         27             10.4.5.4/32[V]   0             FEt1/0/0      10.2.3.3
Local      Outgoing   Prefix           Bytes Label   Outgoing   Next Hop
Label      Label      or Tunnel Id     Switched      interface
36         28             10.5.5.5/32[V]   0             FEt1/0/0      10.2.3.3
```

Following is sample output from the standby router:

Example:

```
Standby-Router# show mpls forwarding
Local      Outgoing   Prefix           Bytes Label   Outgoing   Next Hop
Label      Label      or Tunnel Id     Switched      interface
18         Pop Label      10.3.3.3/32      0             FEt1/0/0      10.2.3.3
19         Pop Label      10.3.4.0/24      0             FEt1/0/0      10.2.3.3

Label      Label      or Tunnel Id     Switched      interface
36         28             10.5.5.5/32[V]   0             FEt1/0/0      10.2.3.3
```

Step 6 **show ipv6 cef vrf** *vrf-name*

Use this command to show preserved forwarding entries for IPv6 and VPNv6 prefixes. This sample output is also from a PE router in a CSC configuration. Enter the command on the active and the standby router. Compare the sample output from the active router with the sample output from the standby router. Following is the output from the active router:

Example:

```
Router# show ipv6 cef vrf vrf1
::/0
  no route
::/127
  discard
A::1/128
  nexthop FE80::A8BB:CCFF:FE03:2101 FastEthernet0/0/0 label 18
A::5/128
  nexthop 10.2.3.3 FastEthernet1/0/0 label 17 24
A::1:2:0/112
  attached to FastEthernet0/0/0
A::1:2:1/128
  attached to FastEthernet0/0/0
A::1:2:2/128
  receive for FastEthernet0/0/0
A::4:5:0/112
  nexthop 10.2.3.3 FastEthernet1/0/0 label 17 21
A::4:5:4/128

Feature Information for SSO and ISSU--MPLS VPN 6VPE and 6PE Support

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 88: Feature Information for SSO and ISSU--MPLS VPN 6VPE and 6PE Support

Feature Name	Releases	Feature Information
ISSU--MPLS VPN 6VPE and 6PE ISSU Support	Cisco IOS XE 3.2S	This feature provides ISSU support for Cisco IOS XE VPN IPv6 provider edge router (6VPE) over MPLS and Cisco IOS XE IPv6 provider edge router (6PE) over MPLS. In Cisco IOS XE 3.2S, this feature was introduced for Cisco ASR 1000 Series Aggregation Services Routers. This feature introduced no new or modified commands.
SSO--MPLS VPN 6VPE and 6PE SSO Support	Cisco IOS XE 3.2S	This feature provides SSO support for Cisco IOS XE VPN IPv6 provider edge router (6VPE) over MPLS and Cisco IOS XE IPv6 provider edge router (6PE) over MPLS. In Cisco IOS XE 3.2S, this feature was introduced for Cisco ASR 1000 Series Aggregation Services Routers. This feature introduced no new or modified commands.

Glossary

6PE router --IPv6 provider edge (PE) router. A router running a Border Gateway Protocol (BGP)-based mechanism to interconnect IPv6 islands over a Multiprotocol Label Switching (MPLS)-enabled IPv4 cloud.

6VPE router --Provider edge router providing Border Gateway Protocol (BGP)-Multiprotocol Label Switching (MPLS) IPv6 Virtual Private Network (VPN) service over an IPv4-based MPLS core. It is a IPv6 VPN provider edge (PE), dual-stack router that implements 6PE concepts on the core-facing interfaces.

BGP --Border Gateway Protocol. An interdomain routing protocol designed for the global Internet. Exterior Border Gateway Protocols (eBGPs) communicate among different autonomous systems. Interior Border Gateway Protocols (iBGPs) communicate among routers within a single autonomous system.

CE router --customer edge router. A router that is part of a customer network and interfaces to a provider edge (PE) router.

Cisco Express Forwarding --An advanced Layer 3 IP switching technology. It optimizes network performance and scalability for all kinds of networks.

eBGP --external Border Gateway Protocol.

graceful restart --A process for helping an RP restart after a node failure has occurred.

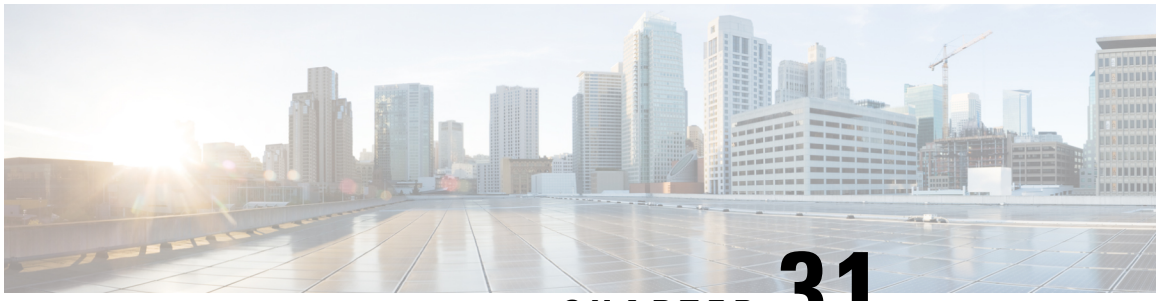
iBGP --Interior Border Gateway Protocol.

ISSU --In Service Software Upgrade. Software upgrade without service interruption.

LDP --Label Distribution Protocol. A standard protocol between Multiprotocol Label Switching (MPLS)-enabled routers to negotiate the labels (addresses) used to forward packets.

MPLS --Multiprotocol Label Switching. A switching method that forwards IP traffic using a label. This label instructs the routers and switches in the network where to forward the packets based on preestablished IP routing information.

NSF --nonstop forwarding. The ability of a router to continue to forward traffic to a router that may be recovering from a failure. Also, the ability of a router recovering from a failure to continue to correctly forward traffic sent to it by a peer.



PE router --provider edge router. The PE router is the entry point into the service provider network. The PE router is typically deployed on the edge of the network and is administered by the service provider. The PE router is the redistribution point between EIGRP and BGP in PE to CE networking.

RIB --Routing Information Base. Also called the routing table.

SSO --stateful switchover. SSO refers to the implementation of Cisco IOS XE software that allows applications and features to maintain a defined state between an active and standby RP. When a switchover occurs, forwarding and sessions are maintained. Along with NSF, SSO makes an RP failure undetectable to the network.

VPN --Enables IP traffic to travel securely over a public TCP/IP network by encrypting traffic from one network to another. A VPN uses tunneling to encrypt all information at the IP level.

VRF --Virtual Private Network (VPN) routing and forwarding instance. A VRF consists of an IP routing table, a derived routing table, a set of interfaces that use the forwarding table. and a set of rules and routing information that defines a customer VPN site that is attached to a provider edge (PE) router.

CHAPTER 31

SSO Support for MPLS TE Autotunnel and Automesh

The SSO Support for MPLS TE Autotunnel and Automesh feature provides full stateful switchover (SSO), Cisco nonstop forwarding (NSF), and In Service Software Upgrade (ISSU) support for autotunnel primary and backup TE tunnels feature and for autotunnel mesh group TE tunnels feature.

The NSF with SSO provides continuous packet forwarding even during a network processor hardware or software failure. In a redundant system, the secondary processor recovers control plane service during a critical failure in the primary processor. SSO synchronizes the network state information between the primary and the secondary processor.

Note For brevity in this document, the Autotunnel Primary and Backup feature is called Autotunnel. The Autotunnel Mesh Groups feature is called Automesh.

- Prerequisites for SSO Support for MPLS TE Autotunnel and Automesh, on page 541
- Restrictions for SSO Support for MPLS TE Autotunnel and Automesh, on page 542
- Information About SSO Support for MPLS TE Autotunnel and Automesh, on page 542
- Additional References, on page 543
- Feature Information for SSO Support for MPLS TE Autotunnel and Automesh, on page 543
- Glossary, on page 544

Prerequisites for SSO Support for MPLS TE Autotunnel and Automesh

- The MPLS TE RSVP Graceful Restart feature must be enabled on the stateful switchover (SSO) device and its neighbor devices.
- NSF must be configured on the IGP that is configured for TE. You must specify either the **nsf cisco** or the **nsf ietf** router configuration command or the recovery of TE tunnels might fail.
- The MPLS TE Autotunnel feature must be configured.
- The MPLS TE Automesh feature must be configured.

Note The SSO Support for MPLS TE Autotunnel and Automesh feature obsoletes the MPLS TE Autotunnel and SSO Coexistence feature available with the MPLS TE Autotunnel feature and the MPLS TE Automesh feature.

Restrictions for SSO Support for MPLS TE Autotunnel and Automesh

- The SSO Support for MPLS TE Autotunnel and Automesh feature is supported only on hardware platforms with dual Route Processors (RPs) that support SSO and Cisco NSF.
- SSO and Fast Reroute (FRR) double failure cases are not supported.
- To keep the Autotunnel and Automesh configurations synchronized between the active and standby RPs, you can no longer modify an existing Autotunnel or Automesh interface by using the **interface tunnel** command. This action is prohibited by the software.
- You can no longer use the following commands as a way for disabling the Autotunnel or the Automesh feature:
  - **clear mpls traffic-eng auto-tunnel primary**
  - **clear mpls traffic-eng auto-tunnel backup**
  - **clear mpls traffic-eng auto-tunnel mesh**

  Instead, use the **no** form of these commands:
  - **no mpls traffic-eng auto-tunnel primary onehop**
  - **no mpls traffic-eng auto-tunnel backup**
  - **no mpls traffic-eng auto-tunnel mesh**

Information About SSO Support for MPLS TE Autotunnel and Automesh

Overview of SSO Support for MPLS TE Autotunnel and Automesh

With the SSO Support for MPLS TE Autotunnel and Automesh feature, once you enable the device for the Autotunnel feature or for the Automesh feature by using the **mpls traffic-eng auto-tunnel primary onehop**, **mpls traffic-eng auto-tunnel backup**, or the **mpls traffic-eng auto-tunnel mesh** commands, the device starts creating the specified type of autotunnel on both the active and standby RPs. No additional configuration is needed to implement the SSO Support for MPLS TE Autotunnel and Automesh feature.

When the **no** form of these commands is executed, the SSO feature is disabled on both the active and the standby RPs.

The Autotunnel feature enables a device to dynamically build backup tunnels and to dynamically create one-hop primary tunnels on all interfaces that have been configured with MPLS TE tunnels.

The Automesh feature allows a network administrator to configure TE label switched paths (LSPs). In a network topology where edge label switch routers (LSRs) are connected by core LSRs, the Automesh feature automatically constructs a mesh of TE LSPs among the provider edge (PE) devices.

Table 89: Feature Information for SSO Support for MPLS TE Autotunnel and Automesh

Feature Name	Releases	Feature Information
SSO Support for MPLS TE Autotunnel and Automesh	15.2(2)S Cisco IOS XE Release 3.6S	The SSO Support for MPLS TE Autotunnel and Automesh feature provides full stateful switchover (SSO), Cisco nonstop forwarding (NSF), and In Service Software Upgrade (ISSU) support for the autotunnel primary and backup TE tunnels and for the autotunnel mesh group TE tunnels. The following commands were introduced or modified: **clear mpls traffic-eng auto-tunnel backup tunnel**, **clear mpls traffic-eng auto-tunnel mesh tunnel**, **clear mpls traffic-eng auto-tunnel primary tunnel**, **debug mpls traffic-eng auto-tunnel backup**, **debug mpls traffic-eng auto-tunnel primary**, **debug mpls traffic-eng ha sso**, **mpls traffic-eng auto-tunnel backup**, **mpls traffic-eng auto-tunnel mesh**, **mpls traffic-eng auto-tunnel primary onehop**, **show ip rsvp high-availability counters**, **show ip rsvp high-availability database**, **show ip rsvp high-availability database summary**, **show ip rsvp high-availability summary**, **show mpls traffic-eng auto-tunnel primary**.

Glossary

backup tunnel—An MPLS traffic engineering tunnel used to protect another (primary) tunnel's traffic when a link or node failure occurs.

Fast Reroute—Fast Reroute (FRR) is a mechanism for protecting MPLS traffic engineering LSPs from link and node failure by locally repairing the LSPs at the point of failure, allowing data to continue to flow on them while their headend devices attempt to establish end-to-end LSPs to replace them. FRR locally repairs the protected LSPs by rerouting them over backup tunnels that bypass failed links or nodes.

graceful restart—A process for helping an RP restart after a node failure has occurred.

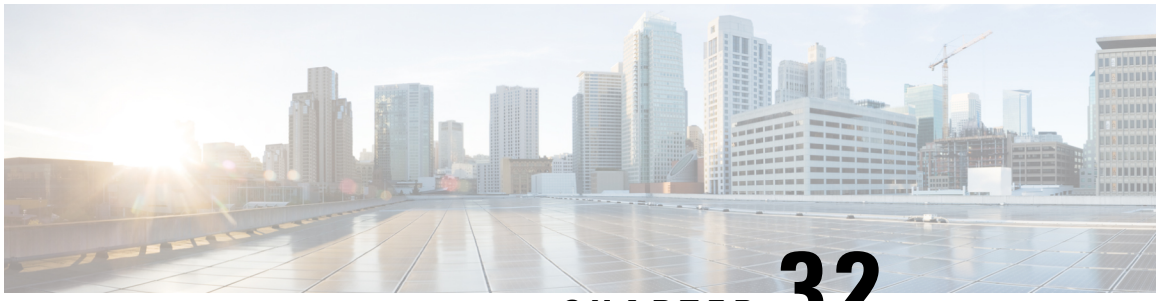
ISSU—In Service Software Upgrade. Software upgrade without service interruption.

LSP—label switched path. A path that a labeled packet follows over several hops, starting at an ingress LSR and ending at an egress LSR.

LSR—label switch router. A Layer 3 device that forwards a packet based on the value of a label encapsulated in the packet.

mesh group—A set of label switch routers (LSRs) that are members of a full or partial network of traffic engineering label switched paths (LSPs).

MPLS—Multiprotocol Label Switching. A switching method that forwards IP traffic using a label. This label instructs the devices in the network where to forward the packets based on preestablished IP routing information.



NSF—nonstop forwarding. The ability of a device to continue to forward traffic to a device that may be recovering from a failure. Also, the ability of a device recovering from a failure to continue to correctly forward traffic sent to it by a peer.

primary tunnel—An MPLS tunnel whose LSP can be fast-rerouted if there is a failure.

SSO—stateful switchover. SSO refers to the implementation of Cisco software that allows applications and features to maintain a defined state between an active and standby RP. When a switchover occurs, forwarding and sessions are maintained. Along with NSF, SSO makes an RP failure undetectable to the network.

TE—traffic engineering. The techniques and processes used to cause routed traffic to travel through the network on a path other than the one that would have been chosen if standard routing methods had been used.

tunnel—A secure communication path between two peers. A traffic engineering tunnel is a label switched tunnel that is used for traffic engineering. Such a tunnel is set up through means other than a normal Layer 3 device.

CHAPTER 32

MPLS Traffic Engineering Nonstop Routing Support

The MPLS Traffic Engineering Nonstop Routing Support feature assists the Multiprotocol Label Switching (MPLS) Traffic Engineering (TE) routing devices to recover from an interruption in service. This feature also defines the checkpoint and recovery scheme for the devices.

- Prerequisites for MPLS Traffic Engineering Nonstop Routing Support, on page 547
- Restrictions for MPLS Traffic Engineering Nonstop Routing Support , on page 548
- How to Configure MPLS Traffic Engineering Nonstop Routing Support, on page 548
- How to Configure MPLS Traffic Engineering Nonstop Routing Support, on page 548
- Verifying MPLS Traffic Engineering Nonstop Routing Support, on page 549
- Configuration Examples for MPLS Traffic Engineering Nonstop Routing Support, on page 551
- Additional References for MPLS Traffic Engineering Nonstop Routing Support, on page 558
- Feature Information for MPLS Traffic Engineering Nonstop Routing Support, on page 559

Prerequisites for MPLS Traffic Engineering Nonstop Routing Support

Your network must support the following Cisco features before you enable Multiprotocol Label Switching (MPLS) Traffic Engineering (TE):

- MPLS
- Cisco Express Forwarding
- Intermediate System-to-Intermediate System (IS-IS) or Open Shortest Path First (OSPF)

Before enabling MPLS TE Nonstop Routing (NSR), a full-mode check needs to be done by the system to verify if the **mpls traffic-eng nsr** command is permitted or is restricted due to conflicts or user privileges.

Restrictions for MPLS Traffic Engineering Nonstop Routing Support

Multiprotocol Label Switching (MPLS) Traffic Engineering (TE) Nonstop Routing (NSR) and Resource Reservation Protocol (RSVP) Graceful Restart (GR) are both mutually exclusive recovery mechanisms. Hence, MPLS TE NSR cannot be enabled when RSVP GR is enabled.

How to Configure MPLS Traffic Engineering Nonstop Routing Support

MPLS Traffic Engineering Nonstop Routing Support Overview

Multiprotocol Label Switching (MPLS) Traffic Engineering (TE) Nonstop Routing (NSR) enables routing devices to recover from an interruption in service. The MPLS TE NSR functionality defines a checkpoint for the control plane of the routing devices. Resource Reservation Protocol (RSVP) Graceful Restart (GR) is another method for recovering and restarting interrupted services.

To avoid conflict and guarantee deterministic behavior, only one of the above mentioned recovery methods can be configured at a given time.

The MPLS TE NSR feature differs from the RSVP GR feature in the following ways:

- MPLS TE NSR devices are fully independent and do not rely on neighbor nodes for a stateful switchover (SSO) recovery.
- MPLS TE NSR supports the SSO recovery of Fast Reroute (FRR) active tunnels.
- MPLS TE NSR has an active standby mode. This helps with most of the recovery states being created before the SSO recovery actually happens, ensuring a faster recovery after SSO.
- MPLS TE NSR **show** commands display recovery information in standby mode as well.
- Label switched paths (LSPs) which are not fully signaled, do not resume signaling after an interruption and will go down on SSO.

How to Configure MPLS Traffic Engineering Nonstop Routing Support

Configuring MPLS Traffic Engineering Nonstop Routing Support

SUMMARY STEPS

1. **enable**

2. **configure terminal**
3. **ip cef**
4. **mpls traffic-eng nsr**
5. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**ip cef** **Example:** `Device(config)# ip cef`	Enables standard Cisco Express Forwarding operations.
Step 4	**mpls traffic-eng nsr** **Example:** `Device(config)# mpls traffic-eng nsr`	Enables the MPLS Traffic Engineering (TE) Non-Stop Routing (NSR) functionality on a device. **Note** Enabling the MPLS TE NSR functionality automatically enables the Resource Reservation Protocol (RSVP) NSR functionality as well.
Step 5	**end** **Example:** `Device(config)# end`	Exits global configuration mode and returns to privileged EXEC mode.

Verifying MPLS Traffic Engineering Nonstop Routing Support

SUMMARY STEPS

1. **enable**
2. **show mpls traffic-eng nsr**
3. **show mpls traffic-eng nsr counters**
4. **show mpls traffic-eng nsr database**

5. **show mpls traffic-eng nsr oos**
6. **show mpls traffic-eng nsr summary**
7. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.

Step 2	**show mpls traffic-eng nsr**
	Example:
	`Device# show mpls traffic-eng nsr`
	`  counters  TE NSR counters`
	`  database  TE NSR check pointed data`
	`  oos  TE NSR out of sync database`
	`  summary  TE NSR summary`
	`  |  Output modifiers`
	`  <cr>`
		Displays options to obtain Multiprotocol Label Switching (MPLS) Traffic Engineering (TE) Nonstop Routing (NSR) configuration information such as the database status, counter numbers, devices which are out of sync, and the summary of all the devices.

Step 3	**show mpls traffic-eng nsr counters** **Example:** `Device# show mpls traffic-eng nsr counters`	Displays information about the data structures or states that are successfully created or removed, along with errors counts.
Step 4	**show mpls traffic-eng nsr database** **Example:** `Device# show mpls traffic-eng nsr database`	Displays information pertaining to the write and read databases supporting MPLS TE NSR. The write and read databases store the data that is used for recovering TE state on a standby device after stateful switchover (SSO).
Step 5	**show mpls traffic-eng nsr oos** **Example:** `Device# show mpls traffic-eng nsr oos`	Displays information pertaining to the out of sync databases supporting MPLS TE NSR. The out of sync databases indicate the devices whose states are not in sync with each other.
Step 6	**show mpls traffic-eng nsr summary** **Example:** `Device# show mpls traffic-eng nsr summary`	Displays a summary of MPLS TE NSR information such as the current TE NSR state (standby-hot / recovering / staling / active), recovery time, and the recovery result (success / failure).
Step 7	**end** **Example:** `Device(config)# end`	Exits privileged EXEC mode.

Configuration Examples for MPLS Traffic Engineering Nonstop Routing Support

Example: Configuring MPLS Traffic Engineering Nonstop Routing Support

The following example shows how to configure Multiprotocol (MPLS) Traffic Engineering (TE) Nonstop Routing (NSR) support on a device:

```
enable
 configure terminal
  ip cef
  mpls traffic-eng nsr
  end
```

Example: Verifying MPLS Traffic Engineering Nonstop Routing Support

Displaying MPLS Traffic Engineering Nonstop Routing Support Verification Options

The following example shows how to display the options that help you verify Multiprotocol Label Switching (MPLS) Traffic Engineering (TE) Nonstop Routing (NSR) information:

```
enable
 show mpls traffic-eng nsr ?
  counters  TE NSR counters
  database  TE NSR check pointed data
  oos       TE NSR out of sync database
  summary   TE NSR summary
  |         Output modifiers
  <cr>
```

Verifying MPLS Traffic Engineering Nonstop Routing Support Counters

The following example shows how to verify information about the data structures or states that are successfully created or removed, along with errors counts:

```
enable
 show mpls traffic-eng nsr counters

State: Active

Bulk sync
  Last bulk sync was successful (entries sent: 24)

Verifying MPLS Traffic Engineering Nonstop Routing Support Databases

The following example shows how to verify information pertaining to the write and read databases supporting MPLS TE NSR. The write and read databases store the data that is used for recovering TE state on a standby device after Stateful Switchover (SSO):

```
Device# show mpls traffic-eng nsr database if-autotun
IF_AUTOTUN WRITE DB

  Header:
    State: Checkpointed     Action: Add
```

```
    Seq #: 14               Flags: 0x0
  Data:
    te_nsr_seq_num: 28
    Tunnel ID: 100 (if_handle: 25), prot_if_handle: 3
    template_unit: n/a, dest: 10.2.0.1, flags=0x0

IF_AUTOTUN READ DB

Device# show mpls traffic-eng nsr database lsp-ac ?
  |  Output modifiers
  <cr>

Device# show mpls traffic-eng nsr database lsp-ac

Feature Information for MPLS Traffic Engineering Nonstop Routing Support

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 90: Feature Information for MPLS Traffic Engineering Nonstop Routing Support

Feature Name	Releases	Feature Information
MPLS Traffic Engineering Nonstop Routing Support	Cisco IOS XE Release 3.10S, 3.13S	The MPLS Traffic Engineering Non-Stop Routing Support feature assists the Multiprotocol Label Switching (MPLS) Traffic Engineering (TE) routing devices to recover from an interruption in service. The MPLS TE Nonstop Routing (NSR) support functionality also defines the checkpoint and recovery scheme for the devices. From Cisco IOS XE 3.13S, support was provided for ASR 903. The following commands were introduced: **mpls traffic-eng nsr** and **show mpls traffic-eng nsr**.

CHAPTER 33

NSR LDP Support

The NSR LDP Support feature allows the Label Distribution Protocol (LDP) to continue to operate across a Router Processor (RP) failure in redundant systems, without losing peer sessions. Before the introduction of nonstop routing (NSR), LDP sessions with peers reset if an RP failover (in a redundant system) or a Cisco In-Service Software Upgrade (ISSU) occurred. When peers reset, traffic is lost while the session is down. Protocol reconvergence occurs after the session is reestablished.

When NSR is enabled, RP failover and Cisco ISSU events are not visible to the peer device, and the LDP sessions that were established prior to failover do not flap. The protocol state learned from the peers persists across an RP failover or Cisco ISSU event and does not need to be relearned.

- Prerequisites for NSR LDP Support, on page 561
- Information About NSR LDP Support, on page 561
- How to Configure NSR LDP Support, on page 564
- Configuration Examples for NSR LDP Support, on page 565

Prerequisites for NSR LDP Support

The Label Distribution Protocol (LDP) must be up and running on the standby Route Processor (RP) for NSR LDP Support to work.

Information About NSR LDP Support

Roles of the Standby Route Processor and Standby LDP

For the NSR LDP Support feature to work, the Label Distribution Protocol (LDP) must be up and running on the standby Route Processor (RP). The LDP component running on the active RP is called the active LDP, and the LDP component running on the standby RP is called the standby LDP.

When nonstop routing (NSR) is enabled, the standby LDP runs independently from the active LDP, but with the assistance of some software components. The standby LDP maintains LDP session states and database information, ready to take over for the active LDP if the failover occurs.

Standby LDP maintains its local database by querying or receiving notifications of interface status change, configuration changes from the CLI, and checkpoints from the active LDP for other information that is not directly available on the standby RP.

To keep the protocol and session-state information synchronized with the active LDP, the standby LDP depends on TCP to replicate all LDP messages on the active RP to the standby RP. The standby LDP processes all received messages, updates its state, but does not send any responses to its neighbors.

The standby LDP performs the following tasks:

- Processes LDP configuration on startup and during steady state
- Processes active LDP checkpoints of state and session information such as LDP adjacencies, remote addresses, remote bindings, and so forth
- Builds its database of local interfaces
- Processes interface change events
- Receives and processes all LDP messages replicated by TCP
- Updates remote address and label databases

After a switchover and notification that the RP has become active, the standby LDP takes over the role of the active LDP and performs the following tasks:

- Sends hello messages immediately to prevent neighbors from reaching the discovery timeout and bringing down the session
- Retransmits any protocol-level response that has not been sent by the previous active LDP
- Readvertises label bindings
- Refreshes all forwarding entries
- Processes and responds to any LDP message from its neighbor

When the NSR LDP Support feature is disabled, the active LDP performs the following tasks:

- Stops checkpointing to the standby LDP
- Continues to manage all existing sessions

The standby LDP performs the following tasks:

- Cleans up all session-state information
- Reverses to the behavior before NSR is enabled

LDP Operating States

When the NSR LDP Support feature is enabled, the Label Distribution Protocol (LDP) operates in the following states:

Initial State

In the initial state, the active Label Distribution Protocol (LDP) process sets up the standby LDP to be ready to support nonstop routing (NSR). The active LDP performs the following tasks:

- Replicates all TCP sessions used by LDP with the standby LDP
- Synchronizes all existing session-state information with the standby LDP
- Synchronizes the LDP database with the standby LDP

LDP could be in the initial state because of one of these conditions:

- NSR is enabled
- NSR was enabled and the standby Route Processor (RP) starts up (asymmetric startup)
- System boots up and NSR is configured (symmetric startup)

Steady State

In the steady state, the active and standby Label Distribution Protocol (LDP) databases are synchronized. The active and standby LDP process the same LDP messages and update their states independently. The standby LDP is ready to take over the active LDP role in a switchover event.

On the active Route Processor (RP), the active LDP performs the following tasks:

- Continues to manage all existing sessions and checkpoints any significant session event to the standby LDP (such as adjacency delete, session shutdown, timers)
- Notifies the standby LDP of new adjacencies and neighbors

On the standby RP, the standby LDP performs these tasks:

- Processes all received messages but does not send any messages to its neighbor
- Processes checkpoint information from the active LDP
- Manages session keepalive timers but does not bring down the session if a keepalive timer times out

Post Switchover

In the post switchover state, the standby Label Distribution Protocol (LDP) process takes over the active LDP role while the active Route Processor (RP) is reloading.

Supported NSR Scenarios

The NSR LDP Support feature is supported under the following scenarios:

- Route Processor (RP) failover or node failure

  The Label Distribution Protocol (LDP) keeps the session up during an RP or node failover because the LDP adjacency and session-state information between LDP on the active and standby RPs are synchronized. As sessions are created on the active RP, new adjacencies are synchronized to the standby RP. If a standby RP is brought online after sessions are already up (asymmetric startup), LDP synchronizes the existing session-state information from the active to the standby RP.

- Cisco In-Service Software Upgrade (ISSU)

  LDP supports Cisco ISSU negotiation between RPs when a standby RP comes online for the MPLS LDP IGP Synchronization feature. Current Cisco ISSU negotiation is not impacted by NSR. For NSR, LDP negotiates messages specific to NSR, which are checkpointed during initial synchronization (adjacency and session-state information).

How to Configure NSR LDP Support

Enabling NSR LDP Support

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls ldp nsr**
4. **exit**
5. **show mpls ldp nsr**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**mpls ldp nsr** **Example:** `Device(config)# mpls ldp nsr`	Enables nonstop routing (NSR) for all Label Distribution Protocol (LDP) sessions for both link and targeted.
Step 4	**exit** **Example:** `Device(config)# exit`	Returns to privileged EXEC mode.

	Command or Action	Purpose
Step 5	**show mpls ldp nsr** **Example:** `Device# show mpls ldp nsr`	Displays whether NSR is enabled.

Troubleshooting Tips for NSR LDP Support

Use the **debug mpls ldp nsr** command to enable the display of Multiprotocol Label Switching (MPLS) Label Distribution Protocol (LDP) nonstop routing (NSR) debugging events for all NSR sessions or for the specified peer.

CHAPTER 34

MPLS Label Distribution Protocol

MPLS Label Distribution Protocol (LDP) enables peer label switch routers (LSRs) in an Multiprotocol Label Switching (MPLS) network to exchange label binding information for supporting hop-by-hop forwarding in an MPLS network. This module explains the concepts related to MPLS LDP and describes how to configure MPLS LDP in a network.

- Information About MPLS Label Distribution Protocol, on page 569
- How to Configure MPLS Label Distribution Protocol, on page 572
- Configuration Examples for MPLS Label Distribution Protocol, on page 587
- Additional References, on page 591

Prerequisites for MPLS Label Distribution Protocol

Label switching on a device requires that Cisco Express Forwarding be enabled on that device.

Information About MPLS Label Distribution Protocol

Introduction to MPLS Label Distribution Protocol

MPLS Label Distribution Protocol (LDP) provides the means for label switch devices (LSRs) to request, distribute, and release label prefix binding information to peer devices in a network. LDP enables LSRs to discover potential peers and to establish LDP sessions with those peers for the purpose of exchanging label binding information.

Multiprotocol Label Switching (MPLS) LDP enables one LSR to inform another LSR of the label bindings it has made. Once a pair of devices communicate the LDP parameters, they establish a label switched path (LSP). MPLS LDP enables LSRs to distribute labels along normally routed paths to support MPLS forwarding. This method of label distribution is also called hop-by-hop forwarding. With IP forwarding, when a packet arrives at a device the device looks at the destination address in the IP header, performs a route lookup, and forwards the packet to the next hop. With MPLS forwarding, when a packet arrives at a device the device looks at the incoming label, looks up the label in a table, and then forwards the packet to the next hop. MPLS LDP is useful for applications that require hop-by-hop forwarding, such as MPLS VPNs.

MPLS Label Distribution Protocol Functional Overview

Cisco Multiprotocol Label Switching (MPLS) Label Distribution Protocol (LDP) provides the building blocks for MPLS-enabled applications, such as MPLS Virtual Private Networks (VPNs).

LDP provides a standard methodology for hop-by-hop, or dynamic label, distribution in an MPLS network by assigning labels to routes that have been chosen by the underlying Interior Gateway Protocol (IGP) routing protocols. The resulting labeled paths, called label switch paths (LIPS), forward label traffic across an MPLS backbone to particular destinations. These capabilities enable service providers to implement MPLS-based IP VPNs and IP+ATM services across multivendor MPLS networks.

Introduction to LDP Sessions

When you enable Multiprotocol Label Switching (MPLS) Label Distribution Protocol (LDP), the label switch routers (LSRs) send out messages to try to find other LSRs with which they can create LDP sessions. The following sections explain the differences between directly connected LDP sessions and nondirectly connected LDP sessions.

Directly Connected MPLS LDP Sessions

If a label switch router (LSR) is one hop from its neighbor, it is directly connected to its neighbor. The LSR sends out Label Distribution Protocol (LDP) link Hello messages as User Datagram Protocol (UDP) packets to all the devices on the subnet (multicast). A neighboring LSR may respond to the link Hello message, allowing the two devices to establish an LDP session. This is called basic discovery.

To initiate an LDP session between devices, the devices determine which device will take the active role and which device will take the passive role. The device that takes the active role establishes the LDP TCP connection session and initiates the negotiation of the LDP session parameters. To determine the roles, the two devices compare their transport addresses. The device with the higher IP address takes the active role and establishes the session.

After the LDP TCP connection session is established, the LSRs negotiate the session parameters, including the method of label distribution to be used. Two methods are available:

- Downstream Unsolicited: An LSR advertises label mappings to peers without being asked to.
- Downstream on Demand: An LSR advertises label mappings to a peer only when the peer asks for them.

Nondirectly Connected MPLS LDP Sessions

If the label switch router (LSR) is more than one hop from its neighbor, it is nondirectly connected to its neighbor. For these nondirectly connected neighbors, the LSR sends out a targeted Hello message as a User Datagram Protocol (UDP) packet, but as a unicast message specifically addressed to that LSR. The nondirectly connected LSR responds to the Hello message and the two devices begin to establish a Label Distribution Protocol (LDP) session. This is called extended discovery.

A Multiprotocol Label Switching (MPLS) LDP targeted session is a label distribution session between devices that are not directly connected. When you create an MPLS traffic engineering tunnel interface, you need to establish a label distribution session between the tunnel headend and the tailend devices. You establish nondirectly connected MPLS LDP sessions by enabling the transmission of targeted Hello messages.

You can use the **mpls ldp neighbor targeted** command to set up a targeted session when other means of establishing targeted sessions do not apply, such as configuring **mpls ip** on a traffic engineering (TE) tunnel or configuring Any Transport over MPLS (AToM) virtual circuits (VCs). For example, you can use this

command to create a targeted session between directly connected MPLS LSRs when MPLS label forwarding convergence time is an issue.

The **mpls ldp neighbor targeted** command can improve label convergence time for directly connected neighbor LSRs when the links directly connecting them are down. When the links between the neighbor LSRs are up, both the link and targeted Hellos maintain the LDP session. If the links between the neighbor LSRs go down, and there is an alternate route between neighbors, the targeted Hellos would maintain the session, allowing the LSRs to retain labels learned from each other. When a link directly connecting the LSRs comes back up, the LSRs can immediately reinstall labels for forwarding use without having to reestablish their LDP session and exchange labels.

The exchange of targeted Hello messages between two nondirectly connected neighbors can occur in several ways, including the following:

- Device 1 sends targeted Hello messages carrying a response request to Device 2. Device 2 sends targeted Hello messages in response if its configuration permits. In this situation, Device 1 is considered to be active and Device 2 is considered to be passive.
- Device 1 and Device 2 both send targeted Hello messages to each other. Both devices are considered to be active. Both, one, or neither device can also be passive, if they have been configured to respond to requests for targeted Hello messages from each other.

The default behavior of an LSR is to ignore requests from other LSRs that send targeted Hello messages. You can configure an LSR to respond to requests for targeted Hello messages by issuing the **mpls ldp discovery targeted-hello accept** command.

The active LSR mandates the protocol that is used for a targeted session. The passive LSR uses the protocol of the received targeted Hello messages.

Introduction to LDP Label Bindings Label Spaces and LDP Identifiers

A Label Distribution Protocol (LDP) label binding is an association between a destination prefix and a label. The label used in a label binding is allocated from a set of possible labels called a label space.

LDP supports two types of label spaces:

- Interface-specific—An interface-specific label space uses interface resources for labels. For example, label-controlled ATM (LC-ATM) interfaces use virtual path identifiers/virtual circuit identifiers (VPIs/VCIs) for labels. Depending on its configuration, an LDP platform may support zero, one, or more interface-specific label spaces.
- Platform-wide—An LDP platform supports a single platform-wide label space for use by interfaces that can share the same labels. For Cisco platforms, all interface types, except LC-ATM, use the platform-wide label space.

LDP uses a 6-byte quantity called an LDP Identifier (or LDP ID) to name label spaces. The LDP ID is made up of the following components:

- The first four bytes, called the LPD router ID, identify the label switch router (LSR) that owns the label space.
- The last two bytes, called the local label space ID, identify the label space within the LSR. For the platform-wide label space, the last two bytes of the LDP ID are always both 0.

The LDP ID takes the following form:

<LDP router ID> : <local label space ID>

The following are examples of LPD IDs:

- 172.16.0.0:0
- 192.168.0.0:3

The device determines the LDP router ID as follows, if the **mpls ldp router-id** command is not executed,

1. The device examines the IP addresses of all operational interfaces.
2. If these IP addresses include loopback interface addresses, the device selects the largest loopback address as the LDP router ID.
3. Otherwise, the device selects the largest IP address pertaining to an operational interface as the LDP router ID.

The normal (default) method for determining the LDP router ID may result in a router ID that is not usable in certain situations. For example, the device might select an IP address as the LDP router ID that the routing protocol cannot advertise to a neighboring device. The **mpls ldp router-id** command allows you to specify the IP address of an interface as the LDP router ID. Make sure the specified interface is operational so that its IP address can be used as the LDP router ID.

When you issue the **mpls ldp router-id** command without the **force** keyword, the device select selects the IP address of the specified interface (provided that the interface is operational) the next time it is necessary to select an LDP router ID, which is typically the next time the interface is shut down or the address is configured.

When you issue the **mpls ldp router-id** command with the **force** keyword, the effect of the **mpls ldp router-id** command depends on the current state of the specified interface:

- If the interface is up (operational) and if its IP address is not currently the LDP router ID, the LDP router ID changes to the IP address of the interface. This forced change in the LDP router ID tears down any existing LDP sessions, releases label bindings learned via the LDP sessions, and interrupts MPLS forwarding activity associated with the bindings.
- If the interface is down (not operational) when the **mpls ldp router-id** *interface* **force** command is issued, when the interface transitions to up, the LDP router ID changes to the IP address of the interface. This forced change in the LDP router ID tears down any existing LDP sessions, releases label bindings learned via the LDP sessions, and interrupts MPLS forwarding activity associated with the bindings.

How to Configure MPLS Label Distribution Protocol

Enabling Directly Connected LDP Sessions

This procedure explains how to configure Multiprotocol Label Switching (MPLS) Label Distribution Protocol (LDP) sessions between two directly connected devices.

SUMMARY STEPS

1. **enable**
2. **configure terminal**

3. **mpls ip**
4. **mpls label protocol** [**ldp** | **tdp** | **both**]
5. **interface** *type number*
6. **mpls ip**
7. **exit**
8. **exit**
9. **show mpls interfaces** [*interface*] [**detail**]
10. **show mpls ldp discovery** [**all** | **vrf** *vpn-name*] [**detail**]
11. **show mpls ldp neighbor** [[**vrf** *vpn-name*] [*address* | *interface*] [**detail**] | **all**]

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**mpls ip** **Example:** `Device(config)# mpls ip`	Configures MPLS hop-by-hop forwarding globally. • The **mpls ip** command is enabled by default; you do not have to specify this command. • Globally enabling MPLS forwarding does not enable it on the device interfaces. You must enable MPLS forwarding on the interfaces as well as for the device.
Step 4	**mpls label protocol** [**ldp**	**tdp**	**both**] **Example:** `Device(config)# mpls label protocol ldp`	Configures the use of LDP on all interfaces. • The keywords that are available depend on the hardware platform. • If you set all interfaces globally to LDP, you can override specific interfaces with either the **tdp** or **both** keyword by specifying the command in interface configuration mode.
Step 5	**interface** *type number* **Example:** `Device(config)# interface fastethernet 0/3/0`	Specifies the interface to be configured and enters interface configuration mode.

	Command or Action	Purpose
Step 6	**mpls ip** **Example:** `Device(config-if)# mpls ip`	Configures MPLS hop-by-hop forwarding on the interface. • You must enable MPLS forwarding on the interfaces as well as for the device.
Step 7	**exit** **Example:** `Device(config-if)# exit`	Exits interface configuration mode and enters global configuration mode.
Step 8	**exit** **Example:** `Device(config)# exit`	Exits global configuration mode and enters privileged EXEC mode.
Step 9	**show mpls interfaces** [*interface*] [**detail**] **Example:** `Device# show mpls interfaces`	Verifies that the interfaces have been configured to use LDP.
Step 10	**show mpls ldp discovery** [**all** | **vrf** *vpn-name*] [**detail**] **Example:** `Device# show mpls ldp discovery`	Verifies that the interface is up and is sending Discovery Hello messages.
Step 11	**show mpls ldp neighbor** [[**vrf** *vpn-name*] [*address* | *interface*] [**detail**] | **all**] **Example:** `Device# show mpls ldp neighbor`	Displays the status of LDP sessions.

Examples

The following **show mpls interfaces** command verifies that interfaces FastEthernet 0/3/0 and 0/3/1 have been configured to use LDP:

```
Device# show mpls interfaces
Interface              IP            Tunnel   BGP Static Operational
FastEthernet0/3/0      Yes (ldp)     No       No  No     Yes
FastEthernet0/3/1      Yes           No       No  No     Yes
```

The following **show mpls ldp discovery** command verifies that the interface is up and is sending LDP Discovery Hello messages (as opposed to TDP Hello messages):

```
Device# show mpls ldp discovery
Local LDP Identifier:
    172.16.12.1:0
    Discovery Sources:
```

```
    Interfaces:
        FastEthernet0/3/0 (ldp): xmit
```

The following example shows that the LDP session between devices was successfully established:

```
Device# show mpls ldp neighbor
Peer LDP Ident: 10.1.1.2:0; Local LDP Ident 10.1.1.1:0
TCP connection: 10.1.1.2.18 - 10.1.1.1.66
State: Oper; Msgs sent/rcvd: 12/11; Downstream
Up time: 00:00:10
LDP discovery sources:
FastEthernet0/1/0, Src IP addr: 10.20.10.2
Addresses bound to peer LDP Ident:
10.1.1.2    10.20.20.1    10.20.10.2
```

Establishing Nondirectly Connected MPLS LDP Sessions

This section explains how to configure nondirectly connected MPLS Label Distribution Protocol (LDP) sessions, which enable you to establish an LDP session between devices that are not directly connected.

Before you begin

- Multiprotocol Label Switching (MPLS) requires Cisco Express Forwarding.
- You must configure the devices at both ends of the tunnel to be active or enable one device to be passive with the **mpls ldp discovery targeted-hello accept** command.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls ip**
4. **mpls label protocol** [**ldp** | **tdp** | **both**]
5. **interface tunnel** *number*
6. **tunnel destination** *ip-address*
7. **mpls ip**
8. **exit**
9. **exit**
10. **show mpls ldp discovery** [**all** | **vrf** *vpn-name*] [**detail**]

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.

	Command or Action	Purpose
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**mpls ip** **Example:** `Device(config)# mpls ip`	Configures MPLS hop-by-hop forwarding globally. • The **mpls ip** command is enabled by default; you do not have to specify this command. • Globally enabling MPLS forwarding does not enable it on the device interfaces. You must enable MPLS forwarding on the interfaces as well as for the device.
Step 4	**mpls label protocol** [**ldp** | **tdp** | **both**] **Example:** `Device(config)# mpls label protocol ldp`	Configures the use of LDP on all interfaces. • The keywords that are available depend on the hardware platform. • If you set all interfaces globally to LDP, you can override specific interfaces with either the **tdp** or **both** keyword by specifying the command in interface configuration mode.
Step 5	**interface tunnel** *number* **Example:** `Device(config)# interface tunnel 1`	Configures a tunnel interface and enters interface configuration mode.
Step 6	**tunnel destination** *ip-address* **Example:** `Device(config-if)# tunnel destination 172.16.1.1`	Assigns an IP address to the tunnel interface.
Step 7	**mpls ip** **Example:** `Device(config-if)# mpls ip`	Configures MPLS hop-by-hop forwarding on the interface. • You must enable MPLS forwarding on the interfaces as well as for the device.
Step 8	**exit** **Example:** `Device(config-if)# exit`	Exits interface configuration mode and enters global configuration mode.
Step 9	**exit** **Example:** `Device(config)# exit`	Exits global configuration mode and enters privileged EXEC mode.

	Command or Action	Purpose
Step 10	**show mpls ldp discovery** [**all** | **vrf** *vpn-name*] [**detail**] **Example:** `Device# show mpls ldp discovery`	Verifies that the interface is up and is sending Discovery Hello messages.

Examples

The following example shows the output of the **show mpls ldp discovery** command for a nondirectly connected LDP session:

```
Device# show mpls ldp discovery
Local LDP Identifier:
          172.16.0.0:0
Discovery Sources:
Interfaces:
POS1/2/0 (ldp): xmit/recv
LDP Id: 172.31.255.255:0
Tunnel1 (ldp): Targeted -> 192.168.255.255
Targeted Hellos:
172.16.0.0 -> 192.168.255.255 (ldp): active, xmit/recv
LDP Id: 192.168.255.255:0
172.16.0.0 -> 192.168.0.0 (ldp): passive, xmit/recv
LDP Id: 192.168.0.0:0
```

This command output indicates that:

- The local label switch router (LSR) (172.16.0.0) sent LDP link Hello messages on interface POS1/2/0 and discovered neighbor 172.31.255.255.
- The local LSR sent LDP targeted Hello messages associated with interface Tunnel1 to target 192.168.255.255. The LSR was configured to use LDP.
- The local LSR is active for targeted discovery activity with 192.168.255.255; this means that the targeted Hello messages it sends to 192.168.255.255 carry a response request. The local LSR was configured to have an LDP session with the nondirectly connected LSR 192.168.255.255.
- The local LSR is not passive from the discovery activity with 192.168.255.255 for one of the following reasons:
  - The targeted Hello messages it receives from 192.168.255.255 do not carry a response request.
  - The local LSR has not been configured to respond to such requests.
- The local LSR sent Tag Distribution Protocol (TDP) directed Hello messages to the target LSR 192.168.0.0. This LSR uses TDP because the Hello messages received from the target LSR 192.168.0.0 were TDP directed Hello messages.
- The local LSR is passive in discovery activity with LSR 192.168.0.0. This means that the directed Hello messages it receives from LSR 192.168.0.0 carry a response request and that the local LSR has been configured with the **mpls ldp discovery targeted-hello accept** command to respond to such requests from LSR 192.168.0.0.

- The local LSR is not active in discovery activity with LSR 192.168.0.0, because no application that requires an LDP session with LSR 192.168.0.0 has been configured on the local LSR.

Saving Configurations MPLS Tag Switching Commands

In releases prior to Cisco IOS Release 12.4(2)T, some Multiprotocol Label Switching (MPLS) commands had both a tag-switching version and an MPLS version. For example, the two commands **tag-switching ip** and **mpls ip** were the same. To support backward compatibility, the tag-switching form of the command was written to the saved configuration.

Starting in Cisco IOS Release 12.4(2)T, the MPLS form of the command is written to the saved configuration.

For example, if an ATM interface is configured using the following commands, which have both a tag-switching form and an MPLS form:

```
Device(config)# interface ATM 3/0
Device(config-if)# ip unnumbered Loopback0
Device(config-if)# tag-switching ip
Device(config-if)# mpls label protocol ldp
```

After you enter these commands and save this configuration or display the running configuration with the **show running-config** command, the commands saved or displayed appear as follows:

```
interface ATM 3/0
ip unnumbered Loopback0
mpls ip
mpls label protocol ldp
```

Specifying the LDP Router ID

The **mpls ldp router-id** command allows you to establish the IP address of an interface as the LDP router ID.

The following steps describe the normal process for determining the LDP router ID:

1. The device considers all the IP addresses of all operational interfaces.
2. If these addresses include loopback interface addresses, the device selects the largest loopback address. Configuring a loopback address helps ensure a stable LDP ID for the device, because the state of loopback addresses does not change. However, configuring a loopback interface and IP address on each device is not required.

The loopback IP address does not become the router ID of the local LDP ID under the following circumstances:

- • If the loopback interface has been explicitly shut down.
  • If the **mpls ldp router-id** command specifies that a different interface should be used as the LDP router ID.

If you use a loopback interface, make sure that the IP address for the loopback interface is configured with a /32 network mask. In addition, make sure that the routing protocol in use is configured to advertise the corresponding /32 network.

1. Otherwise, the device selects the largest interface address.

The device might select a router ID that is not usable in certain situations. For example, the device might select an IP address that the routing protocol cannot advertise to a neighboring device.

The device implements the router ID the next time it is necessary to select an LDP router ID. The effect of the command is delayed until the next time it is necessary to select an LDP router ID, which is typically the next time the interface is shut down or the address is deconfigured.

If you use the **force** keyword with the **mpls ldp router-id** command, the router ID takes effect more quickly. However, implementing the router ID depends on the current state of the specified interface:

- If the interface is up (operational) and its IP address is not currently the LDP router ID, the LDP router ID is forcibly changed to the IP address of the interface. This forced change in the LDP router ID tears down any existing LDP sessions, releases label bindings learned via the LDP sessions, and interrupts Multiprotocol Label Switching (MPLS) forwarding activity associated with the bindings.
- If the interface is down, the LDP router ID is forcibly changed to the IP address of the interface when the interface transitions to up. This forced change in the LDP router ID tears down any existing LDP sessions, releases label bindings learned via the LDP sessions, and interrupts MPLS forwarding activity associated with the bindings.

Before you begin

Make sure the specified interface is operational before assigning it as the Label Distribution Protocol (LDP) router ID.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls ip**
4. **mpls label protocol** [**ldp** | **tdp** | **both**]
5. **mpls ldp router-id** *interface* [**force**]
6. **exit**
7. **show mpls ldp discovery** [**all** | **detail** | **vrf** *vpn-name*]

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.

	Command or Action	Purpose
Step 3	**mpls ip** **Example:** `Device(config)# mpls ip`	Configures MPLS hop-by-hop forwarding globally. • The **mpls ip** command is enabled by default; you do not have to specify this command. • Globally enabling MPLS forwarding does not enable it on the device interfaces. You must enable MPLS forwarding on the interfaces as well as for the device.
Step 4	**mpls label protocol** [**ldp** | **tdp** | **both**] **Example:** `Device(config)# mpls label protocol ldp`	Configures the use of LDP on all interfaces. • The keywords that are available depend on the hardware platform. • If you set all interfaces globally to LDP, you can override specific interfaces with either the **tdp** or **both** keyword by specifying the command in interface configuration mode.
Step 5	**mpls ldp router-id** *interface* [**force**] **Example:** `Device(config)# mpls ldp router-id pos 2/0/0`	Specifies the preferred interface for determining the LDP router ID.
Step 6	**exit** **Example:** `Device(config)# exit`	Exits global configuration mode and enters privileged EXEC mode.
Step 7	**show mpls ldp discovery** [**all** | **detail** | **vrf** *vpn-name*] **Example:** `Device# show mpls ldp discovery`	Displays the LDP identifier for the local device.

Example

The following example assigns interface pos 2/0/0 as the LDP router ID:

```
Device> enable
Device# configure terminal
Device(config)# mpls ip
Device(config)# mpls label protocol ldp
Device(config)# mpls ldp router-id pos 2/0/0 force
```

The following example displays the LDP router ID (10.15.15.15):

```
Device# show mpls ldp discovery
Local LDP Identifier:
    10.15.15.15:0
Discovery Sources:
```

```
Interfaces:
    FastEthernet0/3/0 (ldp): xmit/recv
        LDP Id: 10.14.14.14:0
```

Preserving QoS Settings with MPLS LDP Explicit Null

Normally, the Label Distribution Protocol (LDP) advertises an Implicit Null label for directly connected routes. The Implicit Null label causes the second last (penultimate) label switched router (LSR) to remove the Multiprotocol Label Switching (MPLS) header from the packet. In this case, the penultimate LSR and the last LSR do not have access to the quality of service (QoS) values that the packet carried before the MPLS header was removed. To preserve the QoS values, you can configure the LSR to advertise an explicit NULL label (a label value of zero). The LSR at the penultimate hop forwards MPLS packets with a NULL label instead of forwarding IP packets.

Note An explicit NULL label is not needed when the penultimate hop receives MPLS packets with a label stack that contains at least two labels and penultimate hop popping is performed. In that case, the inner label can still carry the QoS value needed by the penultimate and edge LSR to implement their QoS policy.

When you issue the **mpls ldp explicit-null** command, Explicit Null is advertised in place of Implicit Null for directly connected prefixes.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls ip**
4. **mpls label protocol** [**ldp** | **tdp** | **both**]
5. **interface** *type number*
6. **mpls ip**
7. **exit**
8. **mpls ldp explicit-null** [**for** *prefix-acl* | **to** *peer-acl* | **for** *prefix-acl* **to** *peer-acl*]
9. **exit**
10. **show mpls forwarding-table** [*network* {*mask* | *length*} | **labels** *label* [*-label*] | **interface** *interface* | *next-hop address* | **lsp-tunnel** [*tunnel-id*]] [**vrf** *vpn-name* [**detail**]

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.

	Command or Action	Purpose
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**mpls ip** **Example:** `Device(config)# mpls ip`	Configures MPLS hop-by-hop forwarding globally. • The **mpls ip** command is enabled by default; you do not have to specify this command. • Globally enabling MPLS forwarding does not enable it on the device interfaces. You must enable MPLS forwarding on the interfaces as well as for the device.
Step 4	**mpls label protocol** [**ldp** | **tdp** | **both**] **Example:** `Device(config)# mpls label protocol ldp`	Configures the use of LDP on all interfaces. • The keywords that are available depend on the hardware platform. • If you set all interfaces globally to LDP, you can override specific interfaces with either the **tdp** or **both** keyword by specifying the command in interface configuration mode.
Step 5	**interface** *type number* **Example:** `Device(config)# interface atm 2/2/0`	Specifies the interface to be configured and enters interface configuration mode.
Step 6	**mpls ip** **Example:** `Device(config-if)# mpls ip`	Configures MPLS hop-by-hop forwarding on the interface. • You must enable MPLS forwarding on the interfaces as well as for the device.
Step 7	**exit** **Example:** `Device(config-if)# exit`	Exits interface configuration mode and enters global configuration mode.
Step 8	**mpls ldp explicit-null** [**for** *prefix-acl* | **to** *peer-acl* | **for** *prefix-acl* **to** *peer-acl*] **Example:** `Device(config)# mpls ldp explicit-null`	Advertises an Explicit Null label in situations where it would normally advertise an Implicit Null label.
Step 9	**exit** **Example:** `Device(config)# exit`	Exits global configuration mode and enter privileged EXEC mode.

	Command or Action	Purpose
Step 10	**show mpls forwarding-table** [*network* {*mask* | *length*} | **labels** *label* [*-label*] | **interface** *interface* | *next-hop address* | **lsp-tunnel** [*tunnel-id*]] [**vrf** *vpn-name* [**detail**] **Example:** `Device# show mpls forwarding-table`	Verifies that MPLS packets are forwarded with an explicit-null label (value of 0).

Examples

Enabling explicit-null on an egress LSR causes that LSR to advertise the explicit-null label to all adjacent MPLS devices.

```
Device# configure terminal
Device(config)# mpls ldp explicit-null
```

If you issue the **show mpls forwarding-table** command on an adjacent device, the output shows that MPLS packets are forwarded with an explicit-null label (value of 0). In the following example, the second column shows that entries have outgoing labels of 0, where once they were marked “Pop label”.

```
Device# show mpls forwarding-table

Local  Outgoing    Prefix           Bytes label Outgoing   Next Hop
label  label or VC or Tunnel Id     switched   interface
19     Pop tag     10.12.12.12/32   0          Fa2/1/0    172.16.0.1
22     0           10.14.14.14/32   0          Fa2/0/0    192.168.0.2
23     0           172.24.24.24/32  0          Fa2/0/0    192.168.0.2
24     0           192.168.0.0/8    0          Fa2/0/0    192.168.0.2
25     0           10.15.15.15/32   0          Fa2/0/0    192.168.0.2
26     0           172.16.0.0/8     0          Fa2/0/0    192.168.0.2
27     25          10.16.16.16/32   0          Fa2/0/0    192.168.0.22
28     0           10.34.34.34/32   0          Fa2/0/0    192.168.0.2
```

Enabling explicit-null and specifying the **for** keyword with a standard access control list (ACL) changes all adjacent MPLS devices' tables to swap an explicit-null label for only those entries specified in the access-list. In the following example, an access-list is created that contains the 10.24.24.24/32 entry. Explicit null is configured and the access list is specified.

```
Device# configure terminal
Device(config)# mpls label protocol ldp
Device(config)# access-list 24 permit host 10.24.24.24
Device(config)# mpls ldp explicit-null for 24
```

If you issue the **show mpls forwarding-table** command on an adjacent device, the output shows that the only the outgoing labels for the addresses specified (172.24.24.24/32) change from Pop label to 0. All other Pop label outgoing labels remain the same.

```
Device# show mpls forwarding-table

Local  Outgoing    Prefix           Bytes label Outgoing   Next Hop
label  label or VC or Tunnel Id     switched   interface
19     Pop tag     10.12.12.12/32   0          Fa2/1/0    172.16.0.1
22     0           10.14.14.14/32   0          Fa2/0/0    192.168.0.2
```

```
23     0           172.24.24.24/32   0          Fa2/0/0    192.168.0.2
24     0           192.168.0.0/8     0          Fa2/0/0    192.168.0.2
25     0           10.15.15.15/32    0          Fa2/0/0    192.168.0.2
26     0           172.16.0.0/8      0          Fa2/0/0    192.168.0.2
27     25          10.16.16.16/32    0          Fa2/0/0    192.168.0.22
28     0           10.34.34.34/32    0          Fa2/0/0    192.168.0.2
```

Enabling explicit null and adding the**to** keyword and an access list enables you to advertise explicit-null labels to only those adjacent devices specified in the access-list. To advertise explicit-null to a particular device, you must specify the device's LDP ID in the access-list.

In the following example, an access-list contains the 10.15.15.15/32 entry, which is the LDP ID of an adjacent MPLS device. The device that is configured with explicit null advertises explicit-null labels only to that adjacent device.

```
Device# show mpls ldp discovery

Local LDP Identifier:
    10.15.15.15:0
Discovery Sources:
    Interfaces:
        FastEthernet2/0/0(ldp): xmit/recv
            TDP Id: 10.14.14.14:0
Device# configure terminal
Device(config)# mpls label protocol ldp
Device(config)# access-list 15 permit host 10.15.15.15
Device(config)# mpls ldp explicit-null to 15
```

If you issue the **show mpls forwarding-table** command, the output shows that explicit null labels are going only to the device specified in the access list.

```
Device# show mpls forwarding-table

Local  Outgoing    Prefix            Bytes label Outgoing   Next Hop
label  label or VC or Tunnel Id      switched   interface
19     Pop tag     10.12.12.12/32    0          Fa2/1/0    172.16.0.1
22     0           10.14.14.14/32    0          Fa2/0/0    192.168.0.2
23     0           172.24.24.24/32   0          Fa2/0/0    192.168.0.2
24     0           192.168.0.0/8     0          Fa2/0/0    192.168.0.2
25     0           10.15.15.15/32    0          Fa2/0/0    192.168.0.2
26     0           172.16.0.0/8      0          Fa2/0/0    192.168.0.2
27     25          10.16.16.16/32    0          Fa2/0/0    192.168.0.22
28     0           10.34.34.34/32    0          Fa2/0/0    192.168.0.2
```

Enabling explicit-null with both the **for** and **to** keywords enables you to specify which routes to advertise with explicit-null labels and to which adjacent devices to advertise these explicit-null labels.

```
Device# show access 15

Standard IP access list 15
     permit 10.15.15.15 (7 matches)
Device# show access 24

Standard IP access list 24
     permit 10.24.24.24 (11 matches)
Device# configure terminal
Device(config)# mpls label protocol ldp
Device(config)# mpls ldp explicit-null for 24 to 15
```

If you issue the **show mpls forwarding-table** command, the output shows that it receives explicit null labels for 10.24.24.24/32.

```
Device# show mpls forwarding-table

Local  Outgoing    Prefix            Bytes label Outgoing      Next Hop
label  label or VC or Tunnel Id      switched   interface
17     0  <---     10.24.24.24/32     0          Fe2/0/0        172.16.0.1
20     Pop tag     172.16.0.0/8       0          Fe2/0/0        172.16.0.1
21     20          10.12.12.12/32     0          Fe2/0/0        172.16.0.1
22     16          10.0.0.0/8         0          Fe2/0/0        172.16.0.1
23     21          10.13.13.13/32     0          Fe2/0/0        172.16.0.1
25     Pop tag     10.14.14.14/32     0          Fe2/0/0        172.16.0.1
27     Pop tag     192.168.0.0/8      0          Fe2/0/0        172.16.0.1
28     25          10.16.16.16/32     0          Fe2/0/0        172.16.0.1
29     Pop tag     192.168.34.34/32   0          Fe2/0/0        172.16.0.1
```

Protecting Data Between LDP Peers with MD5 Authentication

You can enable authentication between two Label Distribution Protocol (LDP) peers, which verifies each segment sent on the TCP connection between the peers. You must configure authentication on both LDP peers using the same password; otherwise, the peer session is not established.

Authentication uses the Message Digest 5 (MD5) algorithm to verify the integrity of the communication and authenticate the origin of the message.

To enable authentication, issue the **mpls ldp neighbor password** command. This causes the device to generate an MD5 digest for every segment sent on the TCP connection and check the MD5 digest for every segment received from the TCP connection.

When you configure a password for an LDP neighbor, the device tears down existing LDP sessions and establishes new sessions with the neighbor.

If a device has a password configured for a neighbor, but the neighboring device does not have a password configured, a message such as the following appears on the console who has a password configured while the two devices attempt to establish an LDP session. The LDP session is not established.

%TCP-6-BADAUTH: No MD5 digest from [peer's IP address](11003) to [local device's IP address](646)

Similarly, if the two devices have different passwords configured, a message such as the following appears on the console. The LDP session is not established.

%TCP-6-BADAUTH: Invalid MD5 digest from [peer's IP address](11004) to [local device's IP address](646)

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls ip**
4. **mpls label protocol** [**ldp** | **tdp** | **both**]
5. **mpls ldp neighbor** [**vrf** *vpn-name*] *ip-address* [**password** [**0**-**7**] *password-string*]
6. **exit**
7. **show mpls ldp neighbor** [[**vrf** *vpn-name*] [*address* | *interface*] [**detail**] | **all**]

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**mpls ip** **Example:** `Device(config)# mpls ip`	Configures MPLS hop-by-hop forwarding globally. • The **mpls ip** command is enabled by default; you do not have to specify this command. • Globally enabling MPLS forwarding does not enable it on the device interfaces. You must enable MPLS forwarding on the interfaces as well as for the device.
Step 4	**mpls label protocol** [**ldp** | **tdp** | **both**] **Example:** `Device(config)# mpls label protocol ldp`	Configures the use of LDP on all interfaces. • The keywords that are available depend on the hardware platform. • If you set all interfaces globally to LDP, you can override specific interfaces with either the **tdp** or **both** keyword by specifying the command in interface configuration mode.
Step 5	**mpls ldp neighbor** [**vrf** *vpn-name*] *ip-address* [**password** [**0-7**] *password-string*] **Example:** `Device(config)# mpls ldp neighbor 172.27.0.15 password onethirty9`	Specifies authentication between two LDP peers.
Step 6	**exit** **Example:** `Device(config)# exit`	Exits global configuration mode and enters privileged EXEC mode.
Step 7	**show mpls ldp neighbor** [[**vrf** *vpn-name*] [*address* | *interface*] [**detail**] | **all**] **Example:**	Displays the status of LDP sessions. If the passwords have been set on both LDP peers and the passwords match, the **show mpls ldp neighbor** command displays that the LDP session was successfully established.

	Command or Action	Purpose
	`Device# show mpls ldp neighbor detail`	

Examples

The following example configures a device with the password cisco:

```
Device> enable
Device# configure terminal
Device(config)# mpls ip
Device(config)# mpls label protocol ldp
Device(config)# mpls ldp neighbor 10.1.1.1 password cisco
Device(config)# exit
```

The following example shows that the LDP session between devices was successfully established:

```
Device# show mpls ldp neighbor

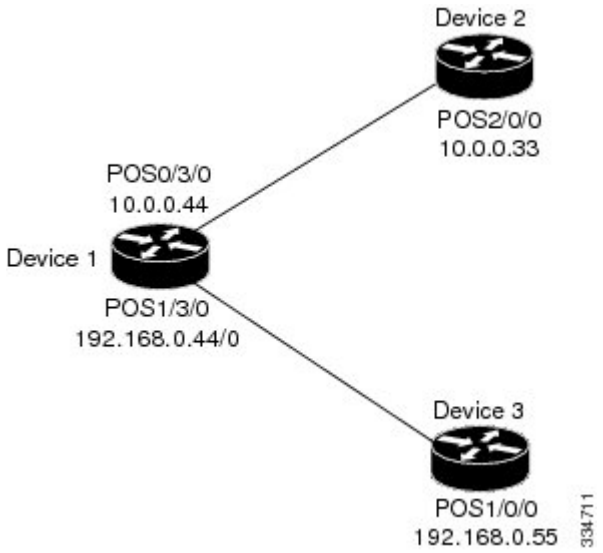
Peer LDP Ident: 10.1.1.2:0; Local LDP Ident 10.1.1.1:0
TCP connection: 10.1.1.2.11118 - 10.1.1.1.646
State: Oper; Msgs sent/rcvd: 12/11; Downstream
Up time: 00:00:10
LDP discovery sources:
FastEthernet1/0/0, Src IP addr: 10.20.10.2
Addresses bound to peer LDP Ident:
10.1.1.2    10.20.20.1    10.20.10.2
```

The following **show mpls ldp neighbor detail** command shows that MD5 is used for the LDP session.

```
Device# show mpls ldp neighbor 10.0.0.21 detail

    Peer LDP Ident: 10.0.0.21:0; Local LDP Ident 10.0.0.22:0
        TCP connection: 10.0.0.21.646 - 10.0.0.22.14709; MD5 on
        State: Oper; Msgs sent/rcvd: 1020/1019; Downstream; Last TIB rev sent 2034
        Up time: 00:00:39; UID: 3; Peer Id 1;
        LDP discovery sources:
          FastEthernet1/1/0; Src IP addr: 172.16.1.1
            holdtime: 15000 ms, hello interval: 5000 ms
        Addresses bound to peer LDP Ident:
          10.0.0.21       10.0.38.28       10.88.88.2      172.16.0.1
          172.16.1.1
        Peer holdtime: 180000 ms; KA interval: 60000 ms; Peer state: estab
```

Configuration Examples for MPLS Label Distribution Protocol



Example: Configuring Directly Connected MPLS LDP Sessions

The figure below shows a sample network for configuring directly connected Label Distribution Protocol (LDP) sessions.

This example configures the following:

- Multiprotocol Label Switching (MPLS) hop-by-hop forwarding for the POS links between Device 1 and Device 2 and between Device 1 and Device 3.
- LDP for label distribution between Device 1 and Device 2.
- LDP for label distribution between Device 1 and Device 3.
- A loopback interface and IP address for each LSR that can be used as the LDP router ID.

Figure 43: Configuration of MPLS LDP

Note The configuration examples below show only the commands related to configuring LDP for Device 1, Device 2, and Device 3 in the sample network shown in the figure above.

Device 1 Configuration

```
ip cef distributed                                  !Assumes R1 supports distributed CEF
interface Loopback0                                 !Loopback interface for LDP ID.
ip address 172.16.0.11 255.255.255.255
!
interface POS0/3/0
ip address 10.0.0.44 255.0.0.0
mpls ip                                              !Enable hop-by-hop MPLS forwarding
mpls label protocol ldp
!
interface POS1/3/0

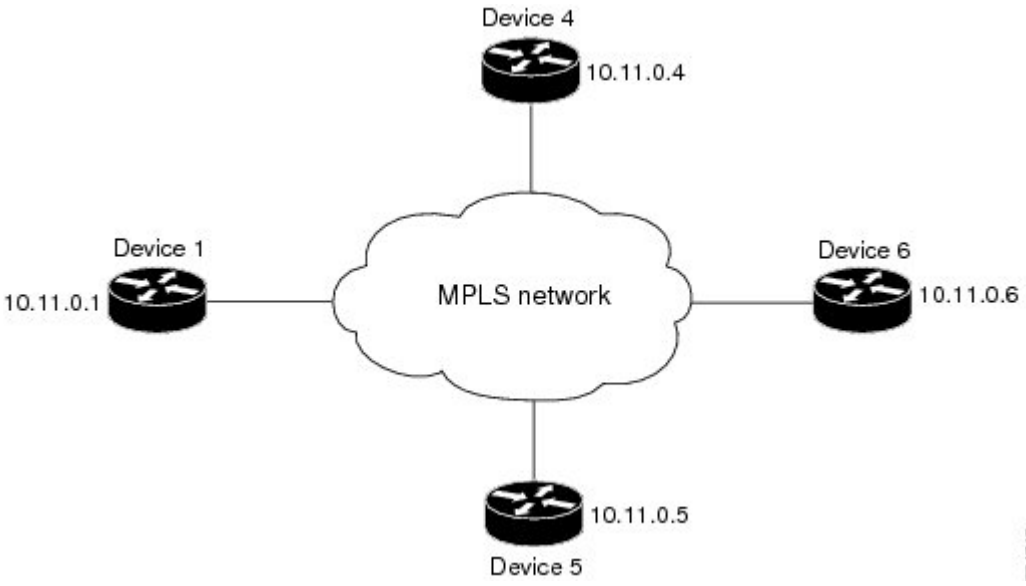
ip address 172.16.0.33 255.255.255.255
!
interface POS1/0/0
ip address 192.168.0.55 255.0.0.0
mpls ip                                                 !Enable hop-by-hop MPLS forwarding
mpls label protocol ldp
```

The LDP configuration for Device 1 uses the **mpls label protocol ldp** command in interface configuration mode. To specify LDP for all interfaces, use the **mpls label protocol ldp** command in global configuration mode without any interface **mpls label protocol** commands.



The configuration of Device 2 also uses the **mpls label protocol ldp** command in interface configuration mode. To specify LDP for all interfaces, use the **mpls label protocol ldp** command in global configuration mode without any interface **mpls label protocol** commands.

Configuring the **mpls ip** command on an interface triggers the transmission of discovery Hello messages for the interface.

Example: Establishing Nondirectly Connected MPLS LDP Sessions

The following examples illustrate the configuration of platforms for Multiprotocol Label Switching (MPLS) Label Distribution Protocol (LDP) nondirectly connected sessions using the sample network shown in the figure below. Note that Devices 1, 4, 5, and 6 in this sample network are not directly connected to each other.

Figure 44: Sample Network for Configuring LDP for Targeted Sessions

The configuration example shows the following:

- Targeted sessions between Devices 1 and 4 use LDP. Devices 1 and 4 are both active.
- Targeted sessions between Devices 1 and 6 use LDP. Device 1 is active and Device 6 is passive.
- Targeted sessions between Devices 1 and 5 use LDP. Device 5 is active.

These examples assume that the active ends of the nondirectly connected sessions are associated with tunnel interfaces, such as MPLS traffic engineering tunnels. They show only the commands related to configuring LDP targeted sessions. The examples do not show configuration of the applications that initiate the targeted sessions.

Device 1 Configuration

Tunnel interfaces Tunnel14 and Tunnel16 specify LDP for targeted sessions associated with these interfaces. The targeted session for Device 5 requires LDP. The **mpls label protocol ldp** command in global configuration mode makes it unnecessary to explicitly specify LDP as part of the configuration from the Tunnel14 and Tunnel16.

```
ip cef distributed             !Device1 supports distributed CEF
mpls label protocol ldp       !Use LDP for all interfaces
interface Loopback0            !Loopback interface for LDP ID.
ip address 10.25.0.11 255.255.255.255
interface Tunnel14             !Tunnel to Device 4 requiring label distribution
tunnel destination 10.11.0.4  !Tunnel endpoint is Device 4
mpls ip                        !Enable hop-by-hop forwarding on the interface
interface Tunnel15             !Tunnel to Device 5 requiring label distribution
tunnel destination 10.11.0.5  !Tunnel endpoint is Device 5
mpls label protocol ldp        !Use LDP for session with Device 5
mpls ip                        !Enable hop-by-hop forwarding on the interface
interface Tunnel16             !Tunnel to Device 6 requiring label distribution
tunnel destination 10.11.0.6  !Tunnel endpoint is Device 6
mpls ip                        !Enable hop-by-hop forwarding on the interface
```

Device 4 Configuration

The **mpls label protocol ldp** command in global configuration mode makes it unnecessary to explicitly specify LDP as part of the configuration for the Tunnel41 targeted session with Device 1.

```
ip cef distributed           !Device 4 supports distributed CEF
mpls label protocol ldp       !Use LDP for all interfaces
interface Loopback0           !Loopback interface for LDP ID.
ip address 10.25.0.44 255.255.255.255
interface Tunnel41            !Tunnel to Device 1 requiring label distribution
tunnel destination 10.11.0.1 !Tunnel endpoint is Device 1
mpls ip                        !Enable hop-by-hop forwarding on the interface
```

Device 5 Configuration

Device 5 uses LDP for all targeted sessions. Therefore, its configuration includes the **mpls label protocol ldp** command.

```
ip cef                       !Device 5 supports CEF
mpls label protocol ldp       !Use LDP for all interfaces
interface Loopback0          !Loopback interface for LDP ID.
ip address 10.25.0.55 255.255.255.255
interface Tunnel51             !Tunnel to Device 1 requiring label distribution
tunnel destination 10.11.0.1  !Tunnel endpoint is Device 1
mpls ip                        !Enable hop-by-hop forwarding on the interface
```

Device 6 Configuration

By default, a device cannot be a passive neighbor in targeted sessions. Therefore, Device 1, Device 4, and Device 5 are active neighbors in any targeted sessions. The **mpls ldp discovery targeted-hello accept** command permits Device 6 to be a passive target in targeted sessions with Device 1. Device 6 can also be an active neighbor in targeted sessions, although the example does not include such a configuration.

```
ip cef distributed                       !Device 6 supports distributed CEF
interface Loopback0                      !Loopback interface for LDP ID.
ip address 10.25.0.66 255.255.255.255
mpls ldp discovery targeted-hellos accept from LDP_SOURCES
                                         !Respond to requests for targeted hellos
                                         !from sources permitted by acl LDP_SOURCES
ip access-list standard LDP_SOURCES      !Define acl for targeted hello sources.
permit 10.11.0.1                        !Accept targeted hello request from Device 1.
deny any                                 !Deny requests from other sources.
```

CHAPTER 35

MPLS LDP Session Protection

The MPLS LDP Session Protection feature provides faster Label Distribution Protocol (LDP) convergence when a link recovers following an outage. MPLS LDP Session Protection protects an LDP session between directly connected neighbors or an LDP session established for a traffic engineering (TE) tunnel.

- Prerequisites for MPLS LDP Session Protection, on page 593
- Restrictions for MPLS LDP Session Protection, on page 593
- Information About MPLS LDP Session Protection, on page 594
- How to Configure MPLS LDP Session Protection, on page 595
- Configuration Examples for MPLS LDP Session Protection, on page 599
- Additional References, on page 602
- Feature Information for MPLS LDP Session Protection, on page 603

Prerequisites for MPLS LDP Session Protection

Label switch routers (LSRs) must be able to respond to Label Distribution Protocol (LDP) targeted hellos. Otherwise, the LSRs cannot establish a targeted adjacency. All devices that participate in MPLS LDP Session Protection must be enabled to respond to targeted hellos. Both neighbor devices must be configured for session protection or one device must be configured for session protection and the other device must be configured to respond to targeted hellos.

Restrictions for MPLS LDP Session Protection

The MPLS LDP Session Protection feature is not supported under the following circumstances:

- With extended access lists
- With LC-ATM devices
- With Tag Distribution Protocol (TDP) sessions

Information About MPLS LDP Session Protection

How MPLS LDP Session Protection Works

MPLS LDP Session Protection maintains Label Distribution Protocol (LDP) bindings when a link fails. MPLS LDP sessions are protected through the use of LDP hello messages. When you enable Multiprotocol Label Switching (MPLS) LDP, the label switch routers (LSRs) send messages to find other LSRs with which they can create LDP sessions.

If the LSR is one hop from its neighbor, it is directly connected to its neighbor. The LSR sends out LDP Hello messages as User Datagram Protocol (UDP) packets to all the devices on the subnet. The hello message is called an LDP Link Hello. A neighboring LSR responds to the hello message, and the two devices begin to establish an LDP session.

If the LSR is more than one hop from its neighbor, it is not directly connected to its neighbor. The LSR sends out a directed hello message as a UDP packet but as a unicast message specifically addressed to that specific LSR. The hello message is called an LDP Targeted Hello. The nondirectly connected LSR responds to the Hello message and the two devices establish an LDP session. (If the path between two LSRs has been traffic engineered and has LDP enabled, the LDP session between them is called a targeted session.)

MPLS LDP Session Protection uses LDP Targeted Hellos to protect LDP sessions. For example, two directly connected devices have LDP enabled and can reach each other through alternate IP routes in the network. An LDP session that exists between two devices is called an LDP Link Hello Adjacency. When MPLS LDP Session Protection is enabled, an LDP Targeted Hello Adjacency is also established for the LDP session. If the link between the two devices fails, the LDP Link Adjacency also fails. However, if the LDP peer is still reachable through IP, the LDP session stays up, because the LDP Targeted Hello Adjacency still exists between the devices. When the directly connected link recovers, the session does not need to be reestablished, and LDP bindings for prefixes do not need to be relearned.

MPLS LDP Session Protection Customization

You can modify MPLS LDP Session Protection by using keywords in the **mpls ldp session protection** command. The following sections explain how to customize the feature:

How Long an LDP Targeted Hello Adjacency Should Be Retained

The default behavior of the **mpls ldp session protection** command allows a Label Distribution Protocol (LDP) Targeted Hello Adjacency to exist indefinitely following the loss of an LDP Link Hello Adjacency. You can issue the **duration** keyword to specify the number of seconds that the LDP Targeted Hello Adjacency is retained after the loss of the LDP Link Hello Adjacency. When the link is lost, a timer starts. If the timer expires, the LDP Targeted Hello Adjacency is removed.

Which Devices Should Have MPLS LDP Session Protection

The default behavior of the **mpls ldp session protection** command allows MPLS LDP Session Protection for all neighbor sessions. You can issue either the **vrf** or **for** keyword to limit the number of neighbor sessions that are protected:

- You can use the **vrf** keyword to select which virtual routing and forwarding (VRF) instance is to be protected if the device is configured with at least one virtual private network (VPN) VRF instance. You

cannot specify more than one VRF with the **mpls ldp session protection** command. To specify multiple VRFs, issue the command multiple times.

- You can create an access list that includes several peer devices. You can specify that access list with the **for** keyword to enable LDP Session Protection for the peer devices in the access control list.

How to Configure MPLS LDP Session Protection

Enabling MPLS LDP Session Protection

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip cef** [**distributed**]
4. **interface loopback** *number*
5. **ip address** *prefix mask*
6. **exit**
7. **interface** *type number*
8. **mpls ip**
9. **mpls label protocol** [**ldp** | **tdp** | **both**]
10. **exit**
11. **mpls ldp session protection** [**vrf** *vpn-name*] [**for** *acl*] [**duration** {**infinite** | *seconds*}]
12. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**ip cef** [**distributed**] **Example:** `Device(config)# ip cef distributed`	Configures distributed Cisco Express Forwarding or Cisco Express Forwarding.

	Command or Action	Purpose
Step 4	**interface loopback** *number* **Example:** `Device(config)# interface Loopback 0`	Configures a loopback interface and enters interface configuration mode.
Step 5	**ip address** *prefix mask* **Example:** `Device(config-if)# ip address 10.25.0.11 255.255.255.255`	Assigns an IP address to the loopback interface.
Step 6	**exit** **Example:** `Device(config-if) exit`	Returns to global configuration mode.
Step 7	**interface** *type number* **Example:** `Device(config)# interface POS 0/3/0`	Specifies the interface to configure and enters interface configuration mode.
Step 8	**mpls ip** **Example:** `Device(config-if)# mpls ip`	Configures MPLS hop-by-hop forwarding for the specified interface.
Step 9	**mpls label protocol** [**ldp** | **tdp** | **both**] **Example:** `Device(config-if)# mpls label protocol ldp`	Configures the use of LDP on a specific interface or on all interfaces. • The keywords that are available depend on the hardware platform. • If you set all interfaces globally to LDP, you can override specific interfaces with either the **tdp** or **both** keyword by specifying the command in interface configuration mode.
Step 10	**exit** **Example:** `Device(config-if)# exit`	Returns to global configuration mode.
Step 11	**mpls ldp session protection** [**vrf** *vpn-name*] [**for** *acl*] [**duration** {**infinite** | *seconds*}] **Example:** `Device(config)# mpls ldp session protection`	Enables MPLS LDP session protection. • The **vrf** *vpn-name* keyword and argument protects Label Distribution Protocol (LDP) sessions for a specified virtual routing and forwarding (VRF) interface.

	Command or Action	Purpose
		• The **for** *acl* keyword and argument specifies a standard IP access control list (ACL) of prefixes to be protected. • The **duration** keyword specifies how long the device should retain the LDP Targeted Hello Adjacency following the loss of the LDP Link Hello Adjacency. • The **infinite** keyword specifies that the LDP Targeted Hello Adjacency should be retained forever after a link is lost. • The *seconds* argument specifies the time in seconds that the LDP Targeted Hello Adjacency should be retained after a link is lost. The range is 30 to 2,147,483 seconds. The **mpls ldp session protection** command entered without a keyword protects all LDP sessions.
Step 12	**exit** **Example:** `Device(config)# exit`	Returns to privileged EXEC mode.

Troubleshooting Tips

Use the **clear mpls ldp neighbor** command if you need to terminate a Label Distribution Protocol (LDP) session after a link goes down. This is useful for situations where the link needs to be taken out of service or needs to be connected to a different neighbor.

To enable the display of events related to MPLS LDP Session Protection, use the **debug mpls ldp session protection** command.

Verifying MPLS LDP Session Protection

SUMMARY STEPS

1. **enable**
2. **show mpls ldp discovery**
3. **show mpls ldp neighbor**
4. **show mpls ldp neighbor detail**
5. **exit**

DETAILED STEPS

Procedure

Step 1 **enable**

Enables privileged EXEC mode. Enter your password, if prompted.

Example:

```
Device> enable
Device#
```

Step 2 **show mpls ldp discovery**

Verifies that the output contains the term xmit/recv for the peer device.

Example:

```
Device# show mpls ldp discovery

 Local LDP Identifier:
    10.0.0.5:0
    Discovery Sources:
    Interfaces:
        ATM50/1/0.5 (ldp): xmit/recv
            LDP Id: 10.0.0.1:0
    Targeted Hellos:
        10.0.0.5 -> 10.0.0.3 (ldp): active, xmit/recv
            LDP Id: 10.0.0.3:0
```

Step 3 **show mpls ldp neighbor**

Verifies that the targeted hellos are active.

Example:

```
Device# show mpls ldp neighbor

Peer LDP Ident: 10.0.0.3:0; Local LDP Ident 10.0.0.5:0
TCP connection: 10.0.0.3.646 - 10.0.0.5.11005
State: Oper; Msgs sent/rcvd: 1453/1464; Downstream
Up time: 21:09:56
LDP discovery sources:
 Targeted Hello 10.0.0.5 -> 10.0.0.3, active
Addresses bound to peer LDP Ident:
 10.3.104.3       10.0.0.2        10.0.0.3
```

Step 4 **show mpls ldp neighbor detail**

Verifies that the MPLS LDP Session Protection state is Ready or Protecting. If the second last line of the output shows Incomplete, the Targeted Hello Adjacency is not up yet.

Example:

```
Device# show mpls ldp neighbor detail

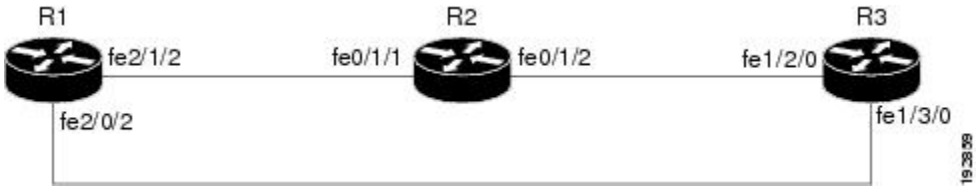
    Peer LDP Ident: 10.16.16.16:0; Local LDP Ident 10.15.15.15:0
        TCP connection: 10.16.16.16.11013 - 10.15.15.15.646
```

```
State: Oper; Msgs sent/rcvd: 53/51; Downstream; Last TIB rev sent 74
Up time: 00:11:32; UID: 1; Peer Id 0;
LDP discovery sources:
  Targeted Hello 10.15.15.15 -> 10.16.16.16, active, passive;
    holdtime: infinite, hello interval: 10000 ms
Addresses bound to peer LDP Ident:
  10.0.0.2        10.16.16.16     10.101.101.101 11.0.0.1
Peer holdtime: 180000 ms; KA interval: 60000 ms; Peer state: estab
Clients: Dir Adj Client
LDP Session Protection enabled, state: Protecting
    duration: infinite
```

Step 5 **exit**

Returns to user EXEC mode.

Example:



```
Device# exit
Device>
```

Configuration Examples for MPLS LDP Session Protection

Example: Configuring MPLS LDP Session Protection

The figure below shows a sample configuration for MPLS LDP Session Protection.

Figure 45: MPLS LDP Session Protection Example

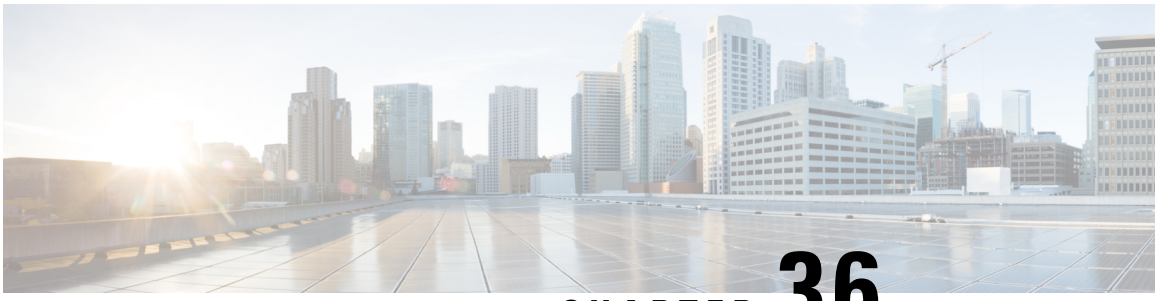
Feature Information for MPLS LDP Session Protection



The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Feature Information for MPLS LDP Session Protection

Table 91: Feature Information for MPLS LDP Session Protection

Feature Name	Releases	Feature Information
MPLS LDP Session Protection		The MPLS LDP Session Protection feature provides faster Label Distribution Protocol (LDP) convergence when a link recovers following an outage. MPLS LDP Session Protection protects an LDP session between directly connected neighbors or an LDP session established for a traffic engineering (TE) tunnel.

CHAPTER 36

MPLS LDP Autoconfiguration

The MPLS LDP Autoconfiguration feature enables you to globally configure Label Distribution Protocol (LDP) on every interface associated with a specified Interior Gateway Protocol (IGP) instance.

- Restrictions for MPLS LDP Autoconfiguration , on page 605
- Information About MPLS LDP Autoconfiguration, on page 606
- How to Configure MPLS LDP Autoconfiguration, on page 606
- Configuration Examples for MPLS LDP Autoconfiguration, on page 614
- Additional References, on page 615
- Feature Information for MPLS LDP Autoconfiguration, on page 616

Restrictions for MPLS LDP Autoconfiguration

- If the Label Distribution Protocol (LDP) is disabled globally, the **mpls ldp autoconfig** command fails and generates a console message explaining that LDP must first be enabled globally by using the **mpls ip** global configuration command.
- If the **mpls ldp autoconfig** command is configured for an IGP instance, you cannot enter the **no mpls ip** global configuration command. To disable LDP, you must first issue the **no mpls ldp autoconfig** command.
- For interfaces running Intermediate System-to-Intermediate System (IS-IS) processes, you can enable Multiprotocol Label Switching (MPLS) for each interface, using the router mode command **mpls ldp autoconfig** or the **mpls ldp igp autoconfig** interface configuration command.
- You specify that the default label distribution protocol is LDP for a device or for an interface. Tag Distribution Protocol (TDP) is not supported.
- The MPLS LDP Autoconfiguration feature is not supported on traffic engineering tunnel interfaces.

Information About MPLS LDP Autoconfiguration

MPLS LDP Autoconfiguration on OSPF and IS-IS Interfaces

The MPLS LDP Autoconfiguration feature enables you to globally enable Label Distribution Protocol (LDP) on every interface associated with an Interior Gateway Protocol (IGP) instance. This feature is supported on Open Shortest Path First (OSPF) and Intermediate System-to-Intermediate System (IS-IS) IGPs. It provides a means to block LDP from being enabled on interfaces that you do not want enabled. The goal of the MPLS LDP Autoconfiguration feature is to make configuration easier, faster, and error free.

You issue the **mpls ldp autoconfig** command to enable LDP on each interface that is running an OSPF or IS-IS process. If you do not want some of the interfaces to have LDP enabled, you can issue the **no mpls ldp igp autoconfig** command on those interfaces.

How to Configure MPLS LDP Autoconfiguration

Configuring MPLS LDP Autoconfiguration with OSPF Interfaces

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls ip**
4. **mpls label protocol ldp**
5. **interface** *type number*
6. **ip address** *prefix mask*
7. **mpls ip**
8. **exit**
9. **router ospf** *process-id*
10. **network** *ip-address wildcard-mask* **area** *area-id*
11. **mpls ldp autoconfig** [**area** *area-id*]
12. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.

	Command or Action	Purpose
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**mpls ip** **Example:** `Device(config)# mpls ip`	Globally enables hop-by-hop forwarding.
Step 4	**mpls label protocol ldp** **Example:** `Device(config)# mpls label protocol ldp`	Specifies the Label Distribution Protocol (LDP) as the default protocol.
Step 5	**interface** *type number* **Example:** `Device(config)# interface gigabitethernet 0/0/0`	Specifies the interface to configure, and enters interface configuration mode.
Step 6	**ip address** *prefix mask* **Example:** `Device(config-if)# ip address 10.25.0.11 255.255.255.255`	Assigns an IP address to the interface.
Step 7	**mpls ip** **Example:** `Device(config-if)# mpls ip`	Enables hop-by-hop forwarding on the interface.
Step 8	**exit** **Example:** `Device(config-if)# exit`	Returns to global configuration mode.
Step 9	**router ospf** *process-id* **Example:** `Device(config)# router ospf 1`	Enables Open Shortest Path First (OSPF) routing, and enters router configuration mode.
Step 10	**network** *ip-address wildcard-mask* **area** *area-id* **Example:** `Device(config-router)# network 10.0.0.0 0.255.255.255 area 3`	Defines an interface on which OSPF runs and defines the area ID for that interface.

	Command or Action	Purpose
Step 11	**mpls ldp autoconfig** [**area** *area-id*] **Example:** `Device(config-router)# mpls ldp autoconfig area 3`	Enables the MPLS LDP Autoconfiguration feature to enable LDP on interfaces belonging to the OSPF process. • If no area is specified, the command applies to all interfaces associated with the OSPF process. If an area ID is specified, then only interfaces associated with that OSPF area are enabled with LDP.
Step 12	**end** **Example:** `Device(config-router)# end`	Returns to privileged EXEC mode.

Disabling MPLS LDP Autoconfiguration from Selected OSPF Interfaces

When you issue the **mpls ldp autoconfig** command, all the interfaces that belong to an Open Shortest Path First (OSPF) area are enabled for the Label Distribution Protocol (LDP). To remove LDP from some interfaces, use the **no mpls ldp igp autoconfig** command on those interfaces. The following configuration steps show how to disable LDP from some of the interfaces after they were configured with the MPLS LDP Autoconfiguration feature with the **mpls ldp autoconfig** command.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type number*
4. **no mpls ldp igp autoconfig**
5. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.

	Command or Action	Purpose
Step 3	**interface** *type number* **Example:** `Device(config)# interface POS 3/0`	Specifies the interface to configure and enters interface configuration mode.
Step 4	**no mpls ldp igp autoconfig** **Example:** `Device(config-if)# no mpls ldp igp autoconfig`	Disables LDP for that interface.
Step 5	**end** **Example:** `Device(config-if)# end`	Returns to privileged EXEC mode.

Verifying MPLS LDP Autoconfiguration with OSPF

SUMMARY STEPS

1. **enable**
2. **show mpls interfaces** [*type number* | **vrf** *vpn-name*] [**all**] [**detail**] [**internal**]
3. **show mpls ldp discovery** [**vrf** *vpn-name* | **all**] [**detail**]

DETAILED STEPS

Procedure

Step 1 **enable**

Enables privileged EXEC mode. Enter your password if prompted.

Step 2 **show mpls interfaces** [*type number* | **vrf** *vpn-name*] [**all**] [**detail**] [**internal**]

Displays the method used to enable the Label Distribution Protocol (LDP) on an interface:

- If LDP is enabled by the **mpls ldp autoconfig** command, the output displays:

Example:

```
IP labeling enabled (ldp):
   IGP config
```

- If LDP is enabled by the **mpls ip** command, the output displays:

Example:

```
IP labeling enabled (ldp):
  Interface config
```

- If LDP is enabled by the **mpls ip** command and the **mpls ldp autoconfig** command, the output displays:

Example:

```
IP labeling enabled (ldp):
  Interface config
  IGP config
```

The following example shows that LDP was enabled on the interface by both the **mpls ip** and **mpls ldp autoconfig** commands:

Example:

Step 3 **show mpls ldp discovery** [**vrf** *vpn-name* | **all**] [**detail**]

Displays how LDP was enabled on the interface. In the following example, LDP was enabled by both the **mpls ip** and **mpls ldp autoconfig** commands:

Example:

Configuring MPLS LDP Autoconfiguration with IS-IS Interfaces

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type number*
4. **ip address** *prefix mask*
5. **ip router isis**
6. **exit**
7. **mpls ip**
8. **mpls label protocol ldp**
9. **router isis**
10. **mpls ldp autoconfig** [**level-1** | **level-2**]
11. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:**	Enters global configuration mode.

	Command or Action	Purpose
	`Device# configure terminal`	
Step 3	**interface** *type number* **Example:** `Device(config)# interface POS 0/2`	Specifies the interface to configure and enters interface configuration mode.
Step 4	**ip address** *prefix mask* **Example:** `Device(config-if)# ip address 10.50.72.4 255.0.0.0`	Assigns an IP address to the interface.
Step 5	**ip router isis** **Example:** `Device(config-if)# ip router isis`	Enables the Intermediate System-to-Intermediate System (IS-IS) for IP on the interface.
Step 6	**exit** **Example:** `Device(config-if)# exit`	Returns to global configuration mode.
Step 7	**mpls ip** **Example:** `Device(config)# mpls ip`	Globally enables hop-by-hop forwarding.
Step 8	**mpls label protocol ldp** **Example:** `Device(config)# mpls label protocol ldp`	Specifies the Label Distribution Protocol (LDP) as the default protocol.
Step 9	**router isis** **Example:** `Device(config)# router isis`	Enables an IS-IS process on the device and enters router configuration mode.
Step 10	**mpls ldp autoconfig** [**level-1** | **level-2**] **Example:** `Device(config-router)# mpls ldp autoconfig`	Enables the LDP for interfaces that belong to an IS-IS process.
Step 11	**end** **Example:** `Device(config-router)# end`	Returns to privileged EXEC mode.

Disabling MPLS LDP Autoconfiguration from Selected IS-IS Interfaces

When you issue the **mpls ldp autoconfig** command, all the interfaces that belong to an Intermediate System-to-Intermediate System (IS-IS) process are enabled for the Label Distribution Protocol (LDP). To remove LDP from some interfaces, use the **no mpls ldp igp autoconfig** command on those interfaces. The following configuration steps show how to disable LDP from some of the interfaces after they were configured with the MPLS LDP Autoconfiguration feature with the **mpls ldp autoconfig** command.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type number*
4. **no mpls ldp igp autoconfig**
5. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**interface** *type number* **Example:** `Device(config)# interface POS 3/0`	Specifies the interface to configure and enters interface configuration mode.
Step 4	**no mpls ldp igp autoconfig** **Example:** `Device(config-if)# no mpls ldp igp autoconfig`	Disables LDP for that interface.
Step 5	**end** **Example:** `Device(config-if)# end`	Returns to privileged EXEC mode.

Verifying MPLS LDP Autoconfiguration with IS-IS

SUMMARY STEPS

1. **enable**
2. **show isis mpls ldp**

DETAILED STEPS

Procedure

Step 1 **enable**

Enables privileged EXEC mode.

Step 2 **show isis mpls ldp**

Shows that the Intermediate System-to-Intermediate System (IS-IS) is configured on the interface and that the Label Distribution Protocol (LDP) is enabled:

Example:

```
Device# show isis mpls ldp

Interface: POS0/2; ISIS tag null enabled
 ISIS is UP on interface
 AUTOCONFIG Information :
   LDP enabled: YES
 SYNC Information :
   Required: NO
```

The output shows:

- IS-IS is up.
- LDP is enabled.

If the MPLS LDP Autoconfiguration feature is not enabled on an interface, the output looks like the following:

Example:

```
Interface: Ethernet0; ISIS tag null enabled
 ISIS is UP on interface
 AUTOCONFIG Information :
   LDP enabled: NO
 SYNC Information :
   Required: NO
```

Troubleshooting Tips

You can use the **debug mpls ldp autoconfig** command to display events that are related to the MPLS LDP Autoconfiguration feature.

Configuration Examples for MPLS LDP Autoconfiguration

Example: MPLS LDP Autoconfiguration with OSPF

The following configuration commands enable the Label Distribution Protocol (LDP) for Open Shortest Path First (OSPF) process 1 area 3. The **mpls ldp autoconfig area 3** command and the OSPF **network** commands enable LDP on POS interfaces 0/0, 0/1, and 1/1. The **no mpls ldp igp autoconfig** command on POS interface 1/0 prevents LDP from being enabled on POS interface 1/0, even though OSPF is enabled for that interface.

```
configure terminal
 interface POS 0/0
  ip address 10.0.0.1 255.0.0.0
!
 interface POS 0/1
  ip address 10.0.1.1 255.0.0.1
!
 interface POS 1/1
  ip address 10.1.1.1 255.255.0.0
!
 interface POS 1/0
  ip address 10.1.0.1 0.1.0.255
  exit
!
 router ospf 1
  network 10.0.0.0 0.0.255.255 area 3
  network 10.1.0.0 0.0.255.255 area 3
  mpls ldp autoconfig area 3
  end
 interface POS 1/0
  no mpls ldp igp autoconfig
```

Example: MPLS LDP Autoconfiguration with IS-IS

The following example shows the configuration of the MPLS LDP Autoconfiguration feature on POS0/2 and 0/3 interfaces, which are running Intermediate System-to-Intermediate System (IS-IS) processes:

```
configure terminal
 interface POS 0/2
  ip address 10.0.0.1 255.0.0.1
  ip router isis
!
 interface POS 0/3
  ip address 10.1.1.1 255.0.1.0
  ip router isis
  exit
mpls ip
mpls label protocol ldp
router isis
mpls ldp autoconfig
```

Feature Information for MPLS LDP Autoconfiguration

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

CHAPTER 37

MPLS LDP IGP Synchronization

The MPLS LDP IGP Synchronization feature ensures that the Label Distribution Protocol (LDP) is fully established before the Interior Gateway Protocol (IGP) path is used for switching.

- Prerequisites for MPLS LDP IGP Synchronization, on page 617
- Restrictions for MPLS LDP IGP Synchronization, on page 617
- Information About MPLS LDP IGP Synchronization, on page 618
- How to Configure MPLS LDP IGP Synchronization, on page 620
- Configuration Examples for MPLS LDP IGP Synchronization, on page 628
- Additional References, on page 629
- Feature Information for MPLS LDP IGP Synchronization, on page 630

Prerequisites for MPLS LDP IGP Synchronization

- This feature is supported only on interfaces running Open Shortest Path First (OSPF) or Intermediate System-to-System (IS-IS) processes.
- This feature works when LDP is enabled on interfaces with either the **mpls ip** or **mpls ldp autoconfig** command.

Restrictions for MPLS LDP IGP Synchronization

- This feature is not supported on tunnel interfaces or LC-ATM interfaces.
- This feature is not supported with interface-local label space or downstream-on-demand (DoD) requests.
- This feature does not support targeted Label Distribution Protocol (LDP) sessions. Therefore, Any Transport over MPLS (AToM) sessions are not supported.
- The Tag Distribution Protocol (TDP) is not supported. You must specify that the default label distribution protocol is LDP for a device or for an interface.

Information About MPLS LDP IGP Synchronization

How MPLS LDP IGP Synchronization Works

Packet loss can occur because the actions of the Interior Gateway Protocol (IGP) and the Label Distribution Protocol (LDP) are not synchronized. Packet loss can occur in the following situations:

- When an IGP adjacency is established, the device begins forwarding packets using the new adjacency before the LDP label exchange completes between the peers on that link.
- If an LDP session closes, the device continues to forward traffic using the link associated with the LDP peer rather than an alternate pathway with a fully synchronized LDP session.

The MPLS LDP IGP Synchronization feature does the following:

- Provides a means to synchronize LDP and IGPs to minimize Multiprotocol Label Switching (MPLS) packet loss.
- Enables you to globally enable LDP IGP synchronization on each interface associated with an IGP Open Shortest Path First (OSPF) or Intermediate System-to-Intermediate System (IS-IS) process.
- Provides a means to disable LDP IGP synchronization on interfaces that you do not want enabled.
- Prevents MPLS packet loss due to synchronization conflicts.
- Works when LDP is enabled on interfaces using either the **mpls ip** or **mpls ldp autoconfig** command.

To enable LDP IGP synchronization on each interface that belongs to an OSPF or IS-IS process, enter the **mpls ldp sync** command. If you do not want some of the interfaces to have LDP IGP synchronization enabled, issue the **no mpls ldp igp sync** command on those interfaces.

If the LDP peer is reachable, the IGP waits indefinitely (by default) for synchronization to be achieved. To limit the length of time the IGP session must wait, enter the **mpls ldp igp sync holddown** command. If the LDP peer is not reachable, the IGP will then establish the adjacency regardless of LDP session state after the timeout has occurred.

When an IGP adjacency is established on a link but LDP IGP synchronization is not yet achieved or is lost, the IGP advertises the max-metric on that link.

MPLS LDP IGP Synchronization with Peers

When the MPLS LDP IGP Synchronization feature is enabled on an interface, the Label Distribution Protocol (LDP) determines if any peer connected by the interface is reachable by looking up the peer's transport address in the routing table. If a routing entry (including longest match or default routing entry) for the peer exists, LDP assumes that LDP Interior Gateway Protocol (IGP) synchronization is required for the interface and notifies the IGP to wait for LDP convergence.

LDP IGP synchronization with peers requires that the routing table be accurate for the peer's transport address. If the routing table shows there is a route for the peer's transport address, that route must be able to reach the peer's transport address. However, if the route is a summary route, a default route, or a statically configured route, it may not the correct route for the peer. You must verify that the route in the routing table can reach the peer’s transport address.

When the routing table has an inaccurate route for the peer's transport address, LDP cannot set up a session with the peer, which causes the IGP to wait for LDP convergence unnecessarily for the sync hold-down time.

MPLS LDP IGP Synchronization Delay Timer

The MPLS LDP IGP Synchronization feature provide the option to configure a delay time for Multiprotocol Label Switching (MPLS) Label Distribution Protocol (LDP) and Interior Gateway Protocol (IGP) synchronization on an interface-by-interface basis. If you want to configure a delay time on an interface, use the **mpls ldp igp sync delay** *delay-time* command in interface configuration mode. To remove the delay timer from a specified interface, enter the **no mpls ldp igp sync delay** command. This command sets the delay time to 0 seconds, but leaves MPLS LDP IGP synchronization enabled.

When LDP is fully established and synchronized, LDP checks the delay timer:

- If you configured a delay time, LDP starts the timer. When the timer expires, LDP checks that synchronization is still valid and notifies the Open Shortest Path First (OSPF) process.
- If you did not configure a delay time, if synchronization is disabled or down, or if an interface was removed from an IGP process, LDP stops the timer and immediately notifies the OSPF process.

If you configure a new delay time while a timer is running, LDP saves the new delay time but does not reconfigure the running timer.

MPLS LDP IGP Synchronization Incompatibility with IGP Nonstop Forwarding

The MPLS LDP IGP Synchronization feature is not supported during the startup period if the Interior Gateway Protocol (IGP) nonstop forwarding (NSF) is configured. The MPLS LDP IGP Synchronization feature conflicts with IGP NSF when the IGP is performing NSF during startup. After the NSF startup is complete, the MPLS LDP IGP Synchronization feature is supported.

MPLS LDP IGP Synchronization Compatibility with LDP Graceful Restart

LDP Graceful Restart protects traffic when a Label Distribution Protocol (LDP) session is lost. If an interface that supports a Graceful Restart-enabled LDP session fails, MPLS LDP IGP synchronization is still achieved on the interface while it is protected by Graceful Restart. MPLS LDP IGP synchronization is eventually lost under the following circumstances:

- If LDP fails to restart before the LDP Graceful Restart reconnect timer expires.
- If an LDP session restarts through other interfaces, but the LDP session on the protected interface fails to recover when the LDP Graceful Restart recovery timer expires.

How to Configure MPLS LDP IGP Synchronization

Configuring MPLS LDP IGP Synchronization with OSPF Interfaces

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls ip**
4. **mpls label protocol ldp**
5. **interface** *type number*
6. **ip address** *prefix mask*
7. **mpls ip**
8. **exit**
9. **router ospf** *process-id*
10. **network** *ip-address wildcard-mask* **area** *area-id*
11. **mpls ldp sync**
12. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**mpls ip** **Example:** `Device(config)# mpls ip`	Globally enables hop-by-hop forwarding.
Step 4	**mpls label protocol ldp** **Example:** `Device(config)# mpls label protocol ldp`	Specifies the Label Distribution Protocol (LDP) as the default protocol.

	Command or Action	Purpose
Step 5	**interface** *type number* **Example:** `Device(config)# interface POS 3/0`	Specifies the interface to configure, and enters interface configuration mode.
Step 6	**ip address** *prefix mask* **Example:** `Device(config-if)# ip address 10.0.0.11 255.255.255.255`	Assigns an IP address to the interface.
Step 7	**mpls ip** **Example:** `Device(config-if)# mpls ip`	Enables hop-by-hop forwarding on the interface.
Step 8	**exit** **Example:** `Device(config-if)# exit`	Returns to global configuration mode.
Step 9	**router ospf** *process-id* **Example:** `Device(config)# router ospf 1`	Enables Open Shortest Path First (OSPF) routing, and enters router configuration mode.
Step 10	**network** *ip-address wildcard-mask* **area** *area-id* **Example:** `Device(config-router)# network 10.0.0.0 0.0.255.255 area 3`	Specifies the interface on which OSPF runs and defines the area ID for that interface.
Step 11	**mpls ldp sync** **Example:** `Device(config-router)# mpls ldp sync`	Enables the Multiprotocol Label Switching (MPLS) Interior Gateway Protocol (IGP) synchronization for interfaces belonging for an OSPF or an Intermediate System-to-Intermediate System (IS-IS) process.
Step 12	**end** **Example:** `Device(config-router)# end`	Returns to privileged EXEC mode.

Disabling MPLS LDP IGP Synchronization from Some OSPF Interfaces

When you issue the **mpls ldp sync** command, all of the interfaces that belong to an Open Shortest Path First (OSPF) process are enabled for Label Distribution Protocol (LDP) Interior Gateway Protocol (IGP)

synchronization. To remove LDP IGP synchronization from some interfaces, use the **no mpls ldp igp sync** command on those interfaces.

Perform the following task to disable LDP IGP synchronization from some OSPF interfaces after they are configured with LDP IGP synchronization through the **mpls ldp sync** command.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type number*
4. **no mpls ldp igp sync**
5. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**interface** *type number* **Example:** `Device(config)# interface POS 0/3/0`	Specifies the interface to configure, and enters interface configuration mode.
Step 4	**no mpls ldp igp sync** **Example:** `Device(config-if)# no mpls ldp igp sync`	Disables MPLS LDP IGP synchronization for that interface.
Step 5	**end** **Example:** `Device(config-if)# end`	Returns to privileged EXEC mode.

Verifying MPLS LDP IGP Synchronization with OSPF

After you configure the interfaces for the Label Distribution Protocol (LDP), Open Shortest Path First (OSPF), and LDP Interior Gateway Protocol (IGP) synchronization, verify that the configuration is working correctly by using the **show mpls ldp igp sync** and **show ip ospf mpls ldp interface** commands.

SUMMARY STEPS

1. **enable**
2. **show mpls ldp igp sync**
3. **show ip ospf mpls ldp interface**
4. **exit**

DETAILED STEPS

Procedure

Step 1 **enable**

Enables privileged EXEC mode. Enter your password if prompted.

Example:

```
Device> enable
Device#
```

Step 2 **show mpls ldp igp sync**

Shows that the Multiprotocol Label Switching (MPLS) LDP IGP synchronization is configured correctly because LDP is configured and the SYNC status shows that synchronization is enabled.

Example:

```
Device# show mpls ldp igp sync

FastEthernet0/0/0:
 LDP configured;  SYNC enabled.
 SYNC status: sync achieved; peer reachable.
 IGP holddown time: infinite.
 Peer LDP Ident: 10.0.0.1:0
 IGP enabled: OSPF 1
```

If MPLS LDP IGP synchronization is not enabled on an interface, the output appears as follows:

Example:

```
FastEthernet0/3/1:
 LDP configured; LDP-IGP Synchronization not enabled.
```

Step 3 **show ip ospf mpls ldp interface**

Shows that the interfaces are properly configured.

Example:

```
Device# show ip ospf mpls ldp interface

FastEthernet0/3/1
  Process ID 1, Area 0
  LDP is configured through LDP autoconfig
  LDP-IGP Synchronization: Yes
  Holddown timer is not configured
  Timer is not running
FastEthernet0/0/2
  Process ID 1, Area 0
  LDP is configured through LDP autoconfig
  LDP-IGP Synchronization: Yes
  Holddown timer is not configured
  Timer is not running
```

Step 4 **exit**

Returns to user EXEC mode.

Example:

```
Device# exit
Device>
```

Configuring MPLS LDP IGP Synchronization with IS-IS Interfaces

Configuring MPLS LDP IGP Synchronization on All IS-IS Interfaces

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls ip**
4. **mpls label protocol ldp**
5. **router isis** *process-name*
6. **mpls ldp sync**
7. **interface** *type number*
8. **ip address** *prefix mask*
9. **ip router isis** *process-name*
10. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:**	Enables privileged EXEC mode. • Enter your password if prompted.

	Command or Action	Purpose
	`Device> enable`	
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**mpls ip** **Example:** `Device(config)# mpls ip`	Globally enables hop-by-hop forwarding.
Step 4	**mpls label protocol ldp** **Example:** `Device(config)# mpls label protocol ldp`	Specifies the Label Distribution Protocol (LDP) as the default label distribution protocol.
Step 5	**router isis** *process-name* **Example:** `Device(config)# router isis ISIS`	Enables the Intermediate System-to-Intermediate System (IS-IS) protocol on the device, specifies an IS-IS process, and enters router configuration mode. **Note** Defining a valid holddown timer is mandatory.
Step 6	**mpls ldp sync** **Example:** `Device(config-router)# mpls ldp sync`	Enables Multiprotocol Label Switching (MPLS) LDP Interior Gateway Protocol (IGP) synchronization on interfaces belonging to an IS-IS process.
Step 7	**interface** *type number* **Example:** `Device(config-router)# interface POS 0/3/0`	Specifies the interface to configure, and enters interface configuration mode.
Step 8	**ip address** *prefix mask* **Example:** `Device(config-if)# ip address 10.25.25.11 255.255.255.0`	Assigns an IP address to the interface.
Step 9	**ip router isis** *process-name* **Example:** `Device(config-if)# ip router isis ISIS`	Enables IS-IS.
Step 10	**end** **Example:**	Returns to privileged EXEC mode.

	Command or Action	Purpose
	`Device(config-if)# end`	

Configuring MPLS LDP IGP Synchronization on an IS-IS Interface

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type number*
4. **ip address** *prefix mask*
5. **ip router isis**
6. **exit**
7. **router isis**
8. **mpls ldp sync**
9. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**interface** *type number* **Example:** `Device(config)# interface POS 0/2/0`	Specifies the interface to configure, and enters interface configuration mode.
Step 4	**ip address** *prefix mask* **Example:** `Device(config-if)# ip address 10.50.72.4 255.0.0.0`	Assigns an IP address to the interface.
Step 5	**ip router isis** **Example:**	Enables the Intermediate System-to-Intermediate System (IS-IS) protocol for IP on the interface.

	Command or Action	Purpose
	`Device(config-if)# ip router isis`	
Step 6	**exit** **Example:** `Device(config-if)# exit`	Returns to global configuration mode.
Step 7	**router isis** **Example:** `Device(config)# router isis`	Enters router configuration mode, and enables an IS-IS process on the device.
Step 8	**mpls ldp sync** **Example:** `Device(config-router)# mpls ldp sync`	Enables Label Distribution Protocol (LDP) Interior Gateway Protocol (IGP) synchronization for interfaces belonging to an IS-IS process.
Step 9	**end** **Example:** `Device(config-router)# end`	Returns to privileged EXEC mode.

Disabling MPLS LDP IGP Synchronization from Some IS-IS Interfaces

When you issue the **mpls ldp sync** command, all of the interfaces that belong to an Intermediate System-to-Intermediate System (IS-IS) process are enabled for Label Distribution Protocol (LDP) Interior Gateway Protocol (IGP) synchronization. To remove LDP IGP synchronization from some interfaces, use the **no mpls ldp igp sync** command on those interfaces.

Perform the following task to disable LDP IGP synchronization from some IS-IS interfaces after they are configured with LDP IGP synchronization through the **mpls ldp sync** command.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type number*
4. **no mpls ldp igp sync**
5. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable**	Enables privileged EXEC mode.

	Command or Action	Purpose
	Example: `Device> enable`	• Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**interface** *type number* **Example:** `Device(config)# interface POS 0/3/0`	Specifies the interface to configure, and enters interface configuration mode.
Step 4	**no mpls ldp igp sync** **Example:** `Device(config-if)# no mpls ldp igp sync`	Disables Multiprotocol Label Switching (MPLS) LDP IGP synchronization for that interface.
Step 5	**end** **Example:** `Device(config-if)# end`	Returns to privileged EXEC mode.

Troubleshooting Tips

Use the **debug mpls ldp igp sync** command to display events related to MPLS LDP IGP synchronization.

Configuration Examples for MPLS LDP IGP Synchronization

Example: MPLS LDP IGP Synchronization with OSPF

The following task shows how to enable the Label Distribution Protocol (LDP) for Open Shortest Path First (OSPF) process 1. The **mpls ldp sync** and the OSPF **network** commands enable LDP on interfaces POS0/0/0, POS0/1/0, and POS1/1/0, respectively. The **no mpls ldp igp sync** command on interface POS1/0/0 prevents LDP from being enabled on interface POS1/0/0, even though OSPF is enabled for that interface.

```
Device# configure terminal
Device(config)# interface POS0/0/0
Device(config-if)# ip address 10.0.0.1
Device(config-if)# mpls ip
!
Device(config)# interface POS0/1/0
Device(config-if)# ip address 10.0.1.1
Device(config-if)# mpls ip
!
Device(config)# interface POS1/1/0
Device(config-if)# ip address 10.1.1.1
```

```
Device(config-if)# mpls ip
!
Device(config)# interface POS1/0/0
Device(config-if)# ip address 10.1.0.1
Device(config-if)# mpls ip
!
Device(config)# router ospf 1
Device(config-router)# network 10.0.0.0 0.0.255.255 area 3
Device(config-router)# network 10.1.0.0 0.0.255.255 area 3
Device(config-router)# mpls ldp sync
Device(config-router)# exit
Device(config)# interface POS1/0/0
Device(config-if)# no mpls ldp igp sync
```

Example: MPLS LDP IGP Synchronization with IS-IS

The following examples show the configuration commands you can use to configure MPLS LDP IGP synchronization on interfaces POS0/2 /0 and POS0/3/0, which are running IS-IS processes:

```
Device# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Device(config)# interface POS0/2/0
Device(config-if)# ip router isis
Device(config-if)# exit
Device(config)# router isis
Device(config-router)# mpls ldp sync
Device(config-router)# exit
.
.
.
Device(config)# interface POS0/3/0
Device(config-if)# ip router isis
Device(config-if)# exit
Device(config)# router isis
Device(config-router)# mpls ldp sync
Device(config-router)# exit
Device(config) exit
Device#
```

Feature Information for MPLS LDP IGP Synchronization

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 92: Feature Information for MPLS LDP IGP Synchronization

Feature Name	Releases	Feature Information
MPLS LDP IGP Synchronization		The MPLS LDP IGP Synchronization feature ensures that LDP is fully established before the IGP path is used for switching.

CHAPTER 38

MPLS LDP Inbound Label Binding Filtering

Multiprotocol Label Switching (MPLS) Label Distribution Protocol (LDP) supports inbound label binding filtering. You can use the MPLS LDP Inbound Label Binding Filtering feature to configure access control lists (ACLs) for controlling the label bindings a label switch router (LSR) accepts from its peer LSRs.

- Restrictions for MPLS LDP Inbound Label Binding Filtering, on page 631
- Information about MPLS LDP Inbound Label Binding Filtering, on page 631

- Feature Information for MPLS LDP Inbound Label Binding Filtering, on page 636
- Glossary, on page 636

Restrictions for MPLS LDP Inbound Label Binding Filtering

Inbound label binding filtering does not support extended access control lists (ACLs); it only supports standard ACLs.

Information about MPLS LDP Inbound Label Binding Filtering

Overview of MPLS LDP Inbound Label Binding Filtering

The MPLS LDP Inbound Label Binding Filtering feature can be used to control the amount of memory used to store Label Distribution Protocol (LDP) label bindings advertised by other devices. For example, in a simple Multiprotocol Label Switching (MPLS) Virtual Private Network (VPN) environment, the VPN provider edge (PE) devices might require label switched paths (LSPs) only to their peer PE devices (that is, they do not need LSPs to core devices). Inbound label binding filtering enables a PE device to accept labels only from other PE devices.

How to Configure MPLS LDP Inbound Label Binding Filtering

Configuring MPLS LDP Inbound Label Binding Filtering

Perform this task to configure a device for inbound label filtering. The following configuration allows the device to accept only the label for prefix 25.0.0.2 from the Label Distribution Protocol (LDP) neighbor device 10.12.12.12.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip access-list standard** *access-list-number*
4. **permit** {*source* [*source-wildcard*] | **any**} [**log**]
5. **exit**
6. **mpls ldp neighbor** [**vrf** *vpn-name*] *nbr-address* **labels accept** *acl*
7. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**ip access-list standard** *access-list-number* **Example:** `Device(config)# ip access-list standard 1`	Defines a standard IP access list with a number.
Step 4	**permit** {*source* [*source-wildcard*] | **any**} [**log**] **Example:** `Device(config-std-nacl)# permit 10.0.0.0`	Specifies one or more prefixes permitted by the access list.
Step 5	**exit** **Example:**	Returns to global configuration mode.

	Command or Action	Purpose
	`Device(config-std-nacl)# exit`	
Step 6	**mpls ldp neighbor** [**vrf** *vpn-name*] *nbr-address* **labels accept** *acl* **Example:** `Device(config)# mpls ldp neighbor 10.12.12.12 labels accept 1`	Specifies the access control list (ACL) to be used to filter label bindings for the specified LDP neighbor.
Step 7	**end** **Example:** `Device(config)# end`	Returns to privileged EXEC mode.

Verifying that MPLS LDP Inbound Label Bindings are Filtered

If inbound filtering is enabled, perform the following tasks to verify that inbound label bindings are filtered.

SUMMARY STEPS

1. **enable**
2. **show mpls ldp neighbor** [**vrf** *vpn-name*] [*address* | *interface*] [**detail**]
3. **show ip access-list** [*access-list-number* | *access-list-name*]
4. **show mpls ldp bindings**
5. **exit**

DETAILED STEPS

Procedure

Step 1 **enable**

Enables privileged EXEC mode. Enter your password if prompted.

Example:

```
Device> enable
Device#
```

Step 2 **show mpls ldp neighbor** [**vrf** *vpn-name*] [*address* | *interface*] [**detail**]

Shows the status of the Label Distribution Protocol (LDP) session, including the name or number of the access control list (ACL) configured for inbound filtering.

Note
To display information about inbound label binding filtering, you must enter the **detail** keyword.

Example:

```
Device# show mpls ldp neighbor 10.12.12.12 detail
 Peer LDP Ident: 10.12.12.12:0; Local LDP Ident 10.13.13.13:0
   TCP connection: 10.12.12.12.646 - 10.13.13.13.12592
   State: Oper; Msgs sent/rcvd: 49/45; Downstream; Last TIB rev sent 1257
   Up time: 00:32:41; UID: 1015; Peer Id 0;
   LDP discovery sources:
    Serial1/0/0; Src IP addr: 192.168.1.1
     holdtime: 15000 ms, hello interval: 5000 ms
   Addresses bound to peer LDP Ident:
    10.0.0.129       10.12.12.12     192.168.1.1
   Peer holdtime: 180000 ms; KA interval: 60000 ms; Peer state: estab
   LDP inbound filtering accept acl: 1
```

Step 3 **show ip access-list** [*access-list-number* | *access-list-name*]

Displays the contents of all current IP access lists or of a specified access list.

Note
It is important that you enter this command to see how the access list is defined; otherwise, you cannot verify inbound label binding filtering.

The following command output shows the contents of IP access list 1:

Example:

```
Device# show ip access 1
Standard IP access list 1
  permit 10.0.0.0, wildcard bits 0.0.0.255 (1 match)
```

Step 4 **show mpls ldp bindings**

Verifies that the label switch router (LSR) has remote bindings only from a specified peer for prefixes permitted by the access list.

Example:

```
Device# show mpls ldp bindings
 tib entry: 10.0.0.0/8, rev 4
     local binding:  tag: imp-null
 tib entry: 10.2.0.0/16, rev 1137
     local binding:  tag: 16
 tib entry: 10.2.0.0/16, rev 1139
     local binding:  tag: 17
 tib entry: 10.12.12.12/32, rev 1257
     local binding:  tag: 18
 tib entry: 10.13.13.13/32, rev 14
     local binding:  tag: imp-null
 tib entry: 10.10.0.0/16, rev 711
     local binding:  tag: imp-null
 tib entry: 10.0.0.0/8, rev 1135
     local binding:  tag: imp-null
     remote binding: tsr: 10.12.12.12:0, tag: imp-null
 tib entry: 10.0.0.0/8, rev 8
     local binding:  tag: imp-null
```

Step 5 **exit**

Returns to user EXEC mode.

Example:

```
Device# exit
Device>
```

Configuration Examples for MPLS LDP Inbound Label Binding Filtering

Examples: MPLS LDP Inbound Label Binding Filtering Configuration

In the following example, the **mpls ldp neighbor labels accept** command is configured with an access control list to filter label bindings received on sessions with the neighbor 10.110.0.10.

Label bindings for prefixes that match 10.b.c.d are accepted, where b is less than or equal to 63, and c and d can be any integer between 0 and 128. Other label bindings received from 10.110.0.10 are rejected.

```
Device# configure terminal
Device(config)# access-list 1 permit 10.63.0.0 0.63.255.255
Device(config)# mpls ldp neighbor 10.110.0.10 labels accept 1
Device(config)# end
```

In the following example, the **show mpls ldp bindings neighbor** command displays label bindings that were learned from 10.110.0.10. This example verifies that the LIB does not contain label bindings for prefixes that have been excluded.

```
Device# show mpls ldp bindings neighbor 10.110.0.10

tib entry: 10.2.0.0/16, rev 4
    remote binding: tsr: 10.110.0.10:0, tag: imp-null
tib entry: 10.43.0.0/16, rev 6
    remote binding: tsr: 10.110.0.10:0, tag: 16
tib entry: 10.52.0.0/16, rev 8
    remote binding: tsr: 10.110.0.10:0, tag: imp-null
```

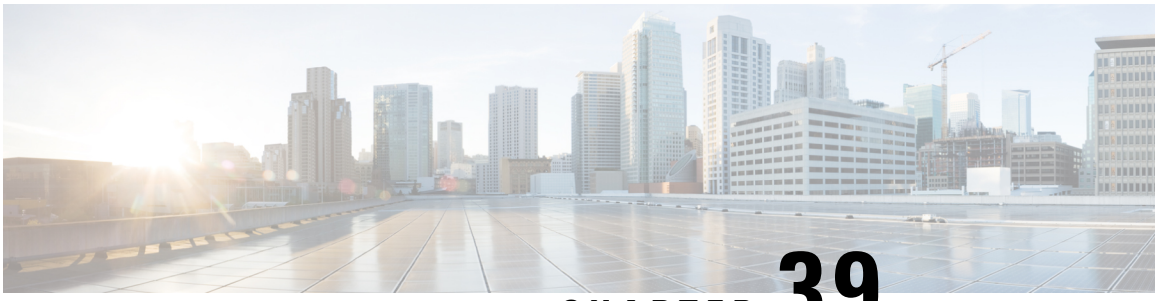
Feature Information for MPLS LDP Inbound Label Binding Filtering

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Glossary



carrier supporting carrier—A situation where one service provider allows another service provider to use a segment of its backbone network. The service provider that provides the segment of the backbone network to the other provider is called the backbone carrier. The service provider that uses the segment of the backbone network is called the customer carrier.

CE device—customer edge device. A device that is part of a customer network and that interfaces to a provider edge (PE) device.

inbound label binding filtering—Allows label switch routers (LSRs) to control which label bindings it will accept from its neighboring LSRs. Consequently, an LSR does not accept or store some label bindings that its neighbors advertise.

label—A short fixed-length identifier that tells switching nodes how to forward data (packets or cells).

label binding—An association between a destination prefix and a label.

CHAPTER 39

MPLS LDP Local Label Allocation Filtering

The MPLS LDP Local Label Allocation Filtering feature introduces CLI commands to modify the way in which Multiprotocol Label Switching (MPLS) Label Distribution Protocol (LDP) handles local label allocation. This MPLS LDP feature enhancement enables the configuration of filtering policies for selective local label binding assignments by LDP to improve LDP scalability and convergence.

- Additional References, on page 655
- Feature Information for MPLS LDP Local Label Allocation Filtering, on page 655
- Glossary, on page 656

Prerequisites for MPLS LDP Local Label Allocation Filtering

The MPLS LDP Local Label Allocation Filtering feature requires the MPLS Forwarding Infrastructure (MFI).

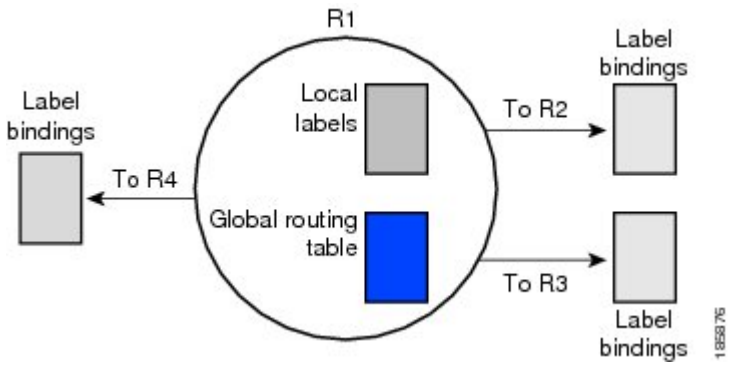
Restrictions for MPLS LDP Local Label Allocation Filtering

- This feature does not support access lists; it supports prefix lists.
- Label Distribution Protocol (LDP) local label allocation configuration for prefix list or host routes is supported only in the global routing table.
- LDP and Routing Information Base (RIB) restart handling does not apply.
- Wildcard Forwarding Equalence Class (FEC) requests are not supported.
- Remote bindings are retained for LDP table entries that are filtered.

Information About MPLS LDP Local Label Allocation Filtering

MPLS LDP Local Label Allocation Filtering Overview

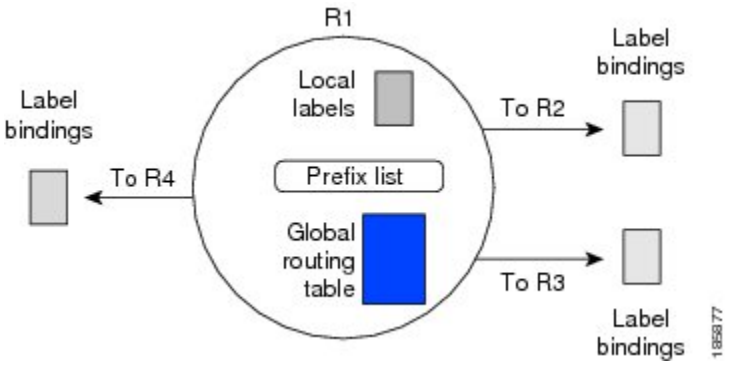
The Label Distribution Protocol (LDP) allocates a local label for every route learned from the Interior Gateway Protocol (IGP). In the absence of inbound and outbound label filtering, these local labels are advertised to and learned by all peers.



In most Layer 3 Virtual Private Network (VPN) configurations only the label switched paths (LSPs) created to reach the /32 host routes or Border Gateway Protocol (BGP) next hops between the provider edge (PE) devices carry traffic and are relevant to the Layer 3 VPNs. LSPs between the PE devices that are not members of a VPN use more memory and create additional processing in LDP across the core.

With the load increases in the service provider domain in the last decade (1997-2007), scalability has become more important in the service provider networks. Controlling the local label allocation could off-load LDP processing of non-VPN LSPs in the service provider network core devices.

The MPLS LDP Local Label Allocation Filtering feature introduces the **mpls ldp label** and **allocate** commands that allow you to configure LDP to selectively allocate local labels for a subset of the prefixes learned from the IGP. You can select that LDP allocate local labels for prefixes configured in a prefix list in the global table or for host routes in the global table.



Local label allocation filtering reduces the number of local labels allocated and therefore the number of messages exchanged with peers. This improves LDP scalability and convergence. The two figures below show how controlling local label allocation can reduce local label space size and greatly reduce the number of advertisements to peers. The first figure below shows default LDP label allocation behavior. LDP allocates a local label for every route and advertises a label binding for every route learned from the IGP.

Figure 46: Default LDP Local Label Allocation Behavior

The figure below shows LDP behavior with local label allocation control configured. The size of the local label space and the number of label binding advertisements are reduced with local label allocation filtering through the use of a prefix list. The decrease in the number of local labels and label binding advertisement messages reduces the amount of memory use and improves convergence time for LDP. The MPLS LDP Local Label Allocation Filtering feature also allows for more efficient use of the label space.

Figure 47: LDP Behavior with Local Label Allocation Controls

The figure above shows that device R1 learns a number of routes from its IGP neighbors on devices R2, R3, and R4. A prefix list defined on device R1 specifies the prefixes for which LDP allocates a local label.

Note In general, the number of Label Information Base (LIB) entries remains the same regardless of the kind of label filtering. This is because the remote label bindings for the prefixes that are filtered are kept in the LIB. Memory use is reduced because local label filtering decreases the number of local labels allocated and the number of label bindings advertised to and stored by the peers of a label switch router (LSR).

Prefix Lists for MPLS LDP Local Label Allocation Filtering Benefits and Description

The MPLS LDP Local Label Allocation Filtering feature allows you to configure the Label Distribution Protocol (LDP) to allocate local labels for a subset of the learned prefixes. LDP accepts the prefix and allocates a local label if the prefix is permitted by a prefix list. If the prefix list is not defined, LDP accepts all prefixes and allocates local labels based on its default mode of operation.

The benefits of using prefix lists for LDP local label allocation filtering are as follows:

- Prefix lists provide more flexibility for specifying a subset of prefixes and masks.
- Prefix lists use a tree-based matching technique. This technique is more efficient than evaluating prefixes or host routes sequentially.
- Prefix lists are easy to modify.

You configure a prefix list for the MPLS LDP Local Label Allocation Filtering feature with the **ip prefix-list** command.

Local Label Allocation Changes and LDP Actions

The MPLS LDP Local Label Allocation Filtering enhancement modifies the Label Distribution Protocol's (LDP's) local label allocation handling. The feature supports local label allocation filtering through the specification of a prefix list or host routes.

With the introduction of this feature, LDP needs to determine whether a prefix filter is already configured to control the local label allocation on the local node. If a prefix list exists, the local label allocation is confined to the list of prefixes permitted by the configured prefix list.

LDP also needs to respond to local label allocation configuration changes and to configuration changes that affect the prefix list that LDP is using. Any of the following configuration changes can trigger LDP actions:

- Creating a local label allocation configuration
- Deleting or changing a local label allocation configuration
- Creating a new prefix list for a local label allocation configuration
- Deleting or changing a prefix list for a local label allocation configuration

LDP responds to local label allocation configuration changes by updating the Label Information Database (LIB) and the forwarding table in the global routing table. To update the LIB after a local label filter configuration change without a session reset, LDP keeps all remote bindings.

If you create a local label allocation configuration without defining a prefix list, no LDP action is required. The local label allocation configuration has no effect because the prefix list is created and permits all prefixes.

If you create or change a prefix list and prefixes that were previously allowed are rejected, LDP goes through a label withdraw and release procedure before the local labels for these prefixes are deallocated.

If you delete a prefix, LDP goes through the label withdraw and release procedure for the LIB local label. If the associated prefix is one for which no LIB entry should be allocated, LDP bypasses this procedure.

The LDP default behavior is to allocate local labels for all non-BGP prefixes. This default behavior does not change with the introduction of this feature and the **mpls ldp label** and **allocate** commands.

Note The local label allocation filtering has no impact on inbound label filtering because both provide LDP filtering independently. The LDP Inbound Label Binding Filtering feature controls label bindings that a label switch router (LSR) accepts from its peer LSRs through the use of access control lists (ACLs). The MPLS LDP Local Label Allocation Filtering feature controls the allocation of local labels through the use of prefix lists or host routes.

LDP Local Label Filtering and BGP Routes

The Label Distribution Protocol (LDP) default behavior is to allocate local labels for all non-Border Gateway Protocol (BGP) prefixes.

LDP does not apply the configured local label filter to redistributed BGP routes in the global table for which BGP allocates local label, but LDP does the advertisements (Inter-AS Option C). LDP neither forwards these entries nor releases the local labels allocated by BGP.

How to Configure MPLS LDP Local Label Allocation Filtering

Creating a Prefix List for MPLS LDP Local Label Allocation Filtering

Perform the following task to create a prefix list for the Label Distribution Protocol (LDP) local label allocation filtering. A prefix list allows LDP to selectively allocate local labels for a subset of the routes learned from the Interior Gateway Protocol {IGP). The decrease in the number of local labels in the LDP Label Information Base (LIB) and the number of label mapping advertisements reduces the amount of memory use and improves convergence time for LDP.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip prefix-list** {*list-name* | *list-number*} [**seq** *number*] {**deny** *network/length* | **permit** *network/length*} [**ge** *ge-length*] [**le** *le-length*]
4. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**ip prefix-list** {*list-name* | *list-number*} [**seq** *number*] {**deny** *network/length* | **permit** *network/length*} [**ge** *ge-length*] [**le** *le-length*] **Example:** `Device(config)# ip prefix-list list1 permit 192.168.0.0/16 le 20`	Creates a prefix list or adds a prefix-list entry. • The *list-name* argument configures a name to identify the prefix list. • The *list-number* argument configures a number to identify the prefix list. • The **seq** *number* keyword and argument apply a sequence number to a prefix-list entry. The range of sequence numbers is 1 to 4294967294. If a sequence number is not entered when this command is configured, a default sequence numbering is applied to the prefix list. The number 5 is applied to the first

	Command or Action	Purpose
		prefix entry, and subsequent unnumbered entries are incremented by 5. • The **deny** keyword denies access for a matching condition. • The **permit** keyword permits access for a matching condition. • The *network*/*length* arguments and keyword configure the network address, and the length of the network mask in bits. The network number can be any valid IP address or prefix. The bit mask can be a number from 0 to 32. • The **ge** *ge-length* keyword and argument specify the lesser value of a range (the "from" portion of the range description) by applying the *ge-length* argument to the range specified. The *ge-length* argument represents the minimum prefix length to be matched. The **ge** keyword represents the greater than or equal to operator. • The **le** *le-length* keyword and argument specify the greater value of a range (the "to" portion of the range description) by applying the *le-length* argument to the range specified. The *le-length* argument represents the maximum prefix length to be matched. The **le** keyword represents the less than or equal to operator.
Step 4	**end** **Example:** `Device(config)# end`	Returns to privileged EXEC mode.

Configuring MPLS LDP Local Label Allocation Filtering

Perform the following task to configure the Label Distribution Protocol (LDP) local allocation filtering. Configuring filtering policies for selective local label binding assignments by LDP improves LDP scalability and convergence. You can configure either a prefix list or host routes as a filter for local label allocation.

Note The **host-routes** keyword for the **allocate** command makes it convenient for you to specify a commonly used set of prefixes.

Note A maximum of one local label allocation filter is supported for the global table.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls ldp label**
4. **allocate global prefix-list** {*list-name* | *list-number*}
5. **allocate global host-routes**
6. **no allocate global** {**prefix-list** {*list-name* | *list-number*} | **host-routes**}
7. **no mpls ldp label**
8. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**mpls ldp label** **Example:** `Device(config)# mpls ldp label`	Enters MPLS LDP label configuration mode to specify how LDP handles local label allocation.
Step 4	**allocate global prefix-list** {*list-name* | *list-number*} **Example:** `Device(config-ldp-lbl)# allocate global prefix-list list1`	Configures local label allocation filters for learned routes for LDP. • The **global** keyword specifies the global routing. • The **prefix-list** keyword specifies a prefix list to be used as a filter for MPLS LDP local label allocation. • The *list-name* argument indicates a name that identifies the prefix list. • The *list-number* argument indicates a number that identifies the prefix list.
Step 5	**allocate global host-routes** **Example:** `Device(config-ldp-lbl)# allocate global host-routes`	Configures local label allocation filters for learned routes for LDP. • The **global** keyword specifies the global routing.

	Command or Action	Purpose
		• The **host-routes** keyword specifies that local label allocation be done for host routes only.
Step 6	**no allocate global** {**prefix-list** {*list-name* | *list-number*} | **host-routes**} **Example:** `Device(config-ldp-lbl)# no allocate global host-routes`	Removes the specific MPLS LDP local label allocation filter without resetting the LDP session. • The **global** keyword specifies the global routing. • The **prefix-list** keyword specifies a prefix list to be used as a filter for MPLS LDP local label allocation. • The *list-name* argument indicates a name that identifies the prefix list. • The *list-number* argument indicates a number that identifies the prefix list. • The **host-routes** keyword specifies that host routes be used as a filter for MPLS LDP local label allocation.
Step 7	**no mpls ldp label** **Example:** `Device(config-ldp-lbl)# no mpls ldp label`	Removes all local label allocation filters configured under the MPLS LDP label configuration mode and restores LDP default behavior for local label allocation without a session reset.
Step 8	**end** **Example:** `Device(config-ldp-lbl)# end`	Returns to privileged EXEC mode.

Verifying MPLS LDP Local Label Allocation Filtering Configuration

SUMMARY STEPS

1. **enable**
2. **show mpls ldp bindings detail**
3. **debug mpls ldp binding filter**
4. **exit**

DETAILED STEPS

Procedure

Step 1 **enable**

Enables privileged EXEC mode. Enter your password if prompted.

Example:

```
Device> enable
Device#
```

Step 2 **show mpls ldp bindings detail**

Verifies that local label allocation filtering is configured as you expect.

Example:

```
Device# show mpls ldp bindings detail

Advertisement spec:
        Prefix acl = bar
Local label filtering spec: host routes.
  lib entry: 10.1.1.1/32, rev 9
  lib entry: 10.10.7.0/24, rev 10
  lib entry: 10.10.8.0/24, rev 11
  lib entry: 10.10.9.0/24, rev 12
  lib entry: 10.41.41.41/32, rev 17
  lib entry: 10.50.50.50/32, rev 15
  lib entry: 10.60.60.60/32, rev 18
  lib entry: 10.70.70.70/32, rev 16
  lib entry: 10.80.80.80/32, rev 14
```

The output of this command verifies that host routes are configured as the local label allocation filter for the device.

Step 3 **debug mpls ldp binding filter**

Verifies that local label allocation filtering was configured properly and to display how LDP accepts or withdraw labels.

Example:

```
Device# debug mpls ldp binding filter
LDP Local Label Allocation Filtering changes debugging is on
.
.
.
```

Step 4 **exit**

Returns to user EXEC mode.

Example:

```
Device# exit
Device>
```

Configuration Examples for MPLS LDP Local Label Allocation Filtering

Examples: Creating a Prefix List for MPLS LDP Local Label Allocation Filtering

The following examples show how to configure a prefix list for MPLS LDP local label allocation filtering.

In this example, prefix list List1 permits only 192.168.0.0/16 prefixes. The Label Distribution Protocol (LDP) accepts 192.168.0.0/16 prefixes, but does not assign a local label for the following prefixes: 192.168.0.0/24 and 192.168.2.0/24. For example:

```
configure terminal
!
ip prefix-list List1 permit 192.168.0.0/16
end
```

In the following example, prefix list List2 permits a range of prefixes from 192.168.0.0/16 to /20 prefixes. LDP accepts 192.168.0.0/16 prefixes, but does not assign local labels for the following prefixes: 192.168.0.0/24 and 192.168.2.0/24.

```
configure terminal
!
ip prefix-list List2 permit 192.168.0.0/16 le 20
end
```

In the following example, prefix list List3 permits a range of prefixes greater than /18. LDP accepts 192.168.17.0/20 and 192.168.2.0/24 prefixes, but does not assign a local label for 192.168.0.0/16.

```
configure terminal
!
ip prefix-list List3 permit 192.168.0.0/16 ge 18
end
```

Examples: Configuring MPLS LDP Local Label Allocation Filtering

This examples shows how to allocate a prefix list to be used as a local label allocation filter:

```
configure terminal
!
ip prefix-list List3 permit 192.168.0.0/16 ge 18
!
mpls ldp label
 allocate global prefix-list List3
 exit
exit
```

Prefix list List3, which permits a range of prefixes greater than /18, is configured as the local label allocation filter for the device. The Label Distribution Protocol (LDP) allows 192.168.17.0/20 and 192.168.2.0/24 prefixes, but withdraws labels for prefixes not in the allowed range.

In the following example, host routes are configured as the local label allocation filter:

```
configure terminal
!
mpls ldp label
 allocate global host-routes
 exit
exit
```

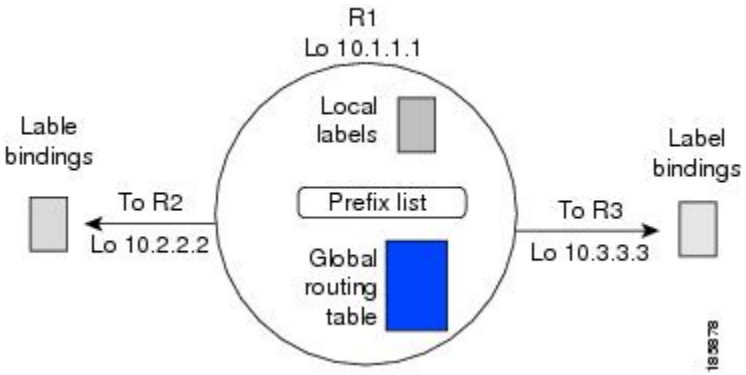
LDP allocates local labels for host routes that are in the global routing table.

In the following example, a specific local label allocation filter is removed:

```
configure terminal
!
mpls ldp label
 no allocate global host-routes
 exit
exit
```

In the following example, all local label allocation filters configured in MPLS LDP label configuration mode are removed and the default LDP local label allocation is restored without a session reset:

```
configure terminal
!
no mpls ldp label
 exit
exit
```



Examples: Sample MPLS LDP Local Label Allocation Filtering Configuration

The figure below is a sample configuration that is used in this section to show how Multiprotocol Label Switching (MPLS) Label Distribution Protocol (LDP) local label allocation filtering works:

- Devices R1, R2, and R3 have loopback addresses 10.1.1.1, 10.2.2.2, and 10.3.3.3 defined and advertised by the Interior Gateway Protocol (IGP), respectively.
- 10.1.1.1 is the router ID of Device R1, 10.2.2.2 is the router ID of Device R2, and 10.3.3.3 is the router ID of Device R3.
- A prefix list is defined on Device R1 to specify the local labels for which LDP allocates a local label.

Device RI learns a number of routes from its IGP neighbors on Devices R2 and R3.

Figure 48: LDP Local Label Allocation Filtering Example

You can use LDP CLI commands to verify the following:

- Device R1 has allocated a local label for the correct subset of the prefixes.
- Devices R2 and R3 did not receive any remote bindings for the prefixes for which Device R1 did not assign a local label.

Routing Table on Device R1

You can enter the **show ip route** command to display the current state of the routing table. The following example shows the routing table on Device R1 based on the figure above:

```
Device# show ip route

Codes: C - connected, S - static, R - RIP, M - mobile, B - BGP
       D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, * - candidate default, U - per-user static route
       o - ODR, P - periodic downloaded static route
Gateway of last resort is not set
     10.0.0.0/32 is subnetted, 1 subnets
C       10.1.1.1 is directly connected, Loopback0
     10.2.0.0/32 is subnetted, 1 subnets
O       10.2.2.2 [110/11] via 10.10.7.1, 00:00:36, FastEthernet1/0/0
     10.3.0.0/32 is subnetted, 1 subnets
O       10.3.3.3 [110/11] via 10.10.9.1, 00:00:36, FastEthernet3/0/0
     10.0.0.0/24 is subnetted, 3 subnets
C       10.10.7.0 is directly connected, FastEthernet1/0/0
O       10.10.8.0 [110/20] via 10.10.9.1, 00:00:36, FastEthernet3/0/0
                  [110/20] via 10.10.7.1, 00:00:36, FastEthernet1/0/0
C       10.10.9.0 is directly connected, FastEthernet3/0/0
```

Local Label Bindings on Devices R1, R2, and R3

You can enter the **show mpls ldp bindings** command on Devices R1, R2, and R3 to display the contents of the Label Information Base (LIB) on each device. In the following examples, the default Label Distribution Protocol (LDP) allocation behavior is in operation; that is, LDP allocates a local label for every route and advertises a label binding for every route learned from the Interior Gateway Protocol (IGP).

LIB on Device R1

This example shows the contents of the LIB on Device R1 based on the configuration in the figure above:

```
Device# show mpls ldp bindings

  lib entry: 10.1.1.1/32, rev 7
        local binding:  label: imp-null
        remote binding: lsr: 10.3.3.3:0, label: 16
        remote binding: lsr: 10.2.2.2:0, label: 17
  lib entry: 10.2.2.2/32, rev 13
        local binding:  label: 1000
        remote binding: lsr: 10.3.3.3:0, label: 18
        remote binding: lsr: 10.2.2.2:0, label: imp-null
  lib entry: 10.3.3.3/32, rev 15
        local binding:  label: 1002
        remote binding: lsr: 10.3.3.3:0, label: imp-null
        remote binding: lsr: 10.2.2.2:0, label: 18
```

```
  lib entry: 10.10.7.0/24, rev 8
        local binding:  label: imp-null
        remote binding: lsr: 10.3.3.3:0, label: 17
        remote binding: lsr: 10.2.2.2:0, label: imp-null
  lib entry: 10.10.8.0/24, rev 11
        local binding:  label: 1001
        remote binding: lsr: 10.3.3.3:0, label: imp-null
        remote binding: lsr: 10.2.2.2:0, label: imp-null
  lib entry: 10.10.9.0/24, rev 9
        local binding:  label: imp-null
        remote binding: lsr: 10.3.3.3:0, label: imp-null
        remote binding: lsr: 10.2.2.2:0, label: 16
```

The local labels assigned to 10.2.2.2 and 10.3.3.3 on Device R1 are advertised to Devices R2 and R3.

LIB on Device R2

This example shows the contents of the LIB on Device R2 based on the configuration in the figure above:

```
Device# show mpls ldp bindings

  lib entry: 10.1.1.1/32, rev 11
        local binding:  label: 17
        remote binding: lsr: 10.3.3.3:0, label: 16
        remote binding: lsr: 10.1.1.1:0, label: imp-null
  lib entry: 10.2.2.2/32, rev 7
        local binding:  label: imp-null
        remote binding: lsr: 10.3.3.3:0, label: 18
        remote binding: lsr: 10.1.1.1:0, label: 1000
  lib entry: 10.3.3.3/32, rev 15
        local binding:  label: 18
        remote binding: lsr: 10.3.3.3:0, label: imp-null
        remote binding: lsr: 10.1.1.1:0, label: 1002
  lib entry: 10.10.7.0/24, rev 8
        local binding:  label: imp-null
        remote binding: lsr: 10.3.3.3:0, label: 17
        remote binding: lsr: 10.1.1.1:0, label: imp-null
  lib entry: 10.10.8.0/24, rev 9
        local binding:  label: imp-null
        remote binding: lsr: 10.3.3.3:0, label: imp-null
        remote binding: lsr: 10.1.1.1:0, label: 1001
  lib entry: 10.10.9.0/24, rev 13
        local binding:  label: 16
        remote binding: lsr: 10.3.3.3:0, label: imp-null
        remote binding: lsr: 10.1.1.1:0, label: imp-null
```

LIB on Device R3

This example shows the contents of the LIB on Device R3 based on the configuration in the figure above:

```
Device # show mpls ldp bindings

  lib entry: 10.1.1.1/32, rev 13
        local binding:  label: 16
        remote binding: lsr: 10.2.2.2:0, label: 17
        remote binding: lsr: 10.1.1.1:0, label: imp-null
  lib entry: 10.2.2.2/32, rev 15
        local binding:  label: 18
        remote binding: lsr: 10.2.2.2:0, label: imp-null
        remote binding: lsr: 10.1.1.1:0, label: 1000
  lib entry: 10.3.3.3/32, rev 7
        local binding:  label: imp-null
```

```
      remote binding: lsr: 10.2.2.2:0, label: 18
      remote binding: lsr: 10.1.1.1:0, label: 1002
lib entry: 10.10.7.0/24, rev 11
      local binding:  label: 17
      remote binding: lsr: 10.2.2.2:0, label: imp-null
      remote binding: lsr: 10.1.1.1:0, label: imp-null
lib entry: 10.10.8.0/24, rev 8
      local binding:  label: imp-null
      remote binding: lsr: 10.2.2.2:0, label: imp-null
      remote binding: lsr: 10.1.1.1:0, label: 1001
lib entry: 10.10.9.0/24, rev 9
      local binding:  label: imp-null
      remote binding: lsr: 10.2.2.2:0, label: 16
      remote binding: lsr: 10.1.1.1:0, label: imp-null
```

Local Label Allocation Filtering Configuration on Device R1

You enter the **mpls ldp label** command to configure a local label allocation filter. The following examples show how to configure a local label allocation filter by host routes only and by a prefix list.

Local Label Allocation Filter—Host Routes Only Configuration

This example shows the selection of host routes as the only filter.

The following local label allocation filtering is defined on Device R1 under MPLS LDP label configuration mode:

```
configure terminal
!
mpls ldp label
 allocate global host-routes
 exit
exit
```

Local Label Allocation Filter—Prefix List Configuration

The following example shows how to configure a local label allocation filter that allows or denies prefixes based on a prefix list:

```
configure terminal
!
mpls ldp label
 allocate global prefix-list ListA
 exit
end
```

ListA is a prefix list defined as:

```
configure terminal
!
ip prefix-list ListA permit 0.0.0.0/32 ge 32
```

Local Label Allocation Filtering Changes Label Bindings on Devices R1, R2, and R3

After configuring a local label allocation filter on Device R1, you can enter the **show mpls ldp bindings** command again to see the changes in the local label bindings in the Label Information Base (LIB) on each device. Changes to the output in the LIB entries are highlighted in bold text.

This sample prefix list is used for the examples in the this section:

```
ip prefix-list ListA permit 0.0.0.0/32 ge 32
```

LIB on Device R1 After Local Label Allocation Filtering

This example shows how the configuration of a local label allocation prefix-list filter changes the contents of the LIB on Device R1:

```
Device# show mpls ldp bindings

  lib entry: 10.1.1.1/32, rev 7
        local binding:  label: imp-null
        remote binding: lsr: 10.3.3.3:0, label: 16
        remote binding: lsr: 10.2.2.2:0, label: 17
  lib entry: 10.2.2.2/32, rev 13
        local binding:  label: 1000
        remote binding: lsr: 10.3.3.3:0, label: 18
        remote binding: lsr: 10.2.2.2:0, label: imp-null
  lib entry: 10.3.3.3/32, rev 15
        local binding:  label: 1002
        remote binding: lsr: 10.3.3.3:0, label: imp-null
        remote binding: lsr: 10.2.2.2:0, label: 18
  lib entry: 10.10.7.0/24, rev 8
        no local binding
        remote binding: lsr: 10.3.3.3:0, label: 17
        remote binding: lsr: 10.2.2.2:0, label: imp-null
  lib entry: 10.10.8.0/24, rev 11
        no local binding
        remote binding: lsr: 10.3.3.3:0, label: imp-null
        remote binding: lsr: 10.2.2.2:0, label: imp-null
  lib entry: 10.10.9.0/24, rev 9
        no local binding
        remote binding: lsr: 10.3.3.3:0, label: imp-null
        remote binding: lsr: 10.2.2.2:0, label: 16
```

Local label bindings for all but 10.2.2.2 and 10.3.3.3 on Device R1 are advertised as withdrawn.

LIB on Device R2 After Local Label Allocation Filtering

This example shows how the configuration of a local label allocation prefix-list filter on Device R1 changes the contents of the LIB on Device R2:

```
Device# show mpls ldp bindings
  lib entry: 10.1.1.1/32, rev 11
        local binding:  label: 17
        remote binding: lsr: 10.3.3.3:0, label: 16
  lib entry: 10.2.2.2/32, rev 7
        local binding:  label: imp-null
        remote binding: lsr: 10.3.3.3:0, label: 18
        remote binding: lsr: 10.1.1.1:0, label: 1000
  lib entry: 10.3.3.3/32, rev 15
        local binding:  label: 18
        remote binding: lsr: 10.3.3.3:0, label: imp-null
        remote binding: lsr: 10.1.1.1:0, label: 1002
lib entry: 10.10.7.0/24, rev 8
        local binding:  label: imp-null
        remote binding: lsr: 10.3.3.3:0, label: 17
  lib entry: 10.10.8.0/24, rev 9
        local binding:  label: imp-null
        remote binding: lsr: 10.3.3.3:0, label: imp-null
  lib entry: 10.10.9.0/24, rev 13
```

```
        local binding:  label: 16
        remote binding: lsr: 10.3.3.3:0, label: imp-null
```

The 10.10.7.0/24, 10.10.8.0/24, and 10.10.9.0/24 prefixes are no longer assigned local labels. Therefore, Device R1 sends no label advertisement for these prefixes.

LIB on Device R3 After Local Label Allocation Filtering

This example shows how the configuration of a local label allocation prefix-list filter on Device R1 changes the contents of the LIB on Device R3:

```
Device# show mpls ldp bindings
  lib entry: 10.1.1.1/32, rev 13
        local binding:  label: 16
        remote binding: lsr: 10.2.2.2:0, label: 17
        remote binding: lsr: 10.1.1.1:0, label: imp-null
  lib entry: 10.2.2.2/32, rev 15
        local binding:  label: 18
        remote binding: lsr: 10.2.2.2:0, label: imp-null
        remote binding: lsr: 10.1.1.1:0, label: 1000
  lib entry: 10.3.3.3/32, rev 7
        local binding:  label: imp-null
        remote binding: lsr: 10.2.2.2:0, label: 18
        remote binding: lsr: 10.1.1.1:0, label: 1002
  lib entry: 10.10.7.0/24, rev 11
        local binding:  label: 17
        remote binding: lsr: 10.2.2.2:0, label: imp-null
  lib entry: 10.10.8.0/24, rev 8
        local binding:  label: imp-null
        remote binding: lsr: 10.2.2.2:0, label: imp-null
  lib entry: 10.10.9.0/24, rev 9
        local binding:  label: imp-null
        remote binding: lsr: 10.2.2.2:0, label: 16
```

The 10.10.7.0/24, 10.10.8.0/24, and 10.10.9.0/24 prefixes are no longer assigned local labels. Again, Device R1 sends no label advertisement for these prefixes.

Command to Display the Local Label Allocation Filter

You can enter the **show mpls ldp detail** command to display the filter used for local label allocation. For example:

```
Device# show mpls ldp bindings detail

Advertisement spec:
        Prefix acl = List1
Local label filtering spec: host routes. ! <--- Local local label filtering spec

  lib entry: 10.1.1.1/32, rev 9
  lib entry: 10.10.7.0/24, rev 10
  lib entry: 10.10.8.0/24, rev 11
  lib entry: 10.10.9.0/24, rev 12
  lib entry: 10.41.41.41/32, rev 17
  lib entry: 10.50.50.50/32, rev 15
  lib entry: 10.60.60.60/32, rev 18
  lib entry: 10.70.70.70/32, rev 16
  lib entry: 10.80.80.80/32, rev 14
```

Feature Information for MPLS LDP Local Label Allocation Filtering

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Glossary

BGP—Border Gateway Protocol. An interdomain routing protocol that replaces Exterior Gateway Protocol (EGP). A BGP system exchanges reachability information with other BGP systems. It is defined by RFC 1163.

CE device—customer edge device. A device that is part of a customer network and that interfaces to a provider edge (PE) device. CE devices do not have routes to associated Virtual Private Networks (VPNs) in their routing tables.

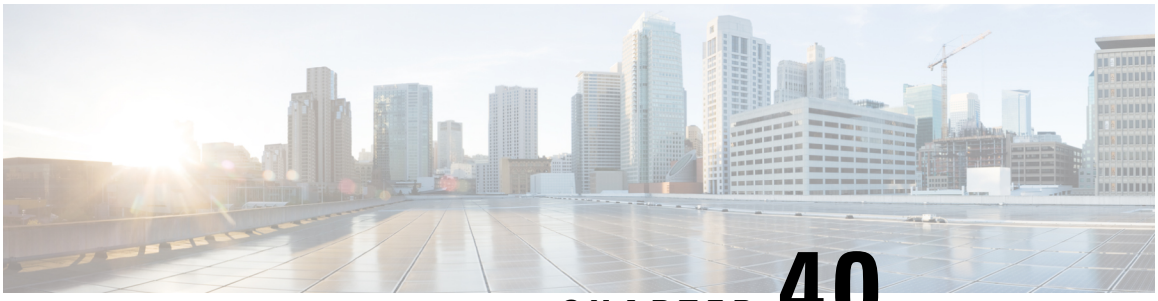
FEC—Forwarding Equivalence Class. A set of packets that can be handled equivalently for the purpose of forwarding and thus is suitable for binding to a single label. The set of packets destined for an address prefix is one example of an FEC.

IGP—Interior Gateway Protocol. Internet protocol used to exchange routing information within a single autonomous system. Examples of common Internet IGP protocols include Interior Gateway Routing Protocol (IGRP), Open Shortest Path First (OSPF), Intermediate System-to-Intermediate System (IS-IS), and Routing Information protocol (RIP).

label—A short fixed-length label that tells switching nodes how to forward data (packets or cells).

LDP—Label Distribution Protocol. A standard protocol between Multiprotocol Label Switching (MPLS)-enabled devices that is used for the negotiation of the labels (addresses) used to forward packets.

LIB—Label Information Base. A database used by a label switch router (LSR) to store labels learned from other LSRs, and labels assigned by the local LSR.



LSP—label switched path. A sequence of hops in which a packet travels from one device to another device by means of label switching mechanisms. A label switched path can be established dynamically, based on normal routing mechanisms, or through configuration.

LSR—label switch router. A device that forwards Multiprotocol Label Switching (MPLS) packets based on the value of a fixed-length label encapsulated in each packet.

MPLS—Multiprotocol Label Switching. A switching method that forwards IP traffic using a label. This label instructs the devices and the switches in the network where to forward the packets. The forwarding of MPLS packets is based on preestablished IP routing information

PE device—provider edge device. A device that is part of a service provider's network connected to a customer edge (CE) device. All Virtual Private Network (VPN) processing occurs in the PE device.

VPN—Virtual Private Network. A secure IP-based network that shares resources on one or more physical networks. A VPN contains geographically dispersed sites that can communicate securely over a shared backbone.

CHAPTER 40

MPLS LDP MD5 Global Configuration

The MPLS LDP MD5 Global Configuration feature provides enhancements to the Label Distribution Protocol (LDP) implementation of the Message Digest 5 (MD5) password. This feature allows you to enable LDP MD5 globally instead of on a per-peer basis. Using this feature you can set up password requirements for a set of LDP neighbors to help prevent unauthorized peers from establishing LDP sessions and to block spoofed TCP messages.

This document provides information about and configuration information for the global configuration of LDP MD5 protection.

- Prerequisites for MPLS LDP MD5 Global Configuration, on page 657
- Restrictions for MPLS LDP MD5 Global Configuration, on page 658
- Information About MPLS LDP MD5 Global Configuration, on page 658
- How to Configure MPLS LDP MD5 Global Configuration, on page 660
- Configuration Examples for MPLS LDP MD5 Global Configuration, on page 671
- Additional References, on page 672
- Feature Information for MPLS LDP MD5 Global Configuration, on page 673
- Glossary, on page 673

Prerequisites for MPLS LDP MD5 Global Configuration

- Cisco Express Forwarding or distributed Cisco Express Forwarding must be enabled on the label switch router (LSR).
- Routing (static or dynamic) must be configured for the LSR.
- Multiprotocol Label Switching (MPLS) Label Distribution Protocol (LDP) must be configured on the LSR. However, you can configure LDP Message Digest 5 (MD5) protection before you configure MPLS LDP. You can then use LDP MD5 protection after you configure MPLS LDP.
- A Virtual Private Network (VPN) routing and forwarding (VRF) instance must be configured if you want to configure MPLS LDP MD5 global configuration for a VRF. If you delete a VRF, the LDP MD5 global configuration for that VRF is automatically removed.

Restrictions for MPLS LDP MD5 Global Configuration

Message Digest 5 (MD5) protection described in this document applies only to Label Distribution Protocol (LDP) sessions. All enhancements described in this document do not affect Tag Distribution Protocol (TDP) sessions.

Information About MPLS LDP MD5 Global Configuration

Enhancements to LDP MD5 Protection for LDP Messages Between Peers

The MPLS LDP MD5 Global Configuration feature provides the following enhancements to the Label Distribution Protocol (LDP) support of Message Digest 5 (MD5) passwords:

- You can specify peers for which MD5 protection is required. This can prevent the establishment of LDP sessions with unexpected peers.
- You can configure passwords for groups of peers. This increases the scalability of LDP password configuration management.
- The established LDP session with a peer is not automatically torn down when the password for that peer is changed. The new password is used the next time an LDP session is established with the peer.
- You can control when the new password is used. You can configure the new password on the peer before forcing the use of the new password.
- If the neighboring nodes support graceful restart, then LDP sessions are gracefully restarted. The LDP MD5 password configuration is checkpointed to the standby Route Processors (RPs). The LDP MD5 password is used by the device when the new active RP attempts to establish LDP sessions with neighbors after the switchover.

LDP session, advertisement, and notification messages are exchanged between two LDP peers over a TCP connection. You can configure the TCP MD5 option to protect LDP messages that are exchanged over a TCP connection. You can configure this protection for each potential LDP peer. As a result, an LDP ignores any LDP hello messages sent from a label switch router (LSR) for which you have not configured a password. (LDP tries to establish an LDP session with each neighbor from which a hello message is received.)

Before the introduction of the MPLS LDP MD5 Global Configuration feature, you needed to configure a separate password for each LDP peer for which you wanted MD5 protection. This was the case even when the same password was used for multiple LDP peers. Before this feature, LDP would tear down LDP sessions with a peer immediately if a password for that peer had changed.

LDP MD5 Password Configuration Information

Before the introduction of the MPLS LDP MD5 Global Configuration feature, the command used for configuring a password for a Label Distribution Protocol (LDP) neighbor was **mpls ldp neighbor** [**vrf** *vrf-name*] *ip-address* **password** [**0** | **7**] *password*. This command configures a password for one neighbor whose router ID is the IP address in the specified virtual routing and forwarding (VRF). A label switch router (LSR) can have zero or one such configuration for each LDP neighbor.

You can use the commands provided by the MPLS LDP MD5 Global Configuration feature to configure passwords for LDP neighbors.

You must understand how LDP determines the password for an LDP session between peers before you configure Message Digest 5 (MD5) password protection for your network. LDP determines the passwords for its sessions based on the commands that you enter.

You can enter an **mpls ldp password vrf** *vrf-name* **required** [**for** *acl*] command, either with an optional *acl* argument that permits the LDP router ID of the neighbor or without an *acl* argument. Make sure that you enter a command that configures a password. Otherwise, LDP might not establish a session with the neighbor in question.

For the commands in the following password-determining process, *A.B.C.D:N* represents the LDP neighbor in VRF vpn1 and the neighbor LDP ID:

- *A.B.C.D* is the neighbor router ID.
- *N* is the neighbor label space ID.

To determine the password for an LDP session for the neighbor label space *A.B.C.D:N*, LDP looks at the password commands in the order indicated by the following statements:

- If you configured the **mpls ldp neighbor vrf vpn1** *A.B.C.D* **password** *pwd-nbr* command: The LDP session password is *pwd-nbr*. LDP looks no further and uses the password you specify. Otherwise, LDP looks to see if you configured one or more **mpls ldp vrf vpn1 password option** commands. LDP considers the commands in order of the ascending *number* arguments (*number-1st to number-n*). For example:
  - **mpls ldp vrf vpn1 password option** *number-1st* **for** *acl-1st pwd-1st*

    LDP compares the peer router ID of the neighbor (*A.B.C.D)* with this command. If *A.B.C.D* is permitted by the command access list *acl-1st*, the session password is the command password, that is, *pwd-1st*.

    If A.B.C.D is not permitted by *acl-1st*, LDP looks at the command with the next ascending *number* argument (*number-2nd*).
  - **mpls ldp vrf vpn1 password option** *number-2nd* **for** *acl-2nd pwd-2nd*

    If *A.B.C.D* is permitted by the command access list *acl-2nd*, the session password is *pwd-2nd*.

    If *A.B.C.D* is not permitted by the access list *acl-2nd*, LDP continues checking *A.B.C.D* against access lists until LDP:
    - Finds *A.B.C.D* permitted by an access list. Then the command password is the session password.
    - Has processed the *number-nth* argument of this command (*n* being the highest *number* argument you configured for this command).
  - If the **mpls ldp vrf vpn1 password option** *number-nth* **for** *acl-nth pwd-nth* command produces no match and, therefore no password, LDP looks to see if you configured the **mpls ldp password vrf vpn1 fallback** *pwd-fback* command.

    If you configured this command, the session password is *pwd-fback*.

    Otherwise, if LDP has not found a password, you did not configure a password for the session. LDP does not use MD5 protection for the session TCP connection.

LDP MD5 Password Configuration for Routing Tables

The MPLS LDP MD5 Global Configuration feature introduces commands that can establish password protection for Label Distribution Protocol (LDP) sessions between LDP neighbors or peers. These commands can apply to routes in the global routing table or in a virtual routing and forwarding (VRF) instance.

By default, if the **vrf** keyword is not specified in the command, the command applies to the global routing table. The following sample commands apply to routes in the global routing table:

```
Device# mpls ldp password required
Device# mpls ldp password option 15 for 99 pwd-acl
Device# mpls ldp password fallback pwd-fbck
```

You can configure LDP Message Digest 5 (MD5) password protection for routes in a VRF only when the VRF is configured on the label switch router (LSR). If you specify a VRF name and a VRF with that name is not configured on the LSR, LDP prints out a warning and discards the command. If you remove a VRF, LDP deletes the password configuration for that VRF. The following sample commands apply to routes in a VRF, for example, VRF vpn1:

```
Device# mpls ldp vrf vpn1 password required
Device# mpls ldp vrf vpn1 password option 15 for 99 pwd-acl
Device# mpls ldp vrf vpn1 password fallback pwd-flbk
```

How LDP Tears Down Sessions

You might require password protection for a certain set of neighbors for security reasons (for example, to prevent Label Distribution Protocol (LDP) sessions being established with unauthorized peers, or to block spoofed TCP messages). To enforce this security, you can configure a password requirement for LDP sessions with those neighbors that must have Message Digest 5 (MD5) protection (TCP session uses a password).

If you configure a password requirement for a neighbor and you did not configure a password for the neighbor, LDP tears down the LDP sessions with the neighbor. LDP also tears down the LDP sessions with the neighbor if you configured a password requirement and a password, and the password is not used in the LDP sessions.

If a password is required for a neighbor and the LDP sessions with the neighbor are established to use a password, any configuration that removes the password for the neighbor causes the LDP sessions to be torn down.

To avoid unnecessary LDP session flapping, you should perform the task as described in the next section and use caution when you change LDP passwords.

How to Configure MPLS LDP MD5 Global Configuration

Identifying LDP Neighbors for LDP MD5 Password Protection

Perform the following task to identify LDP neighbors for LDP MD5 password protection.

Before you begin

Before you start to configure passwords for Label Distribution Protocol (LDP) sessions, you must identify neighbors or groups of peers for which you want to provide Message Digest 5 (MD5) protection. For example:

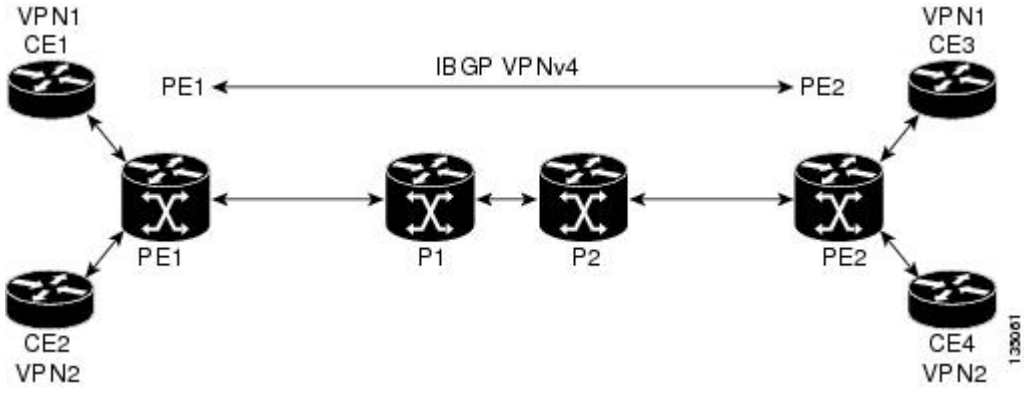
- You might have several customers that all use the same core devices. To ensure security you might want to provide each customer with a different password.
- You could have defined several departmental virtual routing and forwarding (VRF) instances in your network. You could provide password protection for each VRF.
- Certain groups of peers might require password protection for security reasons. Password protection prevents unwanted LDP sessions.

SUMMARY STEPS

1. Identify LDP neighbors or groups of peers for LDP MD5 password protection.
2. Decide what LDP MD5 protection is required for each neighbor or group of peers.

DETAILED STEPS

Procedure



Step 1 Identify LDP neighbors or groups of peers for LDP MD5 password protection.

This task uses the network in the figure below to show how you might identify LDP neighbors for LDP MD5 protection.

The figure below shows a sample network that has the following topology:

- Carrier Supporting Carrier (CSC) is configured between provider edge (PE) device PE1 and customer edge (CE) device CE1 and between PE1 and CE2.
- Internal Border Gateway Protocol (IBGP) Virtual Private Network (VPN) IPv4 (VPNv4) to support Layer 3 VPNs is configured between PE1 and PE2.
- CE1 and CE3 are in VRF VPN1. CE2 and CE4 are in a different VRF, VPN2.

Figure 49: Sample Network: Identifying LDP Neighbors for LDP MD5 Protection

For the sample network in the figure above, you could configure separate passwords on PE1 for the following:

- VRF VPN1
- VRF VPN2

You could also configure a password requirement on PE1 for P1, P2, CE1 and CE2.

Step 2 Decide what LDP MD5 protection is required for each neighbor or group of peers.

Configuring an LDP MD5 Password for LDP Sessions

This section contains information about and instructions for configuring a Label Distribution Protocol (LDP) Message Digest 5 (MD5) password for LDP sessions. You configure an LDP MD5 password to protect your devices from unwanted LDP sessions and provide LDP session security. You can provide LDP session security for a specific neighbor, or for LDP peers from a specific virtual routing and forwarding (VRF) instance or from the global routing table, or for a specific set of LDP neighbors.

After you have identified the LDP neighbor, LDP neighbors, or LDP peers in your network for which you want LDP MD5 password protection, perform the following procedures, as you require, to configure an LDP MD5 password for LDP sessions:

Configuring an LDP MD5 Password for a Specified Neighbor

LDP looks first for a password between the device and neighbor that is configured with the **mpls ldp neighbor** [**vrf** *vrf-name*] *ip-address* **password** *pwd-string* command. If a password is configured with this command, LDP uses that password before checking passwords configured by other commands.

You must add a configuration command for each neighbor or peer for which you want password protection.

Before you begin

Identify the Label Distribution Protocol (LDP) neighbor or peer for which you want Message Digest 5 (MD5) password protection.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls ldp neighbor** [**vrf** *vrf-name*] *ip-address* **password** [**0** | **7**] *password-string*
4. **end**
5. **show mpls ldp neighbor** [**vrf** *vrf-name* | **all**] [*ip-address* | [*interface*] [**detail**] [**graceful-restart**]
6. **show mpls ldp neighbor** [**vrf** *vrf-name*] [*ip-address* | *interface*] **password** [**pending** | **current**]
7. **show mpls ldp discovery** [**vrf** *vrf-name* | **all**] [**detail**]

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.

	Command or Action	Purpose
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.

Step 3	**mpls ldp neighbor** [**vrf** *vrf-name*] *ip-address* **password** [**0** | **7**] *password-string*
	Example:
	`Device(config)# mpls ldp neighbor vrf vpn1 10.1.1.1 password nbrce1pwd`
		Configures a password key for computing MD5 checksums for the session TCP connection with the specified neighbor.
		• The **vrf** *vrf-name* keyword and argument specifies the virtual private network (VPN) routing and forwarding instance for the specified neighbor.
		• The *ip-address* argument specifies the router ID (IP address) that identifies a neighbor.
		• The [**0** | **7**] keywords specify whether the password that follows is encrypted:
		  • **0** specifies a clear-text (nonencrypted) password.
		  • **7** specifies a Cisco proprietary encrypted password.
		• The *password-string* argument defines the password key to be used for computing MD5 checksums for the session TCP connection with the specified neighbor.

Step 4	**end** **Example:** `Device(config)# end`	Returns to privileged EXEC mode.
Step 5	**show mpls ldp neighbor** [**vrf** *vrf-name* | **all**] [*ip-address* | [*interface*] [**detail**] [**graceful-restart**] **Example:** `Device# show mpls ldp neighbor vrf vpn1 detail`	Displays the status of LDP sessions. • The **vrf** *vrf-name* keyword and argument displays the LDP neighbors for the specified VRF instance (*vrf-name*). • The **all** keyword displays LDP neighbor information for all VPNs, including those in the default routing domain. • The *ip-address* argument identifies the neighbor with the IP address for which you configured password protection. • The *interface* argument defines the LDP neighbors accessible over this interface. • The **detail** keyword displays information in long form, including password information for this neighbor. Here are the items displayed:

	Command or Action	Purpose
		• An indication as to whether a password is mandatory for this neighbor (required or not required) • The password source (neighbor, fallback or number [option number]) • An indication as to whether the latest configured password for this neighbor is used by the TCP session (in use) or the TCP session uses an old password (stale) • The **graceful-restart** keyword displays per-neighbor graceful restart information.
Step 6	**show mpls ldp neighbor** [**vrf** *vrf-name*] [*ip-address* | *interface*] **password** [**pending** | **current**] **Example:** `Device# show mpls ldp neighbor vrf vpn1 password`	Displays password information used in established LDP sessions. • The **vrf** *vrf-name* keyword and argument displays the LDP neighbors for the specified VRF instance (*vrf-name*). • The *ip-address* argument identifies the neighbor with the IP address for which you configured password protection. • The *interface* argument defines the LDP neighbors accessible over this interface. • The **pending** keyword displays LDP sessions whose passwords are different from that in the current configuration. • The **current** keyword displays LDP sessions whose password is the same as that in current configuration. If you do not specify an optional keyword for this command, password information for all established LDP sessions is displayed.
Step 7	**show mpls ldp discovery** [**vrf** *vrf-name* | **all**] [**detail**] **Example:** `Device# show mpls ldp discovery vrf vpn1 detail`	Displays the status of the LDP discovery process. • The **vrf** *vrf-name* keyword and argument displays the neighbor discovery information for the specified VRF instance (*vrf-name*). • The **all** keyword displays LDP discovery information for all VPNs, including those in the default routing domain. • The **detail** keyword displays detailed information about all LDP discovery sources on a label switch router (LSR).

Configuring an LDP MD5 Password for LDP Sessions with Peers from a Specified VRF

This task provides you with Label Distribution Protocol (LDP) session protection with peers from a particular virtual routing and forwarding (VRF) instance or the global routing table. If you want a password requirement, you can use the **mpls ldp password required** command.

If only LDP sessions with a set of LDP neighbors need Message Digest 5 (MD5) protection, configure a standard IP access list that permits the desired set of LDP neighbors and denies the rest.

Before you begin

Identify LDP peers for which you want MD5 password protection.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls ldp** [**vrf** *vrf-name*] **password fallback** [**0** | **7**] *password*
4. **mpls ldp** [**vrf** *vrf-name*] **password required** [**for** *acl*]
5. **end**
6. **show mpls ldp discovery** [**vrf** *vrf-name* | **all**] [**detail**]

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.

Step 3	**mpls ldp** [**vrf** *vrf-name*] **password fallback** [**0**	**7**] *password*
		Example:
		`Device(config)# mpls ldp vrf vpn1 password fallback 0 vrfpwdvppn1`
			Configures an MD5 password for LDP sessions with peers.
			• The **vrf** *vrf-name* keyword and argument specifies a VRF configured on the label switch router (LSR).
			• The [**0**
				7] keywords specify whether the password that follows is encrypted:
				  • **0** specifies a clear-text (nonencrypted) password.
				  • **7** specifies a Cisco proprietary encrypted password.
				• The *password* argument specifies the MD5 password to be used for the LDP sessions with peers whose

	Command or Action	Purpose
		connections are established through a named VRF or the global routing table. The example sets up an MD5 password for a VRF.
Step 4	**mpls ldp** [**vrf** *vrf-name*] **password required** [**for** *acl*] **Example:** `Device(config)# mpls ldp vrf vpn1 password required`	Specifies that LDP must use a password when establishing a session between LDP peers. • The **vrf** *vrf-name* keyword and argument specifies a VRF configured on the LSR. • The **for** *acl* keyword and argument names an access list that specifies that a password is mandatory only for LDP sessions with neighbors whose LDP router IDs are permitted by the list. Only standard IP access lists can be used for the *acl* argument.
Step 5	**end** **Example:** `Device(config)# end`	Returns to privileged EXEC mode.
Step 6	**show mpls ldp discovery** [**vrf** *vrf-name* | **all**] [**detail**] **Example:** `Device# show mpls ldp discovery detail`	Displays the status of the LDP discovery process. • The **vrf** *vrf-name* keyword and argument displays the neighbor discovery information for the specified VPN routing and forwarding instance (*vrf-name*). • The **all** keyword displays LDP discovery information for all VPNs, including those in the default routing domain. • The **detail** keyword displays detailed information about all LDP discovery sources on an LSR. Use this command to verify that the password configuration is correct for all LDP neighbors.

Configuring an LDP MD5 Password for LDP Sessions with a Selected Group of Peers

If only Label Distribution Protocol (LDP) sessions with a selected group of peers need Message Digest 5 (MD5) protection, configure a standard IP access list that permits sessions with the desired group of peers (identified by LDP router IDs) and denies session with the rest. Configuring a password and password requirement for these neighbors or peers provides security by preventing LDP sessions from being established with unauthorized peers.

Before you begin

Identify the groups of peers for which you want MD5 password protection and define an access list that permits LDP sessions with the group of peers you require.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls ldp** [**vrf** *vrf-name*] **password option** *number* **for** *acl* [**0** | **7**] *password*
4. **mpls ldp** [**vrf** *vrf-name*] **password required** [**for** *acl*]
5. **end**
6. **show mpls ldp discovery** [**vrf** *vrf-name* | **all**] [**detail**]

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.

Step 3	**mpls ldp** [**vrf** *vrf-name*] **password option** *number* **for** *acl* [**0**	**7**] *password*
		Example:
		`Device(config)# mpls ldp password option 25 for 10 aclpwdfor10`
			Configures an MD5 password for LDP sessions with neighbors whose LDP router IDs are permitted by a specified access list.
			• The **vrf** *vrf-name* keyword and argument specifies a virtual routing and forwarding (VRF) instance configured on the label switch router (LSR).
			• The *number* argument defines the order in which the access lists are evaluated in the determination of a neighbor password. The range is 1 through 32767.
			• The **for** *acl* keyword and argument specifies the name of the access list that includes the LDP router IDs of those neighbors for which the password applies. Only standard IP access list values (1 through 99) can be used for the *acl* argument.
			• The [**0**
				7] keywords specify whether the password that follows is encrypted:
				  • **0** specifies a clear-text (nonencrypted) password.
				  • **7** specifies a Cisco proprietary encrypted password.
				• The *password* argument specifies the MD5 password to be used for the specified LDP sessions.

	Command or Action	Purpose
Step 4	**mpls ldp** [**vrf** *vrf-name*] **password required** [**for** *acl*] **Example:** `Device(config)# mpls ldp password required for 10`	Specifies that LDP must use a password when establishing a session between LDP peers. • The **vrf** *vrf-name* keyword and argument specifies a VRF configured on the LSR. • The **for** *acl* keyword and argument names an access list. The access list specifies a password is mandatory only for LDP sessions with neighbors whose LDP router IDs are permitted by the list. Only standard IP access lists can be used for the *acl* argument.
Step 5	**end** **Example:** `Device(config)# end`	Returns to privileged EXEC mode.
Step 6	**show mpls ldp discovery** [**vrf** *vrf-name* | **all**] [**detail**] **Example:** `Device# show mpls ldp discovery detail`	Displays the status of the LDP discovery process. • The **vrf** *vrf-name* keyword and argument displays the neighbor discovery information for the specified VPN routing and forwarding instance (*vrf-name*). • The **all** keyword displays LDP discovery information for all virtual private networks (VPNs), including those in the default routing domain. • The **detail** keyword displays detailed information about all LDP discovery sources on an LSR. Use this command to verify password configuration is correct for all LDP neighbors.

Verifying the LDP MD5 Configuration

Perform the following task to verify that the Label Distribution Protocol (LDP) Message Digest 5 (MD5) secure sessions are as you configured for all LDP neighbors.

SUMMARY STEPS

1. **enable**
2. **show mpls ldp discovery detail**
3. **show mpls ldp neighbor detail**
4. **show mpls ldp neighbor password** [**pending** | **current**]
5. **exit**

DETAILED STEPS

Procedure

Step 1 **enable**

Enables privileged EXEC mode. Enter your password if prompted.

Example:

```
Device> enable
Device#
```

Step 2 **show mpls ldp discovery detail**

Verifies that the LDP MD5 password information is as you configured for each neighbor.

Example:

```
Device# show mpls ldp discovery detail

 Local LDP Identifier:
    10.1.1.1:0
    Discovery Sources:
    Interfaces:
        Ethernet1/0 (ldp): xmit/recv
            Hello interval: 5000 ms; Transport IP addr: 10.1.1.1
            LDP Id: 10.4.4.4:0
              Src IP addr: 10.0.20.4; Transport IP addr: 10.4.4.4
              Hold time: 15 sec; Proposed local/peer: 15/15 sec
              Password: not required, none, stale
    Targeted Hellos:
        10.1.1.1 -> 10.3.3.3 (ldp): passive, xmit/recv
            Hello interval: 10000 ms; Transport IP addr: 10.1.1.1
            LDP Id: 10.3.3.3:0
              Src IP addr: 10.3.3.3; Transport IP addr: 10.3.3.3
              Hold time: 90 sec; Proposed local/peer: 90/90 sec
              Password: required, neighbor, in use
```

The Password field might display any of the following for the status of the password:

- Required or not required—Indicates whether password configuration is required.
- Neighbor, none, option #, or fallback—Indicates the password source when the password was configured.
- In use (current) or stale (previous)—Indicates the current LDP session password usage status.

Look at the output of the command to verify your configuration.

Step 3 **show mpls ldp neighbor detail**

Verifies that the password information for a neighbor is as you configured.

Example:

```
Device# show mpls ldp neighbor detail

    Peer LDP Ident: 10.3.3.3:0; Local LDP Ident 10.1.1.1:0
        TCP connection: 10.3.3.3.11018 - 10.1.1.1.646
```

```
        Password: required, neighbor, in use
        State: Oper; Msgs sent/rcvd: 167/167; Downstream; Last TIB rev sent 9
        Up time: 02:24:02; UID: 5; Peer Id 3;
        LDP discovery sources:
          Targeted Hello 10.1.1.1 -> 10.3.3.3, passive;
            holdtime: 90000 ms, hello interval: 10000 ms
        Addresses bound to peer LDP Ident:
          10.3.3.3        10.0.30.3
        Peer holdtime: 180000 ms; KA interval: 60000 ms; Peer state: estab
    Peer LDP Ident: 10.4.4.4:0; Local LDP Ident 10.1.1.1:0
        TCP connection: 10.4.4.4.11017 - 10.1.1.1.646
        Password: not required, none, stale
        State: Oper; Msgs sent/rcvd: 9/9; Downstream; Last TIB rev sent 9
        Up time: 00:05:35; UID: 6; Peer Id 1;
        LDP discovery sources:
          Ethernet1/0; Src IP addr: 10.0.20.4
            holdtime: 15000 ms, hello interval: 5000 ms
        Addresses bound to peer LDP Ident:
          10.0.40.4       10.4.4.4        10.0.20.4
        Peer holdtime: 180000 ms; KA interval: 60000 ms; Peer state: estab
```

Step 4 **show mpls ldp neighbor password** [**pending** | **current**]

Verifies that LDP sessions are using the password configuration that you expect, either the same as or different from that in the current configuration. The **pending** keyword displays information for LDP sessions whose password is different from that in the current configuration. The **current** keyword displays information for LDP sessions whose password is the same as that in the current configuration.

Example:

```
Device# show mpls ldp neighbor password

    Peer LDP Ident: 10.4.4.4:0; Local LDP Ident 10.1.1.1:0
        TCP connection: 10.4.4.4.11017 - 10.1.1.1.646
        Password: not required, none, stale
        State: Oper; Msgs sent/rcvd: 57/57
    Peer LDP Ident: 10.3.3.3:0; Local LDP Ident 10.1.1.1:0
        TCP connection: 10.3.3.3.11018 - 10.1.1.1.646
        Password: required, neighbor, in use
        State: Oper; Msgs sent/rcvd: 216/215
Device# show mpls ldp neighbor password pending

    Peer LDP Ident: 10.4.4.4:0; Local LDP Ident 10.1.1.1:0
        TCP connection: 10.4.4.4.11017 - 10.1.1.1.646
        Password: not required, none, stale
        State: Oper; Msgs sent/rcvd: 57/57
Device# show mpls ldp neighbor password current

    Peer LDP Ident: 10.3.3.3:0; Local LDP Ident 10.1.1.1:0
        TCP connection: 10.3.3.3.11018 - 10.1.1.1.646
        Password: required, neighbor, in use
        State: Oper; Msgs sent/rcvd: 216/215
```

This command displays password information used in established LDP sessions. If you do not enter an optional **pending** or **current** keyword for the command, password information for all established LDP sessions is displayed.

Step 5 **exit**

Returns to user EXEC mode. For example:

Example:

```
Device# exit
Device>
```

Configuration Examples for MPLS LDP MD5 Global Configuration

Example: Configuring an LDP MD5 Password for LDP Sessions for a Specified Neighbor

The following example shows how to configure a Label Distribution Protocol (LDP) Message Digest 5 (MD5) password for LDP sessions for a specified neighbor:

```
enable
configure terminal
mpls ldp vrf vpn1 10.1.1.1 password nbrscrtpwd
end
```

This sets up nbrscrtpwd as the password to use for LDP sessions for the neighbor whose LDP router ID is 10.1.1.1. Communication with this neighbor is through VRF vpn1.

Examples: Configuring an LDP MD5 Password for LDP Sessions with Peers from a Specified VRF

The following example shows how to configure a Label Distribution Protocol (LDP) Message Digest 5 (MD5) password for LDP sessions with peers from a specified virtual routing and forwarding (VRF) instance. The password vrfpwdvpn1 is configured for use with LDP peers that communicate using VRF vpn1. A password is required; otherwise, LDP tears down the session.

```
enable
configure terminal
mpls ldp vrf vpn1 password fallback vrfpwdvpn1
mpls ldp vrf vpn1 password required
end
```

The following example shows how to configure a password that is used for sessions for peers that communicate using the global routing table:

```
enable
configure terminal
mpls ldp password fallback vrfpwdvppn1
end
```

Example: Configuring an LDP MD5 Password for LDP Sessions with a Selected Group of Peers

The following example shows how to configure a Label Distribution Protocol (LDP) Message Digest 5 (MD5) password for LDP sessions with a selected group of peers. The required password aclpwdfor10 is configured for access list 10. Only those LDP router IDs permitted in access list 10 are required to use the password.

```
enable
configure terminal
mpls ldp password option 25 for 10 aclpwdfor10
mpls ldp password required for 10
end
```

Access list 10 might look something like this:

```
enable
configure terminal
access-list 10 permit 10.1.1.1
access-list 10 permit 10.3.3.3
access-list 10 permit 10.4.4.4
access-list 10 permit 10.1.1.1
access-list 10 permit 10.2.2.2
end
```

The Cisco Support and Documentation website provides online resources to download documentation, software, and tools. Use these resources to install and configure the software and to troubleshoot and resolve technical issues with Cisco products and technologies. Access to most tools on the Cisco Support and Documentation website requires a Cisco.com user ID and password.	http://www.cisco.com/cisco/web/support/index.html

Feature Information for MPLS LDP MD5 Global Configuration

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Feature Information for MPLS LDP MD5 Global Configuration

Table 93: Feature Information for MPLS LDP MD5 Global Configuration

Feature Name	Releases	Feature Information
MPLS LDP MD5 Global Configuration		The MPLS LDP MD5 Global Configuration feature provides enhancements to the Label Distribution Protocol (LDP) implementation of the Message Digest 5 (MD5) password. This feature allows you to enable LDP MD5 globally instead of on a per-peer basis. With this feature, you can set up password requirements for a set of LDP neighbors to help prevent unauthorized peers from establishing LDP sessions and to block spoofed TCP messages.
		The following commands were modified by this feature: **mpls ldp password fallback**, **mpls ldp password option**, **mpls ldp password required**, **show mpls ldp discovery**, **show mpls ldp neighbor**, **show mpls ldp neighbor password**.

Glossary

BGP—Border Gateway Protocol. An interdomain routing protocol that replaces External Gateway Protocol (EGP). BGP systems exchange reachability information with other BGP systems. BGP is defined by RFC 1163.

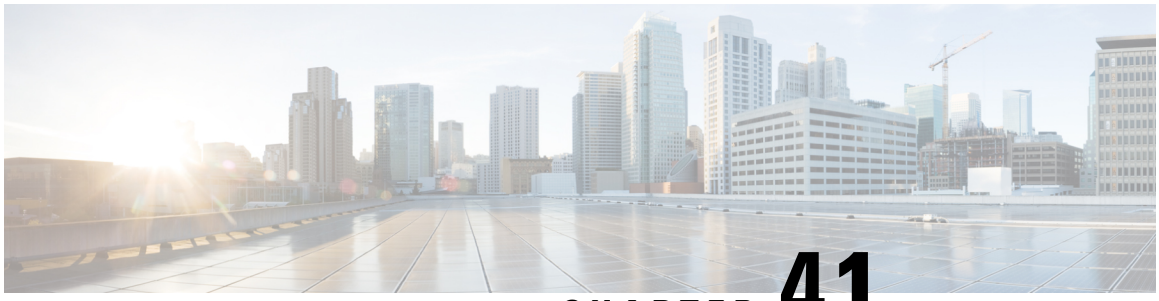
EGP—Exterior Gateway Protocol. An internet protocol for exchanging routing information between autonomous systems. EGP is documented in RFC 904. EGP is not to be confused with the general term exterior gateway protocol. EGP is an obsolete protocol that was replaced by Border Gateway Protocol (BGP).

CE device—customer edge device. A device that is part of a customer network and that interfaces to a provider edge (PE) device.

CSC—Carrier Supporting Carrier. A situation where one service provider allows another service provider to use a segment of its backbone network. The service provider that provides the segment of the backbone network to the other provider is called the backbone carrier. The service provider that uses the segment of the backbone network is called the customer carrier.

LDP—Label Distribution Protocol. A standard protocol between Multiprotocol Label Switching (MPLS)-enabled devices that is uses in the negotiation of the labels used to forward packets. The Cisco proprietary version of this protocol is the Tag Distribution Protocol (TDP).

LDP peer—A label switch router (LSR) that is the receiver of label space information from another LSR. If an LSR has a label space to advertise to another LSR, or to multiple LSRs, one Label Distribution Protocol (LDP) session exists for each LSR (LDP peer) receiving the label space information.



MD5—Message Digest 5. A one-way hashing algorithm that produces a 128-bit hash. Both MD5 and Secure Hash Algorithm (SHA) are variations on MD4 and are designed to strengthen the security of the MD4 hashing algorithm. Cisco uses hashes for authentication within the IPSec framework. SNMP v2 uses MD5 for message authentication, to verify the integrity of the communication, to authenticate the message origin, and to check its timeliness.

MPLS—Multiprotocol Label Switching. A switching method that forwards IP traffic through use of labels. Each label instructs the devices and the switches in the network where to forward a packet based on preestablished IP routing information.

PE device—provider edge device. A device that is part of a service provider's network connected to a customer edge (CE) device. All Multiprotocol Label Switching (MPLS) Virtual Private Network (VPN) processing occurs in the PE device.

VPN—Virtual Private Network. Enables IP traffic to travel securely over a public TCP/IP network by encrypting all traffic forwarded from one network to another. A VPN uses tunneling to encrypt all information at the IP level.

VRF—A VPN routing and forwarding instance. A VRF consists of an IP routing table, a derived forwarding table, a set of interfaces that use the forwarding table, and a set of rules and routing protocols that determine what goes into the forwarding table. In general, a VRF includes the routing information that defines a customer VPN site that is attached to a PE device.

CHAPTER 41

MPLS LDP Lossless MD5 Session Authentication

The MPLS LDP Lossless MD5 Session Authentication feature enables a Multiprotocol Label Switching (MPLS) Label Distribution Protocol (LDP) session to be password-protected without tearing down and reestablishing the LDP session.

- Prerequisites for MPLS LDP Lossless MD5 Session Authentication, on page 675
- Restrictions for MPLS LDP Lossless MD5 Session Authentication, on page 676
- Information About MPLS LDP Lossless MD5 Session Authentication, on page 676
- How to Configure MPLS LDP Lossless MD5 Session Authentication, on page 679
- Configuration Examples for MPLS LDP Lossless MD5 Session Authentication, on page 687
- Additional References, on page 699
- Feature Information for MPLS LDP Lossless MD5 Session Authentication, on page 699

Prerequisites for MPLS LDP Lossless MD5 Session Authentication

The MPLS LDP Lossless MD5 Session Authentication feature is an enhancement to the MPLS LDP MD5 Global Configuration feature. Before configuring the MPLS LDP Lossless MD5 Session Authentication feature, see the “MPLS LDP MD5 Global Configuration” feature module for more information on how the message digest algorithm 5 (MD5) works with Multiprotocol Label Switching (MPLS) Label Distribution Protocol (LDP) to ensure that LDP segments remain properly protected.

Note The MPLS LDP Lossless MD5 Session Authentication feature must be configured before MPLS LDP is configured.

Configure the following features on the label switch router (LSR) before configuring the MPLS LDP Lossless MD5 Session Authentication feature:

- Distributed Cisco Express Forwarding
- Static or dynamic routing
- MPLS Virtual Private Network (VPN) routing and forwarding (VRFs) instances for MPLS VPNs
- MPLS LDP Lossless MD5 Session Authentication for the MPLS VPN VRFs

Note If a VRF is deleted, then the lossless MD5 session authentication for that VRF is automatically removed.

Restrictions for MPLS LDP Lossless MD5 Session Authentication

Message Digest 5 (MD5) protection applies to Label Distribution Protocol {LDP} sessions between peers. Tag Distribution Protocol (TDP) sessions between peers are not protected.

Information About MPLS LDP Lossless MD5 Session Authentication

How MPLS LDP Messages in MPLS LDP Lossless MD5 Session Authentication are Exchanged

Multiprotocol Label Switching (MPLS) Label Distribution Protocol (LDP) messages (discovery, session, advertisement, and notification messages) are exchanged between LDP peers through two channels:

- LDP discovery messages are transmitted as User Datagram Protocol (UDP) packets to the well-known LDP port.
- Session, advertisement, and notification messages are exchanged through a TCP connection established between two LDP peers.

The MPLS LDP Lossless MD5 Session Authentication feature allows an LDP session to be password-protected without tearing down and reestablishing the LDP session. The Message Digest 5 (MD5) password can be implemented and changed without interrupting the LDP session.

The Evolution of MPLS LDP MD5 Password Features

The initial version of Label Distribution Protocol (LDP) Message Digest 5 (MD5) protection allowed authentication to be enabled between two LDP peers and each segment sent on the TCP connection was verified between the peers. Authentication was configured on both LDP peers using the same password; otherwise, the peer session was not established. The **mpls ldp neighbor** command was issued with the **password** keyword. When MD5 protection was enabled, the device tore down the existing LDP sessions and established new sessions with the neighbor device.

An improved MD5 protection feature, called MPLS LDP MD5 Global Configuration, was later introduced that allowed LDP MD5 to be enabled globally instead of on a per-peer basis. Using this feature, password requirements for a set of LDP neighbors could be configured. The MPLS LDP MD5 Global Configuration feature also improved the ability to maintain the LDP session. The LDP session with a peer was not automatically torn down when the password for that peer was changed. The new password was implemented the next time an LDP session was established with the peer.

The MPLS LDP Lossless MD5 Session Authentication feature is based on the MPLS LDP MD5 Global Configuration feature. However, the MPLS LDP Lossless MD5 Session Authentication feature provides the following enhancements:

- Activate or change LDP MD5 session authentication without interrupting the LDP session.
- Configure multiple passwords, so one password can be used now and other passwords later.
- Configure asymmetric passwords, which allows one password to be used for incoming TCP segments and a different password to be used for outgoing TCP segments.
- Configure passwords so that they overlap for a period of time. This functionality is beneficial when the clocks on two label switch routers (LRS) are not synchronized.

These enhancements are available by using the **key-chain** command, which allows different key strings to be used at different times according to the keychain configuration.

Keychains Use with MPLS LDP Lossless MD5 Session Authentication

The MPLS LDP Lossless MD5 Session Authentication feature allows keychains to be used to specify different Message Digest 5 (MD5) keys to authenticate Label Distribution Protocol (LDP) traffic exchanged in each direction.

In the following example, three passwords are configured:

```
key chain ldp-pwd
 key 1
  key-string lab
  send-lifetime 10:00:00 Nov 2 2008 10:00:00 Dec 2 2008
  accept-lifetime 00:00:00 Jan 1 1970 duration 1
 key 2
  key-string lab2
  send-lifetime 00:00:00 Jan 1 1970 duration 1
  accept-lifetime 10:00:00 Nov 2 2008 10:00:00 Nov 17 2008
 key 3
  key-string lab3
  send-lifetime 00:00:00 Jan 1 1970 duration 1
  accept-lifetime 10:00:00 Nov 17 2008 10:00:00 Dec 2 2008
!
mpls ldp password option 1 for nbr-acl key-chain ldp-pwd
```

- Key 1 specifies the lab password. The **send-lifetime** command enables the lab password to authenticate the outgoing TCP segments from November 2, 2008, at 10:00:00 a.m. until December 2, 2008, at 10:00:00 a.m. The **accept-lifetime** command is configured so that the lab password is never used to authenticate incoming TCP segments. The **accept-lifetime** command enables the lab password for 1 second on January 1, 1970. By setting the date to the past and by enabling a duration of 1 second, the password for incoming TCP segments immediately expires. If the **accept-lifetime** command is omitted from the keychain configuration, then the password is always valid for incoming TCP segments.
- Key 2 and key 3 specify the lab2 and lab3 passwords, respectively. The **send-lifetime** commands enable the passwords for 1 second on January 1, 1970. By setting the date to the past and by enabling a duration of 1 second, the passwords for outgoing TCP segments immediately expire. If the **send-lifetime** commands are omitted from the keychain configuration, the passwords are always valid for outgoing TCP segments. The **accept-lifetime** commands for key 2 and key 3 enable the passwords to authenticate the incoming TCP segments from November 2, 2008, at 10:00:00 a.m. until November 17, 2008, at 10:00:00 a.m. and from November 17, 2008, at 10:00:00 a.m. until December 2, 2008, at 10:00:00 a.m., respectively.

Application of Rules to Overlapping Passwords

Overlapping passwords can be useful when two label switch routers (LSRs) have clocks that are not synchronized. The overlapping passwords provide a window to ensure that TCP packets are not dropped. The following rules apply to overlapping passwords:

- If the send-lifetime value for the next password begins before the send-lifetime value of the current password expires, the password with the shorter key ID is used during the overlap period. The send-lifetime value of the current password can be shortened by configuring a shorter send-lifetime value. Similarly, the send-lifetime value of the current password can be lengthened by configuring a longer send-lifetime value.
- If the accept-lifetime value for the next password begins before the accept-lifetime value of the current password expires, both the next password and the current password are used concurrently. The next password information is passed to TCP. If TCP fails to authenticate the incoming segments with the current password, it tries authenticating with the next password. If TCP authenticates a segment using the new password, it discards the current password and uses the new password from that point on.
- If a password for incoming or outgoing segments expires and no additional valid password is configured, one of the following actions take place:
  - If a password is required for the neighbor, the Label Distribution Protocol (LDP) drops the existing session.
  - If a password is not required for the neighbor, LDP attempts to roll over to a session that does not require authentication. This attempt also fails unless the password expires on both LSRs at the same time.

Password Rollover Period Guidelines

Both old and new passwords are valid during a rollover period. This ensures a smooth rollover when clocks are not synchronized between two Label Distribution Protocol (LDP) neighbors. When passwords are configured using a keychain, the rollover period is equal to the accept-lifetime overlap between two successive receive passwords.

The minimum rollover period (the duration between two consecutive Message Digest 5 (MD5) key updates) must be longer than the value of the LDP keepalive interval time to ensure an update of new MD5 authentication keys. If LDP session hold time is configured to its default value of 3 minutes, the LDP keepalive interval is 1 minute. The minimum rollover period should be 5 minutes. However, we recommend that the minimum rollover period is set to between 15 and 30 minutes.

To ensure a seamless rollover, follow these guidelines:

- Ensure that the local time on the peer label switch routers (LSRs) is the same before configuring the keychain.
- Check for error messages (TCP-6-BADAUTH) that indicate keychain misconfiguration.
- Validate the correct keychain configuration by checking for the following password messages:

```
%LDP-5-PWDCFG: Password configuration changed for 10.1.1.1:0
%LDP-5-PWDRO: Password rolled over for 10.1.1.1:0
```

Resolving LDP Password Problems

The Label Distribution Protocol (LDP) displays error messages when an unexpected neighbor attempts to open an LDP session, or the LDP password configuration is invalid. Some existing LDP debugs also display password information.

When a password is required for a potential LDP neighbor, but no password is configured for it, the label switch router (LSR) ignores LDP hello messages from that neighbor. When the LSR processes the hello message and tries to establish a TCP connection with the neighbor, it displays the error message and stops establishing the LDP session with the neighbor. The error is rate-limited and has the following format:

```
00:00:57: %LDP-5-PWD: MD5 protection is required for peer 10.2.2.2:0(glbl), no password
configured
```

When passwords do not match between LDP peers, TCP displays the following error message on the LSR that has the lower router ID; that is, the device that has the passive role in establishing TCP connections:

```
00:01:07: %TCP-6-BADAUTH: Invalid MD5 digest from 10.2.2.2(11051) to 10.1.1.1(646)
```

If one peer has a password configured and the other one does not, TCP displays the following error messages on the LSR that has a password configured:

```
00:02:07: %TCP-6-BADAUTH: No MD5 digest from 10.1.1.1(646) to 10.2.2.2(11099)
```

How to Configure MPLS LDP Lossless MD5 Session Authentication

Configuring MPLS LDP Lossless MD5 Session Authentication Using a Keychain

Perform the following task to configure the MPLS LDP Lossless MD5 Session Authentication feature using a keychain. Keychains allow a different key string to be used at different times according to the keychain configuration. Multiprotocol Label Switching (MPLS) Label Distribution Protocol (LDP) queries the appropriate keychain to obtain the current live key and key ID for the specified keychain.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **access-list** *access-list-number* {**permit** | **deny**} {*type-code wildcard-mask* | *ip-address mask*}
4. **key chain** *name-of-chain*
5. **key** *key-id*
6. **key-string** *string*
7. **accept-lifetime** {*start-time* | **local** *start-time*} {**duration** | *seconds end-time* | **infinite**}
8. **send-lifetime** {*start-time* | **local** *start-time*} {**duration** *seconds end-time* | **infinite**}
9. **exit**
10. **exit**
11. **mpls ldp** [**vrf** *vrf-name*] **password option** *number* **for** *acl* {**key-chain** *keychain-name* | [**0** | **7**] *password*}

12. **exit**
13. **show mpls ldp neighbor** [**vrf** *vrf-name* | **all**] [*ip-address* | *interface*] [**detail**] [**graceful-restart**]

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter the password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**access-list** *access-list-number* {**permit** | **deny**} {*type-code wildcard-mask* | *ip-address mask*} **Example:** `Device(config)# access-list 10 permit 10.2.2.2`	Creates an access list.
Step 4	**key chain** *name-of-chain* **Example:** `Device(config)# key chain ldp-pwd`	Enables authentication for routing protocols and identifies a group of authentication keys. • Enters keychain configuration mode.
Step 5	**key** *key-id* **Example:** `Device(config-keychain)# key 1`	Identifies an authentication key on a keychain. • The *key-id* value must be a numeral. • Enters keychain key configuration mode.
Step 6	**key-string** *string* **Example:** `Device(config-keychain-key)# key-string pwd1`	Specifies the authentication string for a key. • The *string* value can be 1 to 80 uppercase or lowercase alphanumeric characters; the first character cannot be a numeral.
Step 7	**accept-lifetime** {*start-time* | **local** *start-time*} {**duration** | *seconds end-time* | **infinite**} **Example:** `Device(config-keychain-key)# accept-lifetime 10:00:00 Jan 13 2007 10:00:00 Jan 13 2009`	Specifies the time period during which the authentication key on a keychain can be used for verifying incoming TCP segments. The *start-time* argument identifies the time to start and the local *start-time* argument identifies the time to start in the local time zone. Both arguments have the same parameters: **Note**

	Command or Action	Purpose
		The time reference depends on the clock time zone configuration on the device. If no time zone configured, then the default time zone uses the Coordinated Universal Time (UTC) time. If it is configured, either the Eastern Standard Time (EST) or Pacific Standard Time (PST) time zone is used. • *hh:mm:ss* is the time format. • Enter the number of days from 1 to 31. • Enter the name of the month. • Enter the year from the present to 2035. Once the start time is entered, select from the following: • The **duration** keyword sets the key lifetime duration in seconds. • The *end-time* argument sets the time to stop. These parameters are the same as those used for the *start-time* argument. • The **infinite** keyword allows the accept-lifetime period to never expire. If the **no accept-lifetime** value is defined, the associated receive password is valid for authenticating incoming TCP segments.
Step 8	**send-lifetime** {*start-time* | **local** *start-time*} {**duration** *seconds end-time* | **infinite**} **Example:** `Device(config-keychain-key)# send-lifetime 10:00:00 Jan 13 2007 10:00:00 Jan 13 2009`	Specifies the time period during which the authentication key on a keychain can be used for verifying outgoing TCP segments. The *start-time* argument identifies the time to start and the local *start-time* argument identifies the time to start in the local time zone. Both arguments have the same parameters: **Note** The time reference depends on the clock time zone configuration on the device. If no time zone configured, then the default time zone uses the UTC time. If it is configured, either the EST or PST time zone is used. • *hh:mm:ss* is the time format. • Enter the number of days from 1 to 31. • Enter the name of the month. • Enter the year from 1993 to 2035. Once the start time is entered, select from the following:

	Command or Action	Purpose
		• The **duration** keyword sets the send lifetime duration in seconds. • The *end-time* argument sets the time to stop. These parameters are the same as those used for the *start-time* argument. • The **infinite** keyword allows the send lifetime period to never expire. If the **no send-lifetime** value is defined, the associated send password is valid for authenticating outgoing TCP segments.
Step 9	**exit** **Example:** `Device(config-keychain-key)# exit`	Returns to keychain configuration mode.
Step 10	**exit** **Example:** `Device(config-keychain)# exit`	Returns to global configuration mode.

Step 11	**mpls ldp** [**vrf** *vrf-name*] **password option** *number* **for** *acl* {**key-chain** *keychain-name* | [**0** | **7**] *password*}
	Example:
	
	`Device(config)# mpls ldp password option 1 for 10 keychain ldp-pwd`
		Configures a Message Digest 5 (MD5) password for LDP sessions with neighbors whose LDP router IDs are permitted by a specified access list.
		• The **vrf** *vrf-name* keyword-argument pair specifies a virtual routing and forwarding (VRF) configured on the label switch router (LSR).
		• The *number* argument defines the order in which the access lists are evaluated in the determination of a neighbor password. The range is 1 to 32767.
		• The **for** *acl* keyword and argument specifies the name of the access list that includes the LDP router IDs of those neighbors for which the password applies. Only standard IP access list values (1 to 99) can be used for the *acl* argument.
		• The **key-chain** *keychain-name* keyword and argument specifies the name of the keychain to use.
		• The **0** and **7** keywords specify whether the password that follows is hidden (encrypted);
		  • **0** specifies an unencrypted password.
		  • **7** specifies an encrypted password.
		• The *password* argument specifies the MD5 password to be used for the specified LDP sessions.

	Command or Action	Purpose
Step 12	**exit** **Example:** `Device(config)# exit`	Returns to privileged EXEC mode.

Step 13	**show mpls ldp neighbor** [**vrf** *vrf-name* | **all**] [*ip-address* | *interface*] [**detail**] [**graceful-restart**]
	Example:
	`Device# show mpls ldp neighbor detail`
		Displays the status of LDP sessions.
		• The **vrf** *vrf-name* keyword and argument displays the LDP neighbors for the specified VRF instance.
		• The *ip-address* argument identifies the neighbor with the IP address for which password protection is configured.
		• The *interface* argument identifies the LDP neighbors accessible over this interface.
		• The **detail** keyword displays information in long form, including password information for this neighbor. Here are the items displayed:
		  • An indication as to whether a password is mandatory for this neighbor (required/not required)
		  • The password source (neighbor/fallback/number [option number])
		  • An indication as to whether the latest configured password for this neighbor is used by the TCP session (in use) or the TCP session uses an old password (stale)
		• The **graceful-restart** keyword displays per-neighbor graceful restart information.

Enabling the Display of MPLS LDP Password Rollover Changes and Events

When a password is required for a neighbor, but no password is configured for the neighbor, the following debug message is displayed:

```
00:05:04: MDSym5 protection is required for peer 10.2.2.2:0(glbl), but no password configured.
```

To enable the display of events related to configuration changes and password rollover events, perform the following task.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls ldp logging password configuration** [**rate-limit** *number*]

4. **mpls ldp logging password rollover** [**rate-limit** *number*]
5. **exit**
6. **debug mpls ldp transport events**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**mpls ldp logging password configuration** [**rate-limit** *number*] **Example:** `Device(config)# mpls ldp logging password configuration rate-limit 30`	Enables the display of events related to configuration changes. • The output displays events when a new password is configured or an existing password has been changed or deleted. A rate limit of 1 to 60 messages a minute can be specified.
Step 4	**mpls ldp logging password rollover** [**rate-limit** *number*] **Example:** `Device(config)# mpls ldp logging password rollover rate-limit 25`	Enables the display of events related to password rollover events. • Events are displayed when a new password is used for authentication or when authentication is disabled. A rate limit of 1 to 60 messages a minute can be specified.
Step 5	**exit** **Example:** `Device(config)# exit`	Returns to privileged EXEC mode.
Step 6	**debug mpls ldp transport events** **Example:** `Device# debug mpls ldp transport events`	Displays notifications when a session TCP Message Digest 5 (MD5) option is changed. • You can also use the **debug mpls ldp transport connections** command to display notifications when the MD5 option is changed.

Changing MPLS LDP Lossless MD5 Session Authentication Passwords

The MPLS LDP Lossless MD5 Session Authentication feature allows Message Digest 5 (MD5) passwords to be changed for Label Distribution Protocol (LDP) session authentication without having to close and reestablish an existing LDP session.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls ldp** [**vrf** *vrf-name*] **password rollover duration** *minutes*
4. **mpls ldp** [**vrf** *vrf-name*] **password fallback** {**key-chain** *keychain-name* | [**0** | **7**] *password*}
5. **no mpls ldp neighbor** [**vrf** *vrf-name*] *ip-address* **password** *password*
6. **exit**
7. **show mpls ldp neighbor** [**vrf** *vrf-name*] [*ip-address* | *interface*] [**detail**] [**graceful-restart**]

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter the password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**mpls ldp** [**vrf** *vrf-name*] **password rollover duration** *minutes* **Example:** `Device(config)# mpls ldp password rollover duration 7`	Configures the duration before the new password takes effect. • The **vrf** *vrf-name* keyword and argument specifies a virtual routing and forwarding (VRF) configured on the label switch router (LSR). • The *minutes* argument specifies the number of minutes from 5 to 65535 before the password rollover occurs on this device.
Step 4	**mpls ldp** [**vrf** *vrf-name*] **password fallback** {**key-chain** *keychain-name*	[**0**	**7**] *password*} **Example:** `Device(config)# mpls ldp password fallback key-chain fallback`	Configures an MD5 password for LDP sessions with peers. • The **vrf** *vrf-name* keyword and argument specifies a VRF configured on the LSR. • The **key-chain** *keychain-name* keyword and argument specifies the name of the keychain used to specify the

	Command or Action	Purpose

		MD5 key that authenticates the exchange of bidirectional LDP traffic.
		• The **0** and **7** keywords specify whether the password that follows is hidden (encrypted);
		  • **0** specifies an unencrypted password.
		  • **7** specifies an encrypted password.
		• The *password* argument specifies the MD5 password to be used for the specified LDP sessions.

Step 5	**no mpls ldp neighbor** [**vrf** *vrf-name*] *ip-address* **password** *password* **Example:** `Device(config)# no mpls ldp neighbor 10.11.11.11 password lab1`	Disables the configuration of a password for computing MD5 checksums for the session TCP connection with the specified neighbor. • The **vrf** *vrf-name* keyword and argument optionally specifies the VRF instance for the specified neighbor. • The *ip-address* argument identifies the neighbor router ID. • The **password** *password* keyword and argument is necessary so that the device computes MD5 checksums for the session TCP connection with the specified neighbor.
Step 6	**exit** **Example:** `Device(config)# exit`	Returns to privileged EXEC mode.

Step 7	**show mpls ldp neighbor** [**vrf** *vrf-name*] [*ip-address* | *interface*] [**detail**] [**graceful-restart**]
	Example:
	`Device# show mpls ldp neighbor detail`
		Displays the status of LDP sessions.
		• The **vrf** *vrf-name* keyword argument displays the LDP neighbors for the specified VRF instance.
		• The *ip-address* argument identifies the neighbor with the IP address for which password protection is configured.
		• The *interface* argument lists the LDP neighbors accessible over this interface.
		• The **detail** keyword displays information in long form, including password information for this neighbor. Here are the items displayed:
		  • An indication as to whether a password is mandatory for this neighbor (required/not required)
		  • The password source (neighbor/fallback/number [option number])

	Command or Action	Purpose
		• An indication as to whether the latest configured password for this neighbor is used by the TCP session (in use) or the TCP session uses an old password (stale) • The **graceful-restart** keyword displays per-neighbor graceful restart information.

Configuration Examples for MPLS LDP Lossless MD5 Session Authentication

Example: Configuring MPLS LDP Lossless MD5 Session Authentication Using a Keychain (Symmetrical)

The following example shows a configuration of two peer label switch routers (LSRs) that use symmetrical Message Digest 5 (MD5) keys:

LSR1

```
access-list 10 permit 10.2.2.2
mpls ldp password required for 10
mpls ldp password option 1 for 10 ldp-pwd
!
key chain ldp-pwd
 key 1
  key-string pwd1
  send-lifetime 10:00:00 Jan 1 2009 10:00:00 Feb 1 2009
  accept-lifetime 09:00:00 Jan 1 2009 11:00:00 Feb 1 2009
!
interface loopback0
  ip address 10.1.1.1 255.255.255.255
!
interface FastEthernet0/0/0
  ip address 10.0.1.1 255.255.255.254
  mpls label protocol ldp
  mpls ip
```

LSR2

```
access-list 10 permit 10.1.1.1
mpls ldp password required for 10
mpls ldp password option 1 for 10 ldp-pwd
!
key chain ldp-pwd
 key 1
  key-string pwd1
  send-lifetime 10:00:00 Jan 1 2009 10:00:00 Feb 1 2009
  accept-lifetime 09:00:00 Jan 1 2009 11:00:00 Feb 1 2009
!
```

```
interface loopback0
  ip address 10.2.2.2 255.255.255.255
!
interface FastEthernet0/0/0
  ip address 10.0.1.2 255.255.255.254
  mpls label protocol ldp
  mpls ip
```

Example: Configuring MPLS LDP Lossless MD5 Session Authentication Using a Keychain (Asymmetrical)

The following example shows a configuration of two peer label switch routers (LSRs) that use asymmetrical MD5 keys:

LSR1

```
access-list 10 permit 10.2.2.2
mpls ldp password required for 10
mpls ldp password option 1 for 10 ldp-pwd
!
key chain ldp-pwd
 key 1
  key-string pwd1
  accept-lifetime 00:00:00 Jan 1 2005 duration 1
  send-lifetime 10:00:00 Jan 1 2009 10:00:00 Feb 1 2009
 key 2
  key-string pwd2
  accept-lifetime 09:00:00 Jan 1 2009 11:00:00 Feb 1 2009
  send-lifetime 00:00:00 Jan 1 2005 duration 1
!
interface loopback0
  ip address 10.1.1.1 255.255.255.255
!
interface FastEthernet0/0/0
  ip address 10.0.1.1 255.255.255.254
  mpls label protocol ldp
  mpls ip
```

LSR2

```
access-list 10 permit 10.1.1.1
mpls ldp password required for 10
mpls ldp password option 1 for 10 ldp-pwd
!
key chain ldp-pwd
 key 1
  key-string pwd2
  accept-lifetime 00:00:00 Jan 1 2005 duration 1
  send-lifetime 10:00:00 Jan 1 2009 10:00:00 Feb 1 2009
 key 2
  key-string pwd1
  accept-lifetime 09:00:00 Jan 1 2009 11:00:00 Feb 1 2009
  send-lifetime 00:00:00 Jan 1 2005 duration 1
!
interface loopback0
  ip address 10.2.2.2 255.255.255.255
!
interface FastEthernet0/0/0
```

```
ip address 10.0.1.2 255.255.255.254
mpls label protocol ldp
mpls ip
```

Examples: Changing MPLS LDP Lossless MD5 Session Authentication Password

The following example shows the existing password configuration for LSR A, LSR B, and LSR C:

LSR A Existing Configuration

```
mpls ldp router-id loopback0 force
mpls ldp neighbor 10.11.11.11 password lab1
mpls ldp neighbor 10.12.12.12 password lab1
mpls label protocol ldp
!
interface loopback0
ip address 10.10.10.10 255.255.255.255
!
interface FastEthernet1/0/0
ip address 10.2.0.1 255.255.0.0
mpls ip
!
interface FastEthernet2/0/0
ip address 10.0.0.1 255.255.0.0
mpls ip
```

LSR B Existing Configuration

```
mpls ldp router-id loopback0 force
mpls ldp neighbor 10.10.10.10 password lab1
mpls label protocol ldp
!
interface loopback0
ip address 10.11.11.11 255.255.255.255
!
interface FastEthernet1/0/0
ip address 10.2.0.2 255.255.0.0
mpls ip
```

LSR C Existing Configuration

```
mpls ldp router-id loopback0 force
mpls ldp neighbor 10.10.10.10 password lab1
mpls label protocol ldp
!
interface loopback0
ip address 10.12.12.12 255.255.255.255
!
interface FastEthernet2/0/0
ip address 10.0.0.2 255.255.0.0
mpls ip
!
```

The following example shows how the lossless password change is configured using the **mpls ldp password rollover duration** command for LSR A, LSR B, and LSR C so there is enough time to change all the passwords on all of the devices:

LSR A New Configuration

```
mpls ldp password rollover duration 10
mpls ldp password fallback lab2
no mpls ldp neighbor 10.11.11.11 password lab1
no mpls ldp neighbor 10.12.12.12 password lab1
```

LSR B New Configuration

```
mpls ldp password rollover duration 10
mpls ldp password fallback lab2
no mpls ldp neighbor 10.10.10.10 password lab1
```

LSR C New Configuration

```
mpls ldp password rollover duration 10
mpls ldp password fallback lab2
no mpls ldp neighbor 10.10.10.10 password lab1
```

After 10 minutes has elapsed, the password changes. The following system logging message for LSR A confirms that the password rollover was successful:

```
%LDP-5-PWDRO: Password rolled over for 10.11.11.11:0
%LDP-5-PWDRO: Password rolled over for 10.12.12.12:0
```

Examples: Changing MPLS LDP Lossless MD5 Session Authentication Password Using a Rollover Without Keychain

The MPLS LDP Lossless MD5 Session Authentication password can be changed in a lossless way (without tearing down an existing Label Distribution Protocol [LDP] session) by using a password rollover without a keychain.

The following example shows the existing password configuration for LSR A and LSR B:

LSR A Existing Configuration

```
mpls ldp router-id loopback0 force
mpls ldp neighbor 10.11.11.11 password lab1
mpls label protocol ldp
!
interface loopback0
ip address 10.10.10.10 255.255.255.255
!
interface FastEthernet1/0/0 ip address 10.2.0.1 255.255.0.0
mpls ip
```

LSR B Existing Configuration

```
mpls ldp router-id loopback0 force
mpls ldp neighbor 10.10.10.10 password lab1
mpls label protocol ldp
!
interface loopback0
ip address 10.11.11.11 255.255.255.255
```

```
!
interface FastEthernet1/0/0
ip address 10.2.0.2 255.255.0.0
mpls ip
```

The following example shows the new password configuration for LSR A and LSR B:

Note The rollover duration should be large enough so that the passwords can be changed on all impacted devices.

LSR A New Configuration

```
mpls ldp password rollover duration 10
mpls ldp neighbor 10.11.11.11 password lab2
```

LSR B New Configuration

```
mpls ldp password rollover duration 10
mpls ldp neighbor 10.10.10.10 password lab2
```

After 10 minutes (rollover duration), the password changes and the following system logging message confirms the password rollover at LSR A:

```
%LDP-5-PWDRO: Password rolled over for 10.11.11.11:0
```

Example: Changing MPLS LDP Lossless MD5 Session Authentication Password Using a Rollover with a Keychain

The MPLS LDP Lossless MD5 Session Authentication password can be changed in a lossless way by using a password rollover with a keychain. The following configuration example shows the new password keychain configuration for LSR A, LSR B, and LSR C, in which the new password is ldp-pwd.

In the example, the desired keychain is configured first. The first pair of keys authenticate incoming TCP segments (recv key) and compute Message Digest 5 (MD5) digests for outgoing TCP segments (xmit key). These keys should be the same keys as those currently in use; that is, in lab 1. The second recv key in the keychain should be valid after a few minutes. The second xmit key becomes valid at a future time.

Note The rollover duration should be large enough so that the passwords can be changed on all impacted devices.

LSR A New Configuration

```
mpls ldp password rollover duration 10
access-list 10 permit 10.11.11.11
access-list 10 permit 10.12.12.12
!
key chain ldp-pwd
key 10
key-string lab1
send-lifetime 10:00:00 Jan 1 2009 10:30:00 Jan 1 2009
```

```
accept-lifetime 10:00:00 Jan 1 2009 10:45:00 Jan 1 2009
key 11
key-string lab2
send-lifetime 10:30:00 Jan 1 2009 10:30:00 Feb 1 2009
accept-lifetime 10:15:00 Jan 1 2009 10:45:00 Feb 1 2009
key 12
key-string lab3
send-lifetime 10:30:00 Feb 1 2009 10:30:00 Mar 1 2009
accept-lifetime 10:15:00 Feb 1 2009 10:45:00 Mar 1 2009
!
mpls ldp password option 5 for 10 key-chain ldp-pwd
no mpls ldp neighbor 10.11.11.11 password lab1
no mpls ldp neighbor 10.12.12.12 password lab1
```

LSR B New Configuration

```
mpls ldp password rollover duration 10
access-list 10 permit 10.10.10.10
key chain ldp-pwd
key 10
key-string lab1
send-lifetime 10:00:00 Jan 1 2009 10:30:00 Jan 1 2009
accept-lifetime 10:00:00 Jan 1 2009 10:45:00 Jan 1 2009
key 11
key-string lab2
send-lifetime 10:30:00 Jan 1 2009 10:30:00 Feb 1 2009
accept-lifetime 10:15:00 Jan 1 2009 10:45:00 Feb 1 2009
key 12
key-string lab3
send-lifetime 10:30:00 Feb 1 2009 10:30:00 Mar 1 2009
accept-lifetime 10:15:00 Feb 1 2009 10:45:00 Mar 1 2009
!
mpls ldp password option 5 for 10 key-chain ldp-pwd
no mpls ldp neighbor 10.10.10.10 password lab1
```

LSR C New Configuration

```
mpls ldp password rollover duration 10
access-list 10 permit 10.10.10.10
key chain ldp-pwd
key 10
key-string lab1
send-lifetime 10:00:00 Jan 1 2009 10:30:00 Jan 1 2009
accept-lifetime 10:00:00 Jan 1 2009 10:45:00 Jan 1 2009
key 11
key-string lab2
send-lifetime 10:30:00 Jan 1 2009 10:30:00 Feb 1 2009
accept-lifetime 10:15:00 Jan 1 2009 10:45:00 Feb 1 2009
key 12
key-string lab3
send-lifetime 10:30:00 Feb 1 2009 10:30:00 Mar 1 2009
accept-lifetime 10:15:00 Feb 1 2009 10:45:00 Mar 1 2009
!
mpls ldp password option 5 for 10 key-chain ldp-pwd
no mpls ldp neighbor 10.10.10.10 password lab1
```

After 10 minutes, the password changes and the following system logging message confirms the password rollover at LSR A.

```
%LDP-5-PWDRO: Password rolled over for 10.11.11.11:0
%LDP-5-PWDRO: Password rolled over for 10.12.12.12:0
```

Examples: Changing MPLS LDP Lossless MD5 Session Authentication Password Using a Fallback Password with a Keychain

The MPLS LDP Lossless MD5 Session Authentication password can be changed in a lossless way by using a fallback password when doing a rollover with a keychain.

Note The fallback password is used only when there is no other keychain configured. If there is a keychain configured, then the fallback password is not used.

The following example shows the existing password configuration for LSR A, LSR B, and LSR C:

LSR A Existing Configuration

```
mpls ldp router-id loopback0 force
mpls label protocol ldp
!
interface loopback0
ip address 10.10.10.10 255.255.255.255
!
interface FastEthernet1/0/0
ip address 10.2.0.1 255.255.0.0
mpls ip
!
interface FastEthernet2/0/0
ip address 10.0.0.1 255.255.0.0
mpls ip
!
access-list 10 permit 10.11.11.11
access-list 10 permit 10.12.12.12
!
key chain ldp-pwd
key 10
key-string lab1
send-lifetime 10:00:00 Jan 1 2009 10:30:00 Jan 1 2009
accept-lifetime 10:00:00 Jan 1 2009 10:45:00 Jan 1 2009
!
mpls ldp password option 5 for 10 key-chain ldp-pwd
```

LSR B Existing Configuration

```
mpls ldp router-id loopback0 force
mpls label protocol ldp
!
interface loopback0
ip address 10.11.11.11 255.255.255.255
!
interface FastEthernet1/0/0
ip address 10.2.0.2 255.255.0.0
mpls ip
!
access-list 10 permit 10.10.10.10
key chain ldp-pwd
key 10
key-string lab1
send-lifetime 10:00:00 Jan 1 2009 10:30:00 Jan 1 2009
```

```
accept-lifetime 10:00:00 Jan 1 2009 10:45:00 Jan 1 2009
!
mpls ldp password option 5 for 10 key-chain ldp-pwd
```

LSR C Existing Configuration

```
mpls ldp router-id loopback0 force
mpls label protocol ldp
!
interface loopback0
ip address 10.12.12.12 255.255.255.255
!
interface FastEthernet2/0/0
ip address 10.0.0.2 255.255.0.0
mpls ip
!
access-list 10 permit 10.10.10.10
key chain ldp-pwd
key 10
key-string lab1
send-lifetime 10:00:00 Jan 1 2009 10:30:00 Jan 1 2009
accept-lifetime 10:00:00 Jan 1 2009 10:45:00 Jan 1 2009
!
mpls ldp password option 5 for 10 key-chain ldp-pwd
```

Note The fallback keychain is not used unless the keychain *ldp-pwd* is removed using the **no mpls ldp password option 5 for 10 key-chain ldp-pwd** command.

The following example shows the new configuration for LSR A, LSR B, and LSR C, where one keychain is configured with the name *ldp-pwd* and another keychain is configured with the name *fallback* for the fallback password.

Note The rollover duration should be large enough so that the passwords can be changed on all impacted devices.

LSR A New Configuration

```
mpls ldp password rollover duration 10
!
key chain fallback
key 10
key-string fbk1
!
mpls ldp password fallback key-chain fallback
!
no mpls ldp password option 5 for 10 key-chain ldp-pwd
```

LSR B New Configuration

```
mpls ldp password rollover duration 10
!
key chain fallback
key 10
```

```
key-string fbk1
!
mpls ldp password fallback key-chain fallback
!
no mpls ldp password option 5 for 10 key-chain ldp-pwd
```

LSR C New Configuration

```
mpls ldp password rollover duration 10
key chain fallback
key 10
key-string fbk1
!
mpls ldp password fallback key-chain fallback
!
no mpls ldp password option 5 for 10 key-chain ldp-pwd
```

After 10 minutes, the password changes and the following system logging message confirms the password rollover at LSR A:

```
%LDP-5-PWDRO: Password rolled over for 10.11.11.11:0
%LDP-5-PWDRO: Password rolled over for 10.12.12.12:0
```

Examples: Changing MPLS LDP Lossless MD5 Session Authentication Common Misconfiguration

The following sections describe common misconfiguration examples that can occur when the MPLS LDP Lossless MD5 Session Authentication password is migrated in a lossless way. Misconfigurations can lead to undesired behavior in a Label Distribution Protocol (LDP) session.

Examples: Incorrect Keychain LDP Password Configuration

Possible misconfigurations can occur when keychain-based commands are used with the **mpls ldp password option for key-chain** command. If the **accept-lifetime** or **send-lifetime** command is not specified in this configuration, then a misconfiguration can occur when more than two keys are in a keychain.

The following example shows an incorrect keychain configuration with three passwords for LSR A and LSR B in the keychain:

LSR A Incorrect Keychain LDP Password Configuration

```
access-list 10 permit 10.11.11.11
!
key chain ldp-pwd
key 10
key-string lab1
send-lifetime 10:00:00 Jan 1 2009 10:30:00 Jan 1 2009
key 11
key-string lab2
send-lifetime 10:30:00 Jan 1 2009 10:30:00 Feb 1 2009
key 12
key-string lab3
send-lifetime 10:30:00 Feb 1 2009 10:30:00 Mar 1 2009
!
mpls ldp password option 5 for 10 key-chain ldp-pwd
```

LSR B Incorrect Keychain LDP Password Configuration

```
access-list 10 permit 10.10.10.10
key chain ldp-pwd
key 10
key-string lab1
send-lifetime 10:00:00 Jan 1 2009 10:30:00 Jan 1 2009
key 11
key-string lab2
send-lifetime 10:30:00 Jan 1 2009 10:30:00 Feb 1 2009
key 12
key-string lab3
send-lifetime 10:30:00 Feb 1 2009 10:30:00 Mar 1 2009
!
mpls ldp password option 5 for 10 key-chain ldp-pwd
```

In the example, for both LSR A and LSR B, during the period of the third **send-lifetime 10:30:00 Feb 1 2009 10:30:00 Mar 1 2009** command, all three configured keys are valid as receive keys, and only the last configured key is valid as a transmit key. The keychain resolution rules dictate that keys 10 and 11 are used as receive keys, and only the last key 12 can be used as the transmit key. Because the transmit and receive keys are mismatched, the Label Distribution Protocol (LDP) session will not stay active.

Note When more than two passwords are configured in a keychain, the configuration needs to have both **accept-lifetime** and **send-lifetime** commands configured correctly for effective rollovers.

The following example shows the correct keychain configuration with multiple passwords in the keychain:

LSR A Correct Keychain LDP Password Configuration

```
access-list 10 permit 10.11.11.11
!
key chain ldp-pwd
key 10
key-string lab1
send-lifetime 10:00:00 Jan 1 2009 10:30:00 Jan 1 2009
accept-lifetime 10:00:00 Jan 1 2009 10:45:00 Jan 1 2009
key 11
key-string lab2
send-lifetime 10:30:00 Jan 1 2009 10:30:00 Feb 1 2009
accept-lifetime 10:15:00 Jan 1 2009 10:45:00 Feb 1 2009
key 12
key-string lab3
send-lifetime 10:30:00 Feb 1 2009 10:30:00 Mar 1 2009
accept-lifetime 10:15:00 Feb 1 2009 10:45:00 Mar 1 2009
!
mpls ldp password option 5 for 10 key-chain ldp-pwd
```

LSR B Correct Keychain LDP Password Configuration

```
access-list 10 permit 10.10.10.10
key chain ldp-pwd
key 10
key-string lab1
send-lifetime 10:00:00 Jan 1 2009 10:30:00 Jan 1 2009
accept-lifetime 10:00:00 Jan 1 2009 10:45:00 Jan 1 2009
key 11
```

```
key-string lab2
send-lifetime 10:30:00 Jan 1 2009 10:30:00 Feb 1 2009
accept-lifetime 10:15:00 Jan 1 2009 10:45:00 Feb 1 2009
key 12
key-string lab3
send-lifetime 10:30:00 Feb 1 2009 10:30:00 Mar 1 2009
accept-lifetime 10:15:00 Feb 1 2009 10:45:00 Mar 1 2009
!
mpls ldp password option 5 for 10 key-chain ldp-pwd
```

In the example above, for both LSR A and LSR B, during the period of the third **send-lifetime 10:30:00 Feb 1 2009 10:30:00 Mar 1 2009** command, only the last key 12 is valid as transmit and receive keys. Therefore, the LDP session remains active.

Avoiding Access List Configuration Problems

Use caution when modifying or deleting an access list. Any empty access list implies "permit any" by default. So when either the **mpls ldp password option for key-chain** command or the **mpls ldp password option** command is used for MPLS LDP MD5 session authentication, if the access list specified in the command becomes empty as a result of a modification or deletion, then all Label Distribution Protocol (LDP) sessions on the device expect a password. This configuration may cause undesired behavior in LDP sessions. To avoid this scenario, ensure that the proper access list is specified for each label switch router (LSR).

Examples: Changing MPLS LDP Lossless MD5 Session Authentication Using a Second Key to Avoid LDP Session Failure

The MPLS LDP Lossless MD5 Session Authentication feature works when a specified rollover period is configured. Typically, one rollover period overlaps the two accept lifetime values that are configured for two consecutive receive keys. The Label Distribution Protocol (LDP) process requests an update from the keychain manager for the latest valid transmit and receive keys once every minute. LDP compares the latest key set with the keys from the previous update in its database to determine if a key was removed, changed, or rolled over. When the rollover occurs, the LDP process detects the rollover and programs TCP with the next receive key.

The LDP session can fail if LDP is configured to use two keys for the MPLS LDP Lossless MD5 Session Authentication feature where the first key uses a send and accept lifetime value and the second key is not configured. The configuration creates a special case where there are two rollovers but there is only one rollover period.

The following sections provide an example of this problem and a solution:

Example: TCP Authentication and LDP Sessions Can Fail When a Second Rollover Period Is Missing

In the following configuration, the first rollover is from "secondpass" to "firstpass." The second rollover is from "firstpass" back to "secondpass." The only rollover period in this configuration is the overlapping between the "firstpass" and "secondpass." Because one rollover period is missing, LDP performs only the first rollover and not the second rollover, causing TCP authentication to fail and the Label Distribution Protocol (LDP) session to fail.

```
key chain ldp-pwd
 key 1
   key-string firstpass
   accept-lifetime 01:03:00 Sep 10 2009 01:10:00 Sep 10 2009
   send-lifetime 01:05:00 Sep 10 2009 01:08:00 Sep 10 2009
```

```
 key 2
   key-string secondpass
```

TCP authentication and LDP sessions can also fail if the second key has send and accept lifetime configured. In this case the accept lifetime of the first key is a subset of the accept lifetime of the second key. For example:

```
key chain ldp-pwd
 key 1
   key-string firstpass
   accept-lifetime 01:03:00 Sep 10 2009 01:10:00 Sep 10 2009
   send-lifetime 01:05:00 Sep 10 2009 01:08:00 Sep 10 2009
 key 2
   key-string secondpass
   accept-lifetime 01:03:00 Sep 9 2009 01:10:00 Sep 11 2009
   send-lifetime 01:05:00 Sep 9 2009 01:08:00 Sep 11 2009
```

Examples: Reconfigure a Keychain to Prevent TCP Authentication and LDP Session Failures

If the configuration needs to specify the last key in the keychain to always be valid, then configure the keychain to have at least two keys. Each key must be configured with both the send and accept lifetime period. For example:

```
key chain ldp-pwd
 key 1
   key-string firstpass
   accept-lifetime 01:03:00 Sep 10 2008 01:10:00 Sep 10 2008
   send-lifetime 01:05:00 Sep 10 2008 01:08:00 Sep 10 2008
 key 2
   key-string secondpass
   accept-lifetime 01:06:00 Sep 10 2008 01:17:00 Sep 10 2008
   send-lifetime 01:08:00 Sep 10 2008 01:15:00 Sep 10 2008
 key 3
   key-string thirdpass
```

If the configuration needs to specify the first keychain for the time interval, then switch to use the second key forever after that interval. This is done by configuring the start time for the second key to begin shortly before the end time of the first key, and by configuring the second key to be valid forever after that interval. For example:

```
key chain ldp-pwd
 key 1
   key-string firstpass
   accept-lifetime 00:03:00 Sep 10 2008 01:10:00 Sep 10 2008
   send-lifetime 00:05:00 Sep 10 2008 01:08:00 Sep 10 2008
 key 2
   key-string secondpass
   accept-lifetime 01:06:00 Sep 10 2008 infinite
   send-lifetime 01:08:00 Sep 10 2008 infinite
```

If the configuration needs to specify the two keys in the order of the second key, first key, and second key again, then specify three keys in that order with the proper rollover period. For example:

```
key chain ldp-pwd
 key 1
   key-string firstpass
   accept-lifetime 00:03:00 Sep 10 2008 01:10:00 Sep 10 2008
   send-lifetime 00:05:00 Sep 10 2008 01:08:00 Sep 10 2008
 key 2
   key-string secondpass
   accept-lifetime 01:06:00 Sep 10 2008 01:17:00 Sep 10 2008
```

```
  send-lifetime 01:08:00 Sep 10 2008 01:15:00 Sep 10 2008
key 3
  key-string firstpass
  accept-lifetime 01:13:00 Sep 10 2008 infinite
  send-lifetime 01:15:00 Sep 10 2008 infinite
```

Feature Information for MPLS LDP Lossless MD5 Session Authentication

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

CHAPTER 42

MPLS LDP VRF-Aware Static Labels

This document explains how to configure the MPLS LDP VRF-Aware Static Labels feature and Multiprotocol Label Switching (MPLS) static labels. Virtual Private Network routing and forwarding (VRF)-aware static labels can be used at the edge of an MPLS Virtual Private Network (VPN), whereas MPLS static labels can be used only in the MPLS VPN provider core.

Information About MPLS LDP VRF-Aware Static Labels

Overview of MPLS Static Labels and MPLS LDP VRF-Aware Static Labels

Label switch routers (LSRs) dynamically learn the labels they should use to label-switch packets by means of the following label distribution protocols:

- Label Distribution Protocol (LDP), the Internet Engineering Task Force (IETF) standard used to bind labels to network addresses
- Resource Reservation Protocol (RSVP) used to distribute labels for traffic engineering (TE)
- Border Gateway Protocol (BGP) used to distribute labels for Multiprotocol Label Switching (MPLS) virtual private networks (VPNs)

The LSR installs the dynamically learned label into its Label Forwarding Information Base (LFIB).

You can configure static labels for the following purposes:

- To bind labels to IPv4 prefixes to support MPLS hop-by-hop forwarding through neighbor devices that do not implement LDP label distribution. MPLS static labels allow you to configure entries in the MPLS forwarding table and assign label values to forwarding equivalence classes (FECs) learned by LDP. You can manually configure an LSP without running an LDP between the endpoints.
- To create static cross connects to support MPLS label switched path (LSP) midpoints when neighbor devices do not implement the LDP or RSVP label distribution, but do implement an MPLS forwarding path.

- To statically bind a virtual routing and forwarding (VRF)-aware label on a provider edge (PE) device to a customer network prefix (VPN IPv4 prefix). VRF-aware static labels can be used with nonglobal VRF tables, so the labels can be used at the VPN edge. For example, with the Carrier Supporting Carrier (CSC) feature, the backbone carrier can assign specific labels to FECs it advertises to the edge devices of customer carriers. Then, backbone carrier can monitor backbone traffic coming from particular customer carriers for billing or other purposes. Depending on how you configure VRF-aware static labels, they are advertised one of the following ways:
  - By LDP between PE and customer edge (CE) devices within a VRF instance
  - In VPNv4 BGP in the service provider's backbone

Labels Reserved for Static Assignment

Before you can manually assign labels, you must reserve a range of labels to be used for the manual assignment. Reserving the labels ensures that the labels are not dynamically assigned.

How to Configure MPLS LDP VRF-Aware Static Labels

Reserving Labels to Use for MPLS Static Labels and MPLS LDP VRF-Aware Static Labels

To reserve the labels that are to be statically assigned so that the labels are not dynamically assigned, perform the following task.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls label range** *minimum-value maximum-value* [**static** *minimum-static-value maximum-static-value*]
4. **exit**
5. **show mpls label range**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:**	Enters global configuration mode.

	Command or Action	Purpose
	`Device# configure terminal`	
Step 3	**mpls label range** *minimum-value maximum-value* [**static** *minimum-static-value maximum-static-value*] **Example:** `Device(config)# mpls label range 200 100000 static 16 199`	Reserves a range of labels for static labels assignment. The default is that no labels are reserved for static assignment. **Note** You might need to reload the device for the range of labels you reserve to take effect.
Step 4	**exit** **Example:** `Device(config)# exit`	Returns to privileged EXEC mode.
Step 5	**show mpls label range** **Example:** `Device# show mpls label range`	Displays information about the range of values for local labels, including those available for static assignment.

Configuring MPLS Static Labels in the MPLS VPN Provider Core

To configure MPLS static labels in the MPLS virtual private network (VPN) provider core, perform the following task.

MPLS static labels allow you to configure entries in the MPLS forwarding table and assign label values to forwarding equivalence classes (FECs) learned by the Label Distribution Protocol (LDP). You can manually configure a label switched path (LSP) without running a label distribution protocol between the endpoints. In MPLS VPN networks, static labels can be used only in the MPLS VPN provider core.

Note When static MPLS labels are used, LDP must be enabled on the interfaces, even though there is no need to establish an LDP session between devices.

Before you begin

- Globally enable Multiprotocol Label Switching (MPLS) on each label switch router (LSR).
- Enable Cisco Express Forwarding on each LSR.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls static binding ipv4** *prefix mask* {*label* | **input** *label* | **output** *nexthop* {**explicit-null** | **implicit-null** | *label*}}
4. **exit**

5. **show mpls static binding ipv4**
6. **show mpls forwarding-table**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**mpls static binding ipv4** *prefix mask* {*label* | **input** *label* | **output** *nexthop* {**explicit-null** | **implicit-null** | *label*}} **Example:** `Device(config)# mpls static binding ipv4 10.2.2.0 255.255.255.255 input 17`	Specifies static binding of labels to IPv4 prefixes. • Specified bindings are installed automatically in the MPLS forwarding table as routing demands.
Step 4	**exit** **Example:** `Device(config)# exit`	Returns to privileged EXEC mode.
Step 5	**show mpls static binding ipv4** **Example:** `Device# show mpls static binding ipv4`	Displays the configured static labels.
Step 6	**show mpls forwarding-table** **Example:** `Device# show mpls forwarding-table`	Displays the static labels used for MPLS forwarding.

Configuring MPLS Static Cross Connects

You can configure MPLS static cross connects to support MPLS LSP midpoints when neighbor devices do not implement either the Label Distribution Protocol (LDP) or Resource Reservation Protocol (RSVP) label distribution, but do implement an MPLS forwarding path.

Before you begin

- Globally enable Multiprotocol Label Switching (MPLS) on each label switch router (LSR).
- Enable Cisco Express Forwarding on each LSR.

Note
- MPLS static cross-connect labels remain in the Label Forwarding Information Base (LFIB) even if the device to which the entry points goes down.
- MPLS static cross-connect mappings remain in effect even with topology changes.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls static crossconnect** *inlabel out-interface nexthop* {*outlabel* | **explicit-null** | **implicit-null**}
4. **end**
5. **show mpls static crossconnect**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**mpls static crossconnect** *inlabel out-interface nexthop* {*outlabel*	**explicit-null**	**implicit-null**} **Example:** `Device(config)# mpls static crossconnect 45 pos5/0 45 explicit-null`	Specifies static cross connects. **Note** The *nexthop* argument is required for multiaccess interfaces.
Step 4	**end** **Example:** `Device(config)# end`	Returns to privileged EXEC mode.

	Command or Action	Purpose
Step 5	**show mpls static crossconnect** **Example:** `Device# show mpls static crossconnect`	Displays the configured static cross connects.

Configuring MPLS LDP VRF-Aware Static Labels at the Edge of the VPN

You can statically bind a virtual routing and forwarding (VRF)-aware label on a provider edge (PE) device to a customer network prefix (VPN IPv4 prefix). VRF-aware static labels can be used with nonglobal VRF tables, so the labels can be used at the VPN edge.

Before you begin

- Globally enable Multiprotocol Label Switching (MPLS) on each label switch router (LSR).
- Enable Cisco Express Forwarding on each LSR.
- Ensure the MPLS virtual private network (VPN) is configured.
- Ensure that the provider network has the MPLS Label Distribution Protocol (LDP) installed and running.

Note The MPLS LDP VRF-Aware Static Labels feature is supported only with MPLS VPN Carrier Supporting Carrier networks that use MPLS LDP.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls static binding ipv4 vrf** *vpn-name prefix mask* {**input** *label* | *label*}
4. **exit**
5. **show mpls static binding ipv4 vrf** *vpn-name*

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:**	Enters global configuration mode.

	Command or Action	Purpose
	`Device# configure terminal`	
Step 3	**mpls static binding ipv4 vrf** *vpn-name prefix mask* {**input** *label* | *label*} **Example:** `Device(config)# mpls static binding ipv4 vrf vpn100 10.2.0.0 255.255.0.0 input 17`	Binds a prefix to a local label. • Specified bindings are installed automatically in the MPLS forwarding table as routing demands. **Note** You must configure the MPLS VPN and VRFs before creating VRF-aware static labels.
Step 4	**exit** **Example:** `Device(config)# exit`	Returns to privileged EXEC mode.
Step 5	**show mpls static binding ipv4 vrf** *vpn-name* **Example:** `Device(config)# show mpls static binding ipv4 vrf vpn100`	Displays the configured MPLS static bindings.

Troubleshooting Tips

To display information related to static binding events, use the **debug mpls static binding vrf** command.

Configuration Examples for MPLS LDP VRF-Aware Static Labels

Example: Reserving Labels to Use for MPLS Static Labels and MPLS LDP VRF-Aware Static Labels

In the following example, the **mpls label range** command reserves a generic range of labels from 200 to 100000 and configures a static label range of 16 to 199:

```
Device(config)# mpls label range 200 100000 static 16 199
% Label range changes take effect at the next reload.
```

In this example, the output from the **show mpls label range** command indicates that the new label ranges do not take effect until a reload occurs:

```
Device# show mpls label range

Downstream label pool: Min/Max label: 16/100000
   [Configured range for next reload: Min/Max label: 200/100000]
Range for static labels: Min/Max/Number: 16/199
```

In the following output, the **show mpls label range** command, executed after a reload, indicates that the new label ranges are in effect:

```
Device# show mpls label range

Downstream label pool: Min/Max label: 200/100000
Range for static labels: Min/Max/Number: 16/199
```

Example: Configuring MPLS Static Labels in the MPLS VPN Provider Core

The following example configures input and output labels for several prefixes:

```
Device(config)# mpls static binding ipv4 10.0.0.0 255.0.0.0 55
Device(config)# mpls static binding ipv4 10.0.0.0 255.0.0.0 output 10.0.0.66 167
Device(config)# mpls static binding ipv4 10.66.0.0 255.255.0.0 input 17
Device(config)# mpls static binding ipv4 10.66.0.0 255.255.0.0 output 10.13.0.8 explicit-null
```

The **show mpls static binding ipv4** command displays the configured static labels:

```
Device# show mpls static binding ipv4

10.0.0.0/8: Incoming label: 55
  Outgoing labels:
      10.0.0.66   167
10.66.0.0/24: Incoming label: 17
  Outgoing labels:
     10.13.0.8  explicit-null
```

Example: Configuring MPLS LDP VRF-Aware Static Labels at the VPN Edge

In the following example, the **mpls static binding ipv4 vrf** command configures static label bindings. They also configure input (local) labels for various prefixes.

```
Device(config)# mpls static binding ipv4 vrf vpn100 10.0.0.0 10.0.0.0 55
Device(config)# mpls static binding ipv4 vrf vpn100 10.66.0.0 255.255.0.0 input 17
```

In the following output, the **show mpls static binding ipv4 vrf** command displays the configured VRF-aware static bindings:

```
Device# show mpls static binding ipv4 vrf vpn100
 10.0.0.0/8:   (vrf: vpn100)  Incoming label: 55
  Outgoing labels:  None
10.66.0.0/16:   (vrf: vpn100)  Incoming label: 17
  Outgoing labels:  None
```

Feature Information for MPLS LDP VRF-Aware Static Labels

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

CHAPTER 43

MPLS LDP Entropy Label Support

Load balancing is an important tool for engineering traffic across an MPLS network. The MPLS LDP Entropy Label Support feature describes methods of improving load balancing across MPLS networks using entropy labels.

- Information About MPLS LDP Entropy Label Support, on page 711
- How to Configure MPLS LDP Entropy Label Support, on page 712
- Additional References for MPLS LDP Entropy Label Support, on page 717
- Feature Information for MPLS LDP Entropy Label Support, on page 718

Information About MPLS LDP Entropy Label Support

Overview of MPLS LDP Entropy Label

Prior to the MPLS LDP Entropy Label Support feature, at each MPLS hop, a deep packet inspection (DPI) is performed to determine the load balancing. With the introduction of MPLS LDP Entropy Label Support feature, at the ingress interface where MPLS is encapsulated, a DPI is performed to generate an entropy label. At the transit node, there is no need for DPI. The load balancing is done on the entropy label.

The entropy label provides ways of improving load balancing by eliminating the need for DPI at transit Label Switching Routers (LSRs). To eliminate DPI, the ingress LSR of an MPLS label switched path extracts the appropriate keys from a given packet, inputs them to the load balancing function, places the result in an additional label termed entropy label, and as a part of the MPLS label stack, the LSR pushes onto that packet. The transit LSRs use the label stack of the MPLS packet to perform load balancing.

If the transit LSR does not support LDP Entropy Label Capability (ELC), the transit LSR will propagate the label mapping message with the ELC flag so that the ingress LSR will add the entropy label. Any transit LSRs that do not support entropy label will ignore the entropy label and will load balance based on traditional DPI techniques.

Benefits of MPLS LDP Entropy Label Support

Each transit LSR along the path of a given LSP has to try to infer the underlying protocol within an MPLS packet to extract appropriate keys for load balancing. If the transit LSR is unable to infer the MPLS packet's protocol, it will use the topmost (or all) MPLS labels in the label stack as keys for the load-balancing function. The result may be an extremely inequitable distribution of traffic across equal cost paths exiting a LSR. This

is because MPLS labels are fairly coarse-grained forwarding labels that describe a next hop, or provide some demultiplexing or forwarding function, and do not describe the packet's underlying protocol.

For example, an ingress LSR, a Provider Edge (PE) device has detailed knowledge of a packet's contents, typically through a priority configuration of the encapsulations that are expected at a given Provider Edge-Customer Edge interface (IPv4, IPv6, VPLS, etc.), thus ensuring a more even distribution of load balancing for a given flow instead of overloading any particular path. The entropy label is protocol independent, it provides a unified way of load balancing without looking into the protocol header.

LDP Entropy Label Capability Signaling

Entropy Label Capability (ELC) is signaled from egress provider-edge (PE) device to ingress PE device. The egress LSR for a FEC initiates ELC by adding ELC Type Length Value (TLV), if configured, in the label mapping message that it sends to the peers. The presence of the ELC TLV in a label mapping message indicates to ingress LSRs that the egress LSR can process entropy labels for the associated LDP tunnel.

If the entire downstream peers have signaled entropy capability, ELC is propagated, else, it is not added in the label mapping message, and regular load balancing is used.

By configuring entropy labels, ingress LSR enables pushing of Entropy Label Indicator (ELI)/Entropy Label (EL). The ELI/EL value is pushed onto the label stack, if EL is enabled and downstream LSP is EL capable. The LDP processes the ELC TLV and sets EL capability flag accordingly for each LSP.

At the transit and egress LSR, LDP signals ELC, which indicates the ability to process entropy labels to upstream peers if ELC is received from downstream peers for all the next hops in a route.

How to Configure MPLS LDP Entropy Label Support

Enabling MPLS LDP Entropy Label Support

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls ip**
4. **mpls ldp entropy-label** [*label-value*]
5. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.

	Command or Action	Purpose
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**mpls ip** **Example:** `Device(config)# mpls ip`	Configures MPLS hop-by-hop forwarding globally. • The **mpls ip** command is enabled by default; you do not have to specify this command. • Globally enabling MPLS forwarding does not enable it on the device interfaces. You must enable MPLS forwarding on the interfaces as well as for the device.
Step 4	**mpls ldp entropy-label** [*label-value*] **Example:** `Device(config)# mpls ldp entropy-label 7`	Enables entropy label on the egress PE device.
Step 5	**end** **Example:** `Device(config-router)# end`	Returns to privileged EXEC mode.

Verifying MPLS LDP Entropy Label Support

SUMMARY STEPS

1. **enable**
2. **show mpls ldp bindings** [*ip-address* | *mask*] [**detail**]
3. **show mpls infrastructure lfd lte** [*label-value*]
4. **show mpls forwarding-table** [*label-value*]
5. **ping mpls ipv4** [*ip-address* | *mask*] **entropy-label** [*label-value*]
6. **traceroute mpls** [*ip-address* | *mask*] **entropy-label** [*label-value*] [**verbose**]
7. **traceroute mpls multipath** [*ip-address* | *mask*] **entropy-label** [*label-value*] [**verbose**]

DETAILED STEPS

Procedure

Step 1 **enable**

Example:

```
Device> enable
```

Enables privileged EXEC mode.

- Enter your password if prompted.

Step 2 **show mpls ldp bindings** [*ip-address* | *mask*] [**detail**]

Displays the total counts of advertised-to and remote-binding peers in IP address sort order, with remote bindings in tabular format.

Example:

```
Device# show mpls ldp bindings 172.16.0.0/32 detail

lib entry: 172.16.0.0/32, rev 59, chkpt: none, elc
  local binding: label: 20001 (owner LDP)
    Advertised to:
    1.1.1.1:0                    3.3.3.3:0
remote binding: lsr: 1.1.1.1:0, label: 10003 checkpointed, elc
remote binding: lsr: 3.3.3.3:0, label: 30004 checkpointed, elc
```

Step 3 **show mpls infrastructure lfd lte** [*label-value*]

Displays information about the Label Forwarding Database (LFD).

Example:

```
Device# show mpls infrastructure lfd lte 7

7 [table 0]
    ldm: No LDM, LTE Broker
    flags: nsf (0x1)
    plist: NONIP (0x7F45AAD23120) entropy
    output chain:
       label implicit-null()
       entropy label indicator
```

Step 4 **show mpls forwarding-table** [*label-value*]

Displays the MPLS packets that are forwarded with an entropy label indicator label (value of 7).

Example:

```
Device# show mpls forwarding-table 7

    Local      Outgoing     Prefix            Bytes Label        Outgoing     Next Hop
    Label      Label        or Tunnel Id      Switched           Interface
    7          Pop          Label entropy     7468               Exception
```

Step 5 **ping mpls ipv4** [*ip-address* | *mask*] **entropy-label** [*label-value*]

Displays the MPLS label switched path (LSP) connectivity.

Example:

```
Device# ping mpls ipv4 172.16.0.0/32 entropy-label

Sending 5, 72-byte MPLS Echos to 172.16.0.0/32,
           timeout is 2 seconds, send interval is 0 msec,
           over default entropy label:
Type escape sequence to abort.
```

```
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms
 Total Time Elapsed 4 ms
```

Example:

```
Device# ping mpls ipv4 172.16.0.0/32 entropy-label 20

Sending 5, 72-byte MPLS Echos to 172.16.0.0/32,
           timeout is 2 seconds, send interval is 0 msec,
           over entropy label 20:
Type escape sequence to abort.
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms
 Total Time Elapsed 4 ms
```

Step 6 **traceroute mpls** [*ip-address* | *mask*] **entropy-label** [*label-value*] [**verbose**]

Displays MPLS label switched path (LSP) routes that the packets actually take when traveling to their destinations.

Example:

```
Device# traceroute mpls ipv4 172.16.0.0/32 entropy-label verbose

Tracing MPLS Label Switched Path to 172.16.0.0/32, timeout is 2 seconds
       over entropy, default start label
Type escape sequence to abort.

0 192.168.2.20 192.168.2.30 MRU 1500 [Labels: 20001/7/524288 Exp: 0/0/0]
L 1 192.168.2.20 192.168.22.30 MRU 1500 [Labels: 30004/7/524288 Exp: 0/0/0] 1 ms, ret
code 8
L 2 192.168.2.20 192.168.33.30 MRU 1500 [Labels: implicit-null/7/524288 Exp: 0/0/0] 2
ms, ret code 8
! 3 192.168.43.2 1 ms, ret code 3
```

Example:

```
Device# traceroute mpls ipv4 172.16.0.0/32 entropy-label 20 verbose

Tracing MPLS Label Switched Path to 172.16.0.0/32, timeout is 2 seconds
       over entropy, start label 20
Type escape sequence to abort.
0 192.168.12.1 192.168.12.2 MRU 1500 [Labels: 20001/7/20 Exp: 0/0/0]
L 1 192.168.12.2 192.168.22.2 MRU 1500 [Labels: 30004/7/20 Exp: 0/0/0] 1 ms, ret code
8
L 2 192.168.23.2 192.168.42.2 MRU 1500 [Labels: implicit-null/7/20 Exp: 0/0/0] 1 ms,
ret code 8
! 3 192.168.43.2 1 ms, ret code 3
```

Step 7 **traceroute mpls multipath** [*ip-address* | *mask*] **entropy-label** [*label-value*] [**verbose**]

Displays multiple MPLS label switched path (LSP) routes from an egress device to an ingress device.

Example:

```
Device#traceroute mpls multipath ipv4 172.16.0.0/32 entropy-label verbose

Starting LSP Multipath Traceroute for 172.16.0.0/32
     over entropy, default start label

Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
  'L' - labeled output interface, 'B' - unlabeled output interface,
  'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,

CHAPTER 44

L2VPN Protocol-Based CLIs

The L2VPN Protocol-Based CLIs feature provides a set of processes and an improved infrastructure for developing and delivering Cisco IOS software on various Cisco platforms. This feature introduces new commands and modifies or replaces existing commands to achieve a consistent functionality across Cisco platforms and provide cross-Operating System (OS) support.

- Information About L2VPN Protocol-Based CLIs, on page 721
- Additional References, on page 729
- Feature Information for L2VPN Protocol-Based CLIs, on page 730

Information About L2VPN Protocol-Based CLIs

Overview of L2VPN Protocol-Based CLIs

The L2VPN Protocol-Based CLIs feature introduces new commands and modifies or replaces existing commands to achieve a consistent functionality across Cisco platforms and provide cross-Operating System (OS) support.

Note The new, updated, and replacement commands are available in Cisco IOS XE Release 3.7S and Cisco IOS Release 15.3(1)S. However, the legacy commands that are being replaced will be deprecated in later releases.

Benefits of L2VPN Protocol-Based CLIs

The L2VPN Protocol-Based CLIs feature provides the following benefits:

- Consistent user experience across different operating systems.
- Consistent configuration for all Layer 2 VPN (L2VPN) scenarios.
- Enhanced functionality that is achieved by configuring pseudowires as virtual interfaces and monitoring the pseudowires as physical ports.
- Feature configuration such as quality of service (QoS) service policies on individual pseudowires .

- Redundant pseudowire configuration that is independent of the primary pseudowire to provide enhanced high availability.

These benefits are achieved through the following enhancements:

- New service contexts can be created for point-to-point and multipoint Layer 2 services by using the new L2VPN cross connect and L2VPN virtual forwarding interface (VFI) contexts.
  - The L2VPN cross connect context is used for configuring point-to-point pseudowires, pseudowire stitching, and local switching (hair pinning). Ethernet interfaces , Ethernet Flow Points (EFP), ATM interfaces and WAN interfaces (PPP,HDLC,Serial), and pseudowire interfaces can be defined as members of an L2VPN cross connect context.
  - The L2VPN VFI context instantiates Virtual Private LAN Services (VPLS) VFI for multipoint scenarios. Pseudowires can be defined as members of an L2VPN VFI context.
  - Bridge domains are used for multipoint scenarios. EFPs, pseudowires, or VFIs can be configured as members of a bridge domain. Pseudowires can be configured as member of a VFI. The VFI can be configured as a member of a .
- New port contexts can be created (dynamically or manually) for pseudowires by using the pseudowire interface.
- Pseudowire customization can be achieved using interface templates and pseudowire interfaces that are applied to L2VPN context members. Pseudowire customizations include following features:
  - Encapsulation type
  - Control word
  - Maximum Transmission Unit (MTU)
  - Pseudowire signaling type
  - Tunnel selection
- Interworking and redundancy group service attributes can be configured under the L2VPN service context. The redundancy groups are configured independently from the primary pseudowire, which helps achieve zero traffic interruptions while adding, modifying, or deleting backup pseudowires.

L2VPN Protocol-Based CLI Changes

The following commands are introduced in Cisco IOS XE Release 3.7S, Cisco IOS Release 15.3(1)S, and Cisco IOS Release 15.4(1)S:

- **debug l2vpn pseudowire**
- **l2vpn**
- **l2vpn pseudowire static-oam class**
- **monitor event-trace l2vpn**
- **show interface pseudowire**
- **show l2vpn service**

- **shutdown (MPLS)**
- **vc**

The following commands are modified in Cisco IOS XE Release 3.7S and Cisco IOS Release 15.3(1)S:

- **auto-route-target**
- **bridge-domain parameterized vlan**
- **debug condition xconnect fib**
- **debug condition xconnect interface**
- **debug condition xconnect peer**
- **debug condition xconnect segment**
- **description**
- **encapsulation (MPLS)**
- **forward permit l2protocol all**
- **interworking**
- **l2vpn subscriber authorization group**
- **l2vpn xconnect context**
- **load-balance flow**
- **monitor event-trace ac**
- **monitor event-trace atom**
- **monitor event-trace l2tp**
- **monitor peer bfd**
- **mtu**
- **preferred-path**
- **remote circuit id**
- **rd (VPLS)**
- **route-target (VPLS)**
- **sequencing**
- **status**
- **status admin-down disconnect**
- **status control-plane route-watch**
- **status decoupled**
- **status peer topology dual-homed**
- **status protocol notification static**

- **status redundancy**
- **switching tlv**
- **tlv**
- **tlv template**
- **vccv**
- **vccv bfd status signaling**
- **vccv bfd template**
- **vpls-id**
- **vpn id (MPLS)**

The table below lists the legacy commands that will be replaced in future releases. From Cisco IOS XE Release 3.7S and Cisco IOS Release 15.3(1)S both new and legacy commands will coexist until the legacy commands are deprecated in future releases.

Table 95: Replacement Commands Introduced in Cisco IOS XE Release 3.7S and Cisco IOS Release 15.3(1)S

Legacy Command	Replacement Command Introduced in Cisco IOS XE Release 3.7S and Cisco IOS Release 15.3(1)S
backup delay	**redundancy delay (under l2vpn xconnect context)**
bridge-domain (service instance)	**member (bridge-domain)**
clear mpls l2transport fsm state transition	**clear l2vpn atom fsm state transition**
clear mpls l2transport fsm event	**clear l2vpn atom fsm event**
clear xconnect	**clear l2vpn service**
connect (L2VPN local switching)	**l2vpn xconnect context**
debug acircuit	**debug l2vpn acircuit**
debug mpls l2transport checkpoint	**debug l2vpn atom checkpoint**
debug mpls l2transport event-trace	**debug l2vpn atom event-trace**
debug mpls l2transport fast-failure-detect	**debug l2vpn atom fast-failure-detect**
debug mpls l2transport signaling	**debug l2vpn atom signaling**
debug mpls l2transport static-oam	**debug l2vpn atom static-oam**
debug mpls l2transport vc subscriber	**debug l2vpn atom vc**
debug mpls l2transport vc	**debug l2vpn atom vc**
debug mpls l2transport vc vccv bfd event	**debug l2vpn atom vc vccv**
debug vfi	**debug l2vpn vfi**

Legacy Command	Replacement Command Introduced in Cisco IOS XE Release 3.7S and Cisco IOS Release 15.3(1)S
debug vfi checkpoint	**debug l2vpn vfi checkpoint**
debug xconnect	**debug l2vpn xconnect**
debug xconnect rib	**debug l2vpn xconnect rib**

MPLS L2VPN Protocol-Based CLI: Examples

The examples in this section provide the new configurations that are introduced by the MPLS L2VPN Protocol-Based CLIs feature that replace the existing (legacy) MPLS L2VPN CLIs.

MPLS L2VPN VPWS Configuration Using Replacement (or New) Commands

The following example shows the configuration for Virtual Private Wired Service (VPWS)—Ethernet over Multiprotocol Label Switching (EoMPLS). In this example, L2VPN members point to peer ID or virtual circuit (VC) ID. This configuration is used in most cases except when features like quality of service (QoS), need to be applied at the pseudowire level.

```
l2vpn xconnect context foo
  member GigabitEthernet2/1/1 service-instance 300
  member 10.0.0.1 888 encapsulation mpls
!
interface GigabitEthernet2/1/1
  service instance 300
   encapsulation dot1q 30
   rewrite ingress tag pop 1 symmetric
  !
  service instance 400
   encapsulation dot1q 40
   rewrite ingress tag pop 1 symmetric

l2vpn xconnect context faa
  member GigabitEthernet2/1/1 service-instance 400
  member 10.0.0.1 999 encapsulation mpls
!
```

MPLS L2VPN Pseudowire Configuration Using Replacement (or New) Commands

In the following example, L2VPN members point to a pseudowire interface. The pseudowire interface is manually configured and includes peer ID and VC ID. This configuration is used in most cases except when features like quality of service (QoS), need to be applied at the pseudowire level.

```
l2vpn xconnect context foo
  member GigabitEthernet2/1/1 service-instance 300
```

```
  member Pseudowire888
!
interface Pseudowire 888
 encapsulation mpls
 neighbor 10.0.0.1 888
!
interface Pseudowire 999
 encapsulation mpls
 neighbor 10.0.0.1 999
!
interface GigabitEthernet2/1/1
  service instance 300
   encapsulation dot1q 30
   rewrite ingress tag pop 1 symmetric
  !
  service instance 400
   encapsulation dot1q 40
   rewrite ingress tag pop 1 symmetric

l2vpn xconnect context faa
  member GigabitEthernet2/1/1 service-instance 400
  member Pseudowire 999
!
```

MPLS L2VPN Pseudowire Redundancy Configuration Using Replacement (or New) Commands

The following example shows the configuration for pseudowire redundancy. The new configuration shows concise pseudowire redundancy with no submodes or separate groups. This configuration allows the addition of redundant members to a service without service disruption. This configuration also allows modifying or deleting redundant service configurations without service disruption.

```
l2vpn xconnect context sample-pw-redundancy
  member  service-instance 200
  member 10.1.1.1 180 encap mpls group Denver
  member 2.2.2.2 180180 encap mpls group Denver priority 1
  member 3.3.3.3 180181 encap mpls group Denver priority 2
  redundancy delay 1 20 group Denver
!
interface GigabitEthernet2/1/1
  service instance 200
   encapsulation dot1q 100
   rewrite ingress tag pop 1 symmetric
```

MPLS L2VPN Static Pseudowire Configuration Using Replacement (or New) Commands

Note The following configuration is shown for the Provider Edge (PE) 1 router in a network scheme where Customer Edge (CE) 1 and PE 1 and PE 2 and CE 2 traverse through a Provider core (P) router (CE 1—PE 1—P—PE 2—CE 2).

```
interface g2/1/1
service instance 300 ethernet
encapsulation dot1q 300
no shutdown
!
interface pseudowire 100
neighbor 10.4.4.4 121
encapsulation mpls
label 200 300
signaling protocol none
no shutdown
```

```
!
l2vpn xconnect context foo
  member GigabitEthernet2/1/1 service-instance 300
  member pseudowire 100
```

MPLS L2VPN Static Pseudowire Template Configuration Using Replacement (or New) Commands

Note The following configuration is shown for the Provider Edge (PE) 1 router in a network scheme where Customer Edge (CE) 1 and PE 1 and PE 2 and CE 2 traverse through a Provider core (P) router (CE 1—PE 1—P—PE 2—CE 2).

```
template type pseudowire test
encapsulation mpls
signaling protocol none
!
interface g2/1/1
service instance 300 ethernet
encapsulation dot1q 300
no shutdown
!
interface pseudowire 100
neighbor 10.4.4.4 121
source template type pseudowire test
label 200 300
no shutdown
!
l2vpn xconnect context foo
  member GigabitEthernet2/1/1 service-instance 300
  member pseudowire 100
```

MPLS L2VPN Dynamic Pseudowire Template Configuration Using Replacement (or New) Commands

Note The following configuration is shown for the Provider Edge (PE) 1 router in a network scheme where Customer Edge (CE) 1 and PE 1 and PE 2 and CE 2 traverse through a Provider core (P) router (CE 1—PE 1—P—PE 2—CE 2).

```
template type pseudowire test
encapsulation mpls
signaling protocol ldp
!
!
interface g2/1/1
service instance 300 ethernet
encapsulation dot1q 300
no shutdown
!
interface pseudowire 100
neighbor 10.4.4.4 121
source template type pseudowire test
no shutdown
!
l2vpn xconnect context foo
  member GigabitEthernet2/1/1 service-instance 300
  member pseudowire 100
```

MPLS L2VPN Multi-segment Static-Dynamic Pseudowire Template Configuration Using Replacement (or New) Commands

The following PE router configuration is for a multi-segment static-dynamic pseudowire:

```
l2vpn pseudowire tlv template TLV
 tlv mtu 1 4 dec 1500
!
interface pseudowire401
  source template type pseudowire staticTempl
encapsulation mpls
neighbor 10.4.4.4 101
signaling protocol none
label 4401 4301
pseudowire type 4
tlv template TLV
tlv 1 4 dec 1500
tlv vccv-flags C 4 hexstr 0110
!
interface pseudowire501
  source template type pseudowire dynTempl
encapsulation mpls
neighbor 10.2.2.2 101
signaling protocol ldp
```

Displaying MPLS L2VPN Pseudowire Template Configuration Using Replacement (or New) Commands

The following example displays output from the **show interface pseudowire** command:

```
PE1#show interface pseudowire 100
pseudowire100 is up
    Description: Pseudowire Interface
    MTU 1500 bytes, BW 10000000 Kbit
    Encapsulation mpls
    Peer IP 10.4.4.4, VC ID 121
    RX
      21 packets 2623 bytes 0 drops
    TX
      20 packets 2746 bytes 0 drops
```

The following example displays output from the **show template** command:

```
PE1#show template

Template        class/type    Component(s)
ABC             owner        interface pseudowire
 BOUND: pw1
```

Sourcing a Template Under an Interface Pseudowire Using Replacement (or New) Commands

The following example configures the interface pseudowire to inherit all attributes defined from a template on the PE 2 router.

```
PE2(config-subif)#interface pseudowire 100
PE2(config-if)#source template type pseudowire test
PE2(config-if)#neighbor 10.4.4.4 121
PE2(config-if)#no shutdown
```

Feature Information for L2VPN Protocol-Based CLIs

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 96: Feature Information for L2VPN Protocol-Based CLIs

Feature Name	Releases	Feature Information
L2VPN Protocol-Based CLIs	Cisco IOS XE Release 3.7S	The L2VPN Protocol-Based CLIs feature provides a set of processes and an improved infrastructure for developing and delivering Cisco IOS software on various Cisco platforms. This feature introduces new commands and modifies or replaces existing commands to achieve a consistent functionality across Cisco platforms and provide cross-Operating System (OS) support. In Cisco IOS XE Release 3.7S, this feature was introduced on the Cisco ASR 903 Router.

CHAPTER 45

Any Transport over MPLS

This module describes how to configure Any Transport over MPLS (AToM) transports data link layer (Layer 2) packets over a Multiprotocol Label Switching (MPLS) backbone. AToM enables service providers to connect customer sites with existing Layer 2 networks by using a single, integrated, packet-based network infrastructure--a Cisco MPLS network. Instead of using separate networks with network management environments, service providers can deliver Layer 2 connections over an MPLS backbone. AToM provides a common framework to encapsulate and transport supported Layer 2 traffic types over an MPLS network core.

AToM supports the following like-to-like transport types:

- ATM Adaptation Layer Type-5 (AAL5) over MPLS
- ATM Cell Relay over MPLS
- Ethernet over MPLS (port modes)

- Prerequisites for Any Transport over MPLS, on page 731
- Restrictions for Any Transport over MPLS, on page 732
- Information About Any Transport over MPLS, on page 735
- How to Configure Any Transport over MPLS, on page 749
- Configuration Examples for Any Transport over MPLS, on page 830
- Additional References for Any Transport over MPLS, on page 860
- Feature Information for Any Transport over MPLS, on page 860

Prerequisites for Any Transport over MPLS

- IP routing must be configured in the core so that the provider edge (PE) routers can reach each other via IP.
- MPLS must be configured in the core so that a label-switched path (LSP) exists between the PE routers.
- A loopback interface must be configured for originating and terminating Layer 2 traffic. Ensure that the PE routers can access the other router's loopback interface. Note that the loopback interface is not needed in all cases. For example, tunnel selection does not need a loopback interface when AToM is directly mapped to a traffic engineering (TE) tunnel.

Restrictions for Any Transport over MPLS

General Restrictions

The following general restrictions pertain to all transport types under AToM:

- Address format: Configure the Label Distribution Protocol (LDP) router ID on all PE routers to be a loopback address with a /32 mask. Otherwise, some configurations might not function properly.

Ethernet over MPLS (EoMPLS) Restrictions

The following restrictions pertain to the Ethernet over MPLS feature:

- Ethernet over MPLS supports VLAN packets that conform to the IEEE 802.1Q standard. The 802.1Q specification establishes a standard method for inserting VLAN membership information into Ethernet frames. The Inter-Switch Link (ISL) protocol is not supported between the PE and CE routers.
- The AToM control word is supported. However, if the peer PE does not support a control word, the control word is disabled. This negotiation is done by LDP label binding.
- Ethernet packets with hardware-level cyclic redundancy check (CRC) errors, framing errors, and runt packets are discarded on input.

General Restrictions

- In a member configuration, the **l2vpn xconnect context** command does not prompt any error or warning, if you specify without a service instance.
- The **show mpls l2transport vc** <*vcid*> **detail** command output displays few LDP-related information, even in case of static pseudowire.
- Address format--Configure the Label Distribution Protocol (LDP) router ID on all PE routers to be a loopback address with a /32 mask. Otherwise, some configurations might not function properly.
- For PTPoIP configuration with explicit Null MPLS encapsulation, when a Transparent Clock (TC) is placed between a PTP primary and a PTP subordinate, the TC does not update the correction field.
- If an AToM tunnel spans different service providers that exchange MPLS labels using IPv4 Border Gateway Protocol (BGP) (RFC 3107), you add a label to the stack. The maximum MPLS label stack is .
- Hot standby pseudowire (HSPW) convergence without pseudowire grouping increments linearly. For example, for a thousand virtual circuits, it requires about 54 seconds of convergence time. This is applicable only for the Cisco RSP3 Module.

  Clear interface is not the recommended way to measure the convergence numbers.
- With two ECMP paths, load sharing on L2VPN traffic occurs based on odd or even MPLS VC labels. If L2VPN circuits have either odd **or** even MPLS VC labels, load sharing is not performed. But if L2VPN circuits have a combination of both odd **and** even MPLS VC labels, then the odd MPLS VC labels circuits select one link whereas the even MPLS VC labels circuits select another link.

ATM AAL5 over MPLS Restrictions

- AAL5 over MPLS is supported only in SDU mode.

ATM Cell Relay over MPLS Restrictions

- If you have TE tunnels running between the PE routers, you must enable LDP on the tunnel interfaces.
- The F4 end-to-end OAM cells are transparently transported along with the ATM cells. When a permanent virtual path (PVP) or permanent virtual circuit (PVC) is down on one PE router, the label associated with that PVP or PVC is withdrawn. Subsequently, the peer PE router detects the label withdrawal and sends an F4 AIS/RDI signal to its corresponding CE router. The PVP or PVC on the peer PE router remains in the up state.
- VC class configuration mode is not supported in port mode.
- The AToM control word is supported. However, if a peer PE does not support the control word, it is disabled.

For configuring ATM cell relay over MPLS in VP mode, the following restrictions apply:

- If a VPI is configured for VP cell relay, you cannot configure a PVC using the same VPI.
- VP trunking (mapping multiple VPs to one emulated VC label) is not supported. Each VP is mapped to one emulated VC.
- VP mode and VC mode drop idle cells.

Ethernet over MPLS (EoMPLS) Restrictions

- The subinterfaces between the CE and PE routers that are running Ethernet over MPLS must be in the same subnet.
- The subinterface on the adjoining CE router must be on the same VLAN as the PE router.
- Ethernet over MPLS supports VLAN packets that conform to the IEEE 802.1Q standard. The 802.1Q specification establishes a standard method for inserting VLAN membership information into Ethernet frames. The Inter-Switch Link (ISL) protocol is not supported between the PE and CE routers.
- The AToM control word is supported. However, if the peer PE does not support a control word, the control word is disabled.
- Ethernet packets with hardware-level cyclic redundancy check (CRC) errors, framing errors, and runt packets are discarded on input.

Per-Subinterface MTU for Ethernet over MPLS Restrictions

- The following features do not support MTU values in xconnect subinterface configuration mode:
  - Layer 2 Tunnel Protocol Version 3 (L2TPv3)
  - Virtual Private LAN services (VPLS)
  - L2VPN Pseudowire Switching

- The MTU value can be configured in xconnect subinterface configuration mode only on the following interfaces and subinterfaces:
  - Fast Ethernet
  - Gigabit Ethernet
- The router uses an MTU validation process for remote VCs established through LDP, which compares the MTU value configured in xconnect subinterface configuration mode to the MTU value of the remote customer interface. If an MTU value has not been configured in xconnect subinterface configuration mode, then the validation process compares the MTU value of the local customer interface to the MTU value of the remote xconnect, either explicitly configured or inherited from the underlying interface or subinterface.
- When you configure the MTU value in xconnect subinterface configuration mode, the specified MTU value is not enforced by the dataplane. The dataplane enforces the MTU values of the interface (port mode) or subinterface (VLAN mode).
- Ensure that the interface MTU is larger than the MTU value configured in xconnect subinterface configuration mode. If the MTU value of the customer-facing subinterface is larger than the MTU value of the core-facing interface, traffic may not be able to travel across the pseudowire.

Frame Relay over MPLS Restrictions

Frame Relay traffic shaping is not supported with AToM switched VCs.

HDLC over MPLS Restrictions

- Asynchronous interfaces are not supported.
- You must configure HDLC over MPLS on router interfaces only. You cannot configure HDLC over MPLS on subinterfaces.

PPP over MPLS Restrictions

- Zero hops on one router is not supported. However, you can have back-to-back PE routers.
- Asynchronous interfaces are not supported. The connections between the CE and PE routers on both ends of the backbone must have similar link layer characteristics. The connections between the CE and PE routers must both be synchronous.
- Multilink PPP (MLP) is not supported.
- You must configure PPP on router interfaces only. You cannot configure PPP on subinterfaces.

Tunnel Selection Restrictions

- The selected path should be an LSP destined to the peer PE router.
- The selected tunnel must be an MPLS TE tunnel.

- If you specify an IP address, that address must be the IP address of the loopback interface on the remote PE router. The address must have a /32 mask. There must be an LSP destined to that selected address. The LSP need not be a TE tunnel.

Experimental Bits with AToM Restrictions

- You must statically set the experimental (EXP) bits in both the VC label and the LSP tunnel label, because the LSP tunnel label might be removed at the penultimate router.
- For EXP bits and ATM AAL5 over MPLS and for EXP bits and Frame Relay over MPLS, if you do not assign values to the experimental bits, the priority bits in the header's "tag control information" field are set to zero.
- For EXP bits and ATM Cell Relay over MPLS in VC mode, if you do not assign values to the experimental bits, the priority bits in the header's "tag control information" field are set to zero.
- For EXP bits and HDLC over MPLS and PPP over MPLS, if you do not assign values to the experimental bits, zeros are written into the experimental bit fields.

Remote Ethernet Port Shutdown Restrictions

This feature is not symmetrical if the remote PE router is running an older version image or is on another platform that does not support the EoMPLS remote Ethernet port shutdown feature and the local PE is running an image which supports this feature.

Remote Ethernet Port Shutdown is supported only on EFP with encapsulation default.

Information About Any Transport over MPLS

To configure AToM, you must understand the following concepts:

How AToM Transports Layer 2 Packets

AToM encapsulates Layer 2 frames at the ingress PE and sends them to a corresponding PE at the other end of a pseudowire, which is a connection between the two PE routers. The egress PE removes the encapsulation and sends out the Layer 2 frame.

The successful transmission of the Layer 2 frames between PE routers is due to the configuration of the PE routers. You set up the connection, called a pseudowire, between the routers. You specify the following information on each PE router:

- The type of Layer 2 data that will be transported across the pseudowire, such as Ethernet, Frame Relay, or ATM
- The IP address of the loopback interface of the peer PE router, which enables the PE routers to communicate
- A unique combination of peer PE IP address and VC ID that identifies the pseudowire

The following example shows the basic configuration steps on a PE router that enable the transport of Layer 2 packets. Each transport type has slightly different steps.

Step 1 defines the interface or subinterface on the PE router:

```
Router# interface
 interface-type interface-number
```

Step specifies the encapsulation type for the interface, such as dot1q:

```
Router(config-if-srv)# encapsulation
encapsulation-type
```

Step 4 does the following:

- Makes a connection to the peer PE router by specifying the LDP router ID of the peer PE router.
- Specifies a 32-bit unique identifier, called the VC ID, which is shared between the two PE routers.

The combination of the peer router ID and the VC ID must be unique on the router. Two circuits cannot use the same combination of peer router ID and VC ID.

- Specifies the tunneling method used to encapsulate data in the pseudowire. AToM uses MPLS as the tunneling method.

```
Router(config-if-srv)# xconnect
peer-router-id vcid
encapsulation mpls
```

As an alternative, you can set up a pseudowire class to specify the tunneling method and other characteristics. For more information, see the Configuring the Pseudowire Class, on page 749.

How AToM Transports Layer 2 Packets Using Commands Associated with L2VPN Protocol-Based Feature

AToM encapsulates Layer 2 frames at the ingress PE and sends them to a corresponding PE at the other end of a pseudowire, which is a connection between the two PE routers. The egress PE removes the encapsulation and sends out the Layer 2 frame.

The successful transmission of the Layer 2 frames between PE routers is due to the configuration of the PE routers. You set up the connection, called a pseudowire, between the routers. You specify the following information on each PE router:

- The type of Layer 2 data that will be transported across the pseudowire, such as Ethernet, Frame Relay, or ATM
- The IP address of the loopback interface of the peer PE router, which enables the PE routers to communicate
- A unique combination of peer PE IP address and VC ID that identifies the pseudowire

The following example shows the basic configuration steps on a PE router that enable the transport of Layer 2 packets. Each transport type has slightly different steps.

Step 1 defines the interface or subinterface on the PE router:

```
Router# interface
interface-type interface-number
```

Step 3 specifies the encapsulation type for the interface, such as dot1q:

```
Router(config-if)# encapsulation
encapsulation-type
```

Step 3 does the following:

- Makes a connection to the peer PE router by specifying the LDP router ID of the peer PE router.
- Specifies a 32-bit unique identifier, called the VC ID, which is shared between the two PE routers.

The combination of the peer router ID and the VC ID must be unique on the router. Two circuits cannot use the same combination of peer router ID and VC ID.

- Specifies the tunneling method used to encapsulate data in the pseudowire. AToM uses MPLS as the tunneling method.

```
Router(config)# interface pseudowire 100
Router(config-if)# encapsulation mpls
Router(config-if)# neighbor 10.0.0.1 123
Router(config-if)# exit
!
Router(config)# l2vpn xconnect context A
Router(config-xconnect)# member pseudowire 100
```

```
Router(config-xconnect)# exit
```

As an alternative, you can set up a pseudowire class to specify the tunneling method and other characteristics. For more information, see the Configuring the Pseudowire Class, on page 749.

Benefits of AToM

The following list explains some of the benefits of enabling Layer 2 packets to be sent in the MPLS network:

- The AToM product set accommodates many types of Layer 2 packets, including Ethernet and Frame Relay, across multiple Cisco router platforms. This enables the service provider to transport all types of traffic over the backbone and accommodate all types of customers.
- AToM adheres to the standards developed for transporting Layer 2 packets over MPLS. This benefits the service provider that wants to incorporate industry-standard methodologies in the network. Other Layer 2 solutions are proprietary, which can limit the service provider's ability to expand the network and can force the service provider to use only one vendor's equipment.
- Upgrading to AToM is transparent to the customer. Because the service provider network is separate from the customer network, the service provider can upgrade to AToM without disruption of service to the customer. The customers assume that they are using a traditional Layer 2 backbone.

MPLS Traffic Engineering Fast Reroute

AToM can use MPLS traffic engineering (TE) tunnels with fast reroute (FRR) support. AToM VCs can be rerouted around a failed link or node at the same time as MPLS and IP prefixes.

Enabling fast reroute on AToM does not require any special commands; you can use standard fast reroute commands. At the ingress PE, an AToM tunnel is protected by fast reroute when it is routed to an FRR-protected TE tunnel. Both link and node protection are supported for AToM VCs at the ingress PE.

Maximum Transmission Unit Guidelines for Estimating Packet Size

The following calculation helps you determine the size of the packets traveling through the core network. You set the maximum transmission unit (MTU) on the core-facing interfaces of the P and PE routers to accommodate packets of this size. The MTU should be greater than or equal to the total bytes of the items in the following equation:

```
Core MTU >= (Edge MTU + Transport header + AToM header + (MPLS label stack * MPLS label
size))
```

The following sections describe the variables used in the equation.

Edge MTU

The edge MTU is the MTU for the customer-facing interfaces.

Transport Header

The Transport header depends on the transport type. The table below lists the specific sizes of the headers.

Table 97: Header Size of Packets

Transport Type	Packet Size
AAL5	0-32 bytes
Ethernet VLAN	18 bytes
Ethernet Port	14 bytes
Frame Relay DLCI	2 bytes for Cisco encapsulation, 8 bytes for Internet Engineering Task Force (IETF) encapsulation
HDLC	4 bytes
PPP	4 bytes

AToM Header

The AToM header is 4 bytes (control word). The control word is optional for Ethernet, PPP, HDLC, and cell relay transport types. The control word is required for Frame Relay and ATM AAL5 transport types.

MPLS Label Stack

The MPLS label stack size depends on the configuration of the core MPLS network:

- AToM uses one MPLS label to identify the AToM VCs (VC label). Therefore, the minimum MPLS label stack is one for directly connected AToM PEs, which are PE routers that do not have a P router between them.
- If LDP is used in the MPLS network, the label stack size is two (the LDP label and the VC label).
- If a TE tunnel instead of LDP is used between PE routers in the MPLS network, the label stack size is two (the TE label and the VC label).
- If a TE tunnel and LDP are used in the MPLS network (for example, a TE tunnel between P routers or between P and PE routers, with LDP on the tunnel), the label stack is three (TE label, LDP label, VC label).
- If you use MPLS fast reroute in the MPLS network, you add a label to the stack. The maximum MPLS label stack in this case is four (FRR label, TE label, LDP label, VC label).
- If AToM is used by the customer carrier in an MPLS VPN Carrier Supporting Carrier environment, you add a label to the stack. The maximum MPLS label stack in the provider carrier network is .
- If an AToM tunnel spans different service providers that exchange MPLS labels using IPv4 Border Gateway Protocol (BGP) (RFC 3107), you add a label to the stack. The maximum MPLS label stack is
- TE-FRR with BGP labels for layer 2 and layer 3 VPNs must terminate on the BGP gateway because of the four-label limitation.

Other circumstances can increase the MPLS label stack size. Therefore, analyze the complete data path between the AToM tunnel endpoints and determine the maximum MPLS label stack size for your network. Then multiply the label stack size by the size of the MPLS label.

Estimating Packet Size Example

The estimated packet size in the following example is 1526 bytes, based on the following assumptions:

- The edge MTU is 1500 bytes.
- The transport type is Ethernet VLAN, which designates 18 bytes for the transport header.
- The AToM header is 0, because the control word is not used.
- The MPLS label stack is 2, because LDP is used. The MPLS label is 4 bytes.

```
Edge MTU + Transport header + AToM header + (MPLS label stack * MPLS label) = Core MTU
1500     + 18                     + 0      + (2                * 4          ) = 1526
```

You must configure the P and PE routers in the core to accept packets of 1526 bytes.

Per-Subinterface MTU for Ethernet over MPLS

MTU values can be specified in xconnect subinterface configuration mode. When you use xconnect subinterface configuration mode to set the MTU value, you establish a pseudowire connection for situations where the interfaces have different MTU values that cannot be changed.

If you specify an MTU value in xconnect subinterface configuration mode that is outside the range of supported MTU values (64 bytes to the maximum number of bytes supported by the interface), the command might be rejected. If you specify an MTU value that is out of range in xconnect subinterface configuration mode, the router enters the command in subinterface configuration mode.

For example, if you specify an MTU of 1501 in xconnect subinterface configuration mode, and that value is out of range, the router enters the command in subinterface configuration mode, where it is accepted:

```
Router# configure terminal
Router(config)# interface gigabitethernet0/0/2.1
Router(config-subif)# xconnect 10.10.10.1 100 encapsulation mpls
Router(config-subif-xconn)# mtu ?
<64 - 1500> MTU size in bytes
Router(config-subif-xconn)# mtu 1501 <<================
Router(config-subif)# mtu ?
<64 - 17940> MTU size in bytes
```

If the MTU value is not accepted in either xconnect subinterface configuration mode or subinterface configuration mode, then the command is rejected.

Per-Subinterface MTU for Ethernet over MPLS using the commands associated with the L2VPN Protocol-Based CLIs feature

MTU values can be specified in xconnect configuration mode. When you use xconnect configuration mode to set the MTU value, you establish a pseudowire connection for situations where the interfaces have different MTU values that cannot be changed.

If you specify an MTU value in xconnect configuration mode that is outside the range of supported MTU values (64 bytes to the maximum number of bytes supported by the interface), the command might be rejected. If you specify an MTU value that is out of range in xconnect configuration mode, the router enters the command in subinterface configuration mode.

For example, if you specify an MTU of 1501 in xconnect configuration mode, and that value is out of range, the router enters the command in subinterface configuration mode, where it is accepted:

```
Router# configure terminal
Router(config)# interface gigabitethernet0/0/2.1
Router(config)# interface pseudowire 100
Router(config-if)# encapsulation mpls
Router(config-if)# neighbor 10.10.10.1 100
Router(config-if)# mtu ?
<64 - 1500> MTU size in bytes
Router(config-if)# mtu 1501 <<================
Router(config-if)# mtu ?
<64 - 17940> MTU size in bytes
Router(config-if)# exit
!
Router(config)# l2vpn xconnect context A
Router(config-xconnect)# member pseudowire 100 Router
Router(config-xconnect)# member gigabitethernet0/0/2.1
Router(config-xconnect)# exit
```

If the MTU value is not accepted in either xconnect configuration mode or subinterface configuration mode, then the command is rejected.

Frame Relay over MPLS and DTE DCE and NNI Connections

You can configure an interface as a DTE device or a DCE switch, or as a switch connected to a switch with network-to-network interface (NNI) connections. Use the following command in interface configuration mode:

frame-relay intf-type [**dce** | **dte** | **nni**]

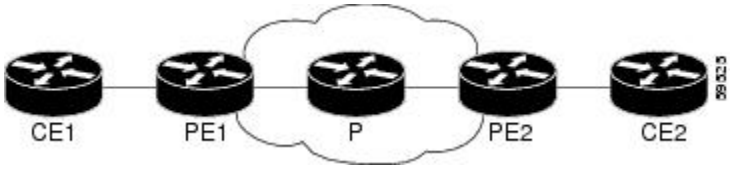
The keywords are explained in the table below.

Table 98: frame-relay intf-type Command Keywords

Keyword	Description
dce	Enables the router or access server to function as a switch connected to a router.
dte	Enables the router or access server to function as a DTE device. DTE is the default.
nni	Enables the router or access server to function as a switch connected to a switch.

Local Management Interface and Frame Relay over MPLS

Local Management Interface (LMI) is a protocol that communicates status information about PVCs. When a PVC is added, deleted, or changed, the LMI notifies the endpoint of the status change. LMI also provides a polling mechanism that verifies that a link is up.



How LMI Works

To determine the PVC status, LMI checks that a PVC is available from the reporting device to the Frame Relay end-user device. If a PVC is available, LMI reports that the status is "Active," which means that all interfaces, line protocols, and core segments are operational between the reporting device and the Frame Relay end-user device. If any of those components is not available, the LMI reports a status of "Inactive."

Note Only the DCE and NNI interface types can report the LMI status.

The figure below is a sample topology that helps illustrate how LMI works.

Figure 50: Sample Topology

In the figure above, note the following:

- CE1 and PE1 and PE2 and CE2 are Frame Relay LMI peers.
- CE1 and CE2 can be Frame Relay switches or end-user devices.
- Each Frame Relay PVC comprises multiple segments.
- The DLCI value is local to each segment and is changed as traffic is switched from segment to segment. Two Frame Relay PVC segments exist in the figure; one is between PE1 and CE1 and the other is between PE2 and CE2.

The LMI protocol behavior depends on whether you have DLCI-to-DLCI or port-to-port connections.

DLCI-to-DLCI Connections

If you have DLCI-to-DLCI connections, LMI runs locally on the Frame Relay ports between the PE and CE devices:

- CE1 sends an active status to PE1 if the PVC for CE1 is available. If CE1 is a switch, LMI checks that the PVC is available from CE1 to the user device attached to CE1.
- PE1 sends an active status to CE1 if the following conditions are met:
  - A PVC for PE1 is available.
  - PE1 received an MPLS label from the remote PE router.
  - An MPLS tunnel label exists between PE1 and the remote PE.

For DTE or DCE configurations, the following LMI behavior exists: The Frame Relay device accessing the network (DTE) does not report the PVC status. Only the network device (DCE) or NNI can report the status. Therefore, if a problem exists on the DTE side, the DCE is not aware of the problem.

Port-to-Port Connections

If you have port-to-port connections, the PE routers do not participate in the LMI status-checking procedures. LMI operates only between the CE routers. The CE routers must be configured as DCE-DTE or NNI-NNI.

For information about LMI, including configuration instructions, see the “Configuring the LMI” section of the Configuring Frame Relay document.

QoS Features Supported with AToM

The tables below list the QoS features supported by AToM.

Table 99: QoS Features Supported with Ethernet over MPLS

QoS Feature	Ethernet over MPLS
Service policy	Can be applied to: • Interface (input and output)
Classification	Supports the following commands: • **match cos** (on interfaces) • **match mpls experimental** (on interfaces) • **match qos-group** (on interfaces) (output policy)
Marking	Supports the following commands: • **set cos** (output policy) • **set discard-class** (input policy) • **set mpls experimental** (input policy) (on interfaces) • **set qos-group** (input policy)

QoS Feature	Ethernet over MPLS
Policing	Supports the following: • Color-aware policing • Multiple-action policing • Single-rate policing • Two-rate policing
Queueing and shaping	Supports the following: • Byte-based WRED • Low Latency Queueing (LLQ) • Weighted Random Early Detection (WRED)

Table 100: QoS Features Supported with Frame Relay over MPLS

QoS Feature	Frame Relay over MPLS
Service policy	Can be applied to: • Interface (input and output) • PVC (input and output)
Classification	Supports the following commands: • **match fr-de** (on interfaces and VCs) • **match fr-dlci** (on interfaces) • **match qos-group**
Marking	Supports the following commands: • **frame-relay congestion management** (output) • **set discard-class** • **set fr-de** (output policy) • **set fr-fecn-becn** (output) • **set mpls experimental** • **set qos-group** • **threshold ecn** (output)

QoS Feature	Frame Relay over MPLS
Policing	Supports the following: • Color-aware policing • Multiple-action policing • Single-rate policing • Two-rate policing
Queueing and shaping	Supports the following: • Byte-based WRED • Class-based weighted fair queueing (CBWFQ) • LLQ • **random-detect discard-class-based** command • Traffic shaping • WRED

Table 101: QoS Features Supported with ATM Cell Relay and AAL5 over MPLS

QoS Feature	ATM Cell Relay and AAL5 over MPLS
Service policy	Can be applied to: • Interface (input and output) • PVC (input and output) • Subinterface (input and output)
Classification	Supports the following commands: • **match mpls experimental** (on VCs) • **match qos-group** (output)
Marking	Supports the following commands: • **random-detect discard-class-based** (input) • **set clp** (output) (on interfaces, subinterfaces, and VCs) • **set discard-class** (input) • **set mpls experimental** (input) (on interfaces, subinterfaces, and VCs) • **set qos-group** (input)

QoS Feature	ATM Cell Relay and AAL5 over MPLS
Policing	Supports the following: • Color-aware policing • Multiple-action policing • Single-rate policing • Two-rate policing
Queueing and shaping	Supports the following: • Byte-based WRED • CBWFQ • Class-based shaping support on ATM PVCs • LLQ • **random-detect discard-class-based** command • WRED

OAM Cell Emulation for ATM AAL5 over MPLS

If a PE router does not support the transport of Operation, Administration, and Maintenance (OAM) cells across a label switched path (LSP), you can use OAM cell emulation to locally terminate or loop back the OAM cells. You configure OAM cell emulation on both PE routers, which emulates a VC by forming two unidirectional LSPs. You use Cisco software commands on both PE routers to enable OAM cell emulation.

After you enable OAM cell emulation on a router, you can configure and manage the ATM VC in the same manner as you would a terminated VC. A VC that has been configured with OAM cell emulation can send loopback cells at configured intervals toward the local CE router. The endpoint can be either of the following:

- End-to-end loopback, which sends OAM cells to the local CE router.
- Segment loopback, which responds to OAM cells to a device along the path between the PE and CE routers.

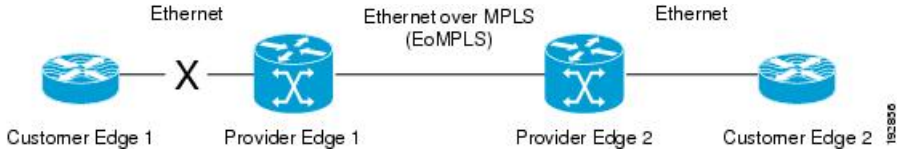
The OAM cells include the following cells:

- Alarm indication signal (AIS)
- Remote defect indication (RDI)

These cells identify and report defects along a VC. When a physical link or interface failure occurs, intermediate nodes insert OAM AIS cells into all the downstream devices affected by the failure. When a router receives an AIS cell, it marks the ATM VC down and sends an RDI cell to let the remote end know about the failure.

OAM Cell Emulation for ATM AAL5 over MPLS in VC Class Configuration Mode

You can configure OAM cell emulation as part of a VC class and then apply the VC class to an interface, a subinterface, or a VC. When you configure OAM cell emulation in VC class configuration mode and then



apply the VC class to an interface, the settings in the VC class apply to all the VCs on the interface, unless you specify a different OAM cell emulation value at a lower level, such as the subinterface or VC level. For example, you can create a VC class that specifies OAM cell emulation and sets the rate of AIS cells to every 30 seconds. You can apply the VC class to an interface. Then, for one PVC, you can enable OAM cell emulation and set the rate of AIS cells to every 15 seconds. All the PVCs on the interface use the cell rate of 30 seconds, except for the one PVC that was set to 15 seconds.

Any Transport over MPLS (AToM) Remote Ethernet Port Shutdown

This Cisco IOS XE feature allows a service provider edge (PE) router on the local end of an Ethernet over MPLS (EoMPLS) pseudowire to detect a remote link failure and cause the shutdown of the Ethernet port on the local customer edge (CE) router. Because the Ethernet port on the local CE router is shut down, the router does not lose data by continuously sending traffic to the failed remote link. This is beneficial if the link is configured as a static IP route.

The figure below illustrates a condition in an EoMPLS WAN, with a down Layer 2 tunnel link between a CE router (Customer Edge 1) and the PE router (Provider Edge 1). A CE router on the far side of the Layer 2 tunnel (Customer Edge 2), continues to forward traffic to Customer Edge 1 through the L2 tunnel.

Figure 51: Remote Link Outage in EoMPLS WAN

Previous to this feature, the Provider Edge 2 router could not detect a failed remote link. Traffic forwarded from Customer Edge 2 to Customer Edge 1 would be lost until routing or spanning tree protocols detected the down remote link. If the link was configured with static routing, the remote link outage would be even more difficult to detect.

With this feature, the Provider Edge 2 router detects the remote link failure and causes a shutdown of the local Customer Edge 2 Ethernet port. When the remote L2 tunnel link is restored, the local interface is automatically restored as well. The possibility of data loss is thus diminished.

With reference to the figure above, the Remote Ethernet Shutdown sequence is generally described as follows:

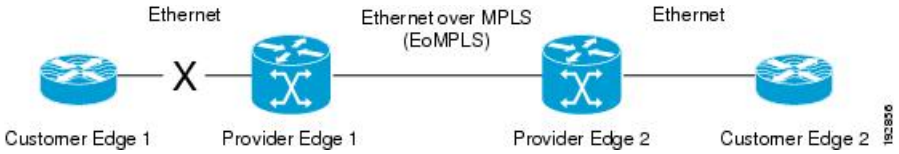
1. The remote link between Customer Edge 1 and Provider Edge 1 fails.
2. Provider Edge 2 detects the remote link failure and disables the transmit laser on the line card interface connected to Customer Edge 2.
3. An RX_LOS error alarm is received by Customer Edge 2 causing Customer Edge 2 to bring down the interface.
4. Provider Edge 2 maintains its interface with Customer Edge 2 in an up state.
5. When the remote link and EoMPLS connection is restored, the Provider Edge 2 router enables the transmit laser.
6. The Customer Edge 2 router brings up its downed interface.

This feature is enabled by default for Ethernet over MPLS (EoMPLS). You can also enable this feature by using the **remote link failure notification** command in xconnect configuration mode as shown in the following example:

```
pseudowire-class eompls
 encapsulation mpls
!
interface GigabitEthernet1/0/0
 xconnect 10.13.13.13 1 pw-class eompls
  remote link failure notification
!
```

This feature can be disabled using the **no remote link failure notification** command in xconnect configuration mode. Use the **show ip interface brief** privileged EXEC command to display the status of all remote L2 tunnel links. Use the **show interface** privileged EXEC command to show the status of the L2 tunnel on a specific interface.

Note The **no remote link failure notification** command will not give notification to clients for remote attachment circuit status down.



Note Remote Ethernet Port Shutdown is supported only on EFP with encapsulation default.

Any Transport over MPLS (AToM) Remote Ethernet Port Shutdown Using Commands Associated with L2VPN Protocol-Based Feature

This Cisco IOS XE feature allows a service provider edge (PE) router on the local end of an Ethernet over MPLS (EoMPLS) pseudowire to detect a remote link failure and cause the shutdown of the Ethernet port on the local customer edge (CE) router. Because the Ethernet port on the local CE router is shut down, the router does not lose data by continuously sending traffic to the failed remote link. This is beneficial if the link is configured as a static IP route.

The figure below illustrates a condition in an EoMPLS WAN, with a down Layer 2 tunnel link between a CE router (Customer Edge 1) and the PE router (Provider Edge 1). A CE router on the far side of the Layer 2 tunnel (Customer Edge 2), continues to forward traffic to Customer Edge 1 through the L2 tunnel.

Figure 52: Remote Link Outage in EoMPLS WAN

Previous to this feature, the Provider Edge 2 router could not detect a failed remote link. Traffic forwarded from Customer Edge 2 to Customer Edge 1 would be lost until routing or spanning tree protocols detected the down remote link. If the link was configured with static routing, the remote link outage would be even more difficult to detect.

With this feature, the Provider Edge 2 router detects the remote link failure and causes a shutdown of the local Customer Edge 2 Ethernet port. When the remote L2 tunnel link is restored, the local interface is automatically restored as well. The possibility of data loss is thus diminished.

With reference to the figure above, the Remote Ethernet Shutdown sequence is generally described as follows:

1. The remote link between Customer Edge 1 and Provider Edge 1 fails.
2. Provider Edge 2 detects the remote link failure and disables the transmit laser on the line card interface connected to Customer Edge 2.
3. An RX_LOS error alarm is received by Customer Edge 2 causing Customer Edge 2 to bring down the interface.
4. Provider Edge 2 maintains its interface with Customer Edge 2 in an up state.
5. When the remote link and EoMPLS connection is restored, the Provider Edge 2 router enables the transmit laser.
6. The Customer Edge 2 router brings up its downed interface.

This feature is enabled by default for Ethernet over MPLS (EoMPLS). You can also enable this feature by using the **remote link failure notification** command in xconnect configuration mode as shown in the following example:

This feature can be disabled using the **no remote link failure notification** command in xconnect configuration mode. Use the **show ip interface brief** privileged EXEC command to display the status of all remote L2 tunnel links. Use the **show interface** privileged EXEC command to show the status of the L2 tunnel on a specific interface.

Note The **no remote link failure notification** command will not give notification to clients for remote attachment circuit status down.

AToM Load Balancing with Single PW

The AToM Load Balancing with Single PW feature enables load balancing for packets within the same pseudowire by further classifying packets within the same pseudowire into different flows based on certain fields in the packet received on an attachment circuit. For example, for Ethernet this load balancing is based on the source MAC address in the incoming packets.

Flow-Aware Transport (FAT) Load Balancing

The Flow-Aware Transport of MPLS Pseudowires feature enables load balancing of packets within the same pseudowire by further classifying the packets into different flows by adding a flow label at the bottom of the MPLS label stack.

Information About EoMPLS over IPv6 GRE Tunnel

Ethernet over MPLS (EoMPLS) is a tunneling mechanism that allows you to tunnel Layer 2 traffic through a Layer 3 MPLS network. EoMPLS is also known as Layer 2 tunneling.

The EoMPLS over IPv6 GRE Tunnel feature supports tunneling of EoMPLS traffic via an IPv6 network by using GRE tunnels. Effective from Cisco IOS XE Release 3.15s, EoMPLS is supported over IPv6 GRE tunnel.

Additional Information on EoMPLS over IPv6 GRE Tunnel

For more information on EoMPLS over IPv6 GRE Tunnel feature, see GRE IPv6 Tunnels chapter of the *Interface and Hardware Component Configuration Guide, Cisco IOS XE Release 3S (ASR 1000)*.

How to Configure Any Transport over MPLS

This section explains how to perform a basic AToM configuration and includes the following procedures:

Configuring the Pseudowire Class

Note In simple configurations, this task is optional. You need not specify a pseudowire class if you specify the tunneling method as part of the **xconnect** command.

- You must specify the **encapsulation mpls** command as part of the pseudowire class or as part of the **xconnect** command for the AToM VCs to work properly. If you omit the **encapsulation mpls** command as part of the **xconnect** command, you receive the following error:

```
% Incomplete command.
```

Procedure

Step 1 **enable**

Example:

```
Router> enable
```

Enables privileged EXEC mode.

- Enter your password if prompted.

Step 2 **configure terminal**

Example:

```
Router# configure terminal
```

Enters global configuration mode.

Step 3 **pseudowire-class** *name*

Example:

```
Router(config)# pseudowire-class atom
```

Establishes a pseudowire class with a name that you specify and enters pseudowire class configuration mode.

Step 4 **encapsulation mpls**

Example:

```
Router(config-pw)# encapsulation mpls
```

Specifies the tunneling encapsulation.

Configuring the Pseudowire Class Using Commands Associated with L2VPN Protocol-Based Feature

Note In simple configurations, this task is optional. You need not specify a pseudowire class if you specify the tunneling method as part of the **l2vpn xconnect context** command.

- You must specify the **encapsulation mpls** command as part of the pseudowire class or as part of the **l2vpn xconnect context** command for the AToM VCs to work properly. If you omit the **encapsulation mpls** command as part of the **l2vpn xconnect context**command, you receive the following error:

```
% Incomplete command.
```

Procedure

Step 1 **enable**

Example:

```
Router> enable
```

Enables privileged EXEC mode.

- Enter your password if prompted.

Step 2 **configure terminal**

Example:

```
Router# configure terminal
```

Enters global configuration mode.

Step 3 **interface pseudowire** *name*

Example:

```
Router(config)# interface pseudowire atom
```

Establishes an interface pseudowire with a name that you specify and enters pseudowire class configuration mode.

Step 4 **encapsulation mpls**

Example:

```
Router(config-pw-class)# encapsulation mpls
```

Specifies the tunneling encapsulation.

Step 5 **neighbor** *peer-address vcid-value*

Example:

```
Router(config-pw-class)#  neighbor 33.33.33.33 1
```

Specifies the peer IP address and virtual circuit (VC) ID value of a Layer 2 VPN (L2VPN) pseudowire.

Changing the Encapsulation Type and Removing a Pseudowire

Once you specify the **encapsulation mpls** command, you cannot remove it using the **no encapsulation mpls** command.

Those methods result in the following error message:

```
Encapsulation changes are not allowed on an existing pw-class.
```

To remove the **encapsulation mpls** command, you must delete the pseudowire with the **no pseudowire-class** command.

To change the type of encapsulation, remove the pseudowire using the **no pseudowire-class** command and reconfigure the pseudowire to specify the new encapsulation type.

Changing the Encapsulation Type and Removing a Pseudowire Using Commands Associated with the L2VPN Protocol-Based Feature

Once you specify the **encapsulation mpls** command, you cannot remove it using the **no encapsulation mpls** command.

Those methods result in the following error message:

To remove the **encapsulation mpls** command, you must delete the pseudowire with the **no interface pseudowire** command.

To change the type of encapsulation, remove the pseudowire using the **no template type pseudowire** command and reconfigure the pseudowire to specify the new encapsulation type.

Configuring ATM AAL5 over MPLS

Configuring ATM AAL5 over MPLS on PVCs

Procedure

Step 1 **enable**

Example:

```
Router> enable
```

Enables privileged EXEC mode.

- Enter your password if prompted.

Step 2 **configure terminal**

Example:

```
Router# configure terminal
```

Enters global configuration mode.

Step 3 **interface** *type slot* / *subslot* / *port* [**.** *subinterface*]

Example:

```
Router(config)# interface atm1/0/0
```

Specifies the interface type and enters interface configuration mode.

Step 4 **pvc** [*name*] *vpi* / *vci* **l2transport**

Example:

```
Router(config-if)# pvc 1/200 l2transport
```

Creates or assigns a name to an ATM PVC and enters L2transport PVC configuration mode.

- The **l2transport** keyword indicates that the PVC is a switched PVC instead of a terminated PVC.

Step 5 **encapsulation aal5**

Example:

```
Router(config-if-atm-l2trans-pvc)# encapsulation aal5
```

Specifies ATM AAL5 encapsulation for the PVC. Make sure you specify the same encapsulation type on the PE and customer edge (CE) routers.

Step 6 **xconnect** *peer-router-id vcid* **encapsulation mpls**

Example:

```
Router(config-if-atm-l2trans-pvc)# xconnect 10.13.13.13 100 encapsulation mpls
```

Binds the attachment circuit to a pseudowire VC.

Step 7 **end**

Example:

```
Router(config-if-atm-l2trans-pvc)# end
```

Exits to privileged EXEC mode.

Step 8 **show mpls l2transport vc**

Example:

```
Router# show mpls l2transport vc
```

Displays output that shows ATM AAL5 over MPLS is configured on a PVC.

Examples

The following is sample output from the **show mpls l2transport vc** command that shows that ATM AAL5 over MPLS is configured on a PVC:

```
Router# show mpls l2transport vc
Local intf   Local circuit          Dest address      VC ID      Status
---------    -------------          ------------      -----      ------
ATM1/0       ATM AAL5 1/100         10.4.4.4           100        UP
```

Configuring ATM AAL5 over MPLS on PVCs using the commands associated with the L2VPN Protocol-Based CLIs feature

Procedure

Step 1 **enable**

Example:

```
Device> enable
```

Enables privileged EXEC mode.

- Enter your password if prompted.

Step 2 **configure terminal**

Example:

```
Device# configure terminal
```

Enters global configuration mode.

Step 3 **interface** *type slot* / *subslot* / *port*[**.** *subinterface*]

Example:

```
Device(config)# interface atm1/0/0
```

Specifies the interface type and enters interface configuration mode.

Step 4 **pvc** [*name*] *vpi* / *vci* **l2transport**

Example:

```
Device(config-if)# pvc 1/200 l2transport
```

Creates or assigns a name to an ATM PVC and enters L2transport PVC configuration mode.

- The **l2transport** keyword indicates that the PVC is a switched PVC instead of a terminated PVC.

Step 5 **encapsulation aal5**

Example:

```
Device(config-if-atm-l2trans-pvc)# encapsulation aal5
```

Specifies ATM AAL5 encapsulation for the PVC. Make sure you specify the same encapsulation type on the PE and customer edge (CE) routers.

Step 6 **end**

Example:

```
Device(config-if-atm-l2trans-pvc)# end
```

Exits to privileged EXEC mode.

Step 7 **interface pseudowire** *number*

Example:

```
Device(config)# interface pseudowire 100
```

Specifies the pseudowire interface and enters interface configuration mode.

Step 8 **encapsulation mpls**

Example:

```
Device(config-if)# encapsulation mpls
```

Specifies that Multiprotocol Label Switching (MPLS) is used as the data encapsulation method.

Step 9 **neighbor** *peer-address vcid-value*

Example:

```
Device(config-if)# neighbor 10.13.13.13 100
```

Specifies the peer IP address and virtual circuit (VC) ID value of the Layer 2 VPN (L2VPN) pseudowire.

Step 10 **exit**

Example:

```
Device(config-if)# exit
```

Exits interface configuration mode.

Step 11 **l2vpn xconnect context** *context-name*

Example:

```
Device(config)# l2vpn xconnect context con1
```

Creates a Layer 2 VPN (L2VPN) cross connect context and enters xconnect configuration mode.

Step 12 **member pseudowire** *interface-number*

Example:

```
Device(config-xconnect)# member pseudowire 100
```

Specifies a member pseudowire to form a Layer 2 VPN (L2VPN) cross connect.

Step 13 **member atm** *interface-number* **pvc** *vpi* / *vci*

Example:

```
Device(config-xconnect)# member atm 100 pvc 1/200
```

Specifies the location of the ATM member interface.

Step 14 **end**

Example:

```
Device(config-xconnect)# end
```

Exits to privileged EXEC mode.

Step 15 **show l2vpn atom vc**

Example:

```
Device# show l2vpn atom vc
```

Displays output that shows ATM AAL5 over MPLS is configured on a PVC.

Examples

The following is sample output from the **show l2vpn atom vc** command that shows that ATM AAL5 over MPLS is configured on a PVC:

```
Device# show l2vpn atom vc
Local intf   Local circuit          Dest address      VC ID      Status
---------    -------------          ------------      -----      ------
ATM1/0       ATM AAL5 1/100         10.4.4.4           100        UP
```

Configuring ATM AAL5 over MPLS in VC Class Configuration Mode

Procedure

Step 1 **enable**

Example:

```
Router> enable
```

Enables privileged EXEC mode.

- Enter your password if prompted.

Step 2 **configure terminal**

Example:

```
Router# configure terminal
```

Enters global configuration mode.

Step 3 **vc-class atm** *vc-class-name*

Example:

```
Router(config)# vc-class atm aal5class
```

Creates a VC class and enters VC class configuration mode.

Step 4 **encapsulation** *layer-type*

Example:

```
Router(config-vc-class)# encapsulation aal5
```

Configures the AAL and encapsulation type.

Step 5 **exit**

Example:

```
Router(config-vc-class)# exit
```

Exits VC class configuration mode.

Step 6 **interface** *type slot* **/** *subslot* **/** *port* [**.** *subinterface*]

Example:

```
Router(config)# interface atm1/0/0
```

Specifies the interface type enters interface configuration mode.

Step 7 **class-int** *vc-class-name*

Example:

```
Router(config-if)# class-int aal5class
```

Applies a VC class to the ATM main interface or subinterface.

Note
You can also apply a VC class to a PVC.

Step 8 **pvc** [*name*] *vpi* / *vci* **l2transport**

Example:

```
Router(config-if)# pvc 1/200 l2transport
```

Creates or assigns a name to an ATM PVC and enters L2transport PVC configuration mode.

- The **l2transport** keyword indicates that the PVC is a switched PVC instead of a terminated PVC.

Step 9 **xconnect** *peer-router-id vcid* **encapsulation mpls**

Example:

```
Router(config-if-atm-l2trans-pvc)# xconnect 10.13.13.13 100 encapsulation mpls
```

Binds the attachment circuit to a pseudowire VC.

Step 10 **end**

Example:

```
Router(config-if-atm-l2trans-pvc)# end
```

Exits to privileged EXEC mode.

Step 11 **show atm class-links**

Example:

```
Router# show atm class-links
```

Displays the type of encapsulation and that the VC class was applied to an interface.

Examples

In the following example, the command output from the **show atm class-links** command verifies that ATM AAL5 over MPLS is configured as part of a VC class. The command output shows the type of encapsulation and that the VC class was applied to an interface.

```
Router# show atm class-links 1/100
Displaying vc-class inheritance for ATM1/0/0.0, vc 1/100:
no broadcast - Not configured - using default
encapsulation aal5 - VC-class configured on main interface
```

Configuring ATM AAL5 over MPLS in VC Class Configuration Mode using the commands associated with the L2VPN Protocol-Based CLIs feature

Procedure

Step 1 **enable**

Example:

```
Router> enable
```

Enables privileged EXEC mode.

- Enter your password if prompted.

Step 2 **configure terminal**

Example:

```
Router# configure terminal
```

Enters global configuration mode.

Step 3 **vc-class atm** *vc-class-name*

Example:

```
Router(config)# vc-class atm aal5class
```

Creates a VC class and enters VC class configuration mode.

Step 4 **encapsulation** *layer-type*

Example:

```
Router(config-vc-class)# encapsulation aal5
```

Configures the AAL and encapsulation type.

Step 5 **exit**

Example:

```
Router(config-vc-class)# exit
```

Exits VC class configuration mode.

Step 6 **interface** *type slot / subslot / port* [**.** *subinterface*]

Example:

```
Router(config)# interface atm1/0/0
```

Specifies the interface type enters interface configuration mode.

Step 7 **class-int** *vc-class-name*

Example:

```
Router(config-if)# class-int aal5class
```

Applies a VC class to the ATM main interface or subinterface.

Note
You can also apply a VC class to a PVC.

Step 8 **pvc** [*name*] *vpi* / *vci* **l2transport**

Example:

```
Router(config-if)# pvc 1/200 l2transport
```

Creates or assigns a name to an ATM PVC and enters L2transport PVC configuration mode.

- The **l2transport** keyword indicates that the PVC is a switched PVC instead of a terminated PVC.

Step 9 **exit**

Example:

```
Router(config-if)# exit
```

Exits interface configuration mode.

Step 10 **interface pseudowire** *number*

Example:

```
Router(config)# interface pseudowire 100
```

Specifies the pseudowire interface and enters interface configuration mode.

Step 11 **encapsulation mpls**

Example:

```
Router(config-if)# encapsulation mpls
```

Specifies that Multiprotocol Label Switching (MPLS) is used as the data encapsulation method.

Step 12 **neighbor** *peer-address vcid-value*

Example:

```
Router(config-if)# neighbor 10.0.0.1 123
```

Specifies the peer IP address and virtual circuit (VC) ID value of the Layer 2 VPN (L2VPN) pseudowire.

Step 13 **exit**

Example:

```
Router(config-if)# exit
```

Exits interface configuration mode.

Step 14 **l2vpn xconnect context** *context-name*

Example:

```
Router(config)# l2vpn xconnect context con1
```

Creates a Layer 2 VPN (L2VPN) cross connect context and enters xconnect configuration mode.

Step 15 **member pseudowire** *interface-number*

Example:

```
Router(config-xconnect)# member pseudowire 100
```

Specifies a member pseudowire to form a Layer 2 VPN (L2VPN) cross connect.

Step 16 **member atm** *interface-number*

Example:

```
Device(config-xconnect)# member atm 100
```

Specifies the location of the ATM member interface.

Step 17 **end**

Example:

```
Router(config-if-atm-l2trans-pvc)# end
```

Exits to privileged EXEC mode.

Step 18 **show atm class-links**

Example:

```
Router# show atm class-links
```

Displays the type of encapsulation and that the VC class was applied to an interface.

Examples

In the following example, the command output from the **show atm class-links** command verifies that ATM AAL5 over MPLS is configured as part of a VC class. The command output shows the type of encapsulation and that the VC class was applied to an interface.

```
Router# show atm class-links 1/100
Displaying vc-class inheritance for ATM1/0/0.0, vc 1/100:
no broadcast - Not configured - using default
encapsulation aal5 - VC-class configured on main interface
```

Configuring OAM Cell Emulation for ATM AAL5 over MPLS

Configuring OAM Cell Emulation for ATM AAL5 over MPLS on PVCs

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type slot / subslot / port* [**.** *subinterface*]
4. **pvc** [*name*] *vpi / vci* **l2transport**
5. **encapsulation aal5**
6. **xconnect** *peer-router-id vcid* **encapsulation mpls**
7. **oam-ac emulation-enable** [*ais-rate*]
8. *oam-pvc manage* [*frequency*]
9. **end**
10. **show atm pvc**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**interface** *type slot / subslot / port* [**.** *subinterface*] **Example:** `Router(config)# interface atm1/0/0`	Specifies the interface type enters interface configuration mode.
Step 4	**pvc** [*name*] *vpi / vci* **l2transport** **Example:** `Router(config-if)# pvc 1/200 l2transport`	Creates or assigns a name to an ATM PVC and enters L2transport PVC configuration mode. • The **l2transport** keyword indicates that the PVC is a switched PVC instead of a terminated PVC.
Step 5	**encapsulation aal5** **Example:**	Specifies ATM AAL5 encapsulation for the PVC. • Specify the same encapsulation type on the PE and CE routers.

	Command or Action	Purpose
	`Router(config-if-atm-l2trans-pvc)# encapsulation aal5`	
Step 6	**xconnect** *peer-router-id vcid* **encapsulation mpls** **Example:** `Router(config-if-atm-l2trans-pvc)# xconnect 10.13.13.13 100 encapsulation mpls`	Binds the attachment circuit to a pseudowire VC.
Step 7	**oam-ac emulation-enable** [*ais-rate*] **Example:** `Router(config-if-atm-l2trans-pvc)# oam-ac emulation-enable 30`	Enables OAM cell emulation for AAL5 over MPLS. The *ais-rate* argument lets you specify the rate at which AIS cells are sent. The default is one cell every second. The range is 0 to 60 seconds.
Step 8	*oam-pvc manage* [*frequency*] **Example:** `Router(config-if-atm-l2trans-pvc)# oam-pvc manage`	Enables the PVC to generate end-to-end OAM loopback cells that verify connectivity on the virtual circuit. The optional *frequency* argument is the interval between transmission of loopback cells and ranges from 0 to 600 seconds. The default value is 10 seconds.
Step 9	**end** **Example:** `Router(config-if-atm-l2trans-pvc)# end`	Exits to privileged EXEC mode.
Step 10	**show atm pvc** **Example:** `Router# show atm pvc`	Displays output that shows OAM cell emulation is enabled on the ATM PVC.

Examples

The following output from the **show atm pvc** command shows that OAM cell emulation is enabled on the ATM PVC:

```
Router# show atm pvc 5/500
ATM4/1/0.200: VCD: 6, VPI: 5, VCI: 500
UBR, PeakRate: 1
AAL5-LLC/SNAP, etype:0x0, Flags: 0x34000C20, VCmode: 0x0

10. **exit**
11. **l2vpn xconnect context** *context-name*
12. **member pseudowire** *interface-number*
13. **member atm** *interface-number* **pvc** *vpi* / *vci*
14. **exit**
15. **pvc** [*name*] *vpi* / *vci* **l2transport**
16. **oam-ac emulation-enable** [*ais-rate*]
17. *oam-pvc manage* [*frequency*]
18. **end**
19. **show atm pvc**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:**	Enters global configuration mode.

	Command or Action	Purpose
	`Router# configure terminal`	
Step 3	**interface** *type slot / subslot / port* [**.** *subinterface*] **Example:** `Router(config)# interface atm1/0/0`	Specifies the interface type enters interface configuration mode.
Step 4	**pvc** [*name*] *vpi / vci* **l2transport** **Example:** `Router(config-if)# pvc 1/200 l2transport`	Creates or assigns a name to an ATM PVC and enters L2transport PVC configuration mode. • The **l2transport** keyword indicates that the PVC is a switched PVC instead of a terminated PVC.
Step 5	**encapsulation aal5** **Example:** `Router(config-if-atm-l2trans-pvc)# encapsulation aal5`	Specifies ATM AAL5 encapsulation for the PVC. • Specify the same encapsulation type on the PE and CE routers.
Step 6	**exit** **Example:** `Router(config-if-atm-l2trans-pvc)# exit`	Exits L2transport PVC configuration mode.
Step 7	**interface pseudowire** *number* **Example:** `Router(config)# interface pseudowire 100`	Specifies the pseudowire interface and enters interface configuration mode.
Step 8	**encapsulation mpls** **Example:** `Router(config-if)# encapsulation mpls`	Specifies that Multiprotocol Label Switching (MPLS) is used as the data encapsulation method.
Step 9	**neighbor** *peer-address vcid-value* **Example:** `Router(config-if)# neighbor 10.0.0.1 123`	Specifies the peer IP address and virtual circuit (VC) ID value of the Layer 2 VPN (L2VPN) pseudowire.
Step 10	**exit** **Example:** `Router(config-if)# exit`	Exits interface configuration mode.
Step 11	**l2vpn xconnect context** *context-name* **Example:** `Router(config)# l2vpn xconnect context con1`	Creates a Layer 2 VPN (L2VPN) cross connect context and enters xconnect configuration mode.

	Command or Action	Purpose
Step 12	**member pseudowire** *interface-number* **Example:** `Router(config-xconnect)# member pseudowire 100`	Specifies a member pseudowire to form a Layer 2 VPN (L2VPN) cross connect.
Step 13	**member atm** *interface-number* **pvc** *vpi* / *vci* **Example:** `Device(config-xconnect)# member atm 100 pvc 1/200`	Specifies the location of the ATM member interface.
Step 14	**exit** **Example:** `Router(config-xconnect)# exit`	Exits xconnect configuration mode.
Step 15	**pvc** [*name*] *vpi* / *vci* **l2transport** **Example:** `Router(config-if)# pvc 1/200 l2transport`	Creates or assigns a name to an ATM PVC and enters L2transport PVC configuration mode.
Step 16	**oam-ac emulation-enable** [*ais-rate*] **Example:** `Router(config-if-atm-l2trans-pvc)# oam-ac emulation-enable 30`	Enables OAM cell emulation for AAL5 over MPLS. The *ais-rate* argument lets you specify the rate at which AIS cells are sent. The default is one cell every second. The range is 0 to 60 seconds.
Step 17	*oam-pvc manage* [*frequency*] **Example:** `Router(config-if-atm-l2trans-pvc)# oam-pvc manage`	Enables the PVC to generate end-to-end OAM loopback cells that verify connectivity on the virtual circuit. The optional *frequency* argument is the interval between transmission of loopback cells and ranges from 0 to 600 seconds. The default value is 10 seconds.
Step 18	**end** **Example:** `Router(config-if-atm-l2trans-pvc)# end`	Exits to privileged EXEC mode.
Step 19	**show atm pvc** **Example:** `Router# show atm pvc`	Displays output that shows OAM cell emulation is enabled on the ATM PVC.

Examples

The following output from the **show atm pvc** command shows that OAM cell emulation is enabled on the ATM PVC:

```
Router# show atm pvc 5/500
ATM4/1/0.200: VCD: 6, VPI: 5, VCI: 500

Status: UP
```

Configuring OAM Cell Emulation for ATM AAL5 over MPLS in VC Class Configuration Mode

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **vc-class atm** *name*
4. **encapsulation** *layer-type*
5. **oam-ac emulation-enable** [*ais-rate*]
6. **oam-pvc manage** [*frequency*]
7. **exit**
8. **interface** *type slot* / *subslot* / *port* [**.** *subinterface*]
9. **class-int** *vc-class-name*
10. **pvc** [*name*] *vpi* / *vci* **l2transport**
11. **xconnect** *peer-router-id vcid* **encapsulation mpls**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.

	Command or Action	Purpose
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**vc-class atm** *name* **Example:** `Router(config)# vc-class atm oamclass`	Creates a VC class and enters VC class configuration mode.
Step 4	**encapsulation** *layer-type* **Example:** `Router(config-vc-class)# encapsulation aal5`	Configures the AAL and encapsulation type.
Step 5	**oam-ac emulation-enable** [*ais-rate*] **Example:** `Router(config-vc-class)# oam-ac emulation-enable 30`	Enables OAM cell emulation for AAL5 over MPLS and specifies the rate at which AIS cells are sent.
Step 6	**oam-pvc manage** [*frequency*] **Example:** `Router(config-vc-class)# oam-pvc manage`	Enables the PVC to generate end-to-end OAM loopback cells that verify connectivity on the virtual circuit.
Step 7	**exit** **Example:** `Router(config-vc-class)# exit`	Exits VC class configuration mode.
Step 8	**interface** *type slot / subslot / port* [**.** *subinterface*] **Example:** `Router(config)# interface atm1/0/0`	Specifies the interface type and enters interface configuration mode.
Step 9	**class-int** *vc-class-name* **Example:** `Router(config-if)# class-int oamclass`	Applies a VC class to the ATM main interface or subinterface. **Note** You can also apply a VC class to a PVC.
Step 10	**pvc** [*name*] *vpi / vci* **l2transport** **Example:** `Router(config-if)# pvc 1/200 l2transport`	Creates or assigns a name to an ATM PVC and enters L2transport PVC configuration mode. • The **l2transport** keyword indicates that the PVC is a switched PVC instead of a terminated PVC.

	Command or Action	Purpose
Step 11	**xconnect** *peer-router-id vcid* **encapsulation mpls** **Example:** `Router(config-if-atm-l2trans-pvc)# xconnect 10.13.13.13 100 encapsulation mpls`	Binds the attachment circuit to a pseudowire VC.

Configuring OAM Cell Emulation for ATM AAL5 over MPLS in VC Class Configuration Mode using the commands associated with the L2VPN Protocol-Based CLIs feature

SUMMARY STEPS

Step 7	**exit** **Example:** `Router(config-vc-class)# exit`	Exits VC class configuration mode.
Step 8	**interface** *type slot / subslot / port* [**.** *subinterface*] **Example:** `Router(config)# interface atm1/0/0`	Specifies the interface type and enters interface configuration mode.
Step 9	**class-int** *vc-class-name* **Example:** `Router(config-if)# class-int oamclass`	Applies a VC class to the ATM main interface or subinterface. **Note** You can also apply a VC class to a PVC.
Step 10	**pvc** [*name*] *vpi* / *vci* **l2transport** **Example:** `Router(config-if)# pvc 1/200 l2transport`	Creates or assigns a name to an ATM PVC and enters L2transport PVC configuration mode. • The **l2transport** keyword indicates that the PVC is a switched PVC instead of a terminated PVC.
Step 11	**end** **Example:**	Exits to privileged EXEC mode.

	Command or Action	Purpose
	`Router(config-if-atm-l2trans-pvc)# end`	
Step 12	**interface pseudowire** *number* **Example:** `Router(config)# interface pseudowire 100`	Specifies the pseudowire interface and enters interface configuration mode.
Step 13	**encapsulation mpls** **Example:** `Router(config-if)# encapsulation mpls`	Specifies that Multiprotocol Label Switching (MPLS) is used as the data encapsulation method.
Step 14	**neighbor** *peer-address vcid-value* **Example:** `Router(config-if)# neighbor 10.0.0.1 123`	Specifies the peer IP address and virtual circuit (VC) ID value of the Layer 2 VPN (L2VPN) pseudowire.
Step 15	**exit** **Example:** `Router(config-if)# exit`	Exits interface configuration mode.
Step 16	**l2vpn xconnect context** *context-name* **Example:** `Router(config)# l2vpn xconnect context con1`	Creates a Layer 2 VPN (L2VPN) cross connect context and enters xconnect configuration mode.
Step 17	**member pseudowire** *interface-number* **Example:** `Router(config-xconnect)# member pseudowire 100`	Specifies a member pseudowire to form a Layer 2 VPN (L2VPN) cross connect.
Step 18	**member atm** *interface-number* **Example:** `Device(config-xconnect)# member atm 100`	Specifies the location of the ATM member interface.
Step 19	**end** **Example:** `Router(config-xconnect)# end`	Exits to privileged EXEC mode.

Configuring ATM Cell Relay over MPLS

Configuring ATM Cell Relay over MPLS in VC Mode

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface atm** *slot* / *subslot* / *port* [**.** *subinterface*]
4. **pvc** *vpi* / *vci* **l2transport**
5. **encapsulation aal0**
6. **xconnect** *peer-router-id vcid* **encapsulation mpls**
7. **end**
8. **show atm vc**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**interface atm** *slot* / *subslot* / *port* [**.** *subinterface*] **Example:** `Router(config)# interface atm1/0/0`	Specifies an ATM interface and enters interface configuration mode.
Step 4	**pvc** *vpi* / *vci* **l2transport** **Example:** `Router(config-if)# pvc 0/100 l2transport`	Assigns a virtual path identifier (VPI) and virtual circuit identifier (VCI) and enters L2transport VC configuration mode.
Step 5	**encapsulation aal0** **Example:** `Router(config-if-atm-l2trans-pvc)# encapsulation aal0`	For ATM cell relay, specifies raw cell encapsulation for the interface. • Make sure you specify the same encapsulation type on the PE and CE routers.

	Command or Action	Purpose
Step 6	**xconnect** *peer-router-id vcid* **encapsulation mpls** **Example:** `Router(config-if-atm-l2trans-pvc)# xconnect 10.13.13.13 100 encapsulation mpls`	Binds the attachment circuit to a pseudowire VC.
Step 7	**end** **Example:** `Router(config-if-atm-l2trans-pvc)# end`	Exits to privileged EXEC mode.
Step 8	**show atm vc** **Example:** `Router# show atm vc`	Verifies that OAM cell emulation is enabled on the ATM VC.

Example

The following sample output from the **show atm vc** command shows that the interface is configured for VC mode cell relay:

```
Router# show atm vc 7
ATM3/0: VCD: 7, VPI: 23, VCI: 100
UBR, PeakRate: 149760
AAL0-Cell Relay, etype:0x10, Flags: 0x10000C2D, VCmode: 0x0
OAM Cell Emulation: not configured
InBytes: 0, OutBytes: 0
Status: UP
```

Configuring ATM Cell Relay over MPLS in VC Mode using the commands associated with the L2VPN Protocol-Based CLIs feature

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface atm** *slot* **/** *subslot* **/** *port* [**.** *subinterface*]
4. **pvc** *vpi* **/** *vci* **l2transport**
5. **encapsulation aal0**
6. **end**
7. **interface pseudowire** *number*
8. **encapsulation mpls**
9. **neighbor** *peer-address vcid-value*
10. **exit**
11. **l2vpn xconnect context** *context-name*
12. **member pseudowire** *interface-number*

13. **member atm** *interface-number*
14. **end**
15. **show atm vc**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**interface atm** *slot* / *subslot* / *port* [**.** *subinterface*] **Example:** `Router(config)# interface atm1/0/0`	Specifies an ATM interface and enters interface configuration mode.
Step 4	**pvc** *vpi* / *vci* **l2transport** **Example:** `Router(config-if)# pvc 0/100 l2transport`	Assigns a virtual path identifier (VPI) and virtual circuit identifier (VCI) and enters L2transport VC configuration mode.
Step 5	**encapsulation aal0** **Example:** `Router(config-if-atm-l2trans-pvc)# encapsulation aal0`	For ATM cell relay, specifies raw cell encapsulation for the interface. • Make sure you specify the same encapsulation type on the PE and CE routers.
Step 6	**end** **Example:** `Router(config-if-atm-l2trans-pvc)# end`	Exits to privileged EXEC mode.
Step 7	**interface pseudowire** *number* **Example:** `Router(config)# interface pseudowire 100`	Specifies the pseudowire interface and enters interface configuration mode.
Step 8	**encapsulation mpls** **Example:**	Specifies that Multiprotocol Label Switching (MPLS) is used as the data encapsulation method.

	Command or Action	Purpose
	`Router(config-if)# encapsulation mpls`	
Step 9	**neighbor** *peer-address vcid-value* **Example:** `Router(config-if)# neighbor 10.0.0.1 123`	Specifies the peer IP address and virtual circuit (VC) ID value of the Layer 2 VPN (L2VPN) pseudowire.
Step 10	**exit** **Example:** `Router(config-if)# exit`	Exits interface configuration mode.
Step 11	**l2vpn xconnect context** *context-name* **Example:** `Router(config)# l2vpn xconnect context con1`	Creates a Layer 2 VPN (L2VPN) cross connect context and enters xconnect configuration mode.
Step 12	**member pseudowire** *interface-number* **Example:** `Router(config-xconnect)# member pseudowire 100`	Specifies a member pseudowire to form a Layer 2 VPN (L2VPN) cross connect.
Step 13	**member atm** *interface-number* **Example:** `Device(config-xconnect)# member atm 100`	Specifies the location of the ATM member interface.
Step 14	**end** **Example:** `Router(config-xconnect)# end`	Exits to privileged EXEC mode.
Step 15	**show atm vc** **Example:** `Router# show atm vc`	Verifies that OAM cell emulation is enabled on the ATM VC.

Example

The following sample output from the **show atm vc** command shows that the interface is configured for VC mode cell relay:

```
Router# show atm vc 7
ATM3/0: VCD: 7, VPI: 23, VCI: 100
UBR, PeakRate: 149760

Configuring ATM Cell Relay over MPLS in VC Mode Using VC Class Configuration Mode

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **vc-class atm** *name*
4. **encapsulation** *layer-type*
5. **exit**
6. **interface** *type slot* / *subslot* / *port* [**.** *subinterface*]
7. **class-int** *vc-class-name*
8. **pvc** [*name*] *vpi* / *vci* **l2transport**
9. **xconnect** *peer-router-id vcid* **encapsulation mpls**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**vc-class atm** *name* **Example:** `Router(config)# vc-class atm cellrelay`	Creates a VC class and enters VC class configuration mode.
Step 4	**encapsulation** *layer-type* **Example:** `Router(config-vc-class)# encapsulation aal0`	Configures the AAL and encapsulation type.
Step 5	**exit** **Example:** `Router(config-vc-class)# exit`	Exits VC class configuration mode.

	Command or Action	Purpose
Step 6	**interface** *type slot / subslot / port* [**.** *subinterface*] **Example:** `Router(config)# interface atm1/0/0`	Specifies the interface type and enters interface configuration mode.
Step 7	**class-int** *vc-class-name* **Example:** `Router(config-if)# class-int cellrelay`	Applies a VC class to the ATM main interface or subinterface. **Note** You can also apply a VC class to a PVC.
Step 8	**pvc** [*name*] *vpi / vci* **l2transport** **Example:** `Router(config-if)# pvc 1/200 l2transport`	Creates or assigns a name to an ATM PVC and enters L2transport PVC configuration mode.
Step 9	**xconnect** *peer-router-id vcid* **encapsulation mpls** **Example:** `Router(config-if-atm-l2trans-pvc)# xconnect 10.13.13.13 100 encapsulation mpls`	Binds the attachment circuit to a pseudowire VC.

Configuring ATM Cell Relay over MPLS in VC Mode Using VC Class Configuration Mode using the commands associated with the L2VPN Protocol-Based CLIs feature

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **vc-class atm** *name*
4. **encapsulation** *layer-type*
5. **exit**
6. **interface** *type slot / subslot / port* [**.** *subinterface*]
7. **class-int** *vc-class-name*
8. **pvc** [*name*] *vpi / vci* **l2transport**
9. **end**
10. **interface pseudowire** *number*
11. **encapsulation mpls**
12. **neighbor** *peer-address vcid-value*
13. **exit**
14. **l2vpn xconnect context** *context-name*
15. **member pseudowire** *interface-number*
16. **member atm** *interface-number*
17. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**vc-class atm** *name* **Example:** `Router(config)# vc-class atm cellrelay`	Creates a VC class and enters VC class configuration mode.
Step 4	**encapsulation** *layer-type* **Example:** `Router(config-vc-class)# encapsulation aal0`	Configures the AAL and encapsulation type.
Step 5	**exit** **Example:** `Router(config-vc-class)# exit`	Exits VC class configuration mode.
Step 6	**interface** *type slot* / *subslot* / *port* [**.** *subinterface*] **Example:** `Router(config)# interface atm1/0/0`	Specifies the interface type and enters interface configuration mode.
Step 7	**class-int** *vc-class-name* **Example:** `Router(config-if)# class-int cellrelay`	Applies a VC class to the ATM main interface or subinterface. **Note** You can also apply a VC class to a PVC.
Step 8	**pvc** [*name*] *vpi* / *vci* **l2transport** **Example:** `Router(config-if)# pvc 1/200 l2transport`	Creates or assigns a name to an ATM PVC and enters L2transport PVC configuration mode.
Step 9	**end** **Example:**	Exits to privileged EXEC mode.

	Command or Action	Purpose
	`Router(config-if-atm-l2trans-pvc)# end`	
Step 10	**interface pseudowire** *number* **Example:** `Router(config)# interface pseudowire 100`	Specifies the pseudowire interface and enters interface configuration mode.
Step 11	**encapsulation mpls** **Example:** `Router(config-if)# encapsulation mpls`	Specifies that Multiprotocol Label Switching (MPLS) is used as the data encapsulation method.
Step 12	**neighbor** *peer-address vcid-value* **Example:** `Router(config-if)# neighbor 10.0.0.1 123`	Specifies the peer IP address and virtual circuit (VC) ID value of the Layer 2 VPN (L2VPN) pseudowire.
Step 13	**exit** **Example:** `Router(config-if)# exit`	Exits interface configuration mode.
Step 14	**l2vpn xconnect context** *context-name* **Example:** `Router(config)# l2vpn xconnect context con1`	Creates a Layer 2 VPN (L2VPN) cross connect context and enters xconnect configuration mode.
Step 15	**member pseudowire** *interface-number* **Example:** `Router(config-xconnect)# member pseudowire 100`	Specifies a member pseudowire to form a Layer 2 VPN (L2VPN) cross connect.
Step 16	**member atm** *interface-number* **Example:** `Device(config-xconnect)# member atm 100`	Specifies the location of the ATM member interface.
Step 17	**end** **Example:** `Router(config-xconnect)# end`	Exits to privileged EXEC mode.

Configuring ATM Cell Relay over MPLS in PVP Mode

SUMMARY STEPS

1. **enable**

2. **configure terminal**
3. **interface atm** *slot* / *subslot* / *port* [**.** *subinterface*]
4. **atm pvp** *vpi* **l2transport**
5. **xconnect** *peer-router-id vcid* **encapsulation mpls**
6. **end**
7. **show atm vp**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**interface atm** *slot* / *subslot* / *port* [**.** *subinterface*] **Example:** `Router(config)# interface atm1/0/0`	Defines the interface and enters interface configuration mode.
Step 4	**atm pvp** *vpi* **l2transport** **Example:** `Router(config-if)# atm pvp 1 l2transport`	Specifies that the PVP is dedicated to transporting ATM cells and enters L2transport PVP configuration mode. • The **l2transport** keyword indicates that the PVP is for cell relay. This mode is for Layer 2 transport only; it is not for regular PVPs.
Step 5	**xconnect** *peer-router-id vcid* **encapsulation mpls** **Example:** `Router(config-if-atm-l2trans-pvp)# xconnect 10.0.0.1 123 encapsulation mpls`	Binds the attachment circuit to a pseudowire VC. The syntax for this command is the same as for all other Layer 2 transports.
Step 6	**end** **Example:** `Router(config-if-atm-l2trans-pvp)# end`	Exits to privileged EXEC mode.
Step 7	**show atm vp** **Example:**	Displays output that shows OAM cell emulation is enabled on the ATM VP.

	Command or Action	Purpose
	`Router# show atm vp`	

Examples

The following output from the **show atm vp** command shows that the interface is configured for VP mode cell relay:

```
Router# show atm vp 1
ATM5/0  VPI: 1, Cell Relay, PeakRate: 149760, CesRate: 0, DataVCs: 1, CesVCs: 0, Status:
ACTIVE
  VCD    VCI   Type   InPkts   OutPkts   AAL/Encap     Status
  6      3     PVC    0        0         F4 OAM        ACTIVE
  7      4     PVC    0        0         F4 OAM        ACTIVE
TotalInPkts: 0, TotalOutPkts: 0, TotalInFast: 0, TotalOutFast: 0,
TotalBroadcasts: 0 TotalInPktDrops: 0, TotalOutPktDrops: 0
```

Configuring ATM Cell Relay over MPLS in PVP Mode using the commands associated with the L2VPN Protocol-Based CLIs feature

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface atm** *slot* / *subslot* / *port* [**.** *subinterface*]
4. **atm pvp** *vpi* **l2transport**
5. **end**
6. **interface pseudowire** *number*
7. **encapsulation mpls**
8. **neighbor** *peer-address vcid-value*
9. **exit**
10. **l2vpn xconnect context** *context-name*
11. **member pseudowire** *interface-number*
12. **member atm** *interface-number* **pvp** *vpi*
13. **end**
14. **show atm vp**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:**	Enables privileged EXEC mode. • Enter your password if prompted.

	Command or Action	Purpose
	`Router> enable`	
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**interface atm** *slot* / *subslot* / *port* [**.** *subinterface*] **Example:** `Router(config)# interface atm1/0/0`	Defines the interface and enters interface configuration mode.
Step 4	**atm pvp** *vpi* **l2transport** **Example:** `Router(config-if)# atm pvp 1 l2transport`	Specifies that the PVP is dedicated to transporting ATM cells and enters L2transport PVP configuration mode. • The **l2transport** keyword indicates that the PVP is for cell relay. This mode is for Layer 2 transport only; it is not for regular PVPs.
Step 5	**end** **Example:** `Router(config-if-atm-l2trans-pvc)# end`	Exits to privileged EXEC mode.
Step 6	**interface pseudowire** *number* **Example:** `Router(config)# interface pseudowire 100`	Specifies the pseudowire interface and enters interface configuration mode.
Step 7	**encapsulation mpls** **Example:** `Router(config-if)# encapsulation mpls`	Specifies that Multiprotocol Label Switching (MPLS) is used as the data encapsulation method.
Step 8	**neighbor** *peer-address vcid-value* **Example:** `Router(config-if)# neighbor 10.0.0.1 123`	Specifies the peer IP address and virtual circuit (VC) ID value of the Layer 2 VPN (L2VPN) pseudowire.
Step 9	**exit** **Example:** `Router(config-if)# exit`	Exits interface configuration mode.
Step 10	**l2vpn xconnect context** *context-name* **Example:**	Creates a Layer 2 VPN (L2VPN) cross connect context and enters xconnect configuration mode.

	Command or Action	Purpose
	`Router(config)# l2vpn xconnect context con1`	
Step 11	**member pseudowire** *interface-number* **Example:** `Router(config-xconnect)# member pseudowire 100`	Specifies a member pseudowire to form a Layer 2 VPN (L2VPN) cross connect.
Step 12	**member atm** *interface-number* **pvp** *vpi* **Example:** `Device(config-xconnect)# member atm 100 pvp 1`	Specifies the location of the ATM member interface.
Step 13	**end** **Example:** `Router(config-xconnect)# end`	Exits to privileged EXEC mode.
Step 14	**show atm vp** **Example:** `Router# show atm vp`	Displays output that shows OAM cell emulation is enabled on the ATM VP.

Examples

The following output from the **show atm vp** command shows that the interface is configured for VP mode cell relay:

```
Router# show atm vp 1
ATM5/0  VPI: 1, Cell Relay, PeakRate: 149760, CesRate: 0, DataVCs: 1, CesVCs: 0, Status:
ACTIVE
  VCD    VCI   Type   InPkts   OutPkts   AAL/Encap     Status
  6      3     PVC    0        0         F4 OAM        ACTIVE
  7      4     PVC    0        0         F4 OAM        ACTIVE
TotalInPkts: 0, TotalOutPkts: 0, TotalInFast: 0, TotalOutFast: 0,
TotalBroadcasts: 0 TotalInPktDrops: 0, TotalOutPktDrops: 0
```

Configuring Ethernet over MPLS

Configuring Ethernet over MPLS in VLAN Mode to Connect Two VLAN Networks That Are in Different Locations.

Procedure

Step 1 **enable**

Example:

```
Router> enable
```

Enables privileged EXEC mode.

- Enter your password if prompted.

Step 2 **configure terminal**

Example:

```
Router# configure terminal
```

Enters global configuration mode.

Step 3 **interface gigabitethernet** *slot* **/** *subslot* **/** *port* [**.** *subinterface*]

Example:

```
Router(config)# interface gigabitethernet4/0/0.1
```

Specifies the Gigabit Ethernet subinterface and enters subinterface configuration mode.

- Make sure the subinterface on the adjoining CE router is on the same VLAN as this PE router.

Step 4 **encapsulation dot1q** *vlan-id*

Example:

```
Router(config-subif)# encapsulation dot1q 100
```

Enables the subinterface to accept 802.1Q VLAN packets.

Step 5 **xconnect** *peer-router-id vcid* **encapsulation mpls**

Example:

```
Router(config-subif)# xconnect 10.0.0.1 123 encapsulation mpls
```

Binds the attachment circuit to a pseudowire VC.

Configuring Ethernet over MPLS in VLAN Mode to Connect Two VLAN Networks That Are in Different Locations using the commands associated with the L2VPN Protocol-Based CLIs feature

Procedure

Step 1 **enable**

Example:

```
Router> enable
```

Enables privileged EXEC mode.

- Enter your password if prompted.

Step 2 **configure terminal**

Example:

```
Router# configure terminal
```

Enters global configuration mode.

Step 3 **interface gigabitethernet** *slot* **/** *subslot* **/** *port* [**.** *subinterface*]

Example:

```
Router(config)# interface gigabitethernet4/0/0.1
```

Specifies the Gigabit Ethernet subinterface and enters subinterface configuration mode.

- Make sure the subinterface on the adjoining CE router is on the same VLAN as this PE router.

Step 4 **encapsulation dot1q** *vlan-id*

Example:

```
Router(config-subif)# encapsulation dot1q 100
```

Enables the subinterface to accept 802.1Q VLAN packets.

Step 5 **end**

Example:

```
Router(config-subif)# end
```

Exits to privileged EXEC mode.

Step 6 **interface pseudowire** *number*

Example:

```
Router(config)# interface pseudowire 100
```

Specifies the pseudowire interface and enters interface configuration mode.

Step 7 **encapsulation mpls**

Example:

```
Router(config-if)# encapsulation mpls
```

Specifies that Multiprotocol Label Switching (MPLS) is used as the data encapsulation method.

Step 8 **neighbor** *peer-address vcid-value*

Example:

```
Router(config-if)# neighbor 10.0.0.1 123
```

Specifies the peer IP address and virtual circuit (VC) ID value of the Layer 2 VPN (L2VPN) pseudowire.

Step 9 **exit**

Example:

```
Router(config-if)# exit
```

Exits interface configuration mode.

Step 10 **l2vpn xconnect context** *context-name*

Example:

```
Router(config)# l2vpn xconnect context con1
```

Creates a Layer 2 VPN (L2VPN) cross connect context and enters xconnect configuration mode.

Step 11 **member pseudowire** *interface-number*

Example:

```
Router(config-xconnect)# member pseudowire 100
```

Specifies a member pseudowire to form a Layer 2 VPN (L2VPN) cross connect.

Step 12 **member gigabitethernet** *interface-number*

Example:

```
Router(config-xconnect)# member GigabitEthernet0/0/0.1
```

Specifies the location of the Gigabit Ethernet member interface.

Step 13 **end**

Example:

```
Router(config-xconnect)# end
```

Exits to privileged EXEC mode.

Configuring Ethernet over MPLS in Port Mode

Procedure

Step 1 **enable**

Example:

```
Router> enable
```

Enables privileged EXEC mode.

- Enter your password if prompted.

Step 2 **configure terminal**

Example:

```
Router# configure terminal
```

Enters global configuration mode.

Step 3 **interface gigabitethernet** *slot* / *subslot* / *port*

Example:

Specifies the Gigabit Ethernet interface and enters interface configuration mode.

Step 4 **xconnect** *peer-router-id vcid* **encapsulation mpls**

Example:

```
Router(config-if)# xconnect 10.0.0.1 123 encapsulation mpls
```

Binds the attachment circuit to a pseudowire VC.

Step 5 **end**

Example:

```
Router(config-if)# end
```

Exits to privileged EXEC mode.

Step 6 **show mpls l2transport vc**

Example:

```
Router# show mpls l2transport vc
```

Displays information about Ethernet over MPLS port mode.

Configuring Ethernet over MPLS in Port Mode Using Commands Associated with the L2VPN Protocol-Based Feature

Procedure

Step 1 **enable**

Example:

```
Device> enable
```

Enables privileged EXEC mode.

- Enter your password if prompted.

Step 2 **configure terminal**

Example:

```
Device# configure terminal
```

Enters global configuration mode.

Step 3 **interface gigabitethernet** *slot* / *subslot* / *port*[**.** *subinterface*]

Example:

```
Device(config)# interface gigabitethernet4/0/0
```

Specifies the Gigabit Ethernet interface and enters interface configuration mode.

- Make sure the interface on the adjoining CE router is on the same VLAN as this PE router.

Step 4 **end**

Example:

```
Device(config-if)# end
```

Exits to privileged EXEC mode.

Step 5 **interface pseudowire** *number*

Example:

```
Device(config)# interface pseudowire 100
```

Specifies the pseudowire interface and enters interface configuration mode.

Step 6 **encapsulation mpls**

Example:

```
Device(config-if)# encapsulation mpls
```

Specifies that Multiprotocol Label Switching (MPLS) is used as the data encapsulation method.

Step 7 **neighbor** *peer-address vcid-value*

Example:

```
Device(config-if)# neighbor 10.0.0.1 123
```

Specifies the peer IP address and virtual circuit (VC) ID value of the Layer 2 VPN (L2VPN) pseudowire.

Step 8 **exit**

Example:

```
Device(config-if)# exit
```

Exits interface configuration mode.

Step 9 **l2vpn xconnect context** *context-name*

Example:

```
Device(config)# l2vpn xconnect context con1
```

Creates a Layer 2 VPN (L2VPN) cross connect context and enters xconnect configuration mode.

Step 10 **member pseudowire** *interface-number*

Example:

```
Device(config-xconnect)# member pseudowire 100
```

Specifies a member pseudowire to form a Layer 2 VPN (L2VPN) cross connect.

Step 11 **member gigabitethernet** *interface-number*

Example:

```
Device(config-xconnect)# member GigabitEthernet0/0/0.1
```

Specifies the location of the Gigabit Ethernet member interface.

Step 12 **end**

Example:

```
Device(config-xconnect)# end
```

Exits to privileged EXEC mode.

Step 13 **end**

Example:

```
Device(config-if)# end
```

Exits to privileged EXEC mode.

Step 14 **show l2vpn atom vc**

Example:

```
Device# show l2vpn atom vc
```

Displays information about Ethernet over MPLS port mode.

Configuring Ethernet over MPLS with VLAN ID Rewrite

Procedure

Step 1 **enable**

Example:

```
Router> enable
```

Enables privileged EXEC mode.

- Enter your password if prompted.

Step 2 **configure terminal**

Example:

```
Router# configure terminal
```

Enters global configuration mode.

Step 3 **interface gigabitethernet** *slot* / *subslot* / *port*

Example:

Specifies the Gigabit Ethernet subinterface and enters subinterface configuration mode.

Step 4 **encapsulation dot1q** *vlan-id*

Example:

```
Router(config-subif)# encapsulation dot1q 100
```

Enables the subinterface to accept 802.1Q VLAN packets.

Step 5 **xconnect** *peer-router-id vcid* **encapsulation mpls**

Example:

```
Router(config-subif)# xconnect 10.0.0.1 123 encapsulation mpls
```

Binds the attachment circuit to a pseudowire VC and enters xconnect configuration mode.

Step 6 **remote circuit id** *remote-vlan-id*

Example:

```
Router(config-subif-xconn)# remote circuit id 101
```

(Optional) Enables you to use VLAN interfaces with different VLAN IDs at both ends of the tunnel.

Step 7 **end**

Example:

```
Router(config-subif-xconn)# end
```

Exits to privileged EXEC mode.

Configuring Ethernet over MPLS with VLAN ID Rewrite Using Commands Associated with the L2VPN Protocol-Based Feature

Procedure

Step 1 **enable**

Example:

```
Router> enable
```

Enables privileged EXEC mode.

- Enter your password if prompted.

Step 2 **configure terminal**

Example:

```
Router# configure terminal
```

Enters global configuration mode.

Step 3 **encapsulation dot1q** *vlan-id*

Example:

```
Router(config-subif)# encapsulation dot1q 100
```

Enables the subinterface to accept 802.1Q VLAN packets.

Step 4 **end**

Example:

```
Router(config-subif)# end
```

Exits to privileged EXEC mode.

Step 5 **interface pseudowire** *number*

Example:

```
Router(config)# interface pseudowire 100
```

Specifies the pseudowire interface and enters interface configuration mode.

Step 6 **encapsulation mpls**

Example:

```
Router(config-if)# encapsulation mpls
```

Specifies that Multiprotocol Label Switching (MPLS) is used as the data encapsulation method.

Step 7 **neighbor** *peer-address vcid-value*

Example:

```
Router(config-if)# neighbor 10.0.0.1 123
```

Specifies the peer IP address and virtual circuit (VC) ID value of the Layer 2 VPN (L2VPN) pseudowire.

Step 8 **exit**

Example:

```
Router(config-if)# exit
```

Exits interface configuration mode.

Step 9 **l2vpn xconnect context** *context-name*

Example:

```
Router(config)# l2vpn xconnect context con1
```

Creates a Layer 2 VPN (L2VPN) cross connect context and enters xconnect configuration mode.

Step 10 **member pseudowire** *interface-number*

Example:

```
Router(config-xconnect)# member pseudowire 100
```

Specifies a member pseudowire to form a Layer 2 VPN (L2VPN) cross connect.

Step 11 **member gigabitethernet** *interface-number*

Example:

Specifies the location of the Gigabit Ethernet member interface.

Step 12 **remote circuit id** *remote-vlan-id*

Example:

```
Router(config-xconnect)# remote circuit id 101
```

(Optional) Enables you to use VLAN interfaces with different VLAN IDs at both ends of the tunnel.

Step 13 **end**

Example:

```
Router(config-xconnect)# end
```

Exits to privileged EXEC mode.

Step 14 **show controllers eompls forwarding-table**

Example:

```
Router# show controllers eompls forwarding-table
```

Displays information about VLAN ID rewrite.

Configuring per-Subinterface MTU for Ethernet over MPLS

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface gigabitethernet** *slot* / *subslot* / *port* [**.** *subinterface*]

4. **mtu** *mtu-value*
5. **interface gigabitethernet** *slot* / *subslot* / *port* [**.** *subinterface*]
6. **encapsulation dot1q** *vlan-id*
7. **xconnect** *peer-router-id vcid* **encapsulation mpls**
8. **mtu** *mtu-value*
9. **end**
10. **show mpls l2transport binding**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**interface gigabitethernet** *slot* / *subslot* / *port* [**.** *subinterface*] **Example:** `Router(config)# interface gigabitethernet4/0/0`	Specifies the Gigabit Ethernet interface and enters interface configuration mode.
Step 4	**mtu** *mtu-value* **Example:** `Router(config-if)# mtu 2000`	Specifies the MTU value for the interface. The MTU value specified at the interface level can be inherited by a subinterface.
Step 5	**interface gigabitethernet** *slot* / *subslot* / *port* [**.** *subinterface*] **Example:** `Router(config-if)# interface gigabitethernet4/0/0.1`	Specifies the Gigabit Ethernet subinterface and enters subinterface configuration mode. Make sure the subinterface on the adjoining CE router is on the same VLAN as this PE router.
Step 6	**encapsulation dot1q** *vlan-id* **Example:** `Router(config-subif)# encapsulation dot1q 100`	Enables the subinterface to accept 802.1Q VLAN packets. The subinterfaces between the CE and PE routers that are running Ethernet over MPLS must be in the same subnet. All other subinterfaces and backbone routers need not be.
Step 7	**xconnect** *peer-router-id vcid* **encapsulation mpls**	Binds the attachment circuit to a pseudowire VC.

	Command or Action	Purpose
	Example: `Router(config-subif)# xconnect 10.0.0.1 123 encapsulation mpls`	The syntax for this command is the same as for all other Layer 2 transports. Enters xconnect subinterface configuration mode.
Step 8	**mtu** *mtu-value* **Example:** `Router(config-if-xconn)# mtu 1400`	Specifies the MTU for the VC.
Step 9	**end** **Example:** `Router(config-if-xconn)# end`	Exits to privileged EXEC mode.
Step 10	**show mpls l2transport binding** **Example:** `Router# show mpls l2transport binding`	Displays the MTU values assigned to the local and remote interfaces.

Configuring per-Subinterface MTU for Ethernet over MPLS using the commands associated with the L2VPN Protocol-Based CLIs feature

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface gigabitethernet** *slot* / *subslot* / *port*[**.** *subinterface*]
4. **mtu** *mtu-value*
5. **interface gigabitethernet** *slot* / *subslot* / *port*[**.** *subinterface*]
6. **encapsulation dot1q** *vlan-id*
7. **end**
8. **interface pseudowire** *number*
9. **encapsulation mpls**
10. **neighbor** *peer-address vcid-value*
11. **mtu** *mtu-value*
12. **exit**
13. **l2vpn xconnect context** *context-name*
14. **member pseudowire** *interface-number*
15. **member gigabitethernet** *interface-number*
16. **end**
17. **show l2vpn atom binding**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**interface gigabitethernet** *slot* / *subslot* / *port*[**.** *subinterface*] **Example:** `Device(config)# interface gigabitethernet4/0/0`	Specifies the Gigabit Ethernet interface and enters interface configuration mode.
Step 4	**mtu** *mtu-value* **Example:** `Device(config-if)# mtu 2000`	Specifies the MTU value for the interface. The MTU value specified at the interface level can be inherited by a subinterface.
Step 5	**interface gigabitethernet** *slot* / *subslot* / *port*[**.** *subinterface*] **Example:** `Device(config-if)# interface gigabitethernet4/0/0.1`	Specifies the Gigabit Ethernet subinterface and enters subinterface configuration mode. Make sure the subinterface on the adjoining CE router is on the same VLAN as this PE router.
Step 6	**encapsulation dot1q** *vlan-id* **Example:** `Device(config-subif)# encapsulation dot1q 100`	Enables the subinterface to accept 802.1Q VLAN packets. The subinterfaces between the CE and PE routers that are running Ethernet over MPLS must be in the same subnet. All other subinterfaces and backbone routers need not be.
Step 7	**end** **Example:** `Device(config-subif)# end`	Exits to privileged EXEC mode.
Step 8	**interface pseudowire** *number* **Example:** `Device(config)# interface pseudowire 100`	Specifies the pseudowire interface and enters interface configuration mode.

	Command or Action	Purpose
Step 9	**encapsulation mpls** **Example:** `Device(config-if)# encapsulation mpls`	Specifies that Multiprotocol Label Switching (MPLS) is used as the data encapsulation method.
Step 10	**neighbor** *peer-address vcid-value* **Example:** `Device(config-if)# neighbor 10.0.0.1 123`	Specifies the peer IP address and virtual circuit (VC) ID value of the Layer 2 VPN (L2VPN) pseudowire.
Step 11	**mtu** *mtu-value* **Example:** `Device(config-if)# mtu 1400`	Specifies the MTU for the VC.
Step 12	**exit** **Example:** `Device(config-if)# exit`	Exits interface configuration mode.
Step 13	**l2vpn xconnect context** *context-name* **Example:** `Device(config)# l2vpn xconnect context con1`	Creates a Layer 2 VPN (L2VPN) cross connect context and enters xconnect configuration mode.
Step 14	**member pseudowire** *interface-number* **Example:** `Device(config-xconnect)# member pseudowire 100`	Specifies a member pseudowire to form a Layer 2 VPN (L2VPN) cross connect.
Step 15	**member gigabitethernet** *interface-number* **Example:** `Device(config-xconnect)# member GigabitEthernet0/0/0.1`	Specifies the location of the Gigabit Ethernet member interface.
Step 16	**end** **Example:** `Device(config-xconnect)# end`	Exits to privileged EXEC mode.
Step 17	**show l2vpn atom binding** **Example:** `Device# show l2vpn atom binding`	Displays Layer 2 VPN (L2VPN) Any Transport over MPLS (AToM) label binding information.

Configuring Frame Relay over MPLS

Configuring Frame Relay over MPLS with DLCI-to-DLCI Connections

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **frame-relay switching**
4. **interface serial** *slot* / *subslot* / *port* [**.** *subinterface*]
5. **encapsulation frame-relay** [**cisco** | **ietf**]
6. **frame-relay intf-type dce**
7. **exit**
8. **connect** *connection-name interface dlci* **l2transport**
9. **xconnect** *peer-router-id vcid* **encapsulation mpls**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**frame-relay switching** **Example:** `Router(config)# frame-relay switching`	Enables PVC switching on a Frame Relay device.
Step 4	**interface serial** *slot* / *subslot* / *port* [**.** *subinterface*] **Example:** `Router(config)# interface serial3/1/0`	Specifies a serial interface and enters interface configuration mode.
Step 5	**encapsulation frame-relay** [**cisco**	**ietf**] **Example:** `Router(config-if)# encapsulation frame-relay ietf`	Specifies Frame Relay encapsulation for the interface. You can specify different types of encapsulations. You can set one interface to Cisco encapsulation and the other interface to IETF encapsulation.

	Command or Action	Purpose
Step 6	**frame-relay intf-type dce** **Example:** `Router(config-if)# frame-relay intf-type dce`	Specifies that the interface is a DCE switch. You can also specify the interface to support Network-to-Network Interface (NNI) and DTE connections.
Step 7	**exit** **Example:** `Router(config-if)# exit`	Exits from interface configuration mode.
Step 8	**connect** *connection-name interface dlci* **l2transport** **Example:** `Router(config)# connect fr1 serial5/0 1000 l2transport`	Defines connections between Frame Relay PVCs and enters connect configuration mode. Using the **l2transport** keyword specifies that the PVC will not be a locally switched PVC, but will be tunneled over the backbone network. The *connection-name* argument is a text string that you provide. The *interface* argument is the interface on which a PVC connection will be defined. The *dlci* argument is the DLCI number of the PVC that will be connected.
Step 9	**xconnect** *peer-router-id vcid* **encapsulation mpls** **Example:** `Router(config-fr-pw-switching)# xconnect 10.0.0.1 123 encapsulation mpls`	Creates the VC to transport the Layer 2 packets. In a DLCI-to DLCI connection type, Frame Relay over MPLS uses the **xconnect** command in connect configuration mode.

Configuring Frame Relay over MPLS with DLCI-to-DLCI Connections using the commands associated with the L2VPN Protocol-Based CLIs feature

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **frame-relay switching**
4. **interface serial** *slot* / *subslot* / *port* [**.** *subinterface*]
5. **encapsulation frame-relay** [**cisco** | **ietf**]
6. **frame-relay intf-type dce**
7. **exit**
8. **connect** *connection-name interface dlci* **l2transport**
9. **end**
10. **interface pseudowire** *number*
11. **encapsulation mpls**
12. **neighbor** *peer-address vcid-value*
13. **exit**

14. **l2vpn xconnect context** *context-name*
15. **member pseudowire** *interface-number*
16. **member** *ip-address vc-id* **encapsulation mpls**
17. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**frame-relay switching** **Example:** `Router(config)# frame-relay switching`	Enables PVC switching on a Frame Relay device.
Step 4	**interface serial** *slot* / *subslot* / *port* [**.** *subinterface*] **Example:** `Router(config)# interface serial3/1/0`	Specifies a serial interface and enters interface configuration mode.
Step 5	**encapsulation frame-relay** [**cisco** | **ietf**] **Example:** `Router(config-if)# encapsulation frame-relay ietf`	Specifies Frame Relay encapsulation for the interface. You can specify different types of encapsulations. You can set one interface to Cisco encapsulation and the other interface to IETF encapsulation.
Step 6	**frame-relay intf-type dce** **Example:** `Router(config-if)# frame-relay intf-type dce`	Specifies that the interface is a DCE switch. You can also specify the interface to support Network-to-Network Interface (NNI) and DTE connections.
Step 7	**exit** **Example:** `Router(config-if)# exit`	Exits from interface configuration mode.

	Command or Action	Purpose
Step 8	**connect** *connection-name interface dlci* **l2transport** **Example:** `Router(config)# connect fr1 serial5/0 1000 l2transport`	Defines connections between Frame Relay PVCs and enters connect configuration mode. Using the **l2transport**keyword specifies that the PVC will not be a locally switched PVC, but will be tunneled over the backbone network. The *connection-name*argument is a text string that you provide. The *interface*argument is the interface on which a PVC connection will be defined. The *dlci*argument is the DLCI number of the PVC that will be connected.
Step 9	**end** **Example:** `Router(config-xconnect-conn-config)# end`	Exits to privileged EXEC mode.
Step 10	**interface pseudowire** *number* **Example:** `Router(config)# interface pseudowire 100`	Specifies the pseudowire interface and enters interface configuration mode.
Step 11	**encapsulation mpls** **Example:** `Router(config-if)# encapsulation mpls`	Specifies that Multiprotocol Label Switching (MPLS) is used as the data encapsulation method.
Step 12	**neighbor** *peer-address vcid-value* **Example:** `Router(config-if)# neighbor 10.0.0.1 123`	Specifies the peer IP address and virtual circuit (VC) ID value of the Layer 2 VPN (L2VPN) pseudowire.
Step 13	**exit** **Example:** `Router(config-if)# exit`	Exits interface configuration mode.
Step 14	**l2vpn xconnect context** *context-name* **Example:** `Router(config)# l2vpn xconnect context con1`	Creates a Layer 2 VPN (L2VPN) cross connect context and enters xconnect configuration mode.
Step 15	**member pseudowire** *interface-number* **Example:** `Router(config-xconnect)# member pseudowire 100`	Specifies a member pseudowire to form a Layer 2 VPN (L2VPN) cross connect.

	Command or Action	Purpose
Step 16	**member** *ip-address vc-id* **encapsulation mpls** **Example:** `Router(config-xconnect)# member 10.0.0.1 123 encapsulation mpls`	Creates the VC to transport the Layer 2 packets.
Step 17	**end** **Example:** `Router(config-xconnect)# end`	Exits to privileged EXEC mode.

Configuring Frame Relay over MPLS with Port-to-Port Connections

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface serial** *slot* / *subslot* / *port* [**.** *subinterface*]
4. **encapsulation hdlc**
5. **xconnect** *peer-router-id vcid* **encapsulation mpls**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**interface serial** *slot* / *subslot* / *port* [**.** *subinterface*] **Example:** `Router(config)# interface serial5/0/0`	Specifies a serial interface and enters interface configuration mode.
Step 4	**encapsulation hdlc** **Example:** `Router(config-if)# encapsulation hdlc`	Specifies that Frame Relay PDUs will be encapsulated in HDLC packets.

	Command or Action	Purpose
Step 5	**xconnect** *peer-router-id vcid* **encapsulation mpls** **Example:** `Router(config-if)# xconnect 10.0.0.1 123 encapsulation mpls`	Creates the VC to transport the Layer 2 packets.

Configuring Frame Relay over MPLS with Port-to-Port Connections using the commands associated with the L2VPN Protocol-Based CLIs feature

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface serial** *slot* / *subslot* / *port* [**.** *subinterface*]
4. **encapsulation hdlc**
5. **end**
6. **interface pseudowire** *number*
7. **encapsulation mpls**
8. **neighbor** *peer-address vcid-value*
9. **exit**
10. **l2vpn xconnect context** *context-name*
11. **member pseudowire** *interface-number*
12. **member** *ip-address vc-id* **encapsulation mpls**
13. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**interface serial** *slot* / *subslot* / *port* [**.** *subinterface*] **Example:** `Router(config)# interface serial5/0/0`	Specifies a serial interface and enters interface configuration mode.

	Command or Action	Purpose
Step 4	**encapsulation hdlc** **Example:** `Router(config-if)# encapsulation hdlc`	Specifies that Frame Relay PDUs will be encapsulated in HDLC packets.
Step 5	**end** **Example:** `Router(config-if)# end`	Exits to privileged EXEC mode.
Step 6	**interface pseudowire** *number* **Example:** `Router(config)# interface pseudowire 100`	Specifies the pseudowire interface and enters interface configuration mode.
Step 7	**encapsulation mpls** **Example:** `Router(config-if)# encapsulation mpls`	Specifies that Multiprotocol Label Switching (MPLS) is used as the data encapsulation method.
Step 8	**neighbor** *peer-address vcid-value* **Example:** `Router(config-if)# neighbor 10.0.0.1 123`	Specifies the peer IP address and virtual circuit (VC) ID value of the Layer 2 VPN (L2VPN) pseudowire.
Step 9	**exit** **Example:** `Router(config-if)# exit`	Exits interface configuration mode.
Step 10	**l2vpn xconnect context** *context-name* **Example:** `Router(config)# l2vpn xconnect context con1`	Creates a Layer 2 VPN (L2VPN) cross connect context and enters xconnect configuration mode.
Step 11	**member pseudowire** *interface-number* **Example:** `Router(config-xconnect)# member pseudowire 100`	Specifies a member pseudowire to form a Layer 2 VPN (L2VPN) cross connect.
Step 12	**member** *ip-address vc-id* **encapsulation mpls** **Example:** `Router(config-xconnect)# member 10.0.0.1 123 encapsulation mpls`	Creates the VC to transport the Layer 2 packets.

	Command or Action	Purpose
Step 13	**end** **Example:** `Router(config-xconnect)# end`	Exits to privileged EXEC mode.

Configuring HDLC or PPP over MPLS

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface serial** *slot* / *subslot* / *port* [**.** *subinterface*]
4. Do one of the following:
   - **encapsulation ppp**
   - **encapsulation hdlc**
5. **xconnect** *peer-router-id vcid* **encapsulation mpls**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**interface serial** *slot* / *subslot* / *port* [**.** *subinterface*] **Example:** `Router(config)# interface serial5/0/0`	Specifies a serial interface and enters interface configuration mode.
Step 4	Do one of the following: • **encapsulation ppp** • **encapsulation hdlc** **Example:** `Router(config-if)# encapsulation ppp`	Specifies HDLC or PPP encapsulation and enters connect configuration mode.

	Command or Action	Purpose
	Example: or **Example:** **Example:** `Router(config-if)# encapsulation hdlc`	
Step 5	**xconnect** *peer-router-id vcid* **encapsulation mpls** **Example:** `Router(config-fr-pw-switching)# xconnect 10.0.0.1 123 encapsulation mpls`	Creates the VC to transport the Layer 2 packets.

Configuring HDLC or PPP over MPLS using the commands associated with the L2VPN Protocol-Based CLIs feature

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface serial** *slot* / *subslot* / *port* [**.** *subinterface*]
4. Do one of the following:
   - **encapsulation ppp**
   - **encapsulation hdlc**
5. **end**
6. **interface pseudowire** *number*
7. **encapsulation mpls**
8. **neighbor** *peer-address vcid-value*
9. **exit**
10. **l2vpn xconnect context** *context-name*
11. **member pseudowire** *interface-number*
12. **member** *ip-address vc-id* **encapsulation mpls**
13. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**interface serial** *slot* / *subslot* / *port* [**.** *subinterface*] **Example:** `Router(config)# interface serial5/0/0`	Specifies a serial interface and enters interface configuration mode.

Step 4	Do one of the following:
	• **encapsulation ppp**
	• **encapsulation hdlc**
	Example:
	`Router(config-if)# encapsulation ppp`
	Example:
	`Router(config-if)# encapsulation hdlc`
		Specifies HDLC or PPP encapsulation and enters connect configuration mode.

Step 5	**end** **Example:** `Router(config-xconnect-conn-config)# end`	Exits to privileged EXEC mode.
Step 6	**interface pseudowire** *number* **Example:** `Router(config)# interface pseudowire 100`	Specifies the pseudowire interface and enters interface configuration mode.
Step 7	**encapsulation mpls** **Example:** `Router(config-if)# encapsulation mpls`	Specifies that Multiprotocol Label Switching (MPLS) is used as the data encapsulation method.
Step 8	**neighbor** *peer-address vcid-value* **Example:**	Specifies the peer IP address and virtual circuit (VC) ID value of the Layer 2 VPN (L2VPN) pseudowire.

	Command or Action	Purpose
	`Router(config-if)# neighbor 10.0.0.1 123`	
Step 9	**exit** **Example:** `Router(config-if)# exit`	Exits interface configuration mode.
Step 10	**l2vpn xconnect context** *context-name* **Example:** `Router(config)# l2vpn xconnect context con1`	Creates a Layer 2 VPN (L2VPN) cross connect context and enters xconnect configuration mode.
Step 11	**member pseudowire** *interface-number* **Example:** `Router(config-xconnect)# member pseudowire 100`	Specifies a member pseudowire to form a Layer 2 VPN (L2VPN) cross connect.
Step 12	**member** *ip-address vc-id* **encapsulation mpls** **Example:** `Router(config-xconnect)# member 10.0.0.1 123 encapsulation mpls`	Creates the VC to transport the Layer 2 packets.
Step 13	**end** **Example:** `Router(config-xconnect)# end`	Exits to privileged EXEC mode.

Configuring Tunnel Selection

Procedure

Step 1 **enable**

Example:

```
Router> enable
```

Enables privileged EXEC mode.

- Enter your password if prompted.

Step 2 **configure terminal**

Example:

```
Router# configure terminal
```

Enters global configuration mode.

Step 3 **pseudowire-class** *name*

Example:

```
Router(config)# pseudowire-class ts1
```

Establishes a pseudowire class with a name that you specify and enters pseudowire configuration mode.

Step 4 **encapsulation mpls**

Example:

```
Router(config-pw)# encapsulation mpls
```

Specifies the tunneling encapsulation. For AToM, the encapsulation type is mpls.

Step 5 **preferred-path** {**interface tunnel** *tunnel-number* | **peer**{*ip-address* | *host-name*}} [**disable-fallback**]

Example:

```
Router(config-pw)# preferred path peer 10.18.18.18
```

Specifies the MPLS traffic engineering tunnel or IP address or hostname to be used as the preferred path.

Step 6 **exit**

Example:

```
Router(config-pw)# exit
```

Exits from pseudowire configuration mode and enables the Tunnel Selection feature.

Step 7 **interface** *type slot / subslot / port*

Example:

```
Router(config)# interface atm1/1/0
```

Specifies an interface type and enters interface configuration mode.

Step 8 **encapsulation** *encapsulation-type*

Example:

```
Router(config-if)# encapsulation aal5
```

Specifies the encapsulation for the interface.

Step 9 **xconnect** *peer-router-id vcid* **pw-class** *name*

Example:

```
Router(config-if)# xconnect 10.0.0.1 123 pw-class ts1
```

Binds the attachment circuit to a pseudowire VC.

Examples

In the following sample output from the **show mpls l2transport vc** command includes the following information about the VCs:

- VC 101 has been assigned a preferred path called Tunnel1. The default path is disabled, because the preferred path specified that the default path should not be used if the preferred path fails.
- VC 150 has been assigned an IP address of a loopback address on PE2. The default path can be used if the preferred path fails.

Command output that is in boldface font shows the preferred path information.

```
Router# show mpls l2transport vc detail
Local interface: Gi0/0/0.1 up, line protocol up, Eth VLAN 222 up
  Destination address: 10.16.16.16, VC ID: 101, VC status: up
    Preferred path: Tunnel1,  active
    Default path: disabled
    Tunnel label: 3, next hop point2point
    Output interface: Tu1, imposed label stack {17 16}
  Create time: 00:27:31, last status change time: 00:27:31
  Signaling protocol: LDP, peer 10.16.16.16:0 up
    MPLS VC labels: local 25, remote 16
    Group ID: local 0, remote 6
    MTU: local 1500, remote 1500
    Remote interface description:
  Sequencing: receive disabled, send disabled
  VC statistics:
    packet totals: receive 10, send 10
    byte totals:   receive 1260, send 1300
    packet drops:  receive 0, send 0
Local interface: ATM1/0/0 up, line protocol up, ATM AAL5 0/50 up
  Destination address: 10.16.16.16, VC ID: 150, VC status: up
    Preferred path: 10.18.18.18, active
    Default path: ready
    Tunnel label: 3, next hop point2point
    Output interface: Tu2, imposed label stack {18 24}
  Create time: 00:15:08, last status change time: 00:07:37
  Signaling protocol: LDP, peer 10.16.16.16:0 up

    Remote interface description:
  Sequencing: receive disabled, send disabled
  VC statistics:
    packet totals: receive 0, send 0
    byte totals:   receive 0, send 0
    packet drops:  receive 0, send 0
```

Troubleshooting Tips

To debug ATM cell packing, issue the **debug atm cell-packing** command.

Configuring Tunnel Selection Using Commands Associated with L2VPN Protocol-Based Feature

Procedure

Step 1 **enable**

Example:

```
Router> enable
```

Enables privileged EXEC mode.

- Enter your password if prompted.

Step 2 **configure terminal**

Example:

```
Router# configure terminal
```

Enters global configuration mode.

Step 3 **template type pseudowire** *name*

Example:

```
Router(config)# template type pseudowire ts1
```

Creates a template pseudowire with a name that you specify and enters pseudowire configuration mode.

Step 4 **encapsulation mpls**

Example:

```
Router(config-pw)# encapsulation mpls
```

Specifies the tunneling encapsulation. For AToM, the encapsulation type is mpls.

Step 5 **preferred-path** {**interface tunnel** *tunnel-number* | **peer** {*ip-address* | *hostname*}} [**disable-fallback**]

Example:

```
Router(config-pw)# preferred path peer 10.18.18.18
```

Specifies the MPLS traffic engineering tunnel or IP address or hostname to be used as the preferred path.

Step 6 **exit**

Example:

```
Router(config-pw)# exit
```

Exits from pseudowire configuration mode and enables the Tunnel Selection feature.

Step 7 **interface** *type slot* / *subslot* / *port*[**.** *subinterface*]

Example:

```
Router(config)# interface atm1/1/0
```

Specifies an interface type and enters interface configuration mode.

Step 8 **encapsulation** *encapsulation-type*

Example:

```
Router(config-if)# encapsulation aal5
```

Specifies the encapsulation for the interface.

Step 9 **end**

Example:

```
Router(config-if)# end
```

Exits to privileged EXEC mode.

Step 10 **interface pseudowire** *number*

Example:

```
Router(config)# interface pseudowire 100
```

Specifies the pseudowire interface and enters interface configuration mode.

Step 11 **source template type pseudowire** *name*

Example:

```
Router(config-if)# source template type pseudowire ts1
```

Configures the source template of type pseudowire named ts1.

Step 12 **neighbor** *peer-address vcid-value*

Example:

```
Router(config-if)#  neighbor 10.0.0.1 123
```

Specifies the peer IP address and virtual circuit (VC) ID value of a Layer 2 VPN (L2VPN) pseudowire.

Step 13 **end**

Example:

```
Router(config-if)# end
```

Exits to privileged EXEC mode.

Step 14 **l2vpn xconnect context** *context-name*

Example:

```
Router(config)# l2vpn xconnect context con1
```

Creates a Layer 2 VPN (L2VPN) cross connect context and enters xconnect configuration mode.

Step 15 **member pseudowire** *interface-number*

Example:

```
Router(config-xconnect)# member pseudowire 100
```

Specifies a member pseudowire to form a Layer 2 VPN (L2VPN) cross connect.

Step 16 **member** *ip-address vc-id* **encapsulation mpls**

Example:

```
Router(config-xconnect)# member 10.0.0.1 123 encapsulation mpls
```

Creates the VC to transport the Layer 2 packets.

Step 17 **end**

Example:

```
Router(config-xconnect)# end
```

Exits to privileged EXEC mode.

Troubleshooting Tips using the commands associated with the L2VPN Protocol-Based CLIs feature

You can use the **debug l2vpn atom vc event** command to troubleshoot tunnel selection. For example, if the tunnel interface that is used for the preferred path is shut down, the default path is enabled. The **debug l2vpn atom vc event** command provides the following output:

```
AToM SMGR [10.2.2.2, 101]: Processing imposition update, vc_handle 62091860, update_action
 3, remote_vc_label 16
AToM SMGR [10.2.2.2, 101]: selected route no parent rewrite: tunnel not up
AToM SMGR [10.2.2.2, 101]: Imposition Programmed, Output Interface: Et3/2
```

Setting Experimental Bits with AToM

Note Only EoMPLS and CEM is supported .

Procedure

Step 1 **enable**

Example:

```
Router> enable
```

Enables privileged EXEC mode.

- Enter your password if prompted.

Step 2 **configure terminal**

Example:

```
Router# configure terminal
```

Enters global configuration mode.

Step 3 **class-map** *class-name*

Example:

```
Router(config)# class-map class1
```

Specifies the user-defined name of the traffic class and enters class map configuration mode.

Step 4 **match any**

Example:

```
Router(config-cmap)# match any
```

Specifies that all packets will be matched. Use only the **any** keyword. Other keywords might cause unexpected results.

Step 5 **policy-map** *policy-name*

Example:

```
Router(config-cmap)# policy-map policy1
```

Specifies the name of the traffic policy to configure and enters policy-map configuration mode.

Step 6 **class** *class-name*

Example:

```
Router(config-pmap)# class class1
```

Specifies the name of a predefined traffic class, which was configured with the **class-map** command, used to classify traffic to the traffic policy and enters policy-map class configuration mode.

Step 7 **set mpls experimental** *value*

Example:

```
Router(config-pmap-c)# set mpls experimental 7
```

Designates the value to which the MPLS bits are set if the packets match the specified policy map.

Step 8 **exit**

Example:

```
Router(config-pmap-c)# exit
```

Exits policy-map class configuration mode.

Step 9 **exit**

Example:

```
Router(config-pmap)# exit
```

Exits policy-map configuration mode.

Step 10 **interface** *type slot / subslot / port*

Example:

```
Router(config)# interface atm1/0/0
```

Specifies the interface type and enters interface configuration mode.

Step 11 **service-policy input** *policy-name*

Example:

```
Router(config-if)# service-policy input policy1
```

Attaches a traffic policy to an interface.

Step 12 **end**

Example:

```
Router(config-if)# end
```

Exits to privileged EXEC mode.

Step 13 **show policy-map interface** *interface-name* [*vc* [*vpi /*] *vci*] [**dlci** *dlci*] [**input** | **output**]

Example:

```
Router# show policy-map interface serial3/0/0
```

Displays the traffic policy attached to an interface.

Enabling the Control Word

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **pseudowire-class cw_enable**
4. **encapsulation mpls**
5. **control-word**
6. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**pseudowire-class cw_enable** **Example:** `Router(config)# pseudowire-class cw_enable`	Enters pseudowire class configuration mode.
Step 4	**encapsulation mpls** **Example:** `Router(config-pw-class)# encapsulation mpls`	Specifies the tunneling encapsulation. • For AToM, the encapsulation type is MPLS.
Step 5	**control-word** **Example:** `Router(config-pw-class)# control-word`	Enables the control word.
Step 6	**end** **Example:** `Router(config-pw-class)# end`	Exits to privileged EXEC mode.

Enabling the Control Word using the commands associated with the L2VPN Protocol-Based CLIs feature

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface pseudowire** *number*
4. **encapsulation mpls**
5. **control-word include**
6. **neighbor** *peer-address vcid-value*

7. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**interface pseudowire** *number* **Example:** `Router(config)# interface pseudowire 1`	Creates an interface pseudowire with a value that you specify and enters pseudowire configuration mode.
Step 4	**encapsulation mpls** **Example:** `Router(config-pw)# encapsulation mpls`	Specifies the tunneling encapsulation. • For AToM, the encapsulation type is mpls.
Step 5	**control-word include** **Example:** `Router(config-pw)# control-word include`	Enables the control word.
Step 6	**neighbor** *peer-address vcid-value* **Example:** `Router(config-pw)#  neighbor 10.0.0.1 123`	Specifies the peer IP address and virtual circuit (VC) ID value of a Layer 2 VPN (L2VPN) pseudowire.
Step 7	**end** **Example:** `Router(config-pw)# end`	Exits to privileged EXEC mode.

Configuring MPLS AToM Remote Ethernet Port Shutdown

Note The Any Transport over MPLS (AToM): Remote Ethernet Port Shutdown feature is automatically enabled by default when an image with the feature supported is loaded on the router.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **pseudowire-class** [*pw-class-name*]
4. **encapsulation mpls**
5. **exit**
6. **xconnect** *peer-ip-address vc-id pw-class pw-class-name*
7. **no remote link failure notification**
8. **remote link failure notification**
9. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**pseudowire-class** [*pw-class-name*] **Example:** `Router(config)# pseudowire-class eompls`	Specifies the name of a Layer 2 pseudowire class and enters pseudowire class configuration mode.
Step 4	**encapsulation mpls** **Example:** `Router(config-pw)# encapsulation mpls`	Specifies that MPLS is used as the data encapsulation method for tunneling Layer 2 traffic over the pseudowire.
Step 5	**exit** **Example:**	Exits to global configuration mode.

	Command or Action	Purpose
	`Router(config-pw)# exit`	
Step 6	**xconnect** *peer-ip-address vc-id pw-class pw-class-name* **Example:** `Router(config-if)# xconnect 10.1.1.1 1 pw-class eompls`	Binds an attachment circuit to a pseudowire, and configures an Any Transport over MPLS (AToM) static pseudowire.
Step 7	**no remote link failure notification** **Example:** `Router(config-if-xconn)# remote link failure notification`	Disables MPLS AToM remote link failure notification and shutdown.
Step 8	**remote link failure notification** **Example:** `Router(config-if-xconn)# remote link failure notification`	Enables MPLS AToM remote link failure notification and shutdown.
Step 9	**end** **Example:** `Router(config-if-xconn)# end`	Exits to privileged EXEC mode.

Configuring MPLS AToM Remote Ethernet Port Shutdown using the commands associated with the L2VPN Protocol-Based CLIs feature

Note The Any Transport over MPLS (AToM): Remote Ethernet Port Shutdown feature is automatically enabled by default when an image with the feature supported is loaded on the router.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **template type pseudowire** [*pseudowire-name*]
4. **encapsulation mpls**
5. **exit**
6. **interface** *type slot / subslot / port*
7. **interface pseudowire** *number*
8. **source template type pseudowire**
9. **neighbor** *peer-address vcid-value*
10. **end**

11. **l2vpn xconnect context** *context-name*
12. **no remote link failure notification**
13. **remote link failure notification**
14. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**template type pseudowire** [*pseudowire-name*] **Example:** `Device(config)# template type pseudowire eompls`	Specifies the name of a Layer 2 pseudowire class and enters pseudowire class configuration mode.
Step 4	**encapsulation mpls** **Example:** `Device(config-pw)# encapsulation mpls`	Specifies that MPLS is used as the data encapsulation method for tunneling Layer 2 traffic over the pseudowire.
Step 5	**exit** **Example:** `Device(config-pw)# exit`	Exits to global configuration mode.
Step 6	**interface** *type slot / subslot / port* **Example:** `Device(config)# interface GigabitEthernet1/0/0`	Configures an interface type and enters interface configuration mode.
Step 7	**interface pseudowire** *number* **Example:** `Device(config-if)# interface pseudowire 100`	Specifies the pseudowire interface.
Step 8	**source template type pseudowire** **Example:**	Configures the source template of type pseudowire named eompls.

	Command or Action	Purpose
	`Device(config-if)# source template type pseudowire eompls`	
Step 9	**neighbor** *peer-address vcid-value* **Example:** `Device(config-if)# neighbor 10.1.1.1 1`	Specifies the peer IP address and virtual circuit (VC) ID value of a Layer 2 VPN (L2VPN) pseudowire.
Step 10	**end** **Example:** `Device(config-if)# end`	Exits to privileged EXEC mode.
Step 11	**l2vpn xconnect context** *context-name* **Example:** `Device(config)# l2vpn xconnect context con1`	Creates a Layer 2 VPN (L2VPN) cross connect context and enters xconnect configuration mode.
Step 12	**no remote link failure notification** **Example:** `Device(config-xconnect)# no remote link failure notification`	Disables MPLS AToM remote link failure notification and shutdown.
Step 13	**remote link failure notification** **Example:** `Device(config-xconnect)# remote link failure notification`	Enables MPLS AToM remote link failure notification and shutdown.
Step 14	**end** **Example:** `Device(config-xconnect)# end`	Exits to privileged EXEC mode.

Configuring AToM Load Balancing with Single PW

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **pseudowire-class** *pw-class-name*
4. **encapsulation mpls**
5. **load-balance flow**
6. **xconnect** *url* **pw-class** *pw-class-name*

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**pseudowire-class** *pw-class-name* **Example:** `Router(config)# pseudowire-class ecmp-class`	Establishes a pseudowire class with a name that you specify, and enters pseudowire class configuration mode.
Step 4	**encapsulation mpls** **Example:** `Router(config-pw-class)# encapsulation mpls`	Specifies the tunneling encapsulation. • For AToM, the encapsulation type is mpls.
Step 5	**load-balance flow** **Example:** `Router(config-pw-class)# load-balance flow`	Enables the AToM Load Balancing with Single PW feature so that load balancing is done on a per-flow basis.
Step 6	**xconnect** *url* **pw-class** *pw-class-name* **Example:** `Router(config-pw-class)# xconnect 10.0.0.1 pw-class ecmp-class`	Binds the attachment circuit to a pseudowire virtual circuit, and enters xconnect configuration mode. • The syntax for this command is the same as for all other Layer 2 transports.

Configuring AToM Load Balancing with Single PW using the commands associated with the L2VPN Protocol-Based CLIs feature

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **template type pseudowire** [*pseudowire-name*]
4. **encapsulation mpls**
5. **load-balance flow**

6. **end**
7. **interface pseudowire** *number*
8. **source template type pseudowire**
9. **neighbor** *peer-address vcid-value*
10. **end**
11. **l2vpn xconnect context** *context-name*
12. **member pseudowire** *interface-number*
13. **member** *ip-address vc-id* **encapsulation mpls**
14. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**template type pseudowire** [*pseudowire-name*] **Example:** `Router(config)# template type pseudowire eompls`	Specifies the name of a Layer 2 pseudowire class and enters pseudowire class configuration mode.
Step 4	**encapsulation mpls** **Example:** `Router(config-pw-class)# encapsulation mpls`	Specifies the tunneling encapsulation. • For AToM, the encapsulation type is mpls.
Step 5	**load-balance flow** **Example:** `Router(config-pw-class)# load-balance flow`	Enables the AToM Load Balancing with Single PW feature so that load balancing is done on a per-flow basis.
Step 6	**end** **Example:** `Router(config-pw-class)# end`	Exits to privileged EXEC mode.
Step 7	**interface pseudowire** *number* **Example:**	Specifies the pseudowire interface and enters interface configuration mode.

	Command or Action	Purpose
	`Router(config)# interface pseudowire 100`	
Step 8	**source template type pseudowire** **Example:** `Router(config-if)# source template type pseudowire ether-pw`	Configures the source template of type pseudowire named ether-pw.
Step 9	**neighbor** *peer-address vcid-value* **Example:** `Router(config-if)#  neighbor 10.1.1.1 1`	Specifies the peer IP address and virtual circuit (VC) ID value of a Layer 2 VPN (L2VPN) pseudowire.
Step 10	**end** **Example:** `Router(config-if)# end`	Exits to privileged EXEC mode.
Step 11	**l2vpn xconnect context** *context-name* **Example:** `Router(config)# l2vpn xconnect context con1`	Creates a Layer 2 VPN (L2VPN) cross connect context and enters xconnect configuration mode.
Step 12	**member pseudowire** *interface-number* **Example:** `Router(config-xconnect)# member pseudowire 100`	Specifies a member pseudowire to form a Layer 2 VPN (L2VPN) cross connect.
Step 13	**member** *ip-address vc-id* **encapsulation mpls** **Example:** `Router(config-xconnect)# member 10.0.0.1 123 encapsulation mpls`	Creates the VC to transport the Layer 2 packets.
Step 14	**end** **Example:** `Router(config-xconnect)# end`	Exits to privileged EXEC mode.

Configuring Flow-Aware Transport (FAT) Load Balancing

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface pseudowire** *name*

4. **encapsulation mpls**
5. **neighbor** *peer-address vcid-value*
6. **signaling protocol ldp**
7. **load-balance flow-label both**
8. **end**
9. **show l2vpn atom vc detail**
10. **show ssm id**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**interface pseudowire** *name* **Example:** `Device(config)# interface pseudowire 1001`	Establishes a pseudowire with a name that you specify, and enters pseudowire class configuration mode.
Step 4	**encapsulation mpls** **Example:** `Device(config-pw-class)# encapsulation mpls`	Specifies the tunneling encapsulation. • For AToM, the encapsulation type is mpls.
Step 5	**neighbor** *peer-address vcid-value* **Example:** `Device(config-pw-class)# neighbor 10.1.1.200 200`	Specifies the peer IP address and virtual circuit (VC) ID value of a Layer 2 VPN (L2VPN) pseudowire.
Step 6	**signaling protocol ldp** **Example:** `Device(config-pw-class)# signaling protocol ldp`	Specifies that the Label Distribution Protocol (LDP) is configured for the pseudowire class.
Step 7	**load-balance flow-label both** **Example:**	Enables the Flow-Aware Transport of MPLS Pseudowire feature and specifies how flow labels are used. It is recommended that you use both as the option for

	Command or Action	Purpose
	`Device(config-pw-class)# load-balance flow-label both`	flow-label. However, if you choose not to use both, you can either use **load-balance flow-label transmit** or **load-balance flow-label receive** if necessary.
Step 8	**end** **Example:** `Device(config-pw-class)# end`	Exits to privileged EXEC mode.
Step 9	**show l2vpn atom vc detail** **Example:** `Device# show l2vpn atom vc detail`	Displays detailed output that shows information about the flow labels configured for the pseudowire.
Step 10	**show ssm id** **Example:** `Device# show ssm id`	Displays information for all Segment Switching Manager (SSM) IDs.

Examples

The following is sample output from the **show mpls l2transport vc 1 detail** command that shows information about the VC details:

```
Device# show mpls l2transport vc 1 detail

Local interface: Te0/5/2 up, line protocol up, Eth VLAN 1 up
  Interworking type is Ethernet
  Destination address: 4.4.4.4, VC ID: 1, VC status: up

Configuring Flow-Aware Transport (FAT) Load Balancing using a template

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **template type pseudowire** [*pseudowire-name*]
4. **encapsulation mpls**
5. **load-balance flow**
6. **load-balance flow-label**

7. **end**
8. **interface pseudowire** *number*
9. **source template type pseudowire**
10. **encapsulation mpls**
11. **neighbor** *peer-address vcid-value*
12. **signaling protocol ldp**
13. **end**
14. **show l2vpn atom vc detail**
15. **show ssm id**
16. **show mpls forwarding-table exact-route**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**template type pseudowire** [*pseudowire-name*] **Example:** `Device(config)# template type pseudowire fatpw`	Specifies the name of a Layer 2 pseudowire class and enters pseudowire class configuration mode.
Step 4	**encapsulation mpls** **Example:** `Device(config-pw-class)# encapsulation mpls`	Specifies the tunneling encapsulation. • For AToM, the encapsulation type is MPLS.
Step 5	**load-balance flow** **Example:** `Device(config-pw-class)# load-balance flow`	Enables the AToM Load Balancing with Single PW feature so that load balancing is done on a per-flow basis.
Step 6	**load-balance flow-label** **Example:** `Device(config-pw-class)# load-balance flow-label both`	Enables the Flow-Aware Transport of MPLS Pseudowires feature and specifies how flow labels are to be used.

	Command or Action	Purpose
Step 7	**end** **Example:** `Device(config-pw-class)# end`	Exits to privileged EXEC mode.
Step 8	**interface pseudowire** *number* **Example:** `Device(config)# interface pseudowire 100`	Specifies the pseudowire interface and enters interface configuration mode.
Step 9	**source template type pseudowire** **Example:** `Device(config-if)# source template type pseudowire fatpw`	Configures the source template of type pseudowire named fatpw.
Step 10	**encapsulation mpls** **Example:** `Device(config-if)# encapsulation mpls`	Specifies the tunneling encapsulation. • For AToM, the encapsulation type is MPLS.
Step 11	**neighbor** *peer-address vcid-value* **Example:** `Device(config-if)# neighbor 10.1.1.1 1`	Specifies the peer IP address and virtual circuit (VC) ID value of a Layer 2 VPN (L2VPN) pseudowire.
Step 12	**signaling protocol ldp** **Example:** `Device(config-if)# signaling protocol ldp`	Specifies that the Label Distribution Protocol (LDP) is configured for the pseudowire class.
Step 13	**end** **Example:** `Device(config-if)# end`	Exits to privileged EXEC mode.
Step 14	**show l2vpn atom vc detail** **Example:** `Device# show l2vpn atom vc detail`	Displays detailed output that shows information about the flow labels configured for the pseudowire.
Step 15	**show ssm id** **Example:** `Device# show ssm id`	Displays information for all Segment Switching Manager (SSM) IDs.

	Command or Action	Purpose
Step 16	**show mpls forwarding-table exact-route** **Example:** `Device# show mpls forwarding-table exact-route label 32 ethernet source 001d.e558.5c1a dest 000e.8379.1c1b detail`	Displays the exact path for the source and destination address pair.

Examples

The following is sample output from the **show l2vpn atom vc detail** command that shows information about the flow labels configured for the pseudowire:

```
Device# show l2vpn atom vc detail

pseudowire100001 is up, VC status is up PW type: Ethernet

```

Example: Ethernet over MPLS with MPLS Traffic Engineering Fast Reroute

The following configuration example and the figure show the configuration of Ethernet over MPLS with fast reroute on AToM PE routers.

Routers PE1 and PE2 have the following characteristics:

- A TE tunnel called Tunnel41 is configured between PE1and PE2, using an explicit path through a link called L1. AToM VCs are configured to travel through the FRR-protected tunnel Tunnel41.
- The link L1 is protected by FRR, the backup tunnel is Tunnel1.
- PE2 is configured to forward the AToM traffic back to PE1 through the L2 link.

Example: Configuring OAM Cell Emulation

The following example shows how to enable OAM cell emulation on an ATM PVC:

```
interface ATM 1/0/0
pvc 1/200 l2transport
encapsulation aal5
xconnect 10.13.13.13 100 encapsulation mpls
oam-ac emulation-enable
oam-pvc manage
```

The following example shows how to set the rate at which an AIS cell is sent every 30 seconds:

```
interface ATM 1/0/0
pvc 1/200 l2transport
encapsulation aal5
xconnect 10.13.13.13 100 encapsulation mpls
oam-ac emulation-enable 30
oam-pvc manage
```

The following example shows how to configure OAM cell emulation for ATM AAL5 over MPLS in VC class configuration mode. The VC class is then applied to an interface.

```
enable
configure terminal
vc-class atm oamclass
encapsulation aal5
oam-ac emulation-enable 30
oam-pvc manage
interface atm1/0/0
class-int oamclass
pvc 1/200 l2transport
xconnect 10.13.13.13 100 encapsulation mpls
```

The following example shows how to configure OAM cell emulation for ATM AAL5 over MPLS in VC class configuration mode. The VC class is then applied to a PVC.

```
enable
configure terminal
vc-class atm oamclass
encapsulation aal5
oam-ac emulation-enable 30
oam-pvc manage
interface atm1/0/0
pvc 1/200 l2transport
class-vc oamclass
xconnect 10.13.13.13 100 encapsulation mpls
```

The following example shows how to configure OAM cell emulation for ATM AAL5 over MPLS in VC class configuration mode. The VC class is then applied to an interface. One PVC is configured with OAM cell emulation at an AIS rate of 10. That PVC uses the AIS rate of 10 instead of 30.

```
enable
configure terminal
vc-class atm oamclass
encapsulation aal5
oam-ac emulation-enable 30
oam-pvc manage
```

```
interface atm1/0/0
class-int oamclass
pvc 1/200 l2transport
oam-ac emulation-enable 10
xconnect 10.13.13.13 100 encapsulation mpls
```

Example: Configuring OAM Cell Emulation using the commands associated with the L2VPN Protocol-Based CLIs feature

The following example shows how to enable OAM cell emulation on an ATM PVC:

```
interface ATM 1/0/0
pvc 1/200 l2transport
encapsulation aal5
interface pseudowire 100
encapsulation mpls
neighbor 10.0.0.1 123
!
l2vpn xconnect context A
member pseudowire 100
member gigabitethernet 0/0/0.1
!
oam-ac emulation-enable
oam-pvc manage
```

The following example shows how to set the rate at which an AIS cell is sent every 30 seconds:

```
interface ATM 1/0/0
pvc 1/200 l2transport
encapsulation aal5
interface pseudowire 100
encapsulation mpls
neighbor 10.0.0.1 123
!
l2vpn xconnect context A
member pseudowire 100
member gigabitethernet 0/0/0.1
!
oam-ac emulation-enable 30
oam-pvc manage
```

The following example shows how to configure OAM cell emulation for ATM AAL5 over MPLS in VC class configuration mode. The VC class is then applied to an interface.

```
enable
configure terminal
vc-class atm oamclass
encapsulation aal5
oam-ac emulation-enable 30
oam-pvc manage
interface atm1/0/0
class-int oamclass
pvc 1/200 l2transport
interface pseudowire 100
encapsulation mpls
neighbor 10.0.0.1 123
!
l2vpn xconnect context A
```

```
member pseudowire 100
member gigabitethernet 0/0/0.1
```

The following example shows how to configure OAM cell emulation for ATM AAL5 over MPLS in VC class configuration mode. The VC class is then applied to a PVC.

```
enable
configure terminal
vc-class atm oamclass
encapsulation aal5
oam-ac emulation-enable 30
oam-pvc manage
interface atm1/0/0
pvc 1/200 l2transport
class-vc oamclass
interface pseudowire 100
encapsulation mpls
neighbor 10.0.0.1 123
!
l2vpn xconnect context A
member pseudowire 100
member gigabitethernet 0/0/0.1
```

The following example shows how to configure OAM cell emulation for ATM AAL5 over MPLS in VC class configuration mode. The VC class is then applied to an interface. One PVC is configured with OAM cell emulation at an AIS rate of 10. That PVC uses the AIS rate of 10 instead of 30.

```
enable
configure terminal
vc-class atm oamclass
encapsulation aal5
oam-ac emulation-enable 30
oam-pvc manage
interface atm1/0/0
class-int oamclass
pvc 1/200 l2transport
oam-ac emulation-enable 10
interface pseudowire 100
encapsulation mpls
neighbor 10.0.0.1 123
!
l2vpn xconnect context A
member pseudowire 100
member gigabitethernet 0/0/0.1
```

Example: Configuring ATM Cell Relay over MPLS

The following example shows how to configure ATM cell relay over MPLS in VC class configuration mode. The VC class is then applied to an interface.

```
enable
configure terminal
vc-class atm cellrelay
encapsulation aal0
interface atm1/0/0
class-int cellrelay
pvc 1/200 l2transport
xconnect 10.13.13.13 100 encapsulation mpls
```

The following example shows how to configure ATM cell relay over MPLS in VC class configuration mode. The VC class is then applied to a PVC.

```
enable
configure terminal
vc-class atm cellrelay
encapsulation aal0
interface atm1/0/0
pvc 1/200 l2transport
class-vc cellrelay
xconnect 10.13.13.13 100 encapsulation mpls
```

The following example shows how to configure a pseudowire class to transport single ATM cells over a virtual path:

```
pseudowire-class vp-cell-relay
encapsulation mpls
interface atm 5/0
atm pvp 1 l2transport
xconnect 10.0.0.1 123 pw-class vp-cell-relay
```

Example: Configuring ATM Cell Relay over MPLS using the commands associated with the L2VPN Protocol-Based CLIs feature

The following example shows how to configure ATM cell relay over MPLS in VC class configuration mode. The VC class is then applied to an interface.

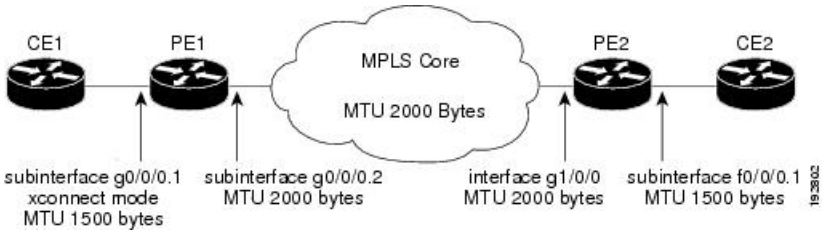
```
enable
configure terminal
vc-class atm cellrelay
encapsulation aal0
interface atm1/0/0
class-int cellrelay
pvc 1/200 l2transport
interface pseudowire 100
encapsulation mpls
neighbor 10.13.13.13 100
!
l2vpn xconnect context A
member pseudowire 100
member gigabitethernet 0/0/0.1
```

The following example shows how to configure ATM cell relay over MPLS in VC class configuration mode. The VC class is then applied to a PVC.

```
enable
configure terminal
vc-class atm cellrelay
encapsulation aal0
interface atm1/0/0
pvc 1/200 l2transport
class-vc cellrelay
interface pseudowire 100
encapsulation mpls
neighbor 10.13.13.13 100
!
l2vpn xconnect context A
```

```
member pseudowire 100
member gigabitethernet 0/0/0.1
```

The following example shows how to configure a pseudowire class to transport single ATM cells over a virtual path:



```
template type pseudowire vp-cell-relay
encapsulation mpls
interface atm 5/0
atm pvp 1 l2transport
interface pseudowire 100
 source template type pseudowire ether-pw
 neighbor 10.0.0.1 123
!
l2vpn xconnect context con1
```

Example: Configuring per-Subinterface MTU for Ethernet over MPLS

The figure below shows a configuration that enables matching MTU values between VC endpoints.

As shown in the figure, PE1 is configured in xconnect subinterface configuration mode with an MTU value of 1500 bytes in order to establish an end-to-end VC with PE2, which also has an MTU value of 1500 bytes. If PE1 was not set with an MTU value of 1500 bytes, in xconnect subinterface configuration mode, the subinterface would inherit the MTU value of 2000 bytes set on the interface. This would cause a mismatch in MTU values between the VC endpoints, and the VC would not come up.

Figure 55: Configuring MTU Values in xconnect Subinterface Configuration Mode

The following examples show the router configurations in the figure above:

CE1 Configuration

```
interface gigabitethernet0/0/0
 mtu 1500
 no ip address
!
interface gigabitethernet0/0/0.1
 encapsulation dot1Q 100
 ip address 10.181.182.1 255.255.255.0
```

PE1 Configuration

```
interface gigabitethernet0/0/0
 mtu 2000
 no ip address
!
interface gigabitethernet0/0/0.1
 encapsulation dot1Q 100
```

```
 xconnect 10.1.1.152 100 encapsulation mpls
  mtu 1500
!
interface gigabitethernet0/0/0.2
 encapsulation dot1Q 200
 ip address 10.151.100.1 255.255.255.0
 mpls ip
```

PE2 Configuration

```
interface gigabitethernet1/0/0
 mtu 2000
 no ip address
!
interface gigabitethernet1/0/0.2
 encapsulation dot1Q 200
 ip address 10.100.152.2 255.255.255.0
 mpls ip
!
interface fastethernet0/0/0
 no ip address
!
interface fastethernet0/0/0.1
 description default MTU of 1500 for FastEthernet
 encapsulation dot1Q 100
 xconnect 10.1.1.151 100 encapsulation mpls
```

CE2 Configuration

```
interface fastethernet0/0/0
 no ip address
interface fastethernet0/0/0.1
 encapsulation dot1Q 100
 ip address 10.181.182.2 255.255.255.0
```

The **show mpls l2transport binding** command, issued from router PE1, shows a matching MTU value of 1500 bytes on both the local and remote routers:

```
Router# show mpls l2transport binding
Destination Address: 10.1.1.152,  VC ID: 100
    Local Label: 100

Example: Configuring MTU Values in xconnect Configuration Mode for L2VPN Interworking

The following example shows an L2VPN Interworking example. The PE1 router has a serial interface configured with an MTU value of 1492 bytes. The PE2 router uses xconnect configuration mode to set a matching MTU of 1492 bytes, which allows the two routers to form an interworking VC. If the PE2 router did not set the MTU value in xconnect configuration mode, the interface would be set to 1500 bytes by default and the VC would not come up.

Note L2VPN interworking is not supported on Cisco ASR 900 RSP3 Module.

PE1 Configuration

```
pseudowire-class atom-ipiw
 encapsulation mpls
 interworking ip
!
interface Loopback0
 ip address 10.1.1.151 255.255.255.255
!
interface Serial2/0/0
 mtu 1492
 no ip address
 encapsulation ppp
 no fair-queue
 serial restart-delay 0
```

```
 xconnect 10.1.1.152 123 pw-class atom-ipiw
!
interface Serial4/0/0
 ip address 10.151.100.1 255.255.255.252
 encapsulation ppp
 mpls ip
 serial restart-delay 0
!
router ospf 1
 log-adjacency-changes
 network 10.1.1.151 0.0.0.0 area 0
 network 10.151.100.0 0.0.0.3 area 0
!
mpls ldp router-id Loopback0
```

PE2 Configuration

```
pseudowire-class atom-ipiw
 encapsulation mpls

```

Example: Configuring MTU Values in xconnect Configuration Mode for L2VPN Interworking Using Commands Associated with L2VPN Protocol-Based Feature

The following example shows an L2VPN Interworking example. The PE1 router has a serial interface configured with an MTU value of 1492 bytes. The PE2 router uses xconnect configuration mode to set a matching MTU of 1492 bytes, which allows the two routers to form an interworking VC. If the PE2 router did not set the MTU value in xconnect configuration mode, the interface would be set to 1500 bytes by default and the VC would not come up.

PE1 Configuration

```
template type pseudowire atom-ipiw
 encapsulation mpls
 interworking ip
!
interface Loopback0
 ip address 10.1.1.151 255.255.255.255
!
interface Serial2/0/0
 mtu 1492
 no ip address
 encapsulation ppp
 no fair-queue
 serial restart-delay 0
interface pseudowire 100
 source template type pseudowire atom-ipiw
 neighbor 10.1.1.152 123
!
l2vpn xconnect context con1
 member <ac_int>
 member pseudowire 100
!

Examples: Configuring Any Transport over MPLS (AToM) Remote Ethernet Port Shutdown

The following example shows how to enable remote Ethernet port shutdown:

```
configure terminal
!
pseudowire-class eompls
 encapsulation mpls
!
interface GigabitEthernet1/0/0
```

```
 xconnect 10.1.1.1 1 pw-class eompls
  remote link failure notification
```

The following example shows how to disable remote Ethernet port shutdown:

```
configure terminal
!
pseudowire-class eompls
 encapsulation mpls
!
interface GigabitEthernet1/0/0
 xconnect 10.1.1.1 1 pw-class eompls
  no remote link failure notification
```

The related **show** command output reports operational status for all remote L2 Tunnels by interface.

```
Router# show interface G1/0/0
GigabitEthernet1/0/0 is L2 Tunnel remote down, line protocol is up
Hardware is GigMac 4 Port GigabitEthernet, address is 0003.ff4e.12a8 (bia 0003.ff4e.12a8)
  Internet address is 10.9.9.2/16
  MTU 1500 bytes, BW 1000000 Kbit, DLY 10 usec, rely 255/255, load 1/255
Router# show ip interface brief
Interface              IP-Address      OK? Method Status Protocol
GigabitEthernet2/0/0 unassigned      YES NVRAM  L2 Tunnel remote down up
GigabitEthernet2/1/0 unassigned      YES NVRAM  administratively down down
```

Note Remote Ethernet port shutdown is enabled by default when EVC "default encapsulation" is configured.

Examples: Configuring Any Transport over MPLS (AToM) Remote Ethernet Port Shutdown Using Commands Associated with L2VPN Protocol-Based Feature

The following example shows how to enable remote Ethernet port shutdown:

```
configure terminal
!
template type pseudowire eompls
 encapsulation mpls
!
interface GigabitEthernet1/0/0
interface pseudowire 100
 source template type pseudowire eompls
 neighbor 10.1.1.1 1
!
l2vpn xconnect context con1
 remote link failure notification
```

The following example shows how to disable remote Ethernet port shutdown:

```
configure terminal
!
template type pseudowire eompls
 encapsulation mpls
!
interface GigabitEthernet1/0/0
 interface pseudowire 100
 source template type pseudowire eompls
```

```
 neighbor 10.1.1.1 1
!
l2vpn xconnect context con1
 no remote link failure notification
```

The related **show** command output reports operational status for all remote L2 Tunnels by interface.

```
Router# show interface G1/0/0
GigabitEthernet1/0/0 is L2 Tunnel remote down, line protocol is up
Hardware is GigMac 4 Port GigabitEthernet, address is 0003.ff4e.12a8 (bia 0003.ff4e.12a8)
  Internet address is 10.9.9.2/16
  MTU 1500 bytes, BW 1000000 Kbit, DLY 10 usec, rely 255/255, load 1/255
Router# show ip interface brief
Interface              IP-Address      OK? Method Status Protocol
GigabitEthernet2/0/0 unassigned      YES NVRAM  L2 Tunnel remote down up
GigabitEthernet2/1/0 unassigned      YES NVRAM  administratively down down
```

Feature Information for Any Transport over MPLS

ß

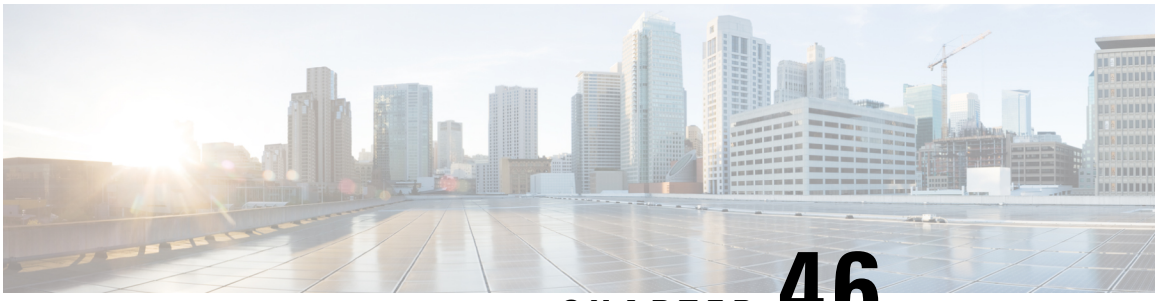

Table 104: Feature Information for Any Transport over MPLS

Feature Name	Releases	Feature Information
Any Transport over MPLS (AToM): ATM AAL5 over MPLS (AAL5oMPLS)	Cisco IOS XE Release 3.2S Cisco IOS XE Release 3.6S	In Cisco IOS XE Release 3.2S, this feature was introduced on the Cisco ASR 1000 Series Aggregation Services Routers. In Cisco IOS XE Release 3.6S, support was added for the Cisco ASR 903 Router. This feature introduced no new or modified commands.
Any Transport over MPLS (AToM): ATM Cell Relay over MPLS: Packed Cell Relay	Cisco IOS XE Release 3.5S	In Cisco IOS XE Release 3.5S, this feature was introduced on the Cisco ASR 1000 Series Aggregation Services Routers. In Cisco IOS XE Release 3.5S, support was added for the Cisco ASR 903 Router.
Any Transport over MPLS (AToM): ATM OAM Emulation	Cisco IOS XE Release 3.2S	In Cisco IOS XE Release 3.2S, this feature was introduced on the Cisco ASR 1000 Series Aggregation Services Routers. This feature introduced no new or modified commands.
	Cisco IOS XE Release 2.5	This feature provides capability to support sequencing of AToM) data plane packets.
Any Transport over MPLS (AToM): Ethernet over MPLS (EoMPLS)	Cisco IOS XE Release 2.4 Cisco IOS XE Release 3.5S	This feature allows you to transport Layer 2 Ethernet VLAN packets from various sources over an MPLS backbone. Ethernet over MPLS extends the usability of the MPLS backbone by enabling it to offer Layer 2 services in addition to already existing Layer 3 services. You can enable the MPLS backbone network to accept Layer 2 VLAN packets by configuring the PE routers at the both ends of the MPLS backbone. In Cisco IOS XE Release 2.4, this feature was introduced on the Cisco ASR 1000 Series Routers. In Cisco IOS XE Release 3.5S, support was added for the Cisco ASR 903 Router.
Any Transport over MPLS (AToM): Ethernet over MPLS: Port Mode (EoMPLS)	Cisco IOS XE Release 2.4	Ethernet over MPLS (EoMPLS) is the transport of Ethernet frames across an MPLS core. It transports all frames received on a particular Ethernet or virtual LAN (VLAN) segment, regardless of the destination Media Access Control (MAC) information. It does not perform MAC learning or MAC look up for forwarding packets from the Ethernet interface. Port mode allows a frame coming into an interface to be packed into an MPLS packet and transported over the MPLS backbone to an egress interface. In Cisco IOS XE Release 2.4, this feature was introduced on the Cisco ASR 1000 Series Routers.

Feature Name	Releases	Feature Information
Any Transport over MPLS-Ethernet over MPLS Enhancements: Fast Reroute	Cisco IOS XE Release 2.4	AToM can use MPLS traffic engineering (TE) tunnels with fast reroute (FRR) support. This features enhances FRR functionality for Ethernet over MPLS (EoMPLS). In Cisco IOS XE Release 2.4, this feature was introduced on the Cisco ASR 1000 Series Routers.
Any Transport over MPLS (AToM): Frame Relay over MPLS (FRoMPLS)	Cisco IOS XE Release 3.2.1S	In Cisco IOS XE Release 3.2.1S, this feature was introduced on the Cisco ASR 1000 Series Aggregation Services Routers. This feature introduced no new or modified commands.
Any Transport over MPLS (AToM): HDLC over MPLS (HDLCoMPLS)	Cisco IOS XE Release 3.2S	In Cisco IOS XE Release 3.2S, this feature was introduced on the Cisco ASR 1000 Series Aggregation Services Routers. This feature introduced no new or modified commands.
Any Transport over MPLS (AToM): Layer 2 Quality of Service (QoS)	Cisco IOS XE Release 2.3	This feature provides support for quality of service (QoS) features such as traffic policing, traffic shaping, packet marking, and mapping of the packets. In Cisco IOS XE Release 2.3, this feature was introduced on the Cisco ASR 1000 Series Routers.
Any Transport over MPLS (AToM): PPP over MPLS (PPPoMPLS)	Cisco IOS XE Release 3.2S	In Cisco IOS XE Release 3.2S, this feature was introduced on the Cisco ASR 1000 Series Aggregation Services Routers. This feature introduced no new or modified commands.
Any Transport over MPLS (AToM): Remote Ethernet Port Shutdown	Cisco IOS XE Release 2.4	This feature allows a service provider edge (PE) router on the local end of an Ethernet over MPLS (EoMPLS) pseudowire to detect a remote link failure and cause the shutdown of the Ethernet port on the local customer edge (CE) router. Because the Ethernet port on the local CE router is shut down, the router does not lose data by continuously sending traffic to the failed remote link. This is beneficial if the link is configured as a static IP route. In Cisco IOS XE Release 2.4, this feature was introduced on the Cisco ASR 1000 Series Routers.
ATM Port Mode Packed Cell Relay over MPLS	Cisco IOS XE Release 3.5S	In Cisco IOS XE Release 3.5S, this feature was introduced on the Cisco ASR 1000 Series Aggregation Services Routers.
ATM VC Class Support	Cisco IOS XE Release 2.3	The ATM VC Class Support feature allows you to specify AAL5 and AAL0 encapsulations as part of a VC class. In Cisco IOS XE Release 2.3, this feature was introduced on the Cisco ASR 1000 Series Routers.

Feature Name	Releases	Feature Information
AToM Tunnel Selection	Cisco IOS XE Release 2.3	The AToM Tunnel Selection feature allows you to specify the path that traffic uses. You can specify either an MPLS TE tunnel or destination IP address or domain name server (DNS) name. You also have the option of specifying whether the VCs should use the default path (the path LDP uses for signaling) if the preferred path is unreachable. This option is enabled by default; you must explicitly disable it. In Cisco IOS XE Release 2.3, this feature was introduced on the Cisco ASR 1000 Series Aggregation Services Routers.
AToM: ATM Cell Relay over MPLS: VP Mode	Cisco IOS XE Release 2.3	The AToM: ATM Cell Relay over MPLS: VP Mode feature allows you to insert one ATM cell in each MPLS packet in VP mode. In Cisco IOS XE Release 2.3, this feature was introduced on the Cisco ASR 1000 Series Routers.
AToM: Single Cell Relay-VC Mode	Cisco IOS XE Release 2.3	The AToM Single Cell Relay-VC Mode feature allows you to insert one ATM cell in each MPLS packet in VC mode. In Cisco IOS XE Release 2.3, this feature was introduced on the Cisco ASR 1000 Series Routers.
MPLS MTU Command for GRE Tunnels	Cisco IOS XE Release 2.6	This feature allows you to set the MPLS MTU size in GRE tunnels to the maximum size besides the current default size. The following command was modified for this release: **mpls mtu**.
MPLS L2VPN Clear Xconnect Command	Cisco IOS XE Release 3.1S	These features enable you to: • Reset a VC associated with an interface, a peer address, or on all the configured xconnect circuit attachments • Set the control word on dynamic pseudowires (L2VPN pseudowire control word configuration • Enable ATM cell packing for static pseudowires. The following commands were introduced or modified by these features: **cell-packing**, **clear xconnect**, **control-word**, **encapsulation**(Any Transport over MPLS), **oam-ac emulation-enable**.

Feature Name	Releases	Feature Information
Per-Subinterface MTU for Ethernet over MPLS (EoMPLS)	Cisco IOS XE Release 2.4	This feature provides you with the ability to specify maximum transmission unit (MTU) values in xconnect subinterface configuration mode. When you use xconnect subinterface configuration mode to set the MTU value, you establish a pseudowire connection for situations where the interfaces have different MTU values that cannot be changed. In Cisco IOS XE Release 2.4, this feature was introduced on the Cisco ASR 1000 Series Aggregation Services Routers. No commands were new or modified for this release.
VLAN ID Rewrite	Cisco IOS XE Release 2.4	The VLAN ID rewrite feature enables you to use VLAN interfaces with different VLAN IDs at both ends of the tunnel. In Cisco IOS XE Release 2.4, this feature was introduced on the Cisco ASR 1000 Series Routers.
AToM Load Balancing with Single PW	Cisco IOS XE Release 3.4S	The AToM Load Balancing with Single PW feature enables load balancing for packets within the same pseudowire by further classifying packets within the same pseudowire into different flows based on some field in the packet received on attachment circuit. In Cisco IOS XE Release 3.4S, this feature was introduced on the Cisco ASR 1000 Series Aggregation Services Routers.
Flow-Aware Transport of MPLS Pseudowires	Cisco IOS XE Release 3.11S	The Flow-Aware Transport of MPLS Pseudowires feature enables load balancing of packets within the same pseudowire by further classifying the packets into different flows by adding a flow label at the bottom of the MPLS label stack.
EoMPLS over IPv6 GRE Tunnel	Cisco IOS XE Release 3.15S	The EoMPLS over IPv6 GRE Tunnel feature supports tunneling of EoMPLS traffic via an IPv6 network by using GRE tunnels.

CHAPTER 46

L2VPN Interworking

Interworking is a transforming function that is required to interconnect two heterogeneous attachment circuits (ACs). Several types of interworking functions exist. The function that is used would depend on the type of ACs being used, the type of data being carried, and the level of functionality required. The two main Layer 2 Virtual Private Network (L2VPN) interworking functions supported in Cisco IOS XE software are bridged and routed interworking.

Layer 2 (L2) transport over multiprotocol label switching (MPLS) and IP already exists for like-to-like ACs, such as Ethernet-to-Ethernet or Point-to-Point Protocol (PPP)-to-PPP. L2VPN Interworking builds on this functionality by allowing disparate ACs to be connected. An interworking function facilitates the translation between different L2 encapsulations.

- Prerequisites for L2VPN Interworking, on page 865
- Restrictions for L2VPN Interworking, on page 866
- Information About L2VPN Interworking, on page 870
- How to Configure L2VPN Interworking, on page 884
- Configuration Examples for L2VPN Interworking, on page 969
- Additional References for L2VPN Interworking, on page 994
- Feature Information for L2VPN Interworking, on page 996

Prerequisites for L2VPN Interworking

Before you configure L2VPN interworking on a device you must enable Cisco Express Forwarding.

HDLC-to-Ethernet Interworking

- Ensure that the serial controller and interface on the High-Level Data Link Control (HDLC) customer edge (CE) and provider edge (PE) devices are configured.

```
enable
 configure terminal
  controller e1 2/0
   channel-group 0 timeslots 1
   no shutdown
!
interface Serial 2/0:0
 no shutdown
end
```

- Before configuring HDLC-to-Ethernet bridged interworking, ensure that bridging is configured on the HDLC CE device.

```
enable
 configure terminal
  bridge irb
  bridge 1 protocol ieee
  bridge 1 route ip
!
interface Serial 2/0:0
 no bridge-group 1
 no ip address
!
interface BVI1
 no ip address
 ip address 192.0.2.1 255.255.255.0
 no shutdown
!
interface Serial 2/0:0
 no ip address
 encapsulation hdlc
 bridge-group 1
  no shutdown
end
```

- Before configuring HDLC-to-Ethernet routed interworking, ensure that an IP address is configured on the HDLC CE device.

```
interface Serial 2/0:0
 ip address 192.0.2.1 255.255.255.0
 encapsulation hdlc
 no shutdown
end
```

Restrictions for L2VPN Interworking

General Restrictions for L2VPN Interworking

This section lists general restrictions that apply to L2VPN interworking. Other restrictions that are platform-specific or device-specific are listed in the following sections.

- MTU configured on the AC should not exceed the MTU in the core of the network because fragmentation is not supported.
- The interworking type on one provider edge (PE) router must match the interworking type on the peer PE router.
- IP interworking with native VLANs is not supported.
- Ethernet VLAN (Type 4) interworking is not supported.
- Only the following Quality of Service (QoS) features are supported with L2VPN interworking:
  - Static IP type of service (ToS) or MPLS experimental bit (EXP) setting in tunnel header.
  - One-to-one mapping of VLAN priority bits to MPLS EXP bits.

- VRF-aware Layer 2 Tunneling Protocol Version 3 (L2TPv3) is not supported on Cisco ASR 1000 platforms.

Restrictions for Routed Interworking

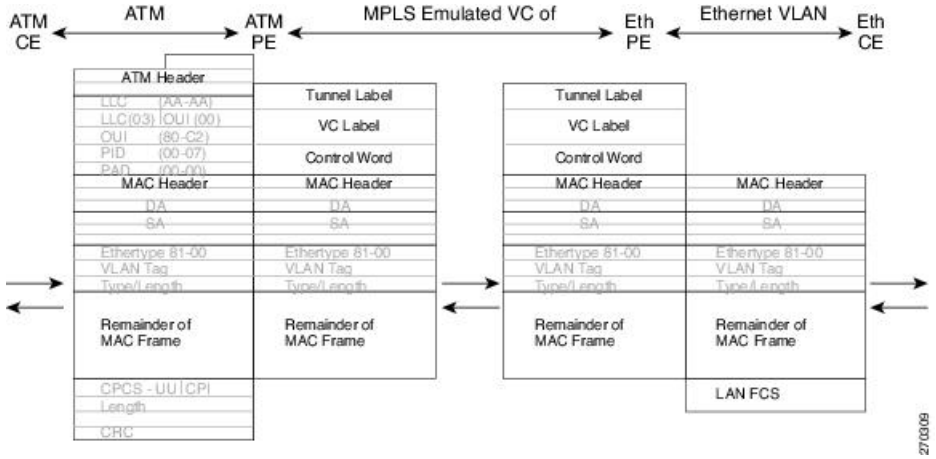
Routed interworking has the following restrictions:

- Multipoint Frame Relay (FR) is not supported.
- QoS classification on IP ToS, DSCP and other IP header fields is not supported.
- Security access control list (ACL) and other features based on IP header fields parsing are not supported.
- In routed mode, only one customer edge (CE) router can be attached to an Ethernet PE router.
- There must be a one-to-one relationship between an AC and the pseudowire. Point-to-multipoint or multipoint-to-point configurations are not supported.
- You must configure routing protocols for point-to-point operation on the CE routers when configuring an Ethernet to non-Ethernet setup.
- In the IP interworking mode, the IPv4 (0800) translation is supported. The PE router captures Address Resolution Protocol (ARP) (0806) packets and responds with its own MAC address (proxy ARP). Everything else is dropped.
- The Ethernet must contain only two IP devices: PE router and CE router. The PE router performs proxy ARP and responds to all ARP requests it receives. Therefore, only one CE router and one PE router should be on the Ethernet segment.
- If the CE routers are doing static routing, you can perform the following tasks:
  - The PE router needs to learn the MAC address of the CE router to correctly forward traffic to it. The Ethernet PE router sends an Internet Control Message Protocol (ICMP) Router Discovery Protocol (RDP) solicitation message with the source IP address as zero. The Ethernet CE router responds to this solicitation message. To configure the Cisco CE router's Ethernet interface to respond to the ICMP RDP solicitation message, issue the **ip irdp** command in interface configuration mode. If you do not configure the CE router, traffic is dropped until the CE router sends traffic toward the PE router.
  - To disable the CE routers from running the router discovery protocol, issue the **ip irdp maxadvertinterval 0** command in interface configuration mode.
- When you change the interworking configuration on an Ethernet PE router, clear the ARP entry on the adjacent CE router so that it can learn the new MAC address. Otherwise, you might experience traffic drops.

Restrictions for PPP Interworking

The following restrictions apply to PPP interworking:

- There must be a one-to-one relationship between a PPP session and the pseudowire. Multiplexing of multiple PPP sessions over the pseudowire is not supported.
- Only IP (IPv4 (0021) interworking is supported. Link Control Protocol (LCP) packets and Internet Protocol Control Protocol (IPCP) packets are terminated at the PE router. Everything else is dropped.



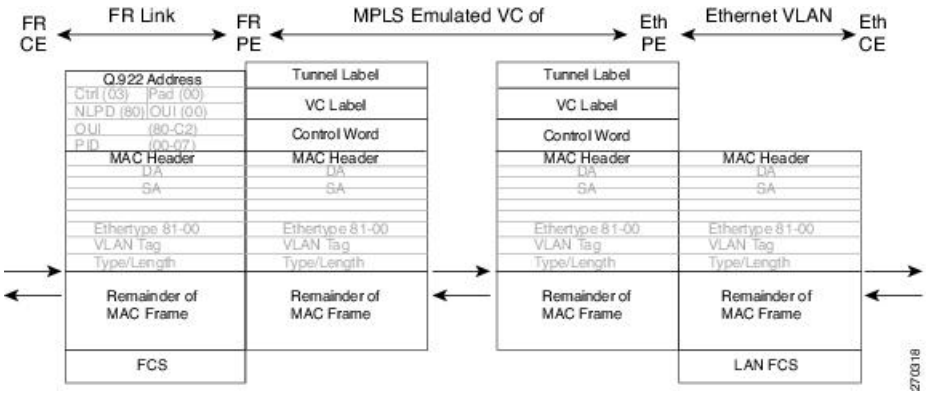
- By default, the PE router assumes that the CE router knows the remote CE router's IP address.
- Password Authentication Protocol (PAP) and Challenge-Handshake Authentication Protocol (CHAP) authentication are supported.

Restrictions for Ethernet/VLAN-to-ATM AAL5 Interworking

The Ethernet/VLAN to ATM AAL5 Any Transport over MPLS (AToM) has the following restrictions:

- Only the following translations are supported; other translations are dropped:
  - Ethernet without LAN FCS (AAAA030080C200070000)
  - Spanning tree (AAAA030080C2000E)
- The ATM encapsulation type supported for bridged interworking is aal5snap. However, ATM encapsulation types supported for routed interworking are aal5snap and aal5mux.
- The existing QoS functionality for ATM is supported, including setting the ATM CLP bit.
- Only ATM AAL5 VC mode is supported. ATM VP and port mode are not supported.
- SVCs are not supported.
- Individual AAL5 ATM cells are assembled into frames before being sent across the pseudowire.
- Non-AAL5 traffic, (such as Operation, Administration, and Maintenance (OAM) cells) is punted to be processed at the route processor (RP) level. A VC that has been configured with OAM cell emulation on the ATM PE router (using the **oam-ac emulation-enable** CLI command) can send end-to-end F5 loopback cells at configured intervals toward the CE router.
- When the pseudowire is down, an F5 end-to-end segment alarm indication signal/remote defect indication (AIS/RDI) is sent from the PE router to the CE router.
- If the Ethernet frame arriving from the Ethernet CE router includes a 802.1Q header (VLAN header), due to the type of endpoint attachment (Ethernet port mode), the VLAN header stays in the frame across the pseudowire (see the figure below).

Figure 57: Protocol Stack for ATM-to-Ethernet AToM Bridged Interworking--with VLAN Header



Restrictions for Ethernet/VLAN-to-Frame Relay Interworking

The Ethernet/VLAN-to-Frame Relay AToM has the following restrictions:

- Only the following translations are supported; other translations are dropped:
  - Ethernet without LAN FCS (0300800080C20007)
  - Spanning tree (0300800080C2000E)
- The PE router automatically supports translation of both Cisco and IETF Frame Relay encapsulation types coming from the CE router, but translates only to IETF when sending to the CE router. This is not a problem for the Cisco CE router, because it can manage IETF encapsulation upon receipt even if it is configured to send a Cisco encapsulation.
- The PVC status signaling works the same way as in the like-to-like case. The PE router reports the PVC status to the CE router based upon the availability of the pseudowire.
- The AC maximum transmission unit (MTU) must be within the supported range of MTUs when connected over MPLS.
- Only Frame Relay DLCI mode is supported. Frame Relay port mode is not supported.
- If the Ethernet frame includes a 802.1Q header (VLAN header), due to the type of endpoint attachment (Ethernet port mode), the VLAN header stays in the frame across the pseudowire (see the figure below).
- Frame Relay encapsulation types supported for routed interworking are Cisco and IETF for incoming traffic. However, IETF is also supported for outgoing traffic traveling to the CE router.

Figure 58: Protocol Stack for Frame Relay-to-Ethernet AToM Bridged Interworking--with VLAN Header

Restrictions for HDLC-to-Ethernet Interworking

- The “none CISCO” High-Level Data Link Control (HDLC) encapsulation is not supported.
- IPv6 is not supported in routed mode.

Information About L2VPN Interworking

Overview of L2VPN Interworking

L2 transport over MPLS and IP already exists for like-to-like ACs, such as Ethernet-to-Ethernet or PPP-to-PPP. L2VPN Interworking builds on this functionality by allowing disparate ACs to be connected. An interworking function facilitates the translation between the different L2 encapsulations.

Only the following interworking combinations are supported:

- ATM-to-Ethernet - Routed interworking
- ATM-to-Ethernet - Bridged interworking
- Frame relay-to-Ethernet - Bridged interworking
- PPP-to-Ethernet - Routed interworking
- HDLC-to-Ethernet - Bridged and Routed interworking

L2VPN Interworking Modes

L2VPN interworking works in either Ethernet (bridged) mode or IP (routed) mode. L2VPN interworking does not support Ethernet VLAN (Type 4) mode. You specify the mode in the following ways:

- If using the older legacy CLI commands, you can use the **interworking** {**ethernet** | **ip**} command in pseudowire-class configuration mode.
- If using the newer L2VPN protocol-based CLI commands, you can use the **interworking** {**ethernet** | **ip**} command in xconnect configuration mode.

The **interworking** command causes the ACs to be terminated locally. The two keywords perform the following functions:

- The **ethernet** keyword causes Ethernet frames to be extracted from the AC and sent over the pseudowire. Ethernet end-to-end transmission is resumed. AC frames that are not Ethernet are dropped. In the case of VLAN, the VLAN tag is removed, leaving an untagged Ethernet frame.
- The **ip** keyword causes IP packets to be extracted from the AC and sent over the pseudowire. AC frames that do not contain IPv4 packets are dropped.

The following sections explain more about Ethernet and IP interworking modes.

Ethernet or Bridged Interworking

Ethernet interworking is also called bridged interworking. Ethernet frames are bridged across the pseudowire. The CE routers could be natively bridging Ethernet or could be routing using a bridged encapsulation model, such as Bridge Virtual Interface (BVI) or Routed Bridge Encapsulation (RBE). The PE routers operate in Ethernet like-to-like mode.

This mode is used to offer the following services:

- LAN services--An example is an enterprise that has several sites, where some sites have Ethernet connectivity to the service provider (SP) network and others have ATM connectivity. If the enterprise wants LAN connectivity to all its sites, traffic from the Ethernet or VLAN of one site can be sent through the IP/MPLS network and encapsulated as bridged traffic over an ATM VC of another site.
- Connectivity services--An example is an enterprise that has different sites that are running an Internal Gateway Protocol (IGP) routing protocol, which has incompatible procedures on broadcast and nonbroadcast links. The enterprise has several sites that are running an IGP, such as Open Shortest Path First (OSPF) or Intermediate System-to-Intermediate System (IS-IS), between the sites. In this scenario, some of the procedures (such as route advertisement or designated router) depend on the underlying L2 protocol and are different for a point-to-point ATM connection versus a broadcast Ethernet connection. Therefore, the bridged encapsulation over ATM can be used to achieve homogenous Ethernet connectivity between the CE routers running the IGP.

IP or Routed Interworking

IP interworking is also called routed interworking. The CE routers encapsulate the IP on the link between the CE router and PE router. A new VC type is used to signal the IP pseudowire in MPLS. Translation between the L2 and IP encapsulations across the pseudowire is required. Special consideration needs to be given to the address resolution and routing protocol operation, because these are handled differently on different L2 encapsulations.

This mode is used to provide IP connectivity between sites, regardless of the L2 connectivity to these sites. It is different from a Layer 3 VPN because it is point-to-point in nature and the service provider does not maintain any customer routing information.

Address resolution is encapsulation dependent:

- Ethernet uses Address Resolution Protocol (ARP)
- ATM uses inverse ARP
- PPP uses IP Control Protocol (IPCP)
- HDLC uses Serial Line ARP (SLARP)

Therefore, address resolution must be terminated on the PE router. End-to-end address resolution is not supported. Routing protocols operate differently over broadcast and point-to-point media. For Ethernet, the CE routers must either use static routing or configure the routing protocols to treat the Ethernet side as a point-to-point network.

In routed interworking, IP packets that are extracted from the ACs are sent over the pseudowire. The pseudowire works in the IP Layer 2 transport (VC type 0x000B) like-to-like mode. The interworking function at network service provider's (NSP) end performs the required adaptation based on the AC technology. Non-IPv4 packets are dropped.

In routed interworking, the following considerations are to be kept in mind:

- Address resolution packets (ARP), inverse ARP, and IPCP are punted to the routing protocol. Therefore, NSP at the PE router must provide the following functionality for address resolution:
  - Ethernet--PE device acts as a proxy-ARP server to all ARP requests from the CE router. The PE router responds with the MAC address of its local interface.
  - ATM and Frame Relay point-to-point--By default, inverse ARP does not run in the point-to-point Frame Relay or ATM subinterfaces. The IP address and subnet mask define the connected prefix; therefore, configuration is not required in the CE devices.

- Interworking requires that the MTUs in both ACs match for the pseudowire to come up. The default MTU in one AC should match with the MTU of other AC. The table below lists the range of MTUs that can be configured for different ACs.

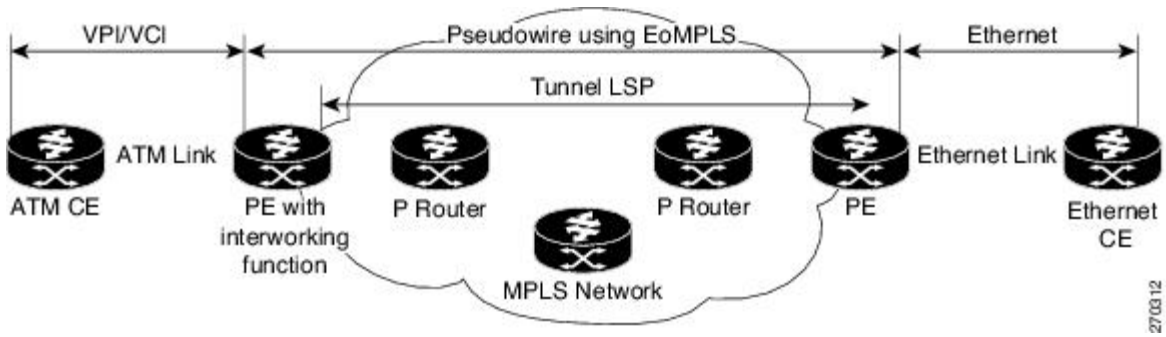
Table 105: Range of MTUs for Different ACs

AC type	Range of MTUs supported
ATM	64 to 17940
Gigabit Ethernet	1500 to 4470
POS	64to 9102
Fast Ethernet	64to 9192

Note The MTU configured on the AC should not exceed the MTU in the core network. This ensures that the traffic is not fragmented.

- The CE routers with Ethernet attachment VCs running OSPF must be configured with the **ospfIfType**option so that the OSPF protocol treats the underlying physical broadcast link as a P2P link.

Ethernet VLAN-to-ATM AAL5 Interworking



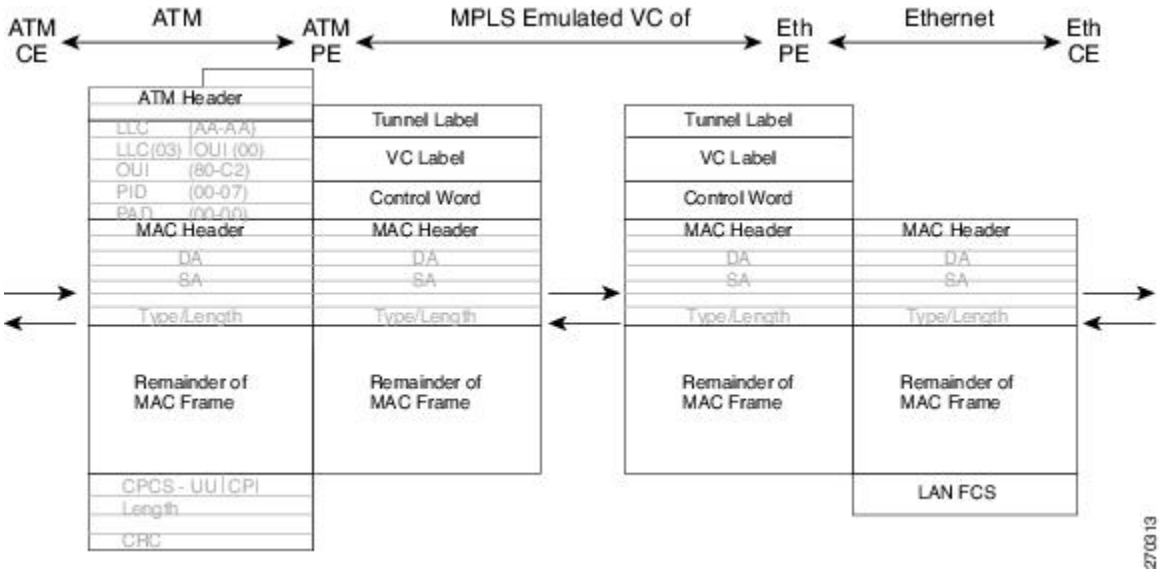
The following topics are covered in this section:

ATM AAL5-to-Ethernet Port AToM--Bridged Interworking

This interworking type provides interoperability between the ATM attachment VC and Ethernet attachment VC connected to different PE routers. Bridged encapsulation corresponding to the bridged (Ethernet) interworking mechanism is used.

The interworking function is performed at the PE router connected to the ATM attachment VC based on multiprotocol encapsulation over ATM AAL5 (see the figure below).

Figure 59: Network Topology for ATM-to-Ethernet AToM Bridged Interworking



The advantage of this architecture is that the Ethernet PE router (connected to the Ethernet segment) operates similarly to Ethernet like-to-like services.

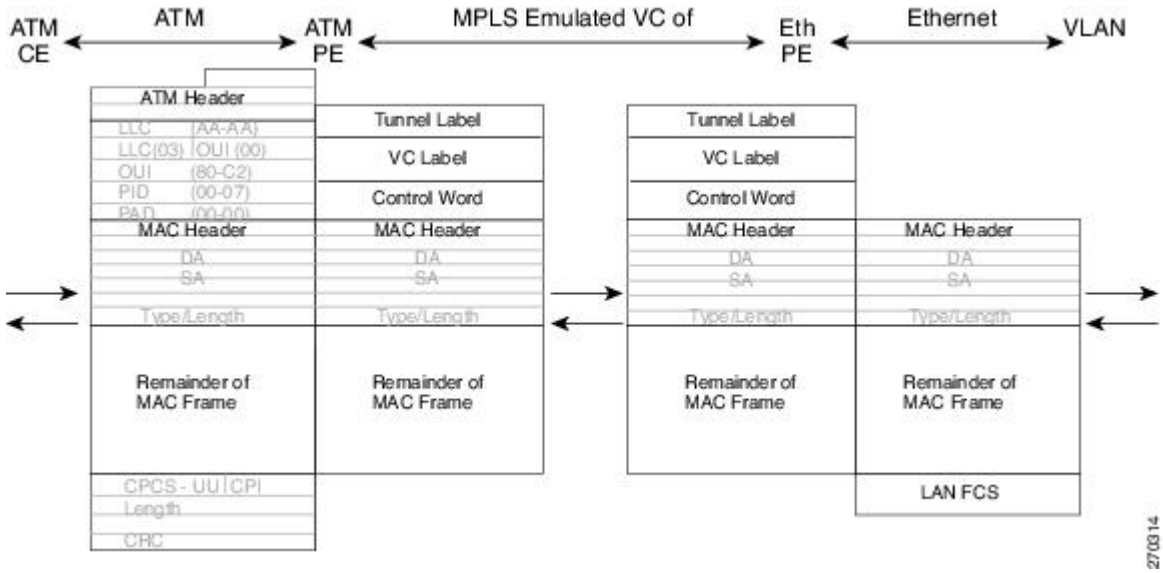
On the PE router with interworking function, in the direction from the ATM segment to MPLS cloud, the bridged encapsulation (ATM/subnetwork access protocol (SNAP) header) is discarded and the Ethernet frame is encapsulated with the labels required to go through the pseudowire using the VC type 5 (Ethernet) (see the figure below).

In the opposite direction, after the label disposition from the MPLS cloud, Ethernet frames are encapsulated over AAL5 using bridged encapsulation.

The figure below shows the protocol stack for ATM-to-Ethernet AToM bridged interworking. The ATM side has an encapsulation type of aal5snap.

Figure 60: Protocol Stack for ATM-to-Ethernet AToM Bridged Interworking--without VLAN Header

ATM AAL5-to-Ethernet VLAN 802.1Q AToM--Bridged Interworking



This interworking type provides interoperability between the ATM attachment VC and Ethernet VLAN attachment VC connected to different PE routers. Bridged encapsulation corresponding to the bridged (Ethernet) interworking mechanism is used.

The interworking function is performed in the same way as for the ATM-to-Ethernet port case, implemented on the PE router connected to the ATM attachment VC. The implementation is based on multiprotocol encapsulation over ATM AAL5 (see the figure below).

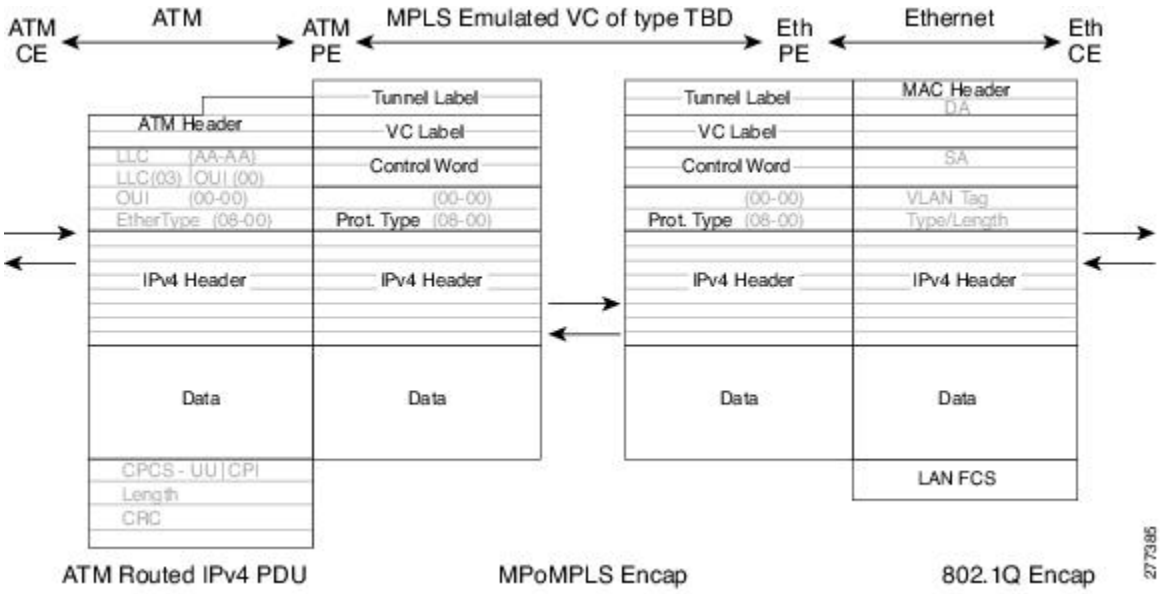
For the PE router connected to the Ethernet side, one major difference exists due the existence of the VLAN header in the incoming packet. The PE router discards the VLAN header of the incoming frames from the VLAN CE router, and the PE router inserts a VLAN header into the Ethernet frames traveling from the MPLS cloud. The frames sent on the pseudowire (with VC type 5) are Ethernet frames without the VLAN header.

Encapsulation over ATM AAL5 is shown in the figure below.

Figure 61: Protocol Stack for ATM -to-VLAN AToM Bridged Interworking

ATM-to-Ethernet--Routed Interworking

To perform routed interworking, both the ATM PE router and Ethernet PE router must be configured. The figure below shows the routed interworking between ATM to Ethernet. The IP encapsulation over the pseudowire is performed on the ATM packets arriving from the ATM CE router.



The address resolution is done at the ATM PE router; it is required when the ATM CE router does an inverse ARP. It is not required when the ATM CE router is configured using Point-to-Point (P2P) subinterfaces or static maps.

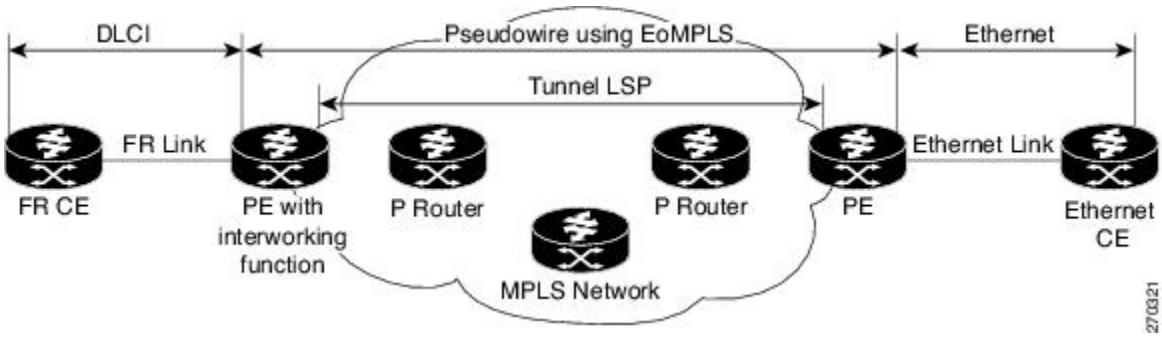
When packets arrive from the Ethernet CE router, the Ethernet PE router removes the L2 frame tag, and then forwards the IP packet to the egress PE router, using IPoMPLS encapsulation over the pseudowire. The Ethernet PE router makes the forwarding decision based on the L2 circuit ID, the VLAN ID, or port ID, of the incoming L2 frame. At the ATM PE router, after label disposition, the IP packets are encapsulated over the AAL5 using routed encapsulation based on RFC 2684.

The address resolution at the Ethernet PE router can be done when the Ethernet CE router configures the static ARP, or by the proxy ARP on the Ethernet PE router. If the proxy ARP is used, the IP address of the remote CE router can be learned dynamically.

Routing protocols need to be configured to operate in the P2P mode on the Ethernet CE router.

Figure 62: Protocol Stack for ATM-to-Ethernet--Routed Interworking

Ethernet VLAN-to-Frame Relay Interworking



The following topics are covered in this section:

Frame Relay DLCI-to-Ethernet Port AToM--Bridged Interworking

This interworking type provides interoperability between the Frame Relay attachment VC and Ethernet attachment VC connected to different PE routers. Bridged encapsulation corresponding to the bridged (Ethernet) interworking mechanism is used.

For an FR-to-Ethernet port case, the interworking function is performed at the PE router connected to the FR attachment VC based on multiprotocol interconnect over Frame Relay (see the figure below). The interworking is implemented similar to an ATM-to-Ethernet case.

Figure 63: Network Topology for FR-to-Ethernet AToM Bridged Interworking

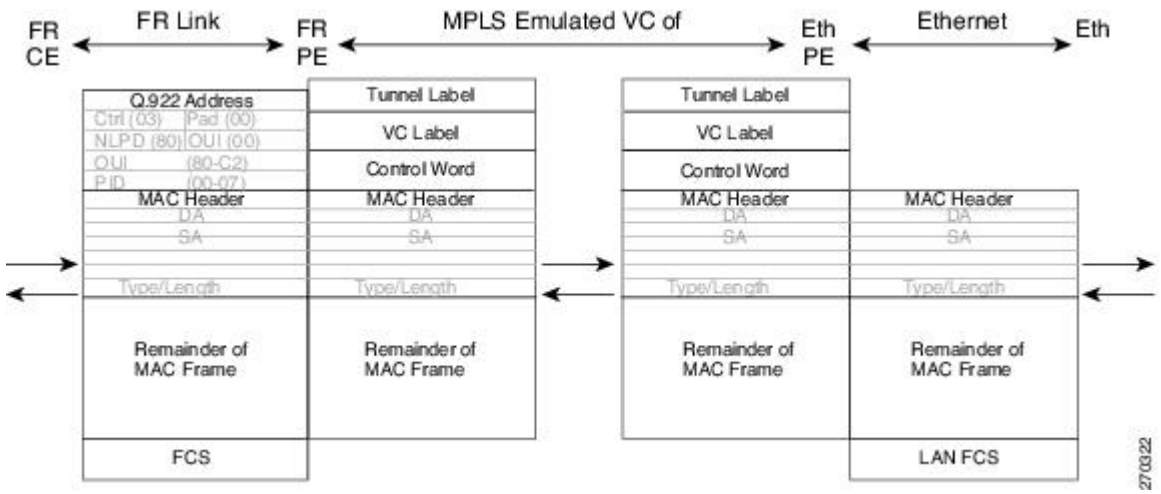
The advantage of this architecture is that the Ethernet PE router (connected to the Ethernet segment) operates similar to Ethernet like-to-like services: a pseudowire label is assigned to the Ethernet port and then the remote Label Distribution Protocol (LDP) session distributes the labels to its peer PE router. Ethernet frames are carried through the MPLS network using Ethernet over MPLS (EoMPLS).

On the PE router with interworking function, in the direction from the Frame Relay segment to the MPLS cloud, the bridged encapsulation (FR/SNAP header) is discarded and the Ethernet frame is encapsulated with the labels required to go through the pseudowire using the VC type 5 (Ethernet) (see the figure below).

In the opposite direction, after the label disposition from the MPLS cloud, Ethernet frames are encapsulated over Frame Relay using bridged encapsulation.

The following translations are supported:

- Ethernet without LAN FCS (0300800080C20007)
- Spanning tree (0300800080C2000E)



The PE router automatically supports translation of both Cisco and IETF Frame Relay encapsulation types coming from the CE, but translates only to IETF when sending to the CE router. This is not a problem for the Cisco CE router, because it can handle IETF encapsulation on receipt even if it is configured to send Cisco encapsulation.

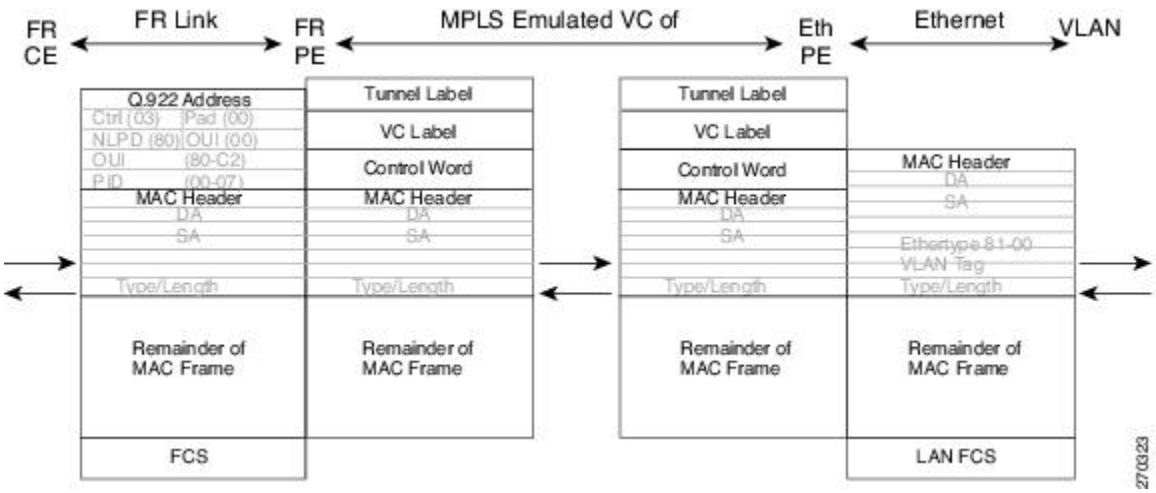
The existing QoS functionality for Frame Relay is supported. The PVC status signaling works the same way as in the like-to-like case. The PE router reports the PVC status to the CE router, based on the availability of the pseudo wire.

The AC MTU must match when connected over MPLS. Only Frame Relay DLCI mode is supported; Frame Relay port mode is not supported in the bridged interworking.

The figure below shows the protocol stack for FR-to-Ethernet bridged interworking.

Figure 64: Protocol Stack for FR-to-Ethernet AToM Bridged Interworking--without VLAN Header

Frame Relay DLCI-to-Ethernet VLAN 802.1Q AToM--Bridged Interworking



This interworking type provides interoperability between the Frame Relay attachment VC and Ethernet VLAN Attachment VC connected to different PE routers. The bridged encapsulation corresponding to the bridged (Ethernet) interworking mechanism is used.

The interworking function is performed in the same way as it is done for the Frame Relay to Ethernet port case; it is implemented on the PE router connected to the Frame Relay attachment VC, based upon a multiprotocol interconnect over Frame Relay (see the figure above).

As in the ATM-to-VLAN case, one difference exists on the Ethernet side due the existence of the VLAN header in the incoming packet. The PE router on the VLAN side discards the VLAN header of the incoming frames from the VLAN CE router, and the PE router inserts a VLAN header into the Ethernet frames traveling from the MPLS cloud. The frames sent on the pseudowire (with VC type 5) are Ethernet frames without the VLAN header.

The figure below shows the protocol stack for FR-to-VLAN AToM bridged interworking.

Figure 65: Protocol Stack for FR-to-VLAN AToM Bridged Interworking

Frame Relay DLCI-to-Ethernet VLAN Qot1Q QinQ AToM - Bridged Interworking

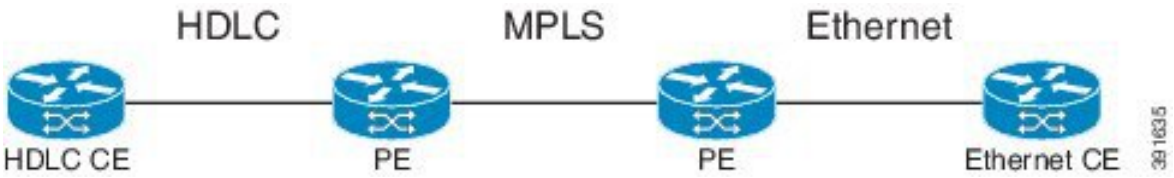
This interworking type provides interoperability between the Frame Relay Attachment VC and Ethernet VLAN Attachment VC connected to different PE routers. The bridged encapsulation corresponding to bridged (Ethernet) interworking mechanism is used.

The interworking function is done in the same way as it is done for FR-to-Ethernet port case; it is implemented on the PE router connected to the Frame Relay attachment VC, based on RFC 2427(Multiprotocol Interconnect over Frame Relay).

When compared with Frame Relay DLCI-to-Ethernet port AToM, there is one major difference on the Ethernet access side, due the existence of the VLAN header in the incoming packet. The PE router on the VLAN side will discard the VLAN header of the incoming frames form the VLAN CE router, and it will insert a VLAN header into the Ethernet frames coming from the MPLS cloud. So the frames sent on the pseudo wire (with VC type 5) will be Ethernet frames without the VLAN header.

The following translations are supported on the Frame Relay PE router:

- Ethernet without LAN FCS (0300800080C20007)
- Spanning tree (0300800080C2000E)



Frame Relay encapsulation types supported for bridged interworking: Cisco and IETF for incoming traffic, IETF only for outgoing traffic towards CE router.

HDLC-to-Ethernet Interworking

High-Level Data Link Control (HDLC) and Ethernet are two independent data link layer transport protocols that utilize the Any Transport over MPLS (AToM) framework to communicate with each other. The interworking function enables translation between two heterogeneous Layer 2 encapsulations over a Multiprotocol Label Switching (MPLS) backbone.

The figure below depicts a simple HDLC-to-Ethernet interworking topology.

Figure 66: HDLC-to-Ethernet interworking topology

HDLC-to-Ethernet interworking supports the following:

- Ethernet or bridged interworking
- IP or routed interworking
- HDLC encapsulation type: CISCO
- Ethernet encapsulation types: IEEE 802.1Q, QinQ, port mode

The HDLC pass-through feature is not affected in any way by HDLC-to-Ethernet interworking.

HDLC-to-Ethernet interworking supports two interworking modes:

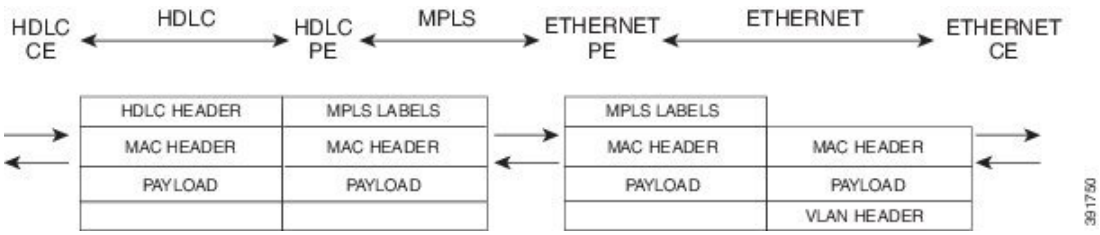
- HDLC-to-Ethernet — Ethernet or Bridged interworking
- HDLC-to-Ethernet — IP or Routed interworking

HDLC-to-Ethernet — Ethernet or Bridged Interworking

HDLC-to-Ethernet bridged interworking provides interoperability between the HDLC attachment virtual circuit (VC) and Ethernet VLAN attachment VC connected to different provider edge (PE) devices. Bridged encapsulation corresponding to the bridged (Ethernet) interworking mechanism is used.

When packets arrive from the HDLC customer edge (CE) device, they consist of the HDLC header, the Ethernet MAC header, and the payload. At the HDLC PE device, the HDLC header is removed, and MPLS labels are inserted. The frames are then routed over the pseudowire to the Ethernet PE device, where the MPLS labels are removed. On the Ethernet side, there are two possibilities. The attachment circuit (AC) is either Ethernet or VLAN.

For an Ethernet attachment circuit (AC), the packets are forwarded to the Ethernet CE device, as is. For a VLAN AC, VLAN headers are added at the VLAN/QinQ subinterface’s AC. The Ethernet VLAN frame is then forwarded to the VLAN CE device.



In the opposite direction (Ethernet / VLAN to HDLC), the VLAN header is present in the incoming packet, if the AC is VLAN. So, when packets arrive from the VLAN CE device, they consist of the VLAN header, the Ethernet MAC header, and the payload. At the Ethernet PE device, the VLAN header is removed at the VLAN/QinQ subinterface's AC, and MPLS labels are inserted. The frames are then routed over the pseudowire

to the HDLC PE device, where the MPLS labels are removed. The HDLC header is added before the Ethernet MAC header. The HDLC frame is then forwarded to the HDLC CE device.

If the AC is Ethernet, packets arriving from the Ethernet CE device consist of the Ethernet MAC header and the payload. At the Ethernet PE device, MPLS labels are inserted at the VLAN/QinQ subinterface's AC. The frames are then routed over the pseudowire to the HDLC PE device, where the MPLS labels are removed. The HDLC header is added before the Ethernet MAC header. The HDLC frame is then forwarded to the HDLC CE device.

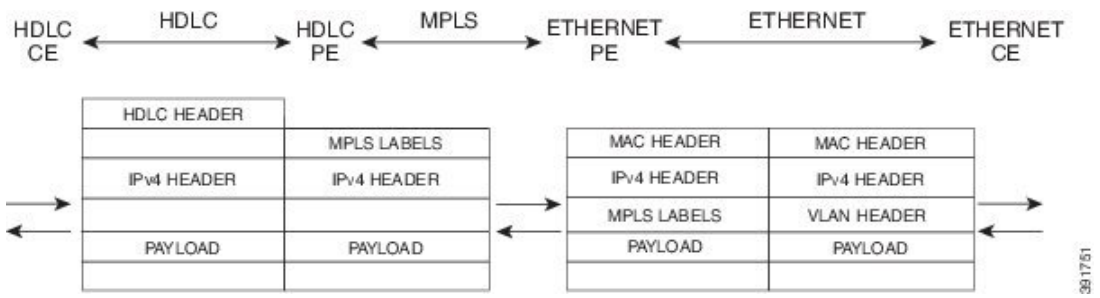
The figure below shows the bridged interworking mode of HDLC-to-Ethernet interworking, with a VLAN AC on the Ethernet side.

Figure 67: HDLC-to-Ethernet — Ethernet or Bridged Interworking

HDLC-to-Ethernet — IP or Routed Interworking

To perform routed interworking, both the HDLC PE device and Ethernet PE device must be configured. The IP encapsulation over the pseudowire is performed on HDLC packets that arrive from the HDLC CE device. The address resolution is done at the HDLC PE device.

When packets arrive from the HDLC CE device, they consist of the HDLC header, the IPv4 header, and the payload. At the HDLC PE device, the HDLC header is removed, and MPLS labels are inserted. The frames are then routed over the pseudowire to the Ethernet PE device, where the MPLS labels are removed. On the Ethernet side, there are two possibilities. The attachment circuit (AC) is either Ethernet or VLAN.



For an Ethernet attachment circuit (AC), the packets are forwarded to the Ethernet CE device, as is. For a VLAN AC, VLAN headers are added at the VLAN/QinQ subinterface’s AC. The Ethernet VLAN frame is then forwarded to the VLAN CE device.

In the opposite direction (Ethernet / VLAN to HDLC), the VLAN header is present in the incoming packet, if the AC is VLAN. So, when packets arrive from the VLAN CE device, they consist of the VLAN header, the Ethernet MAC header, and the payload. At the Ethernet PE device, the MAC header is removed, the VLAN header is removed at the VLAN/QinQ subinterface's AC, and MPLS labels are inserted. The frames are then routed over the pseudowire to the HDLC PE device, where the MPLS labels are removed. The HDLC header is added before the IPv4 header. The HDLC frame is then forwarded to the HDLC CE device.

If the AC is Ethernet, packets arriving from the Ethernet CE device consist of the Ethernet MAC header and the payload. At the Ethernet PE device, the MAC header is removed, and MPLS labels are inserted. The frames are then routed over the pseudowire to the HDLC PE device, where the MPLS labels are removed. The HDLC header is added before the IPv4 header. The HDLC frame is then forwarded to the HDLC CE device.

The figure below shows the routed interworking mode of HDLC-to-Ethernet interworking, with a VLAN AC on the Ethernet side.

Figure 68: HDLC-to-Ethernet — IP or Routed interworking

ATM Local Switching

- ATM like-to-like local switching allows switching data between two physical interfaces where both the segments are of ATM type. The two interfaces must be on the same PE router. The table below lists the supported ATM local switching combinations.

Table 106: ATM local switching - supported combinations

	Same port Point-to-Point	Different port Point-to-Point	Same Port Multipoint	Different Port Multipoint
Port Mode	No	No	No	No
VC-to-VC AAL0	Yes	Yes	Yes	Yes
VC-to-VC AAL5	Yes	Yes	Yes	Yes
VP-to-VP AAL0	No	No	Yes	Yes
VP-to-VP AAL5	No	No	No	No

VC-to-VC Local Switching

VC-to-VC local switching transports cells between two ATM attachment VCs on the same or different port on the PE router. The cells coming to the PE router can be AAL0 or AAL5 encapsulated ATM packets. ATM VC-to-VC local switching can be configured either on point-to-point interface or on multipoint interface.

There are two operation modes for managing OAM cells over ATM local switching interfaces:

- OAM transparent mode: In this mode, the PE router transports F5 OAM cells transparently across local switching interfaces.
- OAM local emulation mode: In this mode, the PE router does not transport OAM cells across local switching interfaces. Instead, the interfaces locally terminate and process F5 OAM cells.

In ATM single cell relay AAL0, the ATM virtual path identifier/virtual channel identifier (VPI/VCI) values of the ingress and egress ATM interfaces of a router must match. If L2 local switching is desired between two ATM VPIs and VCIs, which are on two different interfaces and have values that do not match, ATM AAL5 should be selected. However, if ATM AAL5 uses OAM transparent mode, the VPI and VCI values must match.

ATM OAM can be configured on ATM VC mode local switching AC using the **oam-ac emulation-enable**and **oam-pvc manage** commands. When emulation is enabled on the AC, all OAM cells going through the AC are punted to RP for local processing. The ATM common component processes OAM cells and forwards the cells towards the local CE router. This helps to detect the failures on the PE router by monitoring the response at the CE router end. When the **oam-pvc manage** command is enabled on the AC, the PVC generates end-to-end OAM loopback cells that verify connectivity on the VC.

The following example shows a sample configuration on the ATM PE router:

```
configure terminal
interface atm 4/0.50 multipoint
 no ip address
  no atm enable-ilmi-trap
pvc 100/100 l2transport
 encapsulation aal5
 oam-ac emulation-enable
 oam-pvc manage
interface atm 5/0.100 multipoint
 no ip address
 no atm enable-ilmi-trap
 pvc 100/100 l2transport
  encapsulation aal5
  oam-ac emulation-enable
  oam-pvc manage
connect atm_ls atm 4/0 100/100 atm 5/0 100/100
```

VP-to-VP Local Switching

VP-to-VP local switching transports cells between two VPs on the same port or different ports on the PE router. The cells coming to the PE router can be AAL0 encapsulated ATM packets only. ATM VP-to-VP local switching can be configured only on multipoint interfaces.

There are two operation modes for managing OAM cells over ATM local switching interfaces:

- OAM transparent mode: In this mode, the PE router transports F4 OAM cells transparently across local switching interfaces.
- OAM local emulation mode: In this mode, the PE router do not transport OAM cells across local switching interfaces. Instead, the interfaces locally terminate and process F4 OAM cells.

In ATM single cell relay AAL0, the ATM VPI values of the ingress and egress ATM interfaces on a router must match. If L2 switching is desired between two ATM VPIs which are on two different interfaces and have values that do not match, ATM AAL5 should be selected. If ATM AAL5 uses OAM transparent mode, the VPI value must match. Currently, the ATM VP-to-VP local switching supports only AAL0 encapsulation.

The following example shows a sample configuration on the ATM PE router:

```
configure terminal
interface atm 4/0.100 multipoint
 no ip address
 no atm enable-ilmi-trap
atm pvp 100 l2transport
interface atm 5/0.100 multipoint
 no ip address
 no atm enable-ilmi-trap
atm pvp 100 l2transport
connect atm_ls atm 4/0 100 atm 5/0 100
```

PPP-to-Ethernet AToM-Routed Interworking

In this interworking type, one of the ACs is Ethernet and the other is PPP. Each link is terminated locally on the corresponding PE routers and the extracted layer 3 (L3) packets are transported over a pseudowire.

The PE routers connected to Ethernet and PPP ACs terminate their respective L2 protocols. The PPP session is terminated for both the LCP and the Network Control Protocol (NCP) layers. On the ingress PE router, after extracting L3 packets, each PE router forwards the packets over the already established pseudowire using MPoMPLS encapsulation. On the egress PE router, after performing label disposition, the packets are encapsulated based on the corresponding link layer and are sent to the respective CE router. This interworking scenario requires the support of MPoMPLS encapsulation by the PE routers.

In PPP-to-Ethernet AToM routed interworking mode IPCP is supported. Proxy IPCP is automatically enabled on the PE router when IP interworking is configured on the pseudowire. By default, the PE router gets the IP address it needs to use from the CE router. The PE router accomplishes this by sending an IPCP confreq with the IP address 0.0.0.0. The local CE router has the remote CE router's IP address configured on it. The following example shows a sample configuration on the PPP CE router:

```
interface serial2/0
 ip address 168.65.32.13 255.255.255.0
 encapsulation ppp
peer default ip address 168.65.32.14  *
```

If the remote CE router's IP address cannot be configured on the local CE router, then the remote CE router's IP address can be configured on the PE router using the **ppp ipcp address proxy** *ip address* command on the xconnect PPP interface of PE router. The following example shows a sample configuration on the PPP PE router:

```
pseudowire-class mp
 encapsulation mpls
 protocol ldp
 interworking ip
!
int se2/0
 encap ppp
 xconnect 10.0.0.2 200 pw-class mp
 ppp ipcp address proxy 168.65.32.14
```

PPP-to-Ethernet AToM-Routed Interworking using the commands associated with the L2VPN Protocol-Based CLIs feature

In this interworking type, one of the ACs is Ethernet and the other is PPP. Each link is terminated locally on the corresponding PE routers and the extracted layer 3 (L3) packets are transported over a pseudowire.

The PE routers connected to Ethernet and PPP ACs terminate their respective L2 protocols. The PPP session is terminated for both the LCP and the Network Control Protocol (NCP) layers. On the ingress PE router, after extracting L3 packets, each PE router forwards the packets over the already established pseudowire using MPoMPLS encapsulation. On the egress PE router, after performing label disposition, the packets are encapsulated based on the corresponding link layer and are sent to the respective CE router. This interworking scenario requires the support of MPoMPLS encapsulation by the PE routers.

In PPP-to-Ethernet AToM routed interworking mode IPCP is supported. Proxy IPCP is automatically enabled on the PE router when IP interworking is configured on the pseudowire. By default, the PE router gets the IP address it needs to use from the CE router. The PE router accomplishes this by sending an IPCP confreq with

the IP address 0.0.0.0. The local CE router has the remote CE router's IP address configured on it. The following example shows a sample configuration on the PPP CE router:

```
interface serial2/0
 ip address 168.65.32.13 255.255.255.0
 encapsulation ppp
peer default ip address 168.65.32.14  *
```

If the remote CE router's IP address cannot be configured on the local CE router, then the remote CE router's IP address can be configured on the PE router using the **ppp ipcp address proxy** *ip address* command on the xconnect PPP interface of PE router. The following example shows a sample configuration on the PPP PE router:

```
template type pseudowire mp
 encapsulation mpls
 protocol ldp
 interworking ip
!
int se2/0
 encap ppp
interface pseudowire 100
 source template type pseudowire mp
 neighbor 33.33.33.33 1
!
l2vpn xconnect context con1
 ppp ipcp address proxy 168.65.32.14
```

Static IP Addresses for L2VPN Interworking for PPP

If the PE router needs to perform address resolution with the local CE router for PPP, configure the remote CE router’s IP address on the PE router. Use the **ppp ipcp address proxy** command with the remote CE router’s IP address on the PE router’s xconnect PPP interface. The following example shows a sample configuration:

```
pseudowire-class ip-interworking
 encapsulation mpls
 interworking ip
interface Serial2/0
 encapsulation ppp
 xconnect 10.0.0.2 200 pw-class ip-interworking
 ppp ipcp address proxy 10.65.32.14
```

You can also configure the remote CE router’s IP address on the local CE router with the **peer default ip address** command if the local CE router performs address resolution.

Static IP Addresses for L2VPN Interworking for PPP using the commands associated with the L2VPN Protocol-Based CLIs feature

If the PE router needs to perform address resolution with the local CE router for PPP, configure the remote CE router’s IP address on the PE router. Use the **ppp ipcp address proxy** command with the remote CE router’s IP address on the PE router’s xconnect PPP interface. The following example shows a sample configuration:

```
template type pseudowire ip-interworking
```

```
 encapsulation mpls
 interworking ip
interface Serial2/0
 encapsulation ppp
interface pseudowire 100
 source template type pseudowire ip-interworking
 neighbor 10.0.0.2 200
!
l2vpn xconnect context con1
 ppp ipcp address proxy 10.65.32.14
```

You can also configure the remote CE router's IP address on the local CE router with the **peer default ip address** command if the local CE router performs address resolution.

How to Configure L2VPN Interworking

Configuring L2VPN Interworking

L2VPN interworking allows you to connect disparate ACs. Configuring L2VPN interworking feature requires that you add the **interworking** command to the list of commands that make up the pseudowire. The steps for configuring the pseudowire for L2VPN interworking are included in this section. You use the **interworking**command as part of the overall AToM configuration. For specific instructions on configuring AToM, see the Any Transport over MPLS document.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **pseudowire-class** *name*
4. **encapsulation** {**mpls** | **l2tpv3**}
5. **interworking** {**ethernet** | **ip**}
6. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.

	Command or Action	Purpose
Step 3	**pseudowire-class** *name* **Example:** `Router(config)# pseudowire-class class1`	Establishes a pseudowire class with a name that you specify and enters pseudowire class configuration mode.
Step 4	**encapsulation** {**mpls** | **l2tpv3**} **Example:** `Router(config-pw)# encapsulation mpls`	Specifies the tunneling encapsulation, which is either **mpls** or **l2tpv3**.
Step 5	**interworking** {**ethernet** | **ip**} **Example:** `Router(config-pw)# interworking ip`	Specifies the type of pseudowire and the type of traffic that can flow across it.
Step 6	**end** **Example:** `Router(config-pw)# end`	Exits pseudowire class configuration mode and returns to privileged EXEC mode.

Verifying the L2VPN Configuration

You can verify L2VPN configuration using the following steps:

- You can issue the **show arp** command between the CE routers to ensure that data is being sent:

```
Router# show arp
Protocol   Address       Age (min)   Hardware Addr    Type    Interface
Internet   10.1.1.5           134    0005.0032.0854   ARPA    FastEthernet0/0/0
Internet   10.1.1.7             -    0005.0032.0000   ARPA    FastEthernet0/0/0
```

- You can issue the **ping** command between the CE routers to ensure that data is being sent:

```
Router# ping 10.1.1.5
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 10.1.1.5, timeout is 2 seconds:
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/2/4 ms
```

- You can verify the AToM configuration by using the **show mpls l2transport vc detail** command.

Configuring L2VPN Interworking using the commands associated with the L2VPN Protocol-Based CLIs feature

L2VPN Interworking allows you to connect disparate attachment circuits. Configuring the L2VPN Interworking feature requires that you add the **interworking** command to the list of commands that make up the pseudowire. The steps for configuring the pseudowire for L2VPN Interworking are included in this section. You use the

interworkingcommand as part of the overall AToM or L2TPv3 configuration. For specific instructions on configuring AToM or L2TPv3, see the following documents:

- Layer 2 Tunnel Protocol Version 3
- Any Transport over MPLS

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **hw-module slot** *slot-number* **np mode feature**
4. **interface pseudowire** *number*
5. **encapsulation** {**mpls** | **l2tpv3**}
6. **interworking** {**ethernet** | **ip**}
7. **neighbor** *peer-address vcid-value*

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**hw-module slot** *slot-number* **np mode feature** **Example:** `Router(config)# hw-module slot 3 np mode feature`	(Optional) Enables L2VPN Interworking functionality on the Cisco 12000 series router. **Note** Enter this command only on a Cisco 12000 series Internet router if you use L2TPv3 for L2VPN Interworking on an ISE (Engine 3) or Engine 5 interface. In this case, you must first enable the L2VPN feature bundle on the line card by entering the **hw-module slot** *slot-number* **np mode feature** command.
Step 4	**interface pseudowire** *number* **Example:** `Router(config)# interface pseudowire 1`	Establishes an interface pseudowire with a value that you specify and enters pseudowire class configuration mode.

	Command or Action	Purpose
Step 5	**encapsulation** {**mpls** | **l2tpv3**} **Example:** `Router(config-pw)# encapsulation mpls`	Specifies the tunneling encapsulation, which is either **mpls** or **l2tpv3**.
Step 6	**interworking** {**ethernet** | **ip**} **Example:** `Router(config-pw)# interworking ip`	Specifies the type of pseudowire and the type of traffic that can flow across it. **Note** On the Cisco 12000 series Internet router, Ethernet (bridged) interworking is not supported for L2TPv3. After you configure the L2TPv3 tunnel encapsulation for the pseudowire using the **encapsulation l2tpv3**command, you cannot enter the **interworking ethernet** command.
Step 7	**neighbor** *peer-address vcid-value* **Example:** `Router(config-pw)#  neighbor 10.0.0.1 123`	Specifies the peer IP address and virtual circuit (VC) ID value of a Layer 2 VPN (L2VPN) pseudowire.

Verifying the L2VPN Configuration using the commands associated with the L2VPN Protocol-Based CLIs feature

You can verify L2VPN configuration using the following commands:

- You can issue the **show arp** command between the CE routers to ensure that data is being sent:

```
Device# show arp
Protocol   Address       Age (min)   Hardware Addr    Type    Interface
Internet   10.1.1.5           134    0005.0032.0854   ARPA    FastEthernet0/0/0
Internet   10.1.1.7             -    0005.0032.0000   ARPA    FastEthernet0/0/0
```

- You can issue the **ping** command between the CE routers to ensure that data is being sent:

```
Device# ping 10.1.1.5
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 10.1.1.5, timeout is 2 seconds:
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/2/4 ms
```

- You can verify the AToM configuration by using the **show l2vpn atom vc detail** command.

Configuring Ethernet VLAN-to-ATM AAL5 Interworking

This section explains the following AToM configurations:

ATM AAL5-to-Ethernet Port

You can configure the ATM AAL5-to-Ethernet Port feature on a PE1 router using the following steps:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls label protocol ldp**
4. **interface** *type number*
5. **ip address** *ip-address mask*
6. **pseudowire-class** [*pw-class-name*]
7. **encapsulation mpls**
8. **interworking** {**ethernet** | **ip**}
9. **interface atm** *slot* **/** *subslot* **/** *port* **.** *subinterface number*
10. **pvc** [*name*] *vpi* **/** *vci* **12transport**
11. **encapsulation aal5snap**
12. **xconnect** *ip-address vc-id* **pw-class** *pw-class-name*
13. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password, if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**mpls label protocol ldp** **Example:** `Router(config)# mpls label protocol ldp`	Establishes the label distribution protocol for the platform.
Step 4	**interface** *type number* **Example:** `Router(config)# interface loopback 100`	Configure an interface type and enters interface configuration mode.
Step 5	**ip address** *ip-address mask* **Example:** `Router(config-if)# ip address 10.0.0.100 255.255.255.255`	Sets the primary or secondary IP address for an interface.

	Command or Action	Purpose
Step 6	**pseudowire-class** [*pw-class-name*] **Example:** `Router(config-if)# pseudowire-class atm-eth`	Establishes a pseudowire class with a name that you specify and enters pseudowire class configuration mode.
Step 7	**encapsulation mpls** **Example:** `Router(config-pw)# encapsulation mpls`	Specifies the tunneling encapsulation.
Step 8	**interworking** {**ethernet** | **ip**} **Example:** `Router(config-pw)# interworking ip`	Specifies the type of pseudowire and the type of traffic that can flow across it.
Step 9	**interface atm** *slot* / *subslot* / *port* **.** *subinterface number* **Example:** `Router(config-pw)# interface atm 2/0/0.1`	Configures an ATM interface and enters interface configuration mode.
Step 10	**pvc** [*name*] *vpi* / *vci* **l2transport** **Example:** `Router(config-subif)# pvc 0/200 l2transport`	Assigns a name to an ATM permanent virtual circuit (PVC) and enters ATM virtual circuit configuration mode.
Step 11	**encapsulation aal5snap** **Example:** `Router(config-if-atm-member)# encapsulation aal5snap`	Configures the ATM AAL and encapsulation type for an ATM VC.
Step 12	**xconnect** *ip-address vc-id* **pw-class** *pw-class-name* **Example:** `Router(config-if-atm-member)# xconnect 10.0.0.200 140 pw-class atm-eth`	Binds an AC to a pseudowire and configures an AToM static pseudowire.
Step 13	**end** **Example:** `Router(config-if-xconn)# end`	Exits xconnect configuration mode and returns to privileged EXEC mode.

ATM AAL5-to-Ethernet Port using the commands associated with the L2VPN Protocol-Based CLIs feature

You can configure the ATM AAL5-to-Ethernet Port feature on a PE1 router using the following steps:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls label protocol ldp**
4. **interface** *type number*
5. **ip address** *ip-address mask*
6. **template type pseudowire** [*pw-class-name*]
7. **encapsulation mpls**
8. **interworking** {**ethernet** | **ip**}
9. **interface atm** *slot* / *subslot* / *port* **.** *subinterface number*
10. **pvc** [*name*] *vpi* / *vci* **12transport**
11. **encapsulation aal5snap**
12. **end**
13. **interface pseudowire** *number*
14. **source template type pseudowire** *template-name*
15. **neighbor** *peer-address vcid-value*
16. **exit**
17. **exit**
18. **l2vpn xconnect context** *context-name*
19. **member pseudowire** *interface-number*
20. **member** *ip-address vc-id* **encapsulation mpls**
21. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password, if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**mpls label protocol ldp** **Example:** `Router(config)# mpls label protocol ldp`	Establishes the label distribution protocol for the platform.
Step 4	**interface** *type number* **Example:**	Configure an interface type and enters interface configuration mode.

	Command or Action	Purpose
	`Router(config)# interface loopback 100`	
Step 5	**ip address** *ip-address mask* **Example:** `Router(config-if)# ip address 10.0.0.100 255.255.255.255`	Sets the primary or secondary IP address for an interface.
Step 6	**template type pseudowire** [*pw-class-name*] **Example:** `Router(config-if)# template type pseudowire atm-eth`	Establishes a pseudowire class with a name that you specify and enters pseudowire class configuration mode.
Step 7	**encapsulation mpls** **Example:** `Router(config-pw)# encapsulation mpls`	Specifies the tunneling encapsulation.
Step 8	**interworking** {**ethernet** | **ip**} **Example:** `Router(config-pw)# interworking ip`	Specifies the type of pseudowire and the type of traffic that can flow across it.
Step 9	**interface atm** *slot* / *subslot* / *port* **.** *subinterface number* **Example:** `Router(config-pw)# interface atm 2/0/0.1`	Configures an ATM interface and enters interface configuration mode.
Step 10	**pvc** [*name*] *vpi* / *vci* **12transport** **Example:** `Router(config-subif)# pvc 0/200 l2transport`	Assigns a name to an ATM permanent virtual circuit (PVC) and enters ATM virtual circuit configuration mode.
Step 11	**encapsulation aal5snap** **Example:** `Router(config-if-atm-member)# encapsulation aal5snap`	Configures the ATM AAL and encapsulation type for an ATM VC.
Step 12	**end** **Example:** `Router(config-if-atm-member)# end`	Exits to privileged EXEC mode.
Step 13	**interface pseudowire** *number* **Example:**	Specifies the pseudowire interface and enters interface configuration mode.

	Command or Action	Purpose
	`Router(config)# interface pseudowire 100`	
Step 14	**source template type pseudowire** *template-name* **Example:** `Router(config-if)# source template type pseudowire atm-eth`	Configures the source template of type pseudowire named atm-eth.
Step 15	**neighbor** *peer-address vcid-value* **Example:** `Router(config-if)# neighbor 10.0.0.200 140`	Specifies the peer IP address and virtual circuit (VC) ID value of a Layer 2 VPN (L2VPN) pseudowire.
Step 16	**exit** **Example:** `Router(config-if)# exit`	Exits to privileged EXEC mode.
Step 17	**exit** **Example:** `Router(config-if)# exit`	Exits to privileged EXEC mode.
Step 18	**l2vpn xconnect context** *context-name* **Example:** `Router(config)# l2vpn xconnect context con1`	Creates a Layer 2 VPN (L2VPN) cross connect context and enters xconnect configuration mode.
Step 19	**member pseudowire** *interface-number* **Example:** `Router(config-xconnect)# member pseudowire 100`	Specifies a member pseudowire to form a Layer 2 VPN (L2VPN) cross connect.
Step 20	**member** *ip-address vc-id* **encapsulation mpls** **Example:** `Router(config-xconnect)# member 10.0.0.200 140 encapsulation mpls`	Creates the VC to transport the Layer 2 packets.
Step 21	**end** **Example:** `Router(config-xconnect)# end`	Exits xconnect configuration mode and returns to privileged EXEC mode.

ATM AAL5-to-Ethernet Port on a PE2 Router

You can configure the ATM AAL5-to-Ethernet Port feature on a PE2 router using the following steps:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls label protocol ldp**
4. **interface** *type number*
5. **ip address** *ip-address mask*
6. **pseudowire-class** [*pw-class-name*]
7. **encapsulation mpls**
8. **interworking** {**ethernet** | **ip**}
9. **interface** *type slot / subslot / port*
10. **xconnect** *ip-address vc-id* **pw-class** *pw-class-name*
11. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**mpls label protocol ldp** **Example:** `Router(config)# mpls label protocol ldp`	Establishes the label distribution protocol for the platform.
Step 4	**interface** *type number* **Example:** `Router(config)# interface loopback 100`	Configure an interface type and enters interface configuration mode.
Step 5	**ip address** *ip-address mask* **Example:** `Router(config-if)# ip address 10.0.0.100 255.255.255.255`	Sets the primary or secondary IP address for an interface.
Step 6	**pseudowire-class** [*pw-class-name*] **Example:**	Establishes a pseudowire class with a name that you specify and enters pseudowire class configuration mode.

	Command or Action	Purpose
	`Router(config-if)# pseudowire-class atm-eth`	
Step 7	**encapsulation mpls** **Example:** `Router(config-pw)# encapsulation mpls`	Specifies the tunneling encapsulation.
Step 8	**interworking** {**ethernet** | **ip**} **Example:** `Router(config-pw)# interworking ip`	Specifies the type of pseudowire and the type of traffic that can flow across it.
Step 9	**interface** *type slot / subslot / port* **Example:** `Router(config-pw)# interface gigabitethernet 5/1/0`	Configure an interface and enters interface configuration mode.
Step 10	**xconnect** *ip-address vc-id* **pw-class** *pw-class-name* **Example:** `Router(config-if)# xconnect 10.0.0.100 140 pw-class atm-eth`	Binds an AC to a pseudowire and configures an AToM static pseudowire.
Step 11	**end** **Example:** `Router(config-if-xconn)# end`	Exits xconnect configure mode and returns to privileged EXEC mode.

What to do next

Note When configuring bridged interworking, the PE2 router configuration does not include the **interworking ethernet** command because it is treated as like-to-like, and also because the AC is already an Ethernet port. However, when configuring routed interworking, the **interworking ip** command is required.

ATM AAL5-to-Ethernet Port on a PE2 Router using the commands associated with the L2VPN Protocol-Based CLIs feature

You can configure the ATM AAL5-to-Ethernet Port feature on a PE2 router using the following steps:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls label protocol ldp**
4. **interface** *type number*

5. **ip address** *ip-address mask*
6. **template type pseudowire** [*pseudowire-name*]
7. **encapsulation mpls**
8. **interworking** {**ethernet** | **ip**}
9. **interface** *type slot / subslot / port*
10. **end**
11. **interface pseudowire** *number*
12. **source template type pseudowire** *template-name*
13. **neighbor** *peer-address vcid-value*
14. **exit**
15. **l2vpn xconnect context** *context-name*
16. **member pseudowire** *interface-number*
17. **member** *ip-address vc-id* **encapsulation mpls**
18. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**mpls label protocol ldp** **Example:** `Router(config)# mpls label protocol ldp`	Establishes the label distribution protocol for the platform.
Step 4	**interface** *type number* **Example:** `Router(config)# interface loopback 100`	Configure an interface type and enters interface configuration mode.
Step 5	**ip address** *ip-address mask* **Example:** `Router(config-if)# ip address 10.0.0.100 255.255.255.255`	Sets the primary or secondary IP address for an interface.

	Command or Action	Purpose
Step 6	**template type pseudowire** [*pseudowire-name*] **Example:** `Router(config)# template type pseudowire atm-eth`	Specifies the name of a Layer 2 pseudowire class and enters pseudowire class configuration mode.
Step 7	**encapsulation mpls** **Example:** `Router(config-pw)# encapsulation mpls`	Specifies the tunneling encapsulation.
Step 8	**interworking** {**ethernet** | **ip**} **Example:** `Router(config-pw)# interworking ip`	Specifies the type of pseudowire and the type of traffic that can flow across it.
Step 9	**interface** *type slot / subslot / port* **Example:** `Router(config-pw)# interface gigabitethernet 5/1/0`	Configure an interface and enters interface configuration mode.
Step 10	**end** **Example:** `Router(config-pw)# end`	Exits to privileged EXEC mode.
Step 11	**interface pseudowire** *number* **Example:** `Router(config)# interface pseudowire 100`	Specifies the pseudowire interface and enters interface configuration mode.
Step 12	**source template type pseudowire** *template-name* **Example:** `Router(config-if)# source template type pseudowire atm-eth`	Configures the source template of type pseudowire named atm-eth
Step 13	**neighbor** *peer-address vcid-value* **Example:** `Router(config-if)#  neighbor 10.0.0.100 140`	Specifies the peer IP address and virtual circuit (VC) ID value of a Layer 2 VPN (L2VPN) pseudowire.
Step 14	**exit** **Example:** `Router(config-if)# exit`	Exits to privileged EXEC mode.

	Command or Action	Purpose
Step 15	**l2vpn xconnect context** *context-name* **Example:** `Router(config)# l2vpn xconnect context con1`	Creates a Layer 2 VPN (L2VPN) cross connect context and enters xconnect configuration mode.
Step 16	**member pseudowire** *interface-number* **Example:** `Router(config-xconnect)# member pseudowire 100`	Specifies a member pseudowire to form a Layer 2 VPN (L2VPN) cross connect.
Step 17	**member** *ip-address vc-id* **encapsulation mpls** **Example:** `Router(config-xconnect)# member 10.0.0.100 140 encapsulation mpls`	Creates the VC to transport the Layer 2 packets.
Step 18	**end** **Example:** `Router(config-xconnect)# end`	Exits xconnect configuration mode and returns to privileged EXEC mode.

What to do next

Note When configuring bridged interworking, the PE2 router configuration does not include the **interworking ethernet** command because it is treated as like-to-like, and also because the AC is already an Ethernet port. However, when configuring routed interworking, the **interworking ip** command is required.

ATM AAL5-to-Ethernet VLAN 802.1Q on a PE1 Router

You can configure the ATM AAL5-to-Ethernet VLAN 802.1Q feature on a PE1 router using the following steps:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls label protocol ldp**
4. **interface** *type number*
5. **ip address** *ip-address mask*
6. **pseudowire-class** [*pw-class-name*]
7. **encapsulation mpls**
8. **interworking** {**ethernet** | **ip**}
9. **interface atm** *slot* / *subslot* / *port* **.** *subinterface number*
10. **pvc** [*name*] *vpi* / *vci* **12transport**

11. **encapsulation aal5snap**
12. **xconnect** *ip-address vc-id* **pw-class** *pw-class-name*
13. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**mpls label protocol ldp** **Example:** `Router(config)# mpls label protocol ldp`	Establishes the label distribution protocol for the platform.
Step 4	**interface** *type number* **Example:** `Router(config)# interface loopback 100`	Configure an interface type and enters interface configuration mode.
Step 5	**ip address** *ip-address mask* **Example:** `Router(config-if)# ip address 10.0.0.100 255.255.255.255`	Sets the primary or secondary IP address for an interface.
Step 6	**pseudowire-class** [*pw-class-name*] **Example:** `Router(config-if)# pseudowire-class atm-eth`	Establishes a pseudowire class with a name that you specify and enters pseudowire class configuration mode.
Step 7	**encapsulation mpls** **Example:** `Router(config-pw)# encapsulation mpls`	Specifies the tunneling encapsulation.
Step 8	**interworking** {**ethernet** | **ip**} **Example:**	Specifies the type of pseudowire and the type of traffic that can flow across it.

	Command or Action	Purpose
	`Router(config-pw)# interworking ip`	
Step 9	**interface atm** *slot* **/** *subslot* **/** *port* **.** *subinterface number* **Example:** `Router(config-pw)# interface atm 2/0/0.1`	Configure an ATM interface and enters interface configuration mode.
Step 10	**pvc** [*name*] *vpi* **/** *vci* **12transport** **Example:** `Router(config-subif)# pvc 0/200 l2transport`	Assigns a name to an ATM permanent virtual circuit (PVC) and enters ATM virtual circuit configuration mode.
Step 11	**encapsulation aal5snap** **Example:** `Router(config-if-atm-member)# encapsulation aal5snap`	Configures the ATM AAL and encapsulation type for an ATM VC.
Step 12	**xconnect** *ip-address vc-id* **pw-class** *pw-class-name* **Example:** `Router(config-if-atm-member)# xconnect 10.0.0.200 140 pw-class atm-eth`	Binds an AC to a pseudowire and configures an AToM static pseudowire.
Step 13	**end** **Example:** `Router(config-if-xconn)# end`	Exits xconnect configuration mode and returns to privileged EXEC mode.

ATM AAL5-to-Ethernet VLAN 802.1Q on a PE1 Router using the commands associated with the L2VPN Protocol-Based CLIs feature

You can configure the ATM AAL5-to-Ethernet VLAN 802.1Q feature on a PE1 router using the following steps:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls label protocol ldp**
4. **interface** *type number*
5. **ip address** *ip-address mask*
6. **template type pseudowire** [*pseudowire-name*]
7. **encapsulation mpls**
8. **interworking** {**ethernet** | **ip**}
9. **interface atm** *slot* **/** *subslot* **/** *port* **.** *subinterface number*

10. **pvc** [*name*] *vpi* / *vci* **12transport**
11. **encapsulation aal5snap**
12. **end**
13. **interface pseudowire** *number*
14. **source template type pseudowire** *template-name*
15. **neighbor** *peer-address vcid-value*
16. **exit**
17. **l2vpn xconnect context** *context-name*
18. **member pseudowire** *interface-number*
19. **member** *ip-address vc-id* **encapsulation mpls**
20. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**mpls label protocol ldp** **Example:** `Router(config)# mpls label protocol ldp`	Establishes the label distribution protocol for the platform.
Step 4	**interface** *type number* **Example:** `Router(config)# interface loopback 100`	Configure an interface type and enters interface configuration mode.
Step 5	**ip address** *ip-address mask* **Example:** `Router(config-if)# ip address 10.0.0.100 255.255.255.255`	Sets the primary or secondary IP address for an interface.
Step 6	**template type pseudowire** [*pseudowire-name*] **Example:** `Router(config)# template type pseudowire atm-eth`	Specifies the name of a Layer 2 pseudowire class and enters pseudowire class configuration mode.

	Command or Action	Purpose
Step 7	**encapsulation mpls** **Example:** `Router(config-pw)# encapsulation mpls`	Specifies the tunneling encapsulation.
Step 8	**interworking** {**ethernet** | **ip**} **Example:** `Router(config-pw)# interworking ip`	Specifies the type of pseudowire and the type of traffic that can flow across it.
Step 9	**interface atm** *slot* / *subslot* / *port* **.** *subinterface number* **Example:** `Router(config-pw)# interface atm 2/0/0.1`	Configure an ATM interface and enters interface configuration mode.
Step 10	**pvc** [*name*] *vpi* / *vci* **12transport** **Example:** `Router(config-subif)# pvc 0/200 l2transport`	Assigns a name to an ATM permanent virtual circuit (PVC) and enters ATM virtual circuit configuration mode.
Step 11	**encapsulation aal5snap** **Example:** `Router(config-if-atm-member)# encapsulation aal5snap`	Configures the ATM AAL and encapsulation type for an ATM VC.
Step 12	**end** **Example:** `Router(config-if-atm-member)# end`	Exits to privileged EXEC mode.
Step 13	**interface pseudowire** *number* **Example:** `Router(config)# interface pseudowire 100`	Specifies the pseudowire interface and enters interface configuration mode.
Step 14	**source template type pseudowire** *template-name* **Example:** `Router(config-if)# source template type pseudowire atm-eth`	Configures the source template of type pseudowire named atm-eth
Step 15	**neighbor** *peer-address vcid-value* **Example:** `Router(config-if)#  neighbor 10.0.0.200 140`	Specifies the peer IP address and virtual circuit (VC) ID value of a Layer 2 VPN (L2VPN) pseudowire.

	Command or Action	Purpose
Step 16	**exit** **Example:** `Router(config-if)# exit`	Exits to privileged EXEC mode.
Step 17	**l2vpn xconnect context** *context-name* **Example:** `Router(config)# l2vpn xconnect context con1`	Creates a Layer 2 VPN (L2VPN) cross connect context and enters xconnect configuration mode.
Step 18	**member pseudowire** *interface-number* **Example:** `Router(config-xconnect)# member pseudowire 100`	Specifies a member pseudowire to form a Layer 2 VPN (L2VPN) cross connect.
Step 19	**member** *ip-address vc-id* **encapsulation mpls** **Example:** `Router(config-xconnect)# member 10.0.0.200 140 encapsulation mpls`	Creates the VC to transport the Layer 2 packets.
Step 20	**end** **Example:** `Router(config-xconnect)# end`	Exits xconnect configuration mode and returns to privileged EXEC mode.

ATM AAL5-to-Ethernet VLAN 802.1Q on a PE2 router

You can configure the ATM AAL5-to-Ethernet VLAN 802.1Q feature on a PE2 router using the following steps:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls label protocol ldp**
4. **interface** *type number*
5. **ip address** *ip-address mask*
6. **pseudowire-class** [*pw-class-name*]
7. **encapsulation mpls**
8. **interworking** {**ethernet** | **ip**}
9. **interface** *type slot* / *subslot* / *port* **.** *subinterface-number*
10. **encapsulation dot1q** *vlan-id*
11. **xconnect** *ip-address vc-id* **pw-class** *pw-class-name*
12. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**mpls label protocol ldp** **Example:** `Router(config)# mpls label protocol ldp`	Establishes the label distribution protocol for the platform.
Step 4	**interface** *type number* **Example:** `Router(config)# interface loopback 100`	Configure an interface type and enters interface configuration mode.
Step 5	**ip address** *ip-address mask* **Example:** `Router(config-if)# ip address 10.0.0.100 255.255.255.255`	Sets the primary or secondary IP address for an interface.
Step 6	**pseudowire-class** [*pw-class-name*] **Example:** `Router(config-if)# pseudowire-class atm-eth`	Establishes a pseudowire class with a name that you specify and enters pseudowire class configuration mode.
Step 7	**encapsulation mpls** **Example:** `Router(config-pw)# encapsulation mpls`	Specifies the tunneling encapsulation.
Step 8	**interworking** {**ethernet** | **ip**} **Example:** `Router(config-pw)# interworking ip`	Specifies the type of pseudowire and the type of traffic that can flow across it.

	Command or Action	Purpose
Step 9	**interface** *type slot / subslot / port . subinterface-number* **Example:** `Router(config-pw)# interface gigabitethernet 5/1/0.3`	Configures an interface and enters interface configuration mode.
Step 10	**encapsulation dot1q** *vlan-id* **Example:** `Router(config-if)# encapsulation dot1q 1525`	Enables IEEE 802.1Q encapsulation of traffic on a specified sub interface in a VLAN.
Step 11	**xconnect** *ip-address vc-id* **pw-class** *pw-class-name* **Example:** `Router(config-if)# xconnect 10.0.0.100 140 pw-class atm-eth`	Binds an AC to a pseudowire and configures an AToM static pseudowire.
Step 12	**end** **Example:** `Router(config-if-xconn)# end`	Exits xconnect configuration mode and returns to privileged EXEC mode.

What to do next

Note In the case of ATM AAl5-to-VLAN, the PE2 router configuration includes the **interworking**command for both bridged and routed interworking.

Note To verify the L2VPN interworking status and check the statistics, refer to the Verifying L2VPN Interworking, on page 968.

ATM AAL5-to-Ethernet VLAN 802.1Q on a PE2 router using the commands associated with the L2VPN Protocol-Based CLIs feature

You can configure the ATM AAL5-to-Ethernet VLAN 802.1Q feature on a PE2 router using the following steps:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls label protocol ldp**
4. **interface** *type number*

5. **ip address** *ip-address mask*
6. **template type pseudowire** [*pseudowire-name*]
7. **encapsulation mpls**
8. **interworking** {**ethernet** | **ip**}
9. **interface** *type slot* / *subslot* / *port* **.** *subinterface-number*
10. **encapsulation dot1q** *vlan-id*
11. **end**
12. **interface pseudowire** *number*
13. **source template type pseudowire** *template-name*
14. **neighbor** *peer-address vcid-value*
15. **exit**
16. **l2vpn xconnect context** *context-name*
17. **member pseudowire** *interface-number*
18. **member** *ip-address vc-id* **encapsulation mpls**
19. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**mpls label protocol ldp** **Example:** `Router(config)# mpls label protocol ldp`	Establishes the label distribution protocol for the platform.
Step 4	**interface** *type number* **Example:** `Router(config)# interface loopback 100`	Configure an interface type and enters interface configuration mode.
Step 5	**ip address** *ip-address mask* **Example:** `Router(config-if)# ip address 10.0.0.100 255.255.255.255`	Sets the primary or secondary IP address for an interface.

	Command or Action	Purpose
Step 6	**template type pseudowire** [*pseudowire-name*] **Example:** `Router(config)# template type pseudowire atm-eth`	Specifies the name of a Layer 2 pseudowire class and enters pseudowire class configuration mode.
Step 7	**encapsulation mpls** **Example:** `Router(config-pw)# encapsulation mpls`	Specifies the tunneling encapsulation.
Step 8	**interworking** {**ethernet** | **ip**} **Example:** `Router(config-pw)# interworking ip`	Specifies the type of pseudowire and the type of traffic that can flow across it.
Step 9	**interface** *type slot / subslot / port . subinterface-number* **Example:** `Router(config-pw)# interface gigabitethernet 5/1/0.3`	Configures an interface and enters interface configuration mode.
Step 10	**encapsulation dot1q** *vlan-id* **Example:** `Router(config-if)# encapsulation dot1q 1525`	Enables IEEE 802.1Q encapsulation of traffic on a specified sub interface in a VLAN.
Step 11	**end** **Example:** `Router(config-if)# end`	Exits to privileged EXEC mode.
Step 12	**interface pseudowire** *number* **Example:** `Router(config)# interface pseudowire 100`	Specifies the pseudowire interface and enters interface configuration mode.
Step 13	**source template type pseudowire** *template-name* **Example:** `Router(config-if)# source template type pseudowire atm-eth`	Configures the source template of type pseudowire named atm-eth
Step 14	**neighbor** *peer-address vcid-value* **Example:** `Router(config-if)#  neighbor 10.0.0.100 140`	Specifies the peer IP address and virtual circuit (VC) ID value of a Layer 2 VPN (L2VPN) pseudowire.

	Command or Action	Purpose
Step 15	**exit** **Example:** `Router(config-if)# exit`	Exits to privileged EXEC mode.
Step 16	**l2vpn xconnect context** *context-name* **Example:** `Router(config)# l2vpn xconnect context con1`	Creates a Layer 2 VPN (L2VPN) cross connect context and enters xconnect configuration mode.
Step 17	**member pseudowire** *interface-number* **Example:** `Router(config-xconnect)# member pseudowire 100`	Specifies a member pseudowire to form a Layer 2 VPN (L2VPN) cross connect.
Step 18	**member** *ip-address vc-id* **encapsulation mpls** **Example:** `Router(config-xconnect)# member 10.0.0.100 140 encapsulation mpls`	Creates the VC to transport the Layer 2 packets.
Step 19	**end** **Example:** `Router(config-xconnect)# end`	Exits xconnect configuration mode and returns to privileged EXEC mode.

What to do next

Note In the case of ATM AAl5-to-VLAN, the PE2 router configuration includes the **interworking**command for both bridged and routed interworking.

Note To verify the L2VPN interworking status and check the statistics, refer to the Verifying L2VPN Interworking, on page 968.

Configuring Ethernet VLAN-to-Frame Relay Interworking

This section explains the following AToM configurations and provides examples. The Network Topology for FR-to-Ethernet AToM Bridged Interworking figure above illustrates different AToM configurations.

Frame Relay DLCI-to-Ethernet Port on a PE1 Router

You can configure the Frame Relay DLCI-to-Ethernet Port feature on a PE1 router using the following steps:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls label protocol ldp**
4. **interface** *type number*
5. **ip address** *ip-address mask*
6. **pseudowire-class** [*pw-class-name*]
7. **encapsulation mpls**
8. **interworking ethernet**
9. **interface** *type slot / subslot / port*
10. **encapsulation frame-relay**
11. **connect** *connection-name interface dlci* {*interface dlci* | **l2transport**}
12. **xconnect** *ip-address vc-id* **pw-class** *pw-class-name*
13. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**mpls label protocol ldp** **Example:** `Router(config)# mpls label protocol ldp`	Establishes the label distribution protocol for the platform.
Step 4	**interface** *type number* **Example:** `Router(config)# interface loopback 100`	Configures an interface type and enters interface configuration mode.
Step 5	**ip address** *ip-address mask* **Example:** `Router(config-if)# ip address 10.0.0.100 255.255.255.255`	Sets the primary or secondary IP address for an interface.

	Command or Action	Purpose
Step 6	**pseudowire-class** [*pw-class-name*] **Example:** `Router(config-if)# pseudowire-class fr-eth`	Establishes a pseudowire class with a name that you specify and enters pseudowire class configuration mode.
Step 7	**encapsulation mpls** **Example:** `Router(config-pw)# encapsulation mpls`	Specifies the tunneling encapsulation.
Step 8	**interworking ethernet** **Example:** `Router(config-pw)# interworking ethernet`	Specifies the type of pseudowire and the type of traffic that can flow across it.
Step 9	**interface** *type slot / subslot / port* **Example:** `Router(config-pw)# interface serial 2/0/0`	Configures an interface and enters interface configuration mode.
Step 10	**encapsulation frame-relay** **Example:** `Router(config-if)# encapsulation frame-relay`	Enables Frame Relay encapsulation.
Step 11	**connect** *connection-name interface dlci* {*interface dlci* | **l2transport**} **Example:** `Router(config-if)# connect fr-vlan-1 POS2/3/1 151 l2transport`	Defines the connection between Frame Relay PVCs.
Step 12	**xconnect** *ip-address vc-id* **pw-class** *pw-class-name* **Example:** `Router(config-if)# xconnect 10.0.0.200 151 pw-class pw-class-bridge`	Binds an AC to a pseudowire and configures an AToM static pseudowire.
Step 13	**end** **Example:** `Router(config-if-xconn)# end`	Exits xconnect configuration mode and returns to privileged EXEC mode.

Frame Relay DLCI-to-Ethernet Port on a PE1 Router using the commands associated with the L2VPN Protocol-Based CLIs feature

You can configure the Frame Relay DLCI-to-Ethernet Port feature on a PE1 router using the following steps:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls label protocol ldp**
4. **interface** *type number*
5. **ip address** *ip-address mask*
6. **template type pseudowire** [*pseudowire-name*]
7. **encapsulation mpls**
8. **interworking ethernet**
9. **interface** *type slot / subslot / port*
10. **encapsulation frame-relay**
11. **connect** *connection-name interface dlci* {*interface dlci* | **l2transport**}
12. **end**
13. **interface pseudowire** *number*
14. **source template type pseudowire** *template-name*
15. **neighbor** *peer-address vcid-value*
16. **exit**
17. **l2vpn xconnect context** *context-name*
18. **member pseudowire** *interface-number*
19. **member** *ip-address vc-id* **encapsulation mpls**
20. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**mpls label protocol ldp** **Example:** `Router(config)# mpls label protocol ldp`	Establishes the label distribution protocol for the platform.
Step 4	**interface** *type number* **Example:**	Configures an interface type and enters interface configuration mode.

	Command or Action	Purpose
	`Router(config)# interface loopback 100`	
Step 5	**ip address** *ip-address mask* **Example:** `Router(config-if)# ip address 10.0.0.100 255.255.255.255`	Sets the primary or secondary IP address for an interface.
Step 6	**template type pseudowire** [*pseudowire-name*] **Example:** `Router(config)# template type pseudowire fr-eth`	Specifies the name of a Layer 2 pseudowire class and enters pseudowire class configuration mode.
Step 7	**encapsulation mpls** **Example:** `Router(config-pw)# encapsulation mpls`	Specifies the tunneling encapsulation.
Step 8	**interworking ethernet** **Example:** `Router(config-pw)# interworking ethernet`	Specifies the type of pseudowire and the type of traffic that can flow across it.
Step 9	**interface** *type slot / subslot / port* **Example:** `Router(config-pw)# interface serial 2/0/0`	Configures an interface and enters interface configuration mode.
Step 10	**encapsulation frame-relay** **Example:** `Router(config-if)# encapsulation frame-relay`	Enables Frame Relay encapsulation.
Step 11	**connect** *connection-name interface dlci* {*interface dlci* | **l2transport**} **Example:** `Router(config-if)# connect fr-vlan-1 POS2/3/1 151 l2transport`	Defines the connection between Frame Relay PVCs.
Step 12	**end** **Example:** `Router(config-if)# end`	Exits to privileged EXEC mode.
Step 13	**interface pseudowire** *number* **Example:**	Specifies the pseudowire interface and enters interface configuration mode.

	Command or Action	Purpose
	`Router(config)# interface pseudowire 100`	
Step 14	**source template type pseudowire** *template-name* **Example:** `Router(config-if)# source template type pseudowire pwclass-bridge`	Configures the source template of type pseudowire named pwclass-bridge.
Step 15	**neighbor** *peer-address vcid-value* **Example:** `Router(config-if)# neighbor 10.0.0.200 151`	Specifies the peer IP address and virtual circuit (VC) ID value of a Layer 2 VPN (L2VPN) pseudowire.
Step 16	**exit** **Example:** `Router(config-if)# exit`	Exits to privileged EXEC mode.
Step 17	**l2vpn xconnect context** *context-name* **Example:** `Router(config)# l2vpn xconnect context con1`	Creates a Layer 2 VPN (L2VPN) cross connect context and enters xconnect configuration mode.
Step 18	**member pseudowire** *interface-number* **Example:** `Router(config-xconnect)# member pseudowire 100`	Specifies a member pseudowire to form a Layer 2 VPN (L2VPN) cross connect.
Step 19	**member** *ip-address vc-id* **encapsulation mpls** **Example:** `Router(config-xconnect)# member 10.0.0.200 151 encapsulation mpls`	Creates the VC to transport the Layer 2 packets.
Step 20	**end** **Example:** `Router(config-xconnect)# end`	Exits xconnect configuration mode and returns to privileged EXEC mode.

Frame Relay DLCI-to-Ethernet Port on a PE2 router

You can configure the Frame Relay DLCI-to-Ethernet Port feature on a PE2 router using the following steps:

SUMMARY STEPS

1. **enable**
2. **configure terminal**

3. **mpls label protocol ldp**
4. **interface** *type number*
5. **ip address** *ip-address mask*
6. **pseudowire-class** [*pw-class-name*]
7. **encapsulation mpls**
8. **interworking ethernet**
9. **interface** *type slot / subslot / port*
10. **xconnect** *ip-address vc-id* **pw-class** *pw-class-name*
11. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**mpls label protocol ldp** **Example:** `Router(config)# mpls label protocol ldp`	Establishes the label distribution protocol for the platform.
Step 4	**interface** *type number* **Example:** `Router(config)# interface loopback 100`	Configures an interface type and enters interface configuration mode.
Step 5	**ip address** *ip-address mask* **Example:** `Router(config-if)# ip address 10.0.0.100 255.255.255.255`	Sets the primary or secondary IP address for an interface.
Step 6	**pseudowire-class** [*pw-class-name*] **Example:** `Router(config-if)# pseudowire-class atm-eth`	Establishes a pseudowire class with a name that you specify and enters pseudowire class configuration mode.

	Command or Action	Purpose
Step 7	**encapsulation mpls** **Example:** `Router(config-pw)# encapsulation mpls`	Specifies the tunneling encapsulation.
Step 8	**interworking ethernet** **Example:** `Router(config-pw)# interworking ethernet`	Specifies the type of pseudowire and the type of traffic that can flow across it.
Step 9	**interface** *type slot / subslot / port* **Example:** `Router(config-pw)# interface gigabitethernet 2/0/0`	Configures an interface and enters interface configuration mode.
Step 10	**xconnect** *ip-address vc-id* **pw-class** *pw-class-name* **Example:** `Router(config-if)# xconnect 10.0.0.200 140 pw-class atm-eth`	Binds an AC to a pseudowire and configures an AToM static pseudowire.
Step 11	**end** **Example:** `Router(config-if-xconn)# end`	Exits xconnect configuration mode and returns to privileged EXEC mode.

What to do next

Note When configuring bridged interworking, the PE2 router configuration does not include the **interworking ethernet**command because it is treated as like-to-like, and also because the AC is already an Ethernet port. However, when configuring routed interworking, the PE2 router configuration does include the **interworking ip** command.

Frame Relay DLCI-to-Ethernet Port on a PE2 router using the commands associated with the L2VPN Protocol-Based CLIs feature

You can configure the Frame Relay DLCI-to-Ethernet Port feature on a PE2 router using the following steps:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls label protocol ldp**
4. **interface** *type number*
5. **ip address** *ip-address mask*

6. **template type pseudowire** [*pseudowire-name*]
7. **encapsulation mpls**
8. **interworking ethernet**
9. **interface** *type slot / subslot / port*
10. **end**
11. **interface pseudowire** *number*
12. **source template type pseudowire** *template-name*
13. **neighbor** *peer-address vcid-value*
14. **exit**
15. **l2vpn xconnect context** *context-name*
16. **member pseudowire** *interface-number*
17. **member** *ip-address vc-id* **encapsulation mpls**
18. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**mpls label protocol ldp** **Example:** `Router(config)# mpls label protocol ldp`	Establishes the label distribution protocol for the platform.
Step 4	**interface** *type number* **Example:** `Router(config)# interface loopback 100`	Configures an interface type and enters interface configuration mode.
Step 5	**ip address** *ip-address mask* **Example:** `Router(config-if)# ip address 10.0.0.100 255.255.255.255`	Sets the primary or secondary IP address for an interface.
Step 6	**template type pseudowire** [*pseudowire-name*] **Example:**	Specifies the name of a Layer 2 pseudowire class and enters pseudowire class configuration mode.

	Command or Action	Purpose
	`Router(config)# template type pseudowire atm-eth`	
Step 7	**encapsulation mpls** **Example:** `Router(config-pw)# encapsulation mpls`	Specifies the tunneling encapsulation.
Step 8	**interworking ethernet** **Example:** `Router(config-pw)# interworking ethernet`	Specifies the type of pseudowire and the type of traffic that can flow across it.
Step 9	**interface** *type slot / subslot / port* **Example:** `Router(config-pw)# interface gigabitethernet 2/0/0`	Configures an interface and enters interface configuration mode.
Step 10	**end** **Example:** `Router(config-pw)# end`	Exits to privileged EXEC mode.
Step 11	**interface pseudowire** *number* **Example:** `Router(config)# interface pseudowire 100`	Specifies the pseudowire interface and enters interface configuration mode.
Step 12	**source template type pseudowire** *template-name* **Example:** `Router(config-if)# source template type pseudowire atm-eth`	Configures the source template of type pseudowire named atm-eth
Step 13	**neighbor** *peer-address vcid-value* **Example:** `Router(config-if)#  neighbor 10.0.0.200 140`	Specifies the peer IP address and virtual circuit (VC) ID value of a Layer 2 VPN (L2VPN) pseudowire.
Step 14	**exit** **Example:** `Router(config-if)# exit`	Exits to privileged EXEC mode.
Step 15	**l2vpn xconnect context** *context-name* **Example:** `Router(config)# l2vpn xconnect context con1`	Creates a Layer 2 VPN (L2VPN) cross connect context and enters xconnect configuration mode.

	Command or Action	Purpose
Step 16	**member pseudowire** *interface-number* **Example:** `Router(config-xconnect)# member pseudowire 100`	Specifies a member pseudowire to form a Layer 2 VPN (L2VPN) cross connect.
Step 17	**member** *ip-address vc-id* **encapsulation mpls** **Example:** `Router(config-xconnect)# member 10.0.0.200 140 encapsulation mpls`	Creates the VC to transport the Layer 2 packets.
Step 18	**end** **Example:** `Router(config-xconnect)# end`	Exits xconnect configuration mode and returns to privileged EXEC mode.

What to do next

Note When configuring bridged interworking, the PE2 router configuration does not include the **interworking ethernet**command because it is treated as like-to-like, and also because the AC is already an Ethernet port. However, when configuring routed interworking, the PE2 router configuration does include the **interworking ip** command.

Frame Relay DLCI-to-Ethernet VLAN 802.1Q on a PE1 Router

To configure the Frame Relay DLCI-to-Ethernet VLAN 802.1Q feature on a PE1 router, use the following steps:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls label protocol ldp**
4. **interface** *type number*
5. **ip address** *ip-address mask*
6. **pseudowire-class** [*pw-class-name*]
7. **encapsulation mpls**
8. **interworking** {**ethernet** | **ip**}
9. **frame-relay switching**
10. **interface** *type slot* / *subslot* / *port*
11. **encapsulation frame-relay**
12. **frame-relay intf-type** [**dce**]
13. **connect** *connection-name interface dlci* {*interface dlci* | **l2transport**}
14. **xconnect** *ip-address vc-id* **pw-class** *pw-class-name*

15. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**mpls label protocol ldp** **Example:** `Router(config)# mpls label protocol ldp`	Establishes the label distribution protocol for the platform.
Step 4	**interface** *type number* **Example:** `Router(config)# interface loopback 100`	Configures an interface type and enters interface configuration mode.
Step 5	**ip address** *ip-address mask* **Example:** `Router(config-if)# ip address 10.0.0.100 255.255.255.255`	Sets the primary or secondary IP address for an interface.
Step 6	**pseudowire-class** [*pw-class-name*] **Example:** `Router(config-if)# pseudowire-class atm-eth`	Establishes a pseudowire class with a name that you specify and enters pseudowire class configuration mode.
Step 7	**encapsulation mpls** **Example:** `Router(config-pw)# encapsulation mpls`	Specifies the tunneling encapsulation.
Step 8	**interworking** {**ethernet** | **ip**} **Example:** `Router(config-pw)# interworking ip`	Specifies the type of pseudowire and the type of traffic that can flow across it.

	Command or Action	Purpose
Step 9	**frame-relay switching** **Example:** `Router(config-pw)# frame-relay switching`	Enables PVC switching on a Frame Relay DCE device.
Step 10	**interface** *type slot / subslot / port* **Example:** `Router(config-pw)# interface serial 2/0/0`	Configures an interface and enters interface configuration mode.
Step 11	**encapsulation frame-relay** **Example:** `Router(config-if)# encapsulation frame-relay`	Enables Frame Relay encapsulation.
Step 12	**frame-relay intf-type** [**dce**] **Example:** `Router(config-if)# frame-relay intf-type dce`	Configures a Frame Relay switch type.
Step 13	**connect** *connection-name interface dlci* {*interface dlci* | **l2transport**} **Example:** `Router(config-if)# connect one serial0 16 serial1 100`	Defines the connection between Frame Relay PVCs.
Step 14	**xconnect** *ip-address vc-id* **pw-class** *pw-class-name* **Example:** `Router(config-if)# xconnect 10.0.0.200 140 pw-class atm-eth`	Binds an AC to a pseudowire and configures an AToM static pseudowire.
Step 15	**end** **Example:** `Router(config-if-xconn)# end`	Exits xconnect configuration mode and returns to privileged EXEC mode.

Frame Relay DLCI-to-Ethernet VLAN 802.1Q on a PE1 Router using the commands associated with the L2VPN Protocol-Based CLIs feature

To configure the Frame Relay DLCI-to-Ethernet VLAN 802.1Q feature on a PE1 router, use the following steps:

SUMMARY STEPS

1. **enable**

2. **configure terminal**
3. **mpls label protocol ldp**
4. **interface** *type number*
5. **ip address** *ip-address mask*
6. **template type pseudowire** [*pseudowire-name*]
7. **encapsulation mpls**
8. **interworking** {**ethernet** | **ip**}
9. **frame-relay switching**
10. **interface** *type slot / subslot / port*
11. **encapsulation frame-relay**
12. **frame-relay intf-type** [**dce**]
13. **connect** *connection-name interface dlci* {*interface dlci* | **l2transport**}
14. **end**
15. **interface pseudowire** *number*
16. **source template type pseudowire** *template-name*
17. **neighbor** *peer-address vcid-value*
18. **exit**
19. **l2vpn xconnect context** *context-name*
20. **member pseudowire** *interface-number*
21. **member** *ip-address vc-id* **encapsulation mpls**
22. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**mpls label protocol ldp** **Example:** `Router(config)# mpls label protocol ldp`	Establishes the label distribution protocol for the platform.
Step 4	**interface** *type number* **Example:** `Router(config)# interface loopback 100`	Configures an interface type and enters interface configuration mode.

	Command or Action	Purpose
Step 5	**ip address** *ip-address mask* **Example:** `Router(config-if)# ip address 10.0.0.100 255.255.255.255`	Sets the primary or secondary IP address for an interface.
Step 6	**template type pseudowire** [*pseudowire-name*] **Example:** `Router(config)# template type pseudowire atm-eth`	Specifies the name of a Layer 2 pseudowire class and enters pseudowire class configuration mode.
Step 7	**encapsulation mpls** **Example:** `Router(config-pw)# encapsulation mpls`	Specifies the tunneling encapsulation.
Step 8	**interworking** {**ethernet** | **ip**} **Example:** `Router(config-pw)# interworking ip`	Specifies the type of pseudowire and the type of traffic that can flow across it.
Step 9	**frame-relay switching** **Example:** `Router(config-pw)# frame-relay switching`	Enables PVC switching on a Frame Relay DCE device.
Step 10	**interface** *type slot / subslot / port* **Example:** `Router(config-pw)# interface serial 2/0/0`	Configures an interface and enters interface configuration mode.
Step 11	**encapsulation frame-relay** **Example:** `Router(config-if)# encapsulation frame-relay`	Enables Frame Relay encapsulation.
Step 12	**frame-relay intf-type** [**dce**] **Example:** `Router(config-if)# frame-relay intf-type dce`	Configures a Frame Relay switch type.
Step 13	**connect** *connection-name interface dlci* {*interface dlci* | **l2transport**} **Example:** `Router(config-if)# connect one serial0 16 serial1 100`	Defines the connection between Frame Relay PVCs.

	Command or Action	Purpose
Step 14	**end** **Example:** `Router(config-if)# end`	Exits to privileged EXEC mode.
Step 15	**interface pseudowire** *number* **Example:** `Router(config)# interface pseudowire 100`	Specifies the pseudowire interface and enters interface configuration mode.
Step 16	**source template type pseudowire** *template-name* **Example:** `Router(config-if)# source template type pseudowire atm-eth`	Configures the source template of type pseudowire named atm-eth
Step 17	**neighbor** *peer-address vcid-value* **Example:** `Router(config-if)# neighbor 10.0.0.200 140`	Specifies the peer IP address and virtual circuit (VC) ID value of a Layer 2 VPN (L2VPN) pseudowire.
Step 18	**exit** **Example:** `Router(config-if)# exit`	Exits to privileged EXEC mode.
Step 19	**l2vpn xconnect context** *context-name* **Example:** `Router(config)# l2vpn xconnect context con1`	Creates a Layer 2 VPN (L2VPN) cross connect context and enters xconnect configuration mode.
Step 20	**member pseudowire** *interface-number* **Example:** `Router(config-xconnect)# member pseudowire 100`	Specifies a member pseudowire to form a Layer 2 VPN (L2VPN) cross connect.
Step 21	**member** *ip-address vc-id* **encapsulation mpls** **Example:** `Router(config-xconnect)# member 10.0.0.200 140 encapsulation mpls`	Creates the VC to transport the Layer 2 packets.
Step 22	**end** **Example:** `Router(config-xconnect)# end`	Exits xconnect configuration mode and returns to privileged EXEC mode.

Frame Relay DLCI-to-Ethernet VLAN 802.1Q on a PE2 Router

To configure the Frame Relay DLCI-to-Ethernet VLAN 802.1Q feature on a PE2 router, use the following steps:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls label protocol ldp**
4. **interface** *type number*
5. **ip address** *ip-address mask*
6. **pseudowire-class** [*pw-class-name*]
7. **encapsulation mpls**
8. **interworking** {**ethernet** | **ip**}
9. **interface** *type slot* / *subslot* / *port* . *subinterface-number*
10. **encapsulation dot1q** *vlan-id*
11. **xconnect** *ip-address vc-id* **pw-class** *pw-class-name*
12. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	**mpls label protocol ldp** **Example:** `Router(config)# mpls label protocol ldp`	Establishes the label distribution protocol for the platform.
Step 4	**interface** *type number* **Example:** `Router(config)# interface loopback 100`	Configures an interface type and enters interface configuration mode.
Step 5	**ip address** *ip-address mask* **Example:**	Sets the primary or secondary IP address for an interface.

	Command or Action	Purpose
	`Router(config-if)# ip address 10.0.0.100 255.255.255.255`	
Step 6	**pseudowire-class** [*pw-class-name*] **Example:** `Router(config-if)# pseudowire-class atm-eth`	Establishes a pseudowire class with a name that you specify and enters pseudowire class configuration mode.
Step 7	**encapsulation mpls** **Example:** `Router(config-pw)# encapsulation mpls`	Specifies the tunneling encapsulation.
Step 8	**interworking** {**ethernet** | **ip**} **Example:** `Router(config-pw)# interworking ip`	Specifies the type of pseudowire and the type of traffic that can flow across it.
Step 9	**interface** *type slot / subslot / port . subinterface-number* **Example:** `Router(config-pw)# interface gigabitethernet 5/1/0.3`	Configures an interface and enters interface configuration mode.
Step 10	**encapsulation dot1q** *vlan-id* **Example:** `Router(config-if)# encapsulation dot1q 1525`	Enables IEEE 802.1Q encapsulation of traffic on a specified subinterface in a VLAN.
Step 11	**xconnect** *ip-address vc-id* **pw-class** *pw-class-name* **Example:** `Router(config-if)# xconnect 10.0.0.100 140 pw-class atm-eth`	Binds an AC to a pseudowire and configures an AToM static pseudowire.
Step 12	**end** **Example:** `Router(config-if-xconn)# end`	Exits xconnect configuration mode and returns to privileged EXEC mode.

What to do next

Note In the case of an Frame Relay DLCI-to-VLAN, the PE2 router configuration includes the **interworking**command for both bridged and routed interworking.

Note To verify the L2VPN interworking status and check the statistics, refer to the Verifying L2VPN Interworking, on page 968.

Frame Relay DLCI-to-Ethernet VLAN 802.1Q on a PE2 Router using the commands associated with the L2VPN Protocol-Based CLIs feature

To configure the Frame Relay DLCI-to-Ethernet VLAN 802.1Q feature on a PE2 router, use the following steps:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls label protocol ldp**
4. **interface** *type number*
5. **ip address** *ip-address mask*
6. **pseudowire-class** [*pw-class-name*]
7. **encapsulation mpls**
8. **interworking** {**ethernet** | **ip**}
9. **interface** *type slot / subslot / port . subinterface-number*
10. **encapsulation dot1q** *vlan-id*
11. **end**
12. **interface pseudowire** *number*
13. **source template type pseudowire** *template-name*
14. **exit**
15. **l2vpn xconnect context** *context-name*
16. **member pseudowire** *interface-number*
17. **member** *ip-address vc-id* **encapsulation mpls**
18. **interworking ip**
19. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:**	Enters global configuration mode.

	Command or Action	Purpose
	`Router# configure terminal`	
Step 3	**mpls label protocol ldp** **Example:** `Router(config)# mpls label protocol ldp`	Establishes the label distribution protocol for the platform.
Step 4	**interface** *type number* **Example:** `Router(config)# interface loopback 100`	Configures an interface type and enters interface configuration mode.
Step 5	**ip address** *ip-address mask* **Example:** `Router(config-if)# ip address 10.0.0.100 255.255.255.255`	Sets the primary or secondary IP address for an interface.
Step 6	**pseudowire-class** [*pw-class-name*] **Example:** `Router(config-if)# pseudowire-class atm-eth`	Establishes a pseudowire class with a name that you specify and enters pseudowire class configuration mode.
Step 7	**encapsulation mpls** **Example:** `Router(config-pw)# encapsulation mpls`	Specifies the tunneling encapsulation.
Step 8	**interworking** {**ethernet** | **ip**} **Example:** `Router(config-pw)# interworking ip`	Specifies the type of pseudowire and the type of traffic that can flow across it.
Step 9	**interface** *type slot / subslot / port . subinterface-number* **Example:** `Router(config-pw)# interface gigabitethernet 5/1/0.3`	Configures an interface and enters interface configuration mode.
Step 10	**encapsulation dot1q** *vlan-id* **Example:** `Router(config-if)# encapsulation dot1q 1525`	Enables IEEE 802.1Q encapsulation of traffic on a specified subinterface in a VLAN.
Step 11	**end** **Example:**	Exits to privileged EXEC mode.

	Command or Action	Purpose
	`Router(config-if)# end`	
Step 12	**interface pseudowire** *number* **Example:** `Router(config)# interface pseudowire 100`	Specifies the pseudowire interface and enters interface configuration mode.
Step 13	**source template type pseudowire** *template-name* **Example:** `Router(config-if)# source template type pseudowire ether-pw`	Configures the source template of type pseudowire named ether-pw.
Step 14	**exit** **Example:** `Router(config-if)# exit`	Exits to privileged EXEC mode.
Step 15	**l2vpn xconnect context** *context-name* **Example:** `Router(config)# l2vpn xconnect context con1`	Creates a Layer 2 VPN (L2VPN) cross connect context and enters xconnect configuration mode.
Step 16	**member pseudowire** *interface-number* **Example:** `Router(config-xconnect)# member pseudowire 100`	Specifies a member pseudowire to form a Layer 2 VPN (L2VPN) cross connect.
Step 17	**member** *ip-address vc-id* **encapsulation mpls** **Example:** `Router(config-xconnect)# member 10.0.0.100 140 encapsulation mpls`	Creates the VC to transport the Layer 2 packets.
Step 18	**interworking ip** **Example:** `Router(config-xconnect)# interworking ip`	Establishes an L2VPN cross connect context.
Step 19	**end** **Example:** `Router(config-xconnect)# end`	Exits xconnect configuration mode and returns to privileged EXEC mode.

What to do next

Note In the case of an Frame Relay DLCI-to-VLAN, the PE2 router configuration includes the **interworking**command for both bridged and routed interworking.

Note To verify the L2VPN interworking status and check the statistics, refer to the Verifying L2VPN Interworking, on page 968.

Configuring HDLC-to-Ethernet Interworking

HDLC-to-Ethernet Bridged Interworking on a HDLC PE Device

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **pseudowire-class** [*pw-class-name*]
4. **encapsulation mpls**
5. **interworking ethernet**
6. **interface** *type slot/subslot /port* [**.** *subinterface*]
7. **no ip address** [*ip-address mask*] [**secondary**]
8. **xconnect** *peer-router-id vc id* **pseudowire-class** [*pw-class-name*]
9. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**pseudowire-class** [*pw-class-name*] **Example:** `Device(config)# pseudowire-class pw-iw-ether`	Specifies the name of a Layer 2 pseudowire class and enters pseudowire class configuration mode.

	Command or Action	Purpose
Step 4	**encapsulation mpls** **Example:** `Device(config-pw-class)# encapsulation mpls`	Specifies the tunneling encapsulation as MPLS.
Step 5	**interworking ethernet** **Example:** `Device(config-pw-class)# interworking ethernet`	Specifies Ethernet as the type of pseudowire as well as the type of traffic that can flow across the pseudowire.
Step 6	**interface** *type slot/subslot /port* [**.** *subinterface*] **Example:** `Device(config-pw-class)# interface serial 3/1/0`	Specifies a serial interface and enters interface configuration mode.
Step 7	**no ip address** [*ip-address mask*] [**secondary**] **Example:** `Device(config-if)# no ip address`	Disables IP processing.
Step 8	**xconnect** *peer-router-id vc id* **pseudowire-class** [*pw-class-name*] **Example:** `Device(config-if)# xconnect 198.51.100.2 123 pseudowire-class pw-iw-ether`	Creates the virtual circuit (VC) to transport the Layer 2 packets.
Step 9	**end** **Example:** `Device(config-if)# end`	Exits interface configuration mode and returns to privileged EXEC mode.

HDLC-to-Ethernet Bridged Interworking on a HDLC PE Device Using the Commands Associated with the L2VPN Protocol-Based CLIs Feature

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **template type pseudowire** *name*
4. **encapsulation mpls**
5. **exit**
6. **interface pseudowire** *number*
7. **source template type pseudowire** *name*
8. **encapsulation mpls**
9. **neighbor** *peer-address vc id-value*
10. **signaling protocol ldp**

11. **no shutdown**
12. **exit**
13. **l2vpn xconnect context** *context-name*
14. **interworking ethernet**
15. **member** *interface-type-number*
16. **member pseudowire** *interface-number*
17. **no shutdown**
18. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**template type pseudowire** *name* **Example:** `Device# template type pseudowire temp5`	Creates a template pseudowire with a name that you specify and enters template configuration mode.
Step 4	**encapsulation mpls** **Example:** `Device(config-template)# encapsulation mpls`	Specifies the tunneling encapsulation as MPLS.
Step 5	**exit** **Example:** `Device(config-template)# exit`	Exits template configuration mode and returns to global configuration mode.
Step 6	**interface pseudowire** *number* **Example:** `Device(config)# interface pseudowire 107`	Establishes an interface pseudowire with a value that you specify and enters interface configuration mode.
Step 7	**source template type pseudowire** *name* **Example:** `Device(config-if)# source template type pseudowire temp5`	Configures the source template of type pseudowire named temp5.
Step 8	**encapsulation mpls** **Example:**	Specifies the tunneling encapsulation as MPLS.

	Command or Action	Purpose
	`Device(config-if)# encapsulation mpls`	
Step 9	**neighbor** *peer-address vc id-value* **Example:** `Device(config-if)# neighbor 10.0.0.11 107`	Specifies the peer IP address and virtual circuit (VC) ID value of an L2VPN pseudowire.
Step 10	**signaling protocol ldp** **Example:** `Device(config-if)# signaling protocol ldp`	Specifies that the Label Distribution Protocol (LDP) is configured for the pseudowire class.
Step 11	**no shutdown** **Example:** `Device(config-if)# no shutdown`	Restarts the interface pseudowire.
Step 12	**exit** **Example:** `Device(config-if)# exit`	Exits interface configuration mode and returns to global configuration mode.
Step 13	**l2vpn xconnect context** *context-name* **Example:** `Device(config)# l2vpn xconnect context con1`	Creates an L2VPN cross-connect context and enters xconnect configuration mode.
Step 14	**interworking ethernet** **Example:** `Device(config-xconnect)# interworking ethernet`	Specifies Ethernet as the type of pseudowire as well as the type of traffic that can flow across the pseudowire.
Step 15	**member** *interface-type-number* **Example:** `Device(config-xconnect)# member serial 0/1/0:0`	Specifies the location of the member interface.
Step 16	**member pseudowire** *interface-number* **Example:** `Device(config-xconnect)# member pseudowire 107`	Specifies a member pseudowire to form an L2VPN cross connect.
Step 17	**no shutdown** **Example:** `Device(config-xconnect)# no shutdown`	Restarts the member interface.
Step 18	**end** **Example:** `Device(config-xconnect)# end`	Exits xconnect configuration mode and returns to privileged EXEC mode.

HDLC-to-Ethernet Bridged Interworking (Port Mode) on an Ethernet PE Device

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **pseudowire-class** [*pw-class-name*]
4. **encapsulation mpls**
5. **interworking ethernet**
6. **interface** *type slot/subslot /port* [**.** *subinterface*]
7. **encapsulation mpls**
8. **xconnect** *peer-router-id vc id* **pseudowire-class** [*pw-class-name*]
9. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**pseudowire-class** [*pw-class-name*] **Example:** `Device(config)# pseudowire-class pw-iw-ether`	Specifies the name of a Layer 2 pseudowire class and enters pseudowire class configuration mode.
Step 4	**encapsulation mpls** **Example:** `Device(config-pw-class)# encapsulation mpls`	Specifies the tunneling encapsulation as MPLS.
Step 5	**interworking ethernet** **Example:** `Device(config-pw-class)# interworking ethernet`	Specifies Ethernet as the type of pseudowire as well as the type of traffic that can flow across the pseudowire.
Step 6	**interface** *type slot/subslot /port* [**.** *subinterface*] **Example:** `Device(config-pw-class)# interface gigabitethernet 4/0/0.1`	Specifies the Gigabit Ethernet subinterface and enters subinterface configuration mode. • Ensure that the subinterface on the adjoining Ethernet CE device is on the same VLAN as this Ethernet PE device.

	Command or Action	Purpose
Step 7	**encapsulation mpls** **Example:** `Device(config-subif)# encapsulation mpls`	Specifies the tunneling encapsulation as MPLS.
Step 8	**xconnect** *peer-router-id vc id* **pseudowire-class** [*pw-class-name*] **Example:** `Device(config-subif)# xconnect 198.51.100.2 123 pseudowire-class pw-iw-ether`	Creates the virtual circuit (VC) to transport the Layer 2 packets.
Step 9	**end** **Example:** `Device(config-subif)# end`	Exits subinterface configuration mode and returns to privileged EXEC mode.

23. end

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**interface** *type slot/subslot /port* [**.** *subinterface*] **Example:** `Device(config)# interface fastethernet 4/0/0.1`	Specifies the subinterface and enters subinterface configuration mode. • Ensure that the subinterface on the adjoining Ethernet CE device is on the same VLAN as this Ethernet PE device.
Step 4	**encapsulation mpls** **Example:** `Device(config-subif)# encapsulation mpls`	Specifies the tunneling encapsulation as MPLS.
Step 5	**no ip address** **Example:** `Device(config-subif)# no ip address`	Disables IP processing.
Step 6	**no shutdown** **Example:** `Device(config-subif)# no shutdown`	Restarts the Fast Ethernet subinterface.
Step 7	**exit** **Example:** `Device(config-subif)# exit`	Exits subinterface configuration mode and returns to global configuration mode.
Step 8	**template type pseudowire** *name* **Example:** `Device(config)# template type pseudowire temp4`	Creates a template pseudowire with a name that you specify and enters template configuration mode.
Step 9	**encapsulation mpls** **Example:** `Device(config-template)# encapsulation mpls`	Specifies the tunneling encapsulation as MPLS.

	Command or Action	Purpose
Step 10	**exit** **Example:** `Device(config-template)# exit`	Exits template configuration mode and returns to global configuration mode.
Step 11	**interface pseudowire** *number* **Example:** `Device(config)# interface pseudowire 109`	Establishes an interface pseudowire with a value that you specify and enters interface configuration mode.
Step 12	**source template type pseudowire** *name* **Example:** `Device(config-if)# source template type pseudowire temp4`	Configures the source template of type pseudowire named temp4.
Step 13	**encapsulation mpls** **Example:** `Device(config-if)# encapsulation mpls`	Specifies the tunneling encapsulation as MPLS.
Step 14	**neighbor** *peer-address vc id-value* **Example:** `Device(config-if)# neighbor 10.0.0.15 109`	Specifies the peer IP address and virtual circuit (VC) ID value of an L2VPN pseudowire.
Step 15	**signaling protocol ldp** **Example:** `Device(config-if)# signaling protocol ldp`	Specifies that the Label Distribution Protocol (LDP) is configured for the pseudowire class.
Step 16	**no shutdown** **Example:** `Device(config-if)# no shutdown`	Restarts the interface pseudowire.
Step 17	**exit** **Example:** `Device(config-if)# exit`	Exits interface configuration mode and returns to global configuration mode.
Step 18	**l2vpn xconnect context** *context-name* **Example:** `Device(config)# l2vpn xconnect context con2`	Creates an L2VPN cross-connect context and enters xconnect configuration mode.
Step 19	**interworking ethernet** **Example:** `Device(config-xconnect)# interworking ethernet`	Specifies Ethernet as the type of pseudowire as well as the type of traffic that can flow across the pseudowire.
Step 20	**member** *interface-type-number* **Example:**	Specifies the location of the member interface.

	Command or Action	Purpose
	`Device(config-xconnect)# member fastethernet 4/0/0.1`	
Step 21	**member pseudowire** *interface-number* **Example:** `Device(config-xconnect)# member pseudowire 109`	Specifies a member pseudowire to form an L2VPN cross connect.
Step 22	**no shutdown** **Example:** `Device(config-xconnect)# no shutdown`	Restarts the member interface.
Step 23	**end** **Example:** `Device(config-xconnect)# end`	Exits xconnect configuration mode and returns to privileged EXEC mode.

HDLC-to-Ethernet Bridged Interworking (dot1q and QinQ Modes) on an Ethernet PE Device

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **pseudowire-class** [*pw-class-name*]
4. **encapsulation mpls**
5. **interworking ethernet**
6. **interface** *type slot/subslot /port* [**.** *subinterface*]
7. **encapsulation dot1q** *vlan-id***second dot1q** *vlan-id*
8. **xconnect** *peer-router-id vc id* **pseudowire-class** [*pw-class-name*]
9. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.

	Command or Action	Purpose
Step 3	**pseudowire-class** [*pw-class-name*] **Example:** `Device(config)# pseudowire-class pw-iw-ether`	Specifies the name of a Layer 2 pseudowire class and enters pseudowire class configuration mode.
Step 4	**encapsulation mpls** **Example:** `Device(config-pw-class)# encapsulation mpls`	Specifies the tunneling encapsulation as MPLS.
Step 5	**interworking ethernet** **Example:** `Device(config-pw-class)# interworking ethernet`	Specifies Ethernet as the type of pseudowire as well as the type of traffic that can flow across the pseudowire.
Step 6	**interface** *type slot/subslot /port* [**.** *subinterface*] **Example:** `Device(config-pw-class)# interface gigabitethernet 4/0/0.1`	Specifies the Gigabit Ethernet subinterface and enters subinterface configuration mode. • Ensure that the subinterface on the adjoining Ethernet CE device is on the same VLAN as this Ethernet PE device.
Step 7	**encapsulation dot1q** *vlan-id***second dot1q** *vlan-id* **Example:** `Device(config-subif)# encapsulation dot1q 100 second dot1q 200`	Defines the matching criteria to map QinQ ingress frames on an interface to the appropriate service instance.
Step 8	**xconnect** *peer-router-id vc id* **pseudowire-class** [*pw-class-name*] **Example:** `Device(config-subif)# xconnect 198.51.100.2 123 pseudowire-class pw-iw-ether`	Creates the virtual circuit (VC) to transport the Layer 2 packets.
Step 9	**end** **Example:** `Device(config-subif)# end`	Exits subinterface configuration mode and returns to privileged EXEC mode.

HDLC-to-Ethernet Bridged Interworking (dot1q and QinQ Modes) on an Ethernet PE Device Using the Commands Associated with the L2VPN Protocol-Based CLIs Feature

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type slot/subslot /port* [**.** *subinterface*]

4. **encapsulation dot1q** *vlan-id* **second dot1q** *vlan-id*
5. **no ip address**
6. **no shutdown**
7. **exit**
8. **template type pseudowire** *name*
9. **encapsulation mpls**
10. **exit**
11. **interface pseudowire** *number*
12. **source template type pseudowire** *name*
13. **encapsulation mpls**
14. **neighbor** *peer-address vc id-value*
15. **signaling protocol ldp**

18. **l2vpn xconnect context** *context-name*
19. **interworking ethernet**
20. **member** *interface-type-number*
21. **member pseudowire** *interface-number*
22. **no shutdown**
23. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**interface** *type slot/subslot /port* [**.** *subinterface*] **Example:** `Device(config)# interface fastethernet 4/0/0.1`	Specifies the subinterface and enters subinterface configuration mode. • Ensure that the subinterface on the adjoining Ethernet CE device is on the same VLAN as this Ethernet PE device.
Step 4	**encapsulation dot1q** *vlan-id* **second dot1q** *vlan-id* **Example:** `Device(config-subif)# encapsulation dot1q 100 second dot1q 200`	Defines the matching criteria to map QinQ ingress frames on an interface to the appropriate service instance.

	Command or Action	Purpose
Step 5	**no ip address** **Example:** `Device(config-subif)# no ip address`	Disables IP processing.
Step 6	**no shutdown** **Example:** `Device(config-subif)# no shutdown`	Restarts the Fast Ethernet subinterface.
Step 7	**exit** **Example:** `Device(config-subif)# exit`	Exits subinterface configuration mode and returns to global configuration mode.
Step 8	**template type pseudowire** *name* **Example:** `Device(config)# template type pseudowire temp4`	Creates a template pseudowire with a name that you specify and enters template configuration mode.
Step 9	**encapsulation mpls** **Example:** `Device(config-template)# encapsulation mpls`	Specifies the tunneling encapsulation as MPLS.
Step 10	**exit** **Example:** `Device(config-template)# exit`	Exits template configuration mode and returns to global configuration mode.
Step 11	**interface pseudowire** *number* **Example:** `Device(config)# interface pseudowire 109`	Establishes an interface pseudowire with a value that you specify and enters interface configuration mode.
Step 12	**source template type pseudowire** *name* **Example:** `Device(config-if)# source template type pseudowire temp4`	Configures the source template of type pseudowire named temp4.
Step 13	**encapsulation mpls** **Example:** `Device(config-if)# encapsulation mpls`	Specifies the tunneling encapsulation as MPLS.
Step 14	**neighbor** *peer-address vc id-value* **Example:** `Device(config-if)# neighbor 10.0.0.15 109`	Specifies the peer IP address and virtual circuit (VC) ID value of an L2VPN pseudowire.
Step 15	**signaling protocol ldp** **Example:**	Specifies that the Label Distribution Protocol (LDP) is configured for the pseudowire class.

	Command or Action	Purpose
	`Device(config-if)# signaling protocol ldp`	
Step 16	**no shutdown** **Example:** `Device(config-if)# no shutdown`	Restarts the interface pseudowire.
Step 17	**exit** **Example:** `Device(config-if)# exit`	Exits interface configuration mode and returns to global configuration mode.
Step 18	**l2vpn xconnect context** *context-name* **Example:** `Device(config)# l2vpn xconnect context con2`	Creates an L2VPN cross-connect context and enters xconnect configuration mode.
Step 19	**interworking ethernet** **Example:** `Device(config-xconnect)# interworking ethernet`	Specifies Ethernet as the type of pseudowire as well as the type of traffic that can flow across the pseudowire.
Step 20	**member** *interface-type-number* **Example:** `Device(config-xconnect)# member fastethernet 4/0/0.1`	Specifies the location of the member interface.
Step 21	**member pseudowire** *interface-number* **Example:** `Device(config-xconnect)# member pseudowire 109`	Specifies a member pseudowire to form an L2VPN cross connect.
Step 22	**no shutdown** **Example:** `Device(config-xconnect)# no shutdown`	Restarts the member interface.
Step 23	**end** **Example:** `Device(config-xconnect)# end`	Exits xconnect configuration mode and returns to privileged EXEC mode.

HDLC-to-Ethernet Routed Interworking on a HDLC PE Device

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **pseudowire-class** [*pw-class-name*]
4. **encapsulation mpls**
5. **interworking ip**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.

	Command or Action	Purpose
Step 3	**template type pseudowire** *name* **Example:** `Device# template type pseudowire temp5`	Creates a template pseudowire with a name that you specify and enters template configuration mode.
Step 4	**encapsulation mpls** **Example:** `Device(config-template)# encapsulation mpls`	Specifies the tunneling encapsulation as MPLS.
Step 5	**exit** **Example:** `Device(config-template)# exit`	Exits template configuration mode and returns to global configuration mode.
Step 6	**interface pseudowire** *number* **Example:** `Device(config)# interface pseudowire 107`	Establishes an interface pseudowire with a value that you specify and enters interface configuration mode.
Step 7	**source template type pseudowire** *name* **Example:** `Device(config-if)# source template type pseudowire temp5`	Configures the source template of type pseudowire named temp5.
Step 8	**encapsulation mpls** **Example:** `Device(config-if)# encapsulation mpls`	Specifies the tunneling encapsulation as MPLS.
Step 9	**neighbor** *peer-address vc id-value* **Example:** `Device(config-if)# neighbor 10.0.0.11 107`	Specifies the peer IP address and virtual circuit (VC) ID value of an L2VPN pseudowire.
Step 10	**signaling protocol ldp** **Example:** `Device(config-if)# signaling protocol ldp`	Specifies that the Label Distribution Protocol (LDP) is configured for the pseudowire class.
Step 11	**no shutdown** **Example:** `Device(config-if)# no shutdown`	Restarts the interface pseudowire.
Step 12	**exit** **Example:** `Device(config-if)# exit`	Exits interface configuration mode and returns to global configuration mode.
Step 13	**l2vpn xconnect context** *context-name* **Example:**	Creates an L2VPN cross-connect context and enters xconnect configuration mode.

	Command or Action	Purpose
	`Device(config)# l2vpn xconnect context con1`	
Step 14	**interworking ip** **Example:** `Device(config-xconnect)# interworking ip`	Specifies IP as the type of pseudowire as well as the type of traffic that can flow across the pseudowire.
Step 15	**member** *interface-type-number* **Example:** `Device(config-xconnect)# member serial 0/1/0:0`	Specifies the location of the member interface.
Step 16	**member pseudowire** *interface-number* **Example:** `Device(config-xconnect)# member pseudowire 107`	Specifies a member pseudowire to form an L2VPN cross connect.
Step 17	**no shutdown** **Example:** `Device(config-xconnect)# no shutdown`	Restarts the member interface.
Step 18	**end** **Example:** `Device(config-xconnect)# end`	Exits xconnect configuration mode and returns to privileged EXEC mode.

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**interface** *type slot/subslot /port* [**.** *subinterface*] **Example:** `Device(config)# interface fastethernet 4/0/0.1`	Specifies the subinterface and enters subinterface configuration mode. • Ensure that the subinterface on the adjoining Ethernet CE device is on the same VLAN as this Ethernet PE device.
Step 4	**encapsulation dot1q** *vlan-id* **second dot1q** *vlan-id* **Example:** `Device(config-subif)# encapsulation dot1q 100 second dot1q 200`	Defines the matching criteria to map QinQ ingress frames on an interface to the appropriate service instance.
Step 5	**no ip address** **Example:** `Device(config-subif)# no ip address`	Disables IP processing.
Step 6	**no shutdown** **Example:** `Device(config-subif)# no shutdown`	Restarts the Fast Ethernet subinterface.
Step 7	**exit** **Example:** `Device(config-subif)# exit`	Exits subinterface configuration mode and returns to global configuration mode.
Step 8	**template type pseudowire** *name* **Example:** `Device(config)# template type pseudowire temp4`	Creates a template pseudowire with a name that you specify and enters template configuration mode.
Step 9	**encapsulation mpls** **Example:**	Specifies the tunneling encapsulation as MPLS.

	Command or Action	Purpose
	`Device(config-template)# encapsulation mpls`	
Step 10	**exit** **Example:** `Device(config-template)# exit`	Exits template configuration mode and returns to global configuration mode.
Step 11	**interface pseudowire** *number* **Example:** `Device(config)# interface pseudowire 109`	Establishes an interface pseudowire with a value that you specify and enters interface configuration mode.
Step 12	**source template type pseudowire** *name* **Example:** `Device(config-if)# source template type pseudowire temp4`	Configures the source template of type pseudowire named temp4.
Step 13	**encapsulation mpls** **Example:** `Device(config-if)# encapsulation mpls`	Specifies the tunneling encapsulation as MPLS.
Step 14	**neighbor** *peer-address vc id-value* **Example:** `Device(config-if)# neighbor 10.0.0.15 109`	Specifies the peer IP address and virtual circuit (VC) ID value of an L2VPN pseudowire.
Step 15	**signaling protocol ldp** **Example:** `Device(config-if)# signaling protocol ldp`	Specifies that the Label Distribution Protocol (LDP) is configured for the pseudowire class.
Step 16	**no shutdown** **Example:** `Device(config-if)# no shutdown`	Restarts the interface pseudowire.
Step 17	**exit** **Example:** `Device(config-if)# exit`	Exits interface configuration mode and returns to global configuration mode.
Step 18	**l2vpn xconnect context** *context-name* **Example:** `Device(config)# l2vpn xconnect context con2`	Creates an L2VPN cross-connect context and enters xconnect configuration mode.
Step 19	**interworking ip** **Example:** `Device(config-xconnect)# interworking ip`	Specifies IP as the type of pseudowire as well as the type of traffic that can flow across the pseudowire.

	Command or Action	Purpose
Step 20	**member** *interface-type-number* **Example:** `Device(config-xconnect)# member fastethernet 4/0/0.1`	Specifies the location of the member interface.
Step 21	**member pseudowire** *interface-number* **Example:** `Device(config-xconnect)# member pseudowire 109`	Specifies a member pseudowire to form an L2VPN cross connect.
Step 22	**no shutdown** **Example:** `Device(config-xconnect)# no shutdown`	Restarts the member interface.
Step 23	**end** **Example:** `Device(config-xconnect)# end`	Exits xconnect configuration mode and returns to privileged EXEC mode.

Verifying HDLC-to-Ethernet Interworking (Port Mode) Configuration on a HDLC PE Device

You can use **show** commands to view information about a HDLC-to-Ethernet interworking (port mode) configuration on a HDLC provider edge (PE) device.

SUMMARY STEPS

1. **show mpls l2transport vc**
2. **show mpls l2transport vc detail**
3. **show l2vpn atom vc**
4. **show l2vpn atom vc detail**

DETAILED STEPS

Procedure

Step 1 **show mpls l2transport vc**

The following is sample output from the **show mpls l2transport vc** command which displays basic information about HDLC-to-Ethernet interworking (port mode) configuration on a HDLC PE device:

Example:

```
Device# show mpls l2transport vc

Local intf  Local circuit  Dest address    VC ID      Status
----------- -------------- --------------- ---------- ----------
Se0/1/0:0   HDLC           10.0.0.1        101        UP
```

Step 2 **show mpls l2transport vc detail**

The following is sample output from the **show mpls l2transport vc detail** command which displays detailed information about HDLC-to-Ethernet interworking (port mode) configuration on a HDLC PE device:

Example:

```
Device# show mpls l2transport vc detail

Local interface: Se0/1/0:0 up, line protocol up, HDLC up
Interworking type is Ethernet
Destination address: 10.0.0.1, VC ID: 101, VC status: up
Output interface: Fa0/0/1, imposed label stack {20 22}
Preferred path: not configured
Default path: active
Next hop: 10.0.0.10
Create time: 00:00:19, last status change time: 00:00:15
Last label FSM state change time: 00:00:15
Signaling protocol: LDP, peer 10.0.0.1:0 up
Targeted Hello: 203.0.113.1(LDP Id) -> 10.0.0.1, LDP is UP
Graceful restart: configured and enabled
Non stop routing: not configured and not enabled
Status TLV support (local/remote) : enabled/supported
LDP route watch : enabled
Label/status state machine : established, LruRru
Last local dataplane status rcvd: No fault
Last BFD dataplane status rcvd: Not sent
Last BFD peer monitor status rcvd: No fault
Last local AC circuit status rcvd: No fault
Last local AC circuit status sent: No fault
Last local PW i/f circ status rcvd: No fault
Last local LDP TLV status sent: No fault
Last remote LDP TLV status rcvd: No fault
Last remote LDP ADJ status rcvd: No fault
MPLS VC labels: local 33, remote 22
Group ID: local 0, remote 0
MTU: local 1500, remote 1500
Remote interface description: Connect to CE2
Sequencing: receive disabled, send disabled
Control Word: On
SSO Descriptor: 10.0.0.1/101, local label: 33
Dataplane:
SSM segment/switch IDs: 4274/4273 (used), PWID: 26
VC statistics:
transit packet totals: receive 3, send 6
transit byte totals: receive 162, send 366
transit packet drops: receive 0, seq error 0, send 0
```

Step 3 **show l2vpn atom vc**

The following is sample output from the **show l2vpn atom vc** command which displays basic information about HDLC-to-Ethernet interworking (port mode) configuration on a HDLC PE device:

Example:

```
Device# show l2vpn atom vc

                            Service
Interface Peer ID    VC ID  Type   Name  Status
--------- ---------- ------ ------ ----- ----------
pw101     10.0.0.1   101    p2p    101   UP
```

Step 4 **show l2vpn atom vc detail**

The following is sample output from the **show l2vpn atom vc detail** command which displays detailed information about HDLC-to-Ethernet interworking (port mode) configuration on a HDLC PE device:

Example:

```
Device# show l2vpn atom vc detail

pseudowire101 is up, VC status is up PW type: Ethernet
Create time: 00:00:18, last status change time: 00:00:14

Verifying HDLC-to-Ethernet Interworking (Port Mode) Configuration on an Ethernet PE Device

You can use **show** commands to view information about a HDLC-to-Ethernet interworking (port mode) configuration on an Ethernet PE device.

SUMMARY STEPS

1. **show mpls l2transport vc**
2. **show l2vpn atom vc**
3. **show l2vpn atom vc detail**

DETAILED STEPS

Procedure

Step 1 **show mpls l2transport vc**

The following is sample output from the **show mpls l2transport vc** command which displays basic information about HDLC-to-Ethernet interworking (port mode) configuration on an Ethernet PE device:

Example:

```
Device# show mpls l2transport vc

Local interface: Gi1/0/0 up, line protocol up, Ethernet up
Destination address: 203.0.113.1, VC ID: 101, VC status: up
Output interface: Fa0/0/1, imposed label stack {19 33}
Preferred path: not configured
Default path: active
Next hop: 10.0.0.11
Create time: 00:00:22, last status change time: 00:00:19
Last label FSM state change time: 00:00:19
Signaling protocol: LDP, peer 203.0.113.1:0 up
Targeted Hello: 10.0.0.1(LDP Id) -> 203.0.113.1, LDP is UP
Graceful restart: configured and enabled
Non stop routing: not configured and not enabled
Status TLV support (local/remote) : enabled/supported
LDP route watch : enabled
Label/status state machine : established, LruRru
Last local dataplane status rcvd: No fault
Last BFD dataplane status rcvd: Not sent
Last BFD peer monitor status rcvd: No fault
Last local AC circuit status rcvd: No fault
Last local AC circuit status sent: No fault
Last local PW i/f circ status rcvd: No fault
Last local LDP TLV status sent: No fault
Last remote LDP TLV status rcvd: No fault
Last remote LDP ADJ status rcvd: No fault
MPLS VC labels: local 22, remote 33
Group ID: local 0, remote 0
MTU: local 1500, remote 1500
Remote interface description: Connect to CE1
Sequencing: receive disabled, send disabled
Control Word: On
SSO Descriptor: 203.0.113.1/101, local label: 22
Dataplane:
SSM segment/switch IDs: 4574/4573 (used), PWID: 80
VC statistics:
```

```
transit packet totals: receive 9, send 5
transit byte totals: receive 315, send 380
transit packet drops: receive 0, seq error 0, send 0
```

Step 2 **show l2vpn atom vc**

The following is sample output from the **show l2vpn atom vc** command which displays basic information about HDLC-to-Ethernet interworking (port mode) configuration on an Ethernet PE device:

Example:

```
Device# show l2vpn atom vc

                            Service
Interface Peer ID    VC ID  Type   Name  Status
--------- ---------- ------ ------ ----- ----------
pw101     10.0.0.1   101    p2p    101   UP
```

Step 3 **show l2vpn atom vc detail**

The following is sample output from the **show l2vpn atom vc detail** command which displays detailed information about HDLC-to-Ethernet interworking (port mode) configuration on an Ethernet PE device:

Example:

```
Device# show l2vpn atom vc detail

Verifying HDLC-to-Ethernet Interworking (dot1q Mode) Configuration on an Ethernet PE Device

You can use **show** commands to view information about a HDLC-to-Ethernet interworking (dot1q mode) configuration on an Ethernet PE device.

SUMMARY STEPS

1. **show mpls l2transport vc**
2. **show mpls l2transport vc detail**

3. **show l2vpn atom vc**
4. **show l2vpn atom vc detail**

DETAILED STEPS

Procedure

Step 1 **show mpls l2transport vc**

The following is sample output from the **show mpls l2transport vc** command which displays basic information about HDLC-to-Ethernet interworking (dot1q mode) configuration on an Ethernet PE device:

Example:

```
Device# show mpls l2transport vc

Local intf  Local circuit  Dest address    VC ID      Status
----------- -------------- --------------- ---------- ----------
Gi1/0/0.10  Eth VLAN 10    203.0.113.1     138        UP
```

Step 2 **show mpls l2transport vc detail**

The following is sample output from the **show mpls l2transport vc detail** command which displays detailed information about HDLC-to-Ethernet interworking (dot1q mode) configuration on an Ethernet PE device:

Example:

```
Device# show mpls l2transport vc detail

Local interface: Gi1/0/0.10 up, line protocol up, Eth VLAN 10 up
Interworking type is Ethernet
Destination address: 203.0.113.1, VC ID: 138, VC status: up
Output interface: Fa0/0/1, imposed label stack {19 35}
Preferred path: not configured
Default path: active
Next hop: 10.0.0.11
Create time: 00:00:22, last status change time: 00:00:20
Last label FSM state change time: 00:00:20
Signaling protocol: LDP, peer 203.0.113.1:0 up
Targeted Hello: 10.0.0.1(LDP Id) -> 203.0.113.1, LDP is UP
Graceful restart: configured and enabled

Verifying HDLC-to-Ethernet Interworking (QinQ Mode) Configuration on a HDLC PE Device

You can use **show** commands to view information about a HDLC-to-Ethernet interworking (QinQ mode) configuration on a HDLC PE device.

SUMMARY STEPS

1. **show mpls l2transport vc**
2. **show mpls l2transport vc detail**
3. **show l2vpn atom vc**
4. **show l2vpn atom vc detail**

DETAILED STEPS

Procedure

Step 1 **show mpls l2transport vc**

The following is sample output from the **show mpls l2transport vc** command which displays basic information about HDLC-to-Ethernet interworking (QinQ mode) configuration on a HDLC PE device:

Example:

```
Device# show mpls l2transport vc

Local intf  Local circuit  Dest address    VC ID      Status
----------- -------------- --------------- ---------- ----------
Se0/1/0:0   HDLC           10.0.0.1        145        UP
```

Step 2 **show mpls l2transport vc detail**

The following is sample output from the **show mpls l2transport vc detail** command which displays detailed information about HDLC-to-Ethernet interworking (QinQ mode) configuration on a HDLC PE device:

Example:

```
Device# show mpls l2transport vc detail

Local interface: Se0/1/0:0 up, line protocol up, HDLC up
Interworking type is Ethernet
Destination address: 10.0.0.1, VC ID: 101, VC status: up
Output interface: Fa0/0/1, imposed label stack {20 22}
Preferred path: not configured
Default path: active
Next hop: 10.0.0.10
Create time: 00:00:19, last status change time: 00:00:15
Last label FSM state change time: 00:00:15
Signaling protocol: LDP, peer 10.0.0.1:0 up
Targeted Hello: 203.0.113.1(LDP Id) -> 10.0.0.1, LDP is UP
Graceful restart: configured and enabled
Non stop routing: not configured and not enabled
Status TLV support (local/remote) : enabled/supported
LDP route watch : enabled
Label/status state machine : established, LruRru
Last local dataplane status rcvd: No fault
Last BFD dataplane status rcvd: Not sent
Last BFD peer monitor status rcvd: No fault
Last local AC circuit status rcvd: No fault
Last local AC circuit status sent: No fault
Last local PW i/f circ status rcvd: No fault
Last local LDP TLV status sent: No fault
Last remote LDP TLV status rcvd: No fault
Last remote LDP ADJ status rcvd: No fault
MPLS VC labels: local 33, remote 22
Group ID: local 0, remote 0
MTU: local 1500, remote 1500
Remote interface description: Connect to CE2
Sequencing: receive disabled, send disabled
Control Word: On
SSO Descriptor: 10.0.0.1/101, local label: 33
Dataplane:
SSM segment/switch IDs: 4274/4273 (used), PWID: 26
VC statistics:
transit packet totals: receive 3, send 6
transit byte totals: receive 162, send 366
transit packet drops: receive 0, seq error 0, send 0
```

Step 3 show l2vpn atom vc

The following is sample output from the **show l2vpn atom vc** command which displays basic information about HDLC-to-Ethernet interworking (QinQ mode) configuration on a HDLC PE device:

Example:

```
Device# show l2vpn atom vc

                            Service
Interface Peer ID    VC ID  Type   Name  Status
--------- ---------- ------ ------ ----- ----------
pw145     10.0.0.1   145    p2p    145   UP
```

Step 4 show l2vpn atom vc detail

The following is sample output from the **show l2vpn atom vc detail** command which displays detailed information about HDLC-to-Ethernet interworking (QinQ mode) configuration on a HDLC PE device:

Example:

```
Device# show l2vpn atom vc detail

pseudowire145 is up, VC status is up PW type: Ethernet
```

```
Create time: 00:00:18, last status change time: 00:00:13

Verifying HDLC-to-Ethernet Interworking (QinQ Mode) Configuration on an Ethernet PE Device

You can use **show** commands to view information about a HDLC-to-Ethernet interworking (QinQ mode) configuration on an Ethernet PE device.

SUMMARY STEPS

1. **show mpls l2transport vc**
2. **show mpls l2transport vc detail**
3. **show l2vpn atom vc**
4. **show l2vpn atom vc detail**

DETAILED STEPS

Procedure

Step 1 **show mpls l2transport vc**

The following is sample output from the **show mpls l2transport vc** command which displays basic information about HDLC-to-Ethernet interworking (QinQ mode) configuration on an Ethernet PE device:

Example:

```
Device# show mpls l2transport vc

Local intf  Local circuit  Dest address    VC ID      Status
----------- -------------- --------------- ---------- ----------
Gi1/0/0.10  Eth VLAN 10/20  203.0.113.1    145        UP
```

Step 2 **show mpls l2transport vc detail**

The following is sample output from the **show mpls l2transport vc detail** command which displays detailed information about HDLC-to-Ethernet interworking (QinQ mode) configuration on an Ethernet PE device:

Example:

```
Device# show mpls l2transport vc detail

Local interface: Gi1/0/0.10 up, line protocol up, Eth VLAN 10/20 up
Interworking type is Ethernet
Destination address: 203.0.113.1, VC ID: 145, VC status: up
Output interface: Fa0/0/1, imposed label stack {19 27}
Preferred path: not configured
Default path: active
Next hop: 10.0.0.11
Create time: 00:00:23, last status change time: 00:00:21
Last label FSM state change time: 00:00:21
Signaling protocol: LDP, peer 203.0.113.1:0 up
Targeted Hello: 10.0.0.1(LDP Id) -> 203.0.113.1, LDP is UP
Graceful restart: configured and enabled
Non stop routing: not configured and not enabled
Status TLV support (local/remote) : enabled/supported
LDP route watch : enabled
Label/status state machine : established, LruRru
Last local dataplane status rcvd: No fault
Last BFD dataplane status rcvd: Not sent
Last BFD peer monitor status rcvd: No fault
Last local AC circuit status rcvd: No fault
Last local AC circuit status sent: No fault
Last local PW i/f circ status rcvd: No fault
Last local LDP TLV status sent: No fault
Last remote LDP TLV status rcvd: No fault
Last remote LDP ADJ status rcvd: No fault
MPLS VC labels: local 25, remote 27
Group ID: local 0, remote 0
```

```
MTU: local 1500, remote 1500
Remote interface description: Connect to CE1
Sequencing: receive disabled, send disabled
Control Word: On
SSO Descriptor: 203.0.113.1/145, local label: 25
Dataplane:
SSM segment/switch IDs: 4815/4814 (used), PWID: 124
VC statistics:
transit packet totals: receive 10, send 6
transit byte totals: receive 430, send 456
transit packet drops: receive 0, seq error 0, send 0
```

Step 3 show l2vpn atom vc

The following is sample output from the **show l2vpn atom vc** command which displays basic information about HDLC-to-Ethernet interworking (QinQ mode) configuration on an Ethernet PE device:

Example:

```
Device# show l2vpn atom vc

                            Service
Interface Peer ID    VC ID  Type   Name  Status
--------- ---------- ------ ------ ----- ----------
pw145     203.0.113.1  145    p2p    145   UP
```

Step 4 show l2vpn atom vc detail

The following is sample output from the **show l2vpn atom vc detail** command which displays detailed information about HDLC-to-Ethernet interworking (QinQ mode) configuration on an Ethernet PE device:

Example:

```
Device# show l2vpn atom vc detail

pseudowire145 is up, VC status is up PW type: Ethernet

Verifying L2VPN Interworking

To verify the L2VPN status (in the AToM configuration), use the following commands:

- **show connection** [**all** | **name** | **id** | **elements** | **port**]
- **show xconnect** [**all** | **interface** | **peer**]
- **show mpls l2transport** [**binding** | **checkpoint** | **hw-capability** | **summary** | **vc**]
- **show mpls infrastructure lfd pseudowire vcid**

Verifying L2VPN Interworking using the commands associated with the L2VPN Protocol-Based CLIs feature

To verify the L2VPN status (in the AToM configuration), use the following commands:

- **show connection** [**all** | **name** | **id** | **elements** | **port**]
- **show l2vpn service**[**all** | **interface** | **peer**]
- **show l2vpn atom** [**binding** | **checkpoint** | **hw-capability** | **summary** | **vc**]
- **show mpls infrastructure lfd pseudowire vcid**

Configuration Examples for L2VPN Interworking

Frame Relay DLCI-to-Ethernet VLAN 802.1Q Using Bridged Internetworking Example

The following example shows how to configure the Frame Relay DLCI-to-Ethernet VLAN 802.1Q feature using bridged interworking:

PE1 router	PE2 router
config t mpls label protocol ldp interface Loopback100 ip address 10.0.0.100 255.255.255.255 pseudowire-class fr-vlan encapsulation mpls interworking ethernet frame-relay switching interface serial 2/0/0:1 encapsulation frame-relay frame-relay intf-type dce connect mpls serial 2/0/0:1 567 l2transport xconnect 10.0.0.200 150 pw-class fr-vlan	config t mpls label protocol ldp interface Loopback200 ip address 10.0.0.200 255.255.255.255 pseudowire-class fr-vlan encapsulation mpls interworking ethernet interface gigabitethernet 5/1/0.3 encapsulation dot1q 1525 xconnect 10.0.0.100 150 pw-class fr-vlan

Frame Relay DLCI-to-Ethernet VLAN 802.1Q Using Bridged Internetworking Example using the commands associated with the L2VPN Protocol-Based CLIs feature

The following example shows how to configure the Frame Relay DLCI-to-Ethernet VLAN 802.1Q feature using bridged interworking:

PE1 router	PE2 router
config t mpls label protocol ldp interface Loopback100 ip address 10.0.0.100 255.255.255.255 template type pseudowire fr-vlan encapsulation mpls interworking ethernet frame-relay switching interface serial 2/0/0:1 encapsulation frame-relay frame-relay intf-type dce connect mpls serial 2/0/0:1 567 l2transport interface pseudowire 100 source template type pseudowire fr-vlan neighbor 10.0.0.200 150 ! l2vpn xconnect context con1 member pseudowire 100 member 10.0.0.200 150 encapsulation mpls	config t mpls label protocol ldp interface Loopback200 ip address 10.0.0.200 255.255.255.255 template type pseudowire fr-vlan encapsulation mpls interworking ethernet interface gigabitethernet 5/1/0.3 encapsulation dot1q 1525 interface pseudowire 100 source template type pseudowire fr-vlan neighbor 10.0.0.100 150 ! l2vpn xconnect context con1 member pseudowire 100 member 10.0.0.100 150 encapsulation mpls

ATM AAL5-to-Ethernet VLAN 802.1Q Using Bridged Internetworking Example

The following example shows how to configure the ATM AAL5-to-Ethernet VLAN 802.1Q feature using bridged interworking:

PE1 router	PE2 router
config t mpls label protocol ldp interface Loopback100 ip address 10.0.0.100 255.255.255.255 pseudowire-class atm-vlan encapsulation mpls interworking ethernet interface atm 2/0/0 pvc 0/200 l2transport encapsulation aal5snap xconnect 10.0.0.200 140 pw-class atm-vlan	config t mpls label protocol ldp interface Loopback200 ip address 10.0.0.200 255.255.255.255 pseudowire-class atm-vlan encapsulation mpls interworking ethernet interface gigabitethernet 5/1/0.3 encapsulation dot1q 1525 xconnect 10.0.0.100 140 pw-class atm-vlan

ATM AAL5-to-Ethernet VLAN 802.1Q Using Bridged Internetworking Example using the commands associated with the L2VPN Protocol-Based CLIs feature

The following example shows how to configure the ATM AAL5-to-Ethernet VLAN 802.1Q feature using bridged interworking:

PE1 router	PE2 router
config t mpls label protocol ldp interface Loopback100 ip address 10.0.0.100 255.255.255.255 template type pseudowire atm-vlan encapsulation mpls interworking ethernet interface atm 2/0/0 pvc 0/200 l2transport encapsulation aal5snap interface pseudowire 100 source template type pseudowire atm-vlan neighbor 10.0.0.200 140 ! l2vpn xconnect context con1 member pseudowire 100 member 10.0.0.200 140 encapsulation mpls	config t mpls label protocol ldp interface Loopback200 ip address 10.0.0.200 255.255.255.255 template type pseudowire atm-vlan encapsulation mpls interworking ethernet interface gigabitethernet 5/1/0.3 encapsulation dot1q 1525 interface pseudowire 100 source template type pseudowire atm-vlan neighbor 10.0.0.100 140 ! l2vpn xconnect context con1 member pseudowire 100 member 10.0.0.200 140 encapsulation mpls

ATM AAL5-to-Ethernet Port Using Routed Interworking Example

The following example shows how to configure the ATM AAL5-to-Ethernet Port feature using routed interworking:

PE1 router	PE2 router
config t mpls label protocol ldp interface Loopback100 ip address 10.0.0.100 255.255.255.255 pseudowire-class atm-eth encapsulation mpls interworking ip interface atm 2/0.1 pvc 0/200 l2transport encapsulation aal5 xconnect 10.0.0.200 140 pw-class atm-eth	config t mpls label protocol ldp interface Loopback200 ip address 10.0.0.200 255.255.255.255 pseudowire-class atm-eth encapsulation mpls interworking ip interface gigabitethernet 5/1/0 xconnect 10.0.0.100 140 pw-class atm-eth

Frame Relay DLCI-to-Ethernet Port Using Routed Interworking Example

The following example shows how to configure the Frame Relay DLCI-to-Ethernet Port feature using routed interworking:

PE1 router	PE2 router
config t mpls label protocol ldp interface Loopback100 ip address 10.0.0.100 255.255.255.255 pseudowire-class fr-eth encapsulation mpls interworking ip frame-relay switching interface serial 2/0/0:1 encapsulation frame-relay frame-relay intf-type dce frame-relay interface-dlci 567 switched connect fr-vlan-1 POS2/3/1 151 l2transport xconnect 10.0.0.200 151 pw-class pw-class-bridge	config t mpls label protocol ldp interface Loopback200 ip address 10.0.0.200 255.255.255.255 pseudowire-class fr-eth encapsulation mpls interworking ip interface gigabitethernet 5/1/0 xconnect 10.0.0.100 150 pw-class fr-eth

Frame Relay DLCI-to-Ethernet Port Using Routed Interworking Example using the commands associated with the L2VPN Protocol-Based CLIs feature

The following example shows how to configure the Frame Relay DLCI-to-Ethernet Port feature using routed interworking:

PE1 router	PE2 router
config t mpls label protocol ldp interface Loopback100 ip address 10.0.0.100 255.255.255.255 template type pseudowire fr-eth encapsulation mpls interworking ip frame-relay switching interface serial 2/0/0:1 encapsulation frame-relay frame-relay intf-type dce frame-relay interface-dlci 567 switched connect fr-vlan-1 POS2/3/1 151 l2transport interface pseudowire 100 source template type pseudowire fr-eth neighbor 10.0.0.200 140 ! l2vpn xconnect context con1 member pseudowire 100 member 10.0.0.200 140 encapsulation mpls	config t mpls label protocol ldp interface Loopback200 ip address 10.0.0.200 255.255.255.255 template type pseudowire fr-eth encapsulation mpls interworking ip interface gigabitethernet 5/1/0 interface pseudowire 100 source template type pseudowire fr-eth neighbor 10.0.0.200 140 ! l2vpn xconnect context con1 member pseudowire 100 member 10.0.0.200 140 encapsulation mpls

Ethernet-to-VLAN over AToM--Bridged Example

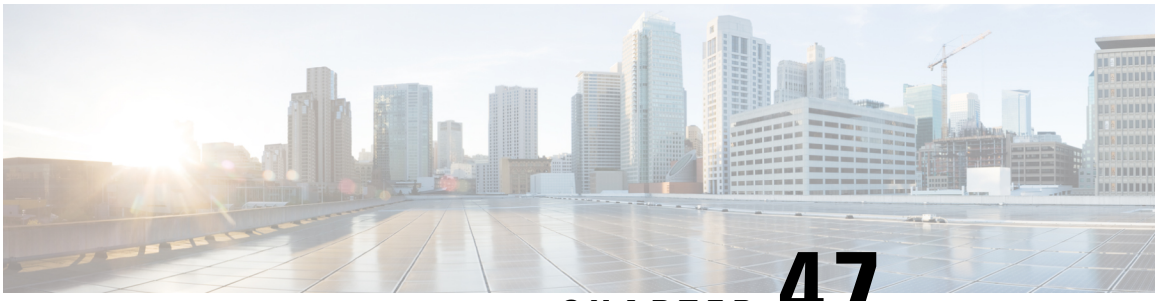
MIBs

MIB	MIBs Link
No new or modified MIBs are supported by this feature, and support for existing MIBs has not been modified by this feature.	To locate and download MIBs for selected platforms, Cisco IOS releases, and feature sets, use Cisco MIB Locator found at the following URL: http://www.cisco.com/go/mibs



Technical Assistance

Description	Link
The Cisco Support website provides extensive online resources, including documentation and tools for troubleshooting and resolving technical issues with Cisco products and technologies. Access to most tools on the Cisco Support website requires a Cisco.com user ID and password. If you have a valid service contract but do not have a user ID or password, you can register on Cisco.com.	http://www.cisco.com/techsupport

Feature Information for L2VPN Interworking

Table 107: Feature Information for L2VPN Interworking

Feature Name	Releases	Feature Information
L2VPN Interworking	Cisco IOS XE Release 2.4 Cisco IOS XE Release 3.3S	This feature allows disparate ACs to be connected. An interworking function facilitates the translation between the different Layer 2 encapsulations. The following commands were introduced or modified: **debug frame-relay pseudowire**, **debug ssm**, **interworking**, **mtu**, **pseudowire-class**, **show l2tun session**, **show l2tun tunnel** , **show mpls l2transport vc**, **show platform**.
L2VPN Interworking: Ethernet to VLAN Interworking	Cisco IOS XE Release 2.4	This feature allows interworking by stripping the VLAN tags and sending them as untagged frames on the remote end.
L2VPN Interworking: Ethernet VLAN to Frame Relay	Cisco IOS XE Release 3.3S	This feature allows interworking of Ethernet VLANs with Frame Relay DLCIs. The following command was modified: **interworking**
L2VPN Interworking: Ethernet VLAN to PPP	Cisco IOS XE Release 3.3S	The L2VPN interworking - Ethernet VLAN-to-PPP feature allows disparate ACs to be connected. An interworking function facilitates the translation between the following Layer 2 encapsulations.
L2VPN Interworking: Frame Relay to ATM (Bridged Mode)	Cisco IOS XE Release 3.6S	This feature allows Frame Relay to ATM Interworking using bridged and routed mode encapsulation.
L2VPN Interworking: HDLC to Ethernet Interworking	Cisco IOS XE Release 3.13S	High-Level Data Link Control (HDLC) and Ethernet are two independent data link layer transport protocols that utilize the Any Transport over MPLS (AToM) framework to communicate with each other. The interworking function enables translation between two heterogeneous Layer 2 encapsulations over a Multiprotocol Label Switching (MPLS) backbone. In Cisco IOS XE Release 3.13S, this feature was introduced on the Cisco ASR 1000 Series Aggregation Services Routers. This feature introduced no new or modified commands.

CHAPTER 47

L2VPN Pseudowire Preferential Forwarding

The L2VPN: Pseudowire Preferential Forwarding feature allows you to configure the pseudowires so that you can use **ping** and **show** commands to find status information for the pseudowires before, during, and after a switchover.

- Prerequisites for L2VPN—Pseudowire Preferential Forwarding, on page 997
- Guidelines and Limitations for L2VPN--Pseudowire Preferential Forwarding, on page 998
- Information About L2VPN--Pseudowire Preferential Forwarding, on page 998
- How to Configure L2VPN--Pseudowire Preferential Forwarding, on page 999
- Configuration Examples for L2VPN--Pseudowire Preferential Forwarding, on page 1002
- Additional References, on page 1005
- Feature Information for L2VPN--Pseudowire Preferential Forwarding, on page 1006

Prerequisites for L2VPN—Pseudowire Preferential Forwarding

- Before configuring the L2VPN: Pseudowire Preferential Forwarding feature, you should understand the concepts in the following documents:
  - Preferential Forwarding Status Bit Definition (draft-ietf-pwe3-redundancy-bit-xx.txt)
  - *MPLS Pseudowire Status Signaling*
  - *L2VPN Pseudowire Redundancy*
  - *NSF/SSO--Any Transport over MPLS and AToM Graceful Restart*
  - *MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV*
- The PE routers must be configured with the following features:
  - *L2VPN Pseudowire Redundancy*
  - *NSF/SSO--Any Transport over MPLS and AToM Graceful Restart*
- The L2VPN: Pseudowire Preferential Forwarding feature requires that the following mechanisms be in place to enable you to detect a failure in the network:
  - *Label switched paths (LSPs) Ping/Traceroute and Any Transport over MPLS Virtual Circuit Connection Verification (AToM VCCV)*
  - *Local Management Interface (LMI)*
  - *Operation, Administration, and Maintenance (OAM)*

Guidelines and Limitations for L2VPN--Pseudowire Preferential Forwarding

- Only ATM attachment circuits are supported.
- The following features are not supported:
  - Port mode cell relay
  - Any Transport over MPLS: AAL5 over MPLS
  - VC cell packing
  - OAM emulation
  - ILMI/PVC-D
  - Permanent virtual circuit (PVC) Range
  - L2TPv3 Pseudowire Redundancy
  - Local switching
  - Multiple backup pseudowires
  - Static pseudowires

Information About L2VPN--Pseudowire Preferential Forwarding

Overview of L2VPN--Pseudowire Preferential Forwarding

The L2VPN: Pseudowire Preferential Forwarding feature allows you to configure pseudowires so that you can use **ping** , **traceroute** , and **show** commands to find status information before, during, and after a switchover. The implementation of this feature is based on *Preferential Forwarding Status Bit Definition* (draft-ietf-pwe3-redundancy-bit-xx.txt). The L2VPN: Pseudowire Preferential Forwarding feature provides the following enhancements for displaying information about the pseudowires:

- You can issue **ping mpls** commands on the backup pseudowires.
- You can display status of the pseudowires before, during, and after a switchover using the **show xconnect** and **show mpls l2transport vc** commands.

Note In a single-segment pseudowire, the PE routers at each end of the pseudowire serve as the termination points. In multisegment pseudowires, the terminating PE routers serve as the termination points.

Overview of L2VPN—Pseudowire Preferential Forwarding using the commands associated with the L2VPN Protocol-Based CLIs feature

The L2VPN: Pseudowire Preferential Forwarding feature allows you to configure pseudowires so that you can use **ping**, **traceroute**, and **show** commands to find status information before, during, and after a switchover. The implementation of this feature is based on *Preferential Forwarding Status Bit Definition*

(draft-ietf-pwe3-redundancy-bit-xx.txt). The L2VPN: Pseudowire Preferential Forwarding feature provides the following enhancements for displaying information about the pseudowires:

- You can issue **ping mpls** commands on the backup pseudowires.
- You can display status of the pseudowires before, during, and after a switchover using the **show l2vpn service** and **show l2vpn atom vc** commands.

Note In a single-segment pseudowire, the PE routers at each end of the pseudowire serve as the termination points. In multisegment pseudowires, the terminating PE routers serve as the termination points.

How to Configure L2VPN--Pseudowire Preferential Forwarding

Configuring the Pseudowire Connection Between PE Routers

You set up a connection called a pseudowire between the routers to transmit Layer 2 frames between PE routers.

As part of the pseudowire configuration, issue the **status redundancy master** command to make it the master. This enables the L2VPN: Pseudowire Preferential Forwarding feature to display the status of the active and backup pseudowires. By default, the PE router is in slave mode.

Note One pseudowire must be the master, and the other must be the slave. You cannot configure both pseudowires as master or slave.

Note You must specify the **encapsulation mpls** command as part of the pseudowire class in order for the AToM VCs to work properly. If you omit the **encapsulation mpls** command, you receive the following error: % Incomplete command.

Before you begin

The PE routers must be configured for the L2VPN Pseudowire Redundancy and NSF/SSO--Any Transport over MPLS and AToM Graceful Restart features. See the following documents for configuration instructions.

- *L2VPN Pseudowire Redundancy*
- *NSF/SSO--Any Transport over MPLS and AToM Graceful Restart*

SUMMARY STEPS

1. **configure terminal**
2. **pseudowire-class name**
3. **encapsulation mpls**

4. **status redundancy** {**master**| **slave**}
5. **interworking** {**ethernet** | **ip**}

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**configure terminal** **Example:** `switch# configure terminal`	Enters global configuration mode.
Step 2	**pseudowire-class name** **Example:** `switch(config)# pseudowire-class atom`	Establishes a pseudowire class with a name that you specify, and enters pseudowire class configuration mode.
Step 3	**encapsulation mpls** **Example:** `switch(config-pw)# encapsulation mpls`	Specifies the tunneling encapsulation. • For AToM, the encapsulation type is mpls.
Step 4	**status redundancy** {**master**| **slave**} **Example:** `switch(config-pw)# status redundancy master`	Configures the pseudowire as the master or slave. This enables the L2VPN: Pseudowire Preferential Forwarding feature to display the status of the active and backup pseudowires. • By default, the PE router is in slave mode. **Note** One pseudowire must be the master, and the other must be the slave. You cannot configure both pseudowires as master or slave.
Step 5	**interworking** {**ethernet**	**ip**} **Example:** `switch(config-pw)# interworking ip`	(Optional) Enables the translation between the different Layer 2 encapsulations.

Configuring the Pseudowire Connection Between PE Routers

You set up a connection called a pseudowire between the routers to transmit Layer 2 frames between PE routers.

As part of the pseudowire configuration, issue the **status redundancy master** command to make it the master. This enables the L2VPN: Pseudowire Preferential Forwarding feature to display the status of the active and backup pseudowires. By default, the PE router is in slave mode.

Note One pseudowire must be the master, and the other must be the slave. You cannot configure both pseudowires as master or slave.

Note You must specify the **encapsulation mpls** command as part of the pseudowire class in order for the AToM VCs to work properly. If you omit the **encapsulation mpls** command, you receive the following error: % Incomplete command.

Before you begin

The PE routers must be configured for the L2VPN Pseudowire Redundancy and NSF/SSO--Any Transport over MPLS and AToM Graceful Restart features. See the following documents for configuration instructions.

- *L2VPN Pseudowire Redundancy*
- *NSF/SSO--Any Transport over MPLS and AToM Graceful Restart*

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface pseudowire** *number*
4. **encapsulation mpls**
5. **neighbor** *peer-address vcid-value*
6. **status redundancy** {**master**| **slave**}
7. **interworking** {**ethernet** | **ip**}

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**interface pseudowire** *number* **Example:**	Establishes an interface pseudowire with a value that you specify, and enters pseudowire class configuration mode.

	Command or Action	Purpose
	`Device(config)# interface pseudowire 1`	
Step 4	**encapsulation mpls** **Example:** `Device(config-pw)# encapsulation mpls`	Specifies the tunneling encapsulation. • For AToM, the encapsulation type is mpls.
Step 5	**neighbor** *peer-address vcid-value* **Example:** `Router(config-pw)#  neighbor 10.0.0.1 123`	Specifies the peer IP address and virtual circuit (VC) ID value of a Layer 2 VPN (L2VPN) pseudowire.
Step 6	**status redundancy** {**master**| **slave**} **Example:** `Device(config-pw)# status redundancy master`	Configures the pseudowire as the master or slave. This enables the L2VPN: Pseudowire Preferential Forwarding feature to display the status of the active and backup pseudowires. • By default, the PE router is in slave mode. **Note** One pseudowire must be the master, and the other must be the slave. You cannot configure both pseudowires as master or slave.
Step 7	**interworking** {**ethernet** | **ip**} **Example:** `Device(config-pw)# interworking ip`	(Optional) Enables the translation between the different Layer 2 encapsulations.

Configuration Examples for L2VPN--Pseudowire Preferential Forwarding

Example: L2VPN--Pseudowire Preferential Forwarding Configuration

The following commands configure a PE router with the L2VPN: Pseudowire Preferential Forwarding feature:

```
mpls ldp graceful-restart
mpls ip
mpls label protocol ldp
mpls ldp router-id Loopback0 force
mpls ldp advertise-labels
!
pseudowire-class mpls
 encapsulation mpls
 status redundancy master
interface ATM0/2/0.1 multipoint
```

```
 logging event subif-link-status
 atm pvp 50 l2transport
  xconnect 10.1.1.2 100 pw-class mpls
   backup peer 10.1.1.3 100 encap mpls
end
```

Example: L2VPN--Pseudowire Preferential Forwarding Configuration using the commands associated with the L2VPN Protocol-Based CLIs feature

The following commands configure a PE router with the L2VPN: Pseudowire Preferential Forwarding feature:

```
mpls ldp graceful-restart
mpls ip
mpls label protocol ldp
mpls ldp router-id Loopback0 force
mpls ldp advertise-labels
!
interface pseudowire1
 encapsulation mpls
 status redundancy master
 neighbor 10.0.0.1 123
interface ATM0/2/0.1 multipoint
 logging event subif-link-status
 atm pvp 50 l2transport
  interface pseudowire 100
  encapsulation mpls
  neighbor 10.1.1.2 100
!
l2vpn xconnect context A
 member pseudowire 100
 member atm 100
end
```

Example: Displaying the Status of the Pseudowires

The following examples show the status of the active and backup pseudowires before, during, and after a switchover.

The **show mpls l2transport vc** command on the active PE router displays the status of the pseudowires:

```
Router# show mpls l2transport vc

Local intf     Local circuit              Dest address    VC ID      Status
-------------  -------------------------- --------------- ---------- ----------
AT0/2/0/0.1    ATM VPC CELL 50            10.1.1.2         100        UP
AT0/2/0/0.1    ATM VPC CELL 50            10.1.1.3         100        STANDBY
```

The **show mpls l2transport vc** command on the backup PE router displays the status of the pseudowires. The active pseudowire on the backup PE router has the HOTSTANDBY status.

```
Router1-standby# show mpls l2transport vc

Local intf     Local circuit              Dest address    VC ID      Status
-------------  -------------------------- --------------- ---------- ----------
AT0/2/0/0.1    ATM VPC CELL 50            10.1.1.2         100        HOTSTANDBY
AT0/2/0/0.1    ATM VPC CELL 50            10.1.1.3         100        DOWN
```

During a switchover, the status of the active and backup pseudowires changes:

```
Router# show mpls l2transport vc

Local intf     Local circuit              Dest address    VC ID      Status
-------------  -------------------------- --------------- ---------- ----------
AT0/2/0/0.1    ATM VPC CELL 50            10.1.1.2         100        RECOVERING
AT0/2/0/0.1    ATM VPC CELL 50            10.1.1.3         100        DOWN
```

After the switchover is complete, the recovering pseudowire shows a status of UP:

```
Router# show mpls l2transport vc

Local intf     Local circuit              Dest address    VC ID      Status
-------------  -------------------------- --------------- ---------- ----------
AT0/2/0/0.1    ATM VPC CELL 50            10.1.1.2         100        UP
AT0/2/0/0.1    ATM VPC CELL 50            10.1.1.3         100        STANDBY
```

The **show xconnect** command displays the standby (SB) state for the backup pseudowire, which is independent of the stateful switchover mode of the router:

```
Router# show xconnect all

Legend:    XC ST=Xconnect State  S1=Segment1 State  S2=Segment2 State
  UP=Up       DN=Down            AD=Admin Down      IA=Inactive
  SB=Standby  HS=Hot Standby     RV=Recovering      NH=No Hardware
XC ST        Segment 1                                  S1 Segment 2
            S2
------+---------------------------------+--+---------------------------------+---------
UP pri ac   AT1/1/0/0.1/1/1:220/220(ATM V  UP mpls 10.193.193.3:330            UP
IA sec ac   AT1/1/0/0.1/1/1:220/220(ATM V  UP mpls 10.193.193.3:331            SB
```

The **ping mpls** and **traceroute mpls** commands show that the dataplane is active on the backup pseudowire:

```
Router# ping mpls pseudowire 10.193.193.22 331

%Total number of MS-PW segments is less than segment number; Adjusting the segment number
to 1
Sending 5, 100-byte MPLS Echos to 10.193.193.22,

Feature Information for L2VPN--Pseudowire Preferential Forwarding

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 108: Feature Information for L2VPN: Pseudowire Preferential Forwarding

Feature Name	Releases	Feature Information
L2VPN: Pseudowire Preferential Forwarding	Cisco IOS XE Release 2.3	This feature allows you to configure the pseudowires so that you can use **ping** and **show** commands to find status information of the pseudowires before, during, and after a switchover. The following commands were introduced or modified: **show mpls l2transport vc**, **show xconnect**, **status redundancy**.

CHAPTER 48

L2VPN Multisegment Pseudowires

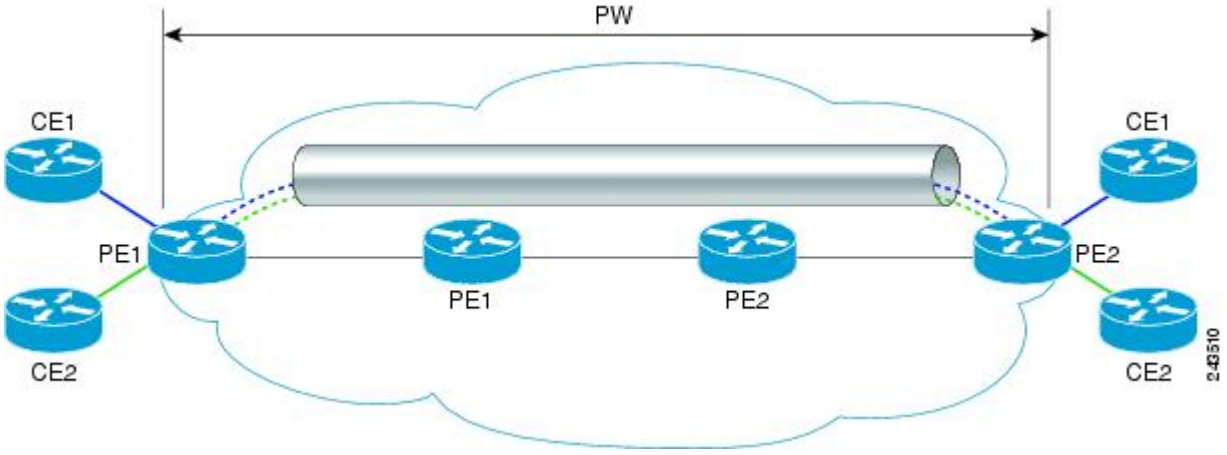
The L2VPN Multisegment Pseudowires feature enables you to configure two or more Layer 2 pseudowire segments that function as a single pseudowire. The L2VPN Multisegment Pseudowires feature span multiple cores or autonomous systems of the same or different carrier networks.

- Prerequisites for L2VPN Multisegment Pseudowires, on page 1007
- Restrictions for L2VPN Multisegment Pseudowires, on page 1007
- Information About L2VPN Multisegment Pseudowires, on page 1008
- How to Configure L2VPN Multisegment Pseudowires, on page 1009
- Additional References, on page 1017
- Feature Information for L2VPN Multisegment Pseudowires, on page 1018

Prerequisites for L2VPN Multisegment Pseudowires

Before configuring this feature, see the following documents:

- Any Transport over MPLS
- *L2VPN Pseudowire Switching*
- MPLS LSP Ping/Traceroute for LDP/TE, and LSP Ping for VCCV
- Pseudowire Setup and Maintenance Using the Label Distribution Protocol (LDP) (RFC 4447)

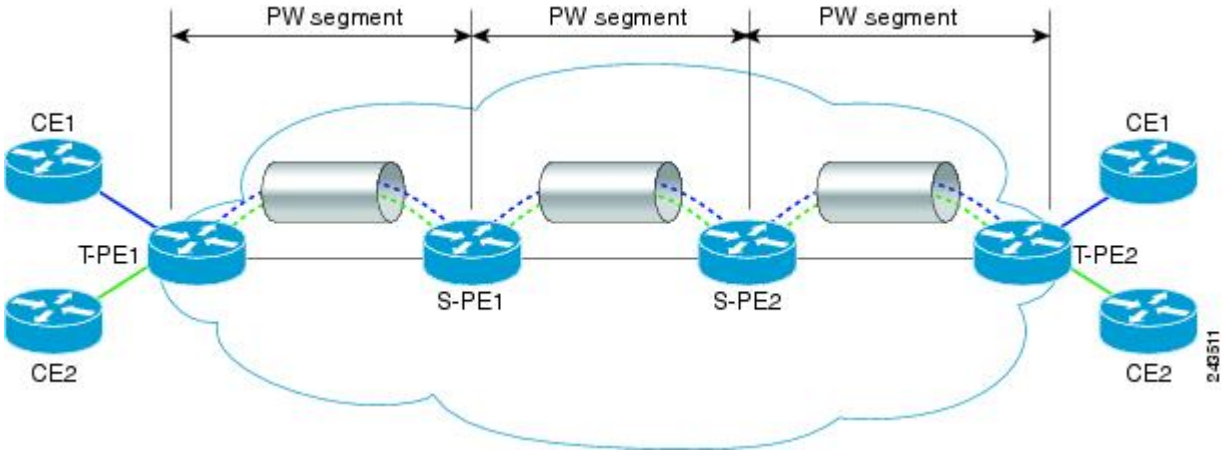


Restrictions for L2VPN Multisegment Pseudowires

- Only Mutliprotocol (MPLS) Layer 2 pseudowires are supported.
- Only manual configuration of the pseudowires (including S-PE and T-PE routers) is supported.
- The L2VPN Pseudowire Switching feature is supported for pseudowires advertised with FEC 128. FEC 129 is not supported.
- The S-PE router is limited to 1600 pseudowires.

Information About L2VPN Multisegment Pseudowires

L2VPN Pseudowire Defined



An L2VPN pseudowire (PW) is a tunnel established between two provider edge (PE) routers across the core carrying the Layer 2 payload encapsulated as MPLS data, as shown in the figure below. This helps carriers migrate from traditional Layer 2 networks such as Frame Relay and ATM to an MPLS core. In the L2VPN pseudowire shown in the figure, the PWs between two PE routers are located within the same autonomous system. Routers PE1 and PE2 are called terminating PE routers (T-PEs). Attachment circuits are bounded to the PW on these PE routers.

L2VPN Multisegment Pseudowire Defined

An L2VPN multisegment pseudowire (MS-PW) is a set of two or more PW segments that function as a single PW. It is also known as switched PW. MS-PWs span multiple cores or autonomous systems of the same or different carrier networks. A L2VPN MS-PW can include up to 254 PW segments.

The figure below is an example of a Multisegment Pseudowire topology.

The end routers are called terminating PE routers (T-PEs), and the switching routers are called S-PE routers. The S-PE router terminates the tunnels of the preceding and succeeding PW segments in an MS-PW. The S-PE router can switch the control and data planes of the preceding and succeeding PW segments of the MS-PW. An MS-PW is declared to be up when all the single-segment PWs are up. For more information, see the *L2VPN Pseudowire Switching* document.

How to Configure L2VPN Multisegment Pseudowires

Configuring L2VPN Multisegment Pseudowires

Perform the following steps on the S-PE routers to create L2VPN Multisegment Pseudowires.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. mpls label protocol ldp
4. **mpls ldp router-id** *interface* **force**
5. **pseudowire-class** name
6. **encapsulation mpls**
7. **switching tlv**
8. **exit**
9. **l2 vfi** *name* **point-to-point**
10. **description** *string*
11. **neighbor** *ip-address vcid {* **encapsulation mpls** **pw-class** *pw-class-name}*

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Router> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Router# configure terminal`	Enters global configuration mode.
Step 3	mpls label protocol ldp **Example:** `Router(config)# mpls label protocol ldp`	Configures the use of Label Distribution Protocol (LDP) on all interfaces.

	Command or Action	Purpose
Step 4	**mpls ldp router-id** *interface* **force** **Example:** `Router(config)# mpls ldp router-id loopback0 force`	Specifies the preferred interface for determining the LDP router ID.
Step 5	**pseudowire-class** name **Example:** `Router(config)# pseudowire-class atom`	Establishes a pseudowire class with a name that you specify, and enters pseudowire class configuration mode.
Step 6	**encapsulation mpls** **Example:** `Router(config-pw-class)# encapsulation mpls`	Specifies the tunneling encapsulation. • For MPLS L2VPNs, the encapsulation type is **mpls**.
Step 7	**switching tlv** **Example:** `Router(config-pw-class)# switching tlv`	(Optional) Enables the advertisement of the switching point type-length variable (TLV) in the label binding. • This command is enabled by default.
Step 8	**exit** **Example:** `Router(config-pw-class)# exit`	Exits pseudowire class configuration mode.
Step 9	**l2 vfi** *name* **point-to-point** **Example:** `Router(config)# l2 vfi atomtunnel point-to-point`	Creates a point-to-point Layer 2 virtual forwarding interface (VFI) and enters VFI configuration mode.
Step 10	**description** *string* **Example:** `Router(config-vfi)# description segment1`	Provides a description of the switching provider edge router for a multisegment pseudowire.
Step 11	**neighbor** *ip-address vcid {* **encapsulation mpls pw-class** *pw-class-name}* **Example:** `Router(config-vfi)# neighbor 10.0.0.1 100 pw-class mpls`	Sets up an emulated VC. • Specify the IP address and the VC ID of the peer router. Also specify the pseudowire class to use for the emulated VC. **Note** Only two **neighbor**commands are allowed for each **l2 vfi point-to-point** command.

Configuring L2VPN Multisegment Pseudowires using the commands associated with the L2VPN Protocol-Based CLIs feature

Perform this task on the S-PE routers to create L2VPN multisegment pseudowires.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **mpls label protocol ldp**
4. **mpls ldp router-id** *interface* **force**
5. **interface pseudowire** *number*
6. **encapsulation mpls**
7. **switching tlv**
8. **neighbor** *peer-address vcid-value*
9. **exit**
10. **l2vpn xconnect context** *context-name*
11. **description** *string*
12. **member** *ip-address vcid* **encapsulation mpls**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**mpls label protocol ldp** **Example:** `Device(config)# mpls label protocol ldp`	Configures the use of Label Distribution Protocol (LDP) on all interfaces.
Step 4	**mpls ldp router-id** *interface* **force** **Example:** `Device(config)# mpls ldp router-id loopback0 force`	Specifies the preferred interface for determining the LDP router ID.

	Command or Action	Purpose
Step 5	**interface pseudowire** *number* **Example:** `Device(config)# interface pseudowire 1`	Establishes an interface pseudowire with a value that you specify, and enters pseudowire configuration mode.
Step 6	**encapsulation mpls** **Example:** `Device(config-pw)# encapsulation mpls`	Specifies the tunneling encapsulation. • For MPLS L2VPNs, the encapsulation type is **mpls**.
Step 7	**switching tlv** **Example:** `Device(config-pw)# switching tlv`	(Optional) Enables the advertisement of the switching point type-length variable (TLV) in the label binding. • This command is enabled by default.
Step 8	**neighbor** *peer-address vcid-value* **Example:** `Router(config-pw)#  neighbor 10.0.0.1 123`	Specifies the peer IP address and virtual circuit (VC) ID value of a Layer 2 VPN (L2VPN) pseudowire.
Step 9	**exit** **Example:** `Device(config-pw)# exit`	Exits pseudowire configuration mode.
Step 10	**l2vpn xconnect context** *context-name* **Example:** `Device(config)# l2vpn xconnect context con1`	Creates a Layer 2 VPN (L2VPN) cross connect context and enters xconnect configuration mode.
Step 11	**description** *string* **Example:** `Device(config-xconnect)# description segment1`	Provides a description of the switching provider edge router for a multisegment pseudowire.
Step 12	**member** *ip-address vcid* **encapsulation mpls** **Example:** `Device(config-xconnect)# member 10.10.10.10 1 encapsulation mpls`	Specifies the devices that form a point-to-point Layer 2 VPN (L2VPN) virtual forwarding interface (VFI) connection. **Note** Only two **member**commands are allowed for each **l2vpn xconnect context** command.

Displaying Information About the L2VPN Multisegment Pseudowires

SUMMARY STEPS

1. **show mpls l2transport binding**
2. **show mpls l2transport vc detail**

DETAILED STEPS

Procedure

Step 1 **show mpls l2transport binding**

Use the **show mpls l2transport binding** command to display information about the pseudowire switching point, as shown in bold in the output. (In the following examples PE1 and PE4 are the T-PE routers.)

Example:

```
Router# show mpls l2transport binding

  Destination Address: 10.1.1.1,  VC ID: 102
    Local Label:  17
        Cbit: 1,    VC Type: FastEthernet,    GroupID: 0
        MTU: 1500,   Interface Desc: n/a
        VCCV: CC Type: CW [1], RA [2], TTL [3]
              CV Type: LSPV [2]
    Remote Label: 16
        Cbit: 1,    VC Type: FastEthernet,    GroupID: 0
        MTU: 1500,   Interface Desc: n/a
        VCCV: CC Type: CW [1], RA [2], TTL [3]
              CV Type: LSPV [2]
        PW Switching Point:
             Vcid   local IP addr      remote IP addr      Description
             101    10.11.11.11        10.20.20.20         PW Switching Point PE3
             100    10.20.20.20        10.11.11.11         PW Switching Point PE2
```

Step 2 **show mpls l2transport vc detail**

Use the **show mpls l2transport vc detail** command to display status of the pseudowire switching point. In the following example, the output (shown in bold) displays the segment that is the source of the fault of the multisegment pseudowire:

Example:

```
Router# show mpls l2transport vc detail
Local interface: Se3/0/0 up, line protocol up, HDLC up
  Destination address: 12.1.1.1, VC ID: 100, VC status: down
    Output interface: Se2/0, imposed label stack {23}
    Preferred path: not configured
    Default path: active
    Next hop: point2point
  Create time: 00:03:02, last status change time: 00:01:41
  Signaling protocol: LDP, peer 10.1.1.1:0 up
    Targeted Hello: 10.1.1.4(LDP Id) -> 10.1.1.1, LDP is UP
    Status TLV support (local/remote)   : enabled/supported
      LDP route watch                   : enabled
      Label/status state machine        : established, LruRrd
      Last local dataplane   status rcvd: No fault
```

```
    Last local SSS circuit status rcvd: No fault
    Last local SSS circuit status sent: DOWN(PW-tx-fault)
    Last local  LDP TLV    status sent: No fault
    Last remote LDP TLV    status rcvd: DOWN(PW-tx-fault)
     PW Switching Point:
     Fault type  Vcid   local IP addr   remote IP addr   Description
     PW-tx-fault  101   10.1.1.1        10.1.1.1         S-PE2
    Last remote LDP ADJ    status rcvd: No fault
  MPLS VC labels: local 19, remote 23
  Group ID: local 0, remote 0
  MTU: local 1500, remote 1500
  Remote interface description:
Sequencing: receive disabled, send disabled
VC statistics:
  packet totals: receive 16, send 27
  byte totals:   receive 2506, send 3098
  packet drops:  receive 0, seq error 0, send 0
```

Displaying Information About the L2VPN Multisegment Pseudowires using the commands associated with the L2VPN Protocol-Based CLIs feature

SUMMARY STEPS

1. **show l2vpn atom binding**
2. **show l2vpn atom vc detail**

DETAILED STEPS

Procedure

Step 1 show l2vpn atom binding

Use the **show l2vpn atom binding** command to display information about the pseudowire switching point, as shown in bold in the output. (In the following examples PE1 and PE4 are the T-PE routers.)

Example:

```
Device# show l2vpn atom binding

  Destination Address: 10.1.1.1,  VC ID: 102
    Local Label:  17
        Cbit: 1,    VC Type: FastEthernet,    GroupID: 0
        MTU: 1500,   Interface Desc: n/a
        VCCV: CC Type: CW [1], RA [2], TTL [3]
              CV Type: LSPV [2]
    Remote Label: 16
        Cbit: 1,    VC Type: FastEthernet,    GroupID: 0
        MTU: 1500,   Interface Desc: n/a
        VCCV: CC Type: CW [1], RA [2], TTL [3]
              CV Type: LSPV [2]
        PW Switching Point:
             Vcid   local IP addr      remote IP addr      Description
```

```
101    10.11.11.11        10.20.20.20         PW Switching Point PE3
100    10.20.20.20        10.11.11.11         PW Switching Point PE2
```

Step 2 **show l2vpn atom vc detail**

Use the **show l2vpn atom vc detail** command to display status of the pseudowire switching point. In the following example, the output (shown in bold) displays the segment that is the source of the fault of the multisegment pseudowire:

Example:

```
Device# show l2vpn atom vc detail
Local interface: Se3/0/0 up, line protocol up, HDLC up
  Destination address: 12.1.1.1, VC ID: 100, VC status: down
    Output interface: Se2/0, imposed label stack {23}
    Preferred path: not configured
    Default path: active
    Next hop: point2point
  Create time: 00:03:02, last status change time: 00:01:41
  Signaling protocol: LDP, peer 10.1.1.1:0 up
    Targeted Hello: 10.1.1.4(LDP Id) -> 10.1.1.1, LDP is UP
    Status TLV support (local/remote)   : enabled/supported
      LDP route watch                   : enabled
      Label/status state machine        : established, LruRrd

      Last local SSS circuit status rcvd: No fault
      Last local SSS circuit status sent: DOWN(PW-tx-fault)
      Last local  LDP TLV    status sent: No fault
      Last remote LDP TLV    status rcvd: DOWN(PW-tx-fault)
       PW Switching Point:
       Fault type  Vcid   local IP addr   remote IP addr   Description
       PW-tx-fault  101   10.1.1.1        10.1.1.1         S-PE2
      Last remote LDP ADJ    status rcvd: No fault
    MPLS VC labels: local 19, remote 23
    Group ID: local 0, remote 0
    MTU: local 1500, remote 1500
    Remote interface description:
  Sequencing: receive disabled, send disabled
  VC statistics:
    packet totals: receive 16, send 27
    byte totals:   receive 2506, send 3098
    packet drops:  receive 0, seq error 0, send 0
```

Performing ping mpls and trace mpls Operations on the L2VPN Multisegment Pseudowires

You can use the **ping mpls** and **trace mpls**commands to verify that all the segments of the MPLS multisegment pseudowire are operating.

You can use the **ping mpls** command to verify connectivity at the following pseudowire points:

- From one end of the pseudowire to the other
- From one of the pseudowires to a specific segment
- The segment between two adjacent S-PE routers

You can use the **trace mpls**command to verify connectivity at the following pseudowire points:

- From one end of the pseudowire to the other
- From one of the pseudowires to a specific segment
- The segment between two adjacent S-PE routers
- A range of segments

SUMMARY STEPS

1. **ping mpls pseudowire** *destination-address vc-id* [**segment** *segment-number*]
2. **trace mpls pseudowire** *destination-address vc-id* **segment** *segment-number segment-number*

DETAILED STEPS

Procedure

Step 1 **ping mpls pseudowire** *destination-address vc-id* [**segment** *segment-number*]

Where:

- *destination-address* is the address of the S-PE router, which is the end of the segment from the direction of the source.
- *vc-id* is the VC ID of the segment from the source to the next PE router.
- **segment** *segment-number is optional and specifies the segment you want to ping.*

The following examples use the topology shown in the second figure above :

- To perform an end-to-end ping operation from T-PE1 to T-PE2, enter the following command:

ping mpls pseudowire *<addr-of-S-PE1> <vc-id between T-PE1 and S-PE1>*

- To perform a ping operation from T-PE1 to segment 2, enter the following command:

ping mpls pseudowire *<addr-of-S-PE1> <vc-id between T-PE1 and S-PE1>* **segment 2**

Example:

Step 2 **trace mpls pseudowire** *destination-address vc-id* **segment** *segment-number segment-number*

Where:

- *destination-address is the address of the next S-PE router from the original of the trace.*
- *vc-id* is the VC ID of the segment from which the **trace** command is issued.
- *segment-number* indicates the segment upon which the trace operation will act. If you enter two segment numbers, the traceroute operation will perform a trace on that range of routers.

The following examples use the topology shown in the second figure above :

- To perform a trace operation from T-PE1 to segment 2 of the multisegment pseudowire, enter the following command:

trace mpls pseudowire *<addr-of-S-PE1> <vc-id between T-PE1 and S-PE1>* **segment 2**

This example performs a trace from T-PE1 to S-PE2.

- To perform a trace operation on a range of segments, enter the following command. This example performs a trace from S-PE2 to T-PE2.

trace mpls pseudowire *<addr-of-S-PE1> <vc-id between T-PE1 and S-PE1>* **segment 2 4**

The following command performs a trace operation on S-PE router 10.10.10.9, on segment 1 and then on segment 2:

Example:

```
router# trace mpls pseudowire 10.10.10.9 220 segment 1
Tracing MS-PW segments within range [1-1] peer address 10.10.10.9 and timeout 2 seconds
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
  'L' - labeled output interface, 'B' - unlabeled output interface,
  'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
  'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
  'P' - no rx intf label prot, 'p' - premature termination of LSP,
  'R' - transit router, 'I' - unknown upstream index,
  'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.
L 1 10.10.9.9 0 ms [Labels: 18 Exp: 0]
    local 10.10.10.22 remote 10.10.10.9 vc id 220
router# trace mpls pseudowire 10.10.10.9 220 segment 2
Tracing MS-PW segments within range [1-2] peer address 10.10.10.9 and timeout 2 seconds
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
  'L' - labeled output interface, 'B' - unlabeled output interface,
  'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
  'M' - malformed request, 'm' - unsupported tlvs, 'N' - no label entry,
  'P' - no rx intf label prot, 'p' - premature termination of LSP,
  'R' - transit router, 'I' - unknown upstream index,
  'X' - unknown return code, 'x' - return code 0
Type escape sequence to abort.
L 1 10.10.9.9 4 ms [Labels: 18 Exp: 0]
    local 10.10.10.22 remote 10.10.10.9 vc id 220
! 2 10.10.3.3 4 ms [Labels: 16 Exp: 0]
    local 10.10.10.9 remote 10.10.10.3 vc id 220
```

Feature Information for L2VPN Multisegment Pseudowires

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 109: Feature Information for L2VPN Multisegment Pseudowires

Feature Name	Releases	Feature Information
MPLS OAM Support for Multisegment Pseudowires	Cisco IOS XE Release 2.3 Cisco IOS XE Release 3.5S	The L2VPN Multisegment Pseudowires feature enables you to configure two or more Layer 2 pseudowire segments that function as a single pseudowire. The L2VPN Multisegment Pseudowires feature span multiple cores or autonomous systems of the same or different carrier networks. In isco IOS XE Release 2.3, this feature was introduced and implemented on the Cisco ASR 1000 Series Routers. In Cisco IOS XE Release 3.5S, support was added for the Cisco ASR 903 Router. The following commands were introduced or modified: **description** (l2 vfi), **ping mpls**, **show mpls l2transport binding**, **show mpls l2transport vc**, **switching tlv**, **trace mpls**.

CHAPTER 49

MPLS Quality of Service

The MPLS Quality of Service feature (formerly named as the MPLS CoS feature) enables you to provide differentiated services across an MPLS network. To satisfy a wide range of networking requirements, you can specify the class of service applicable to each transmitted IP packet. Different classes of service can be established for IP packets by setting the IP precedence bit in the header of each packet.

- Prerequisites for MPLS Quality of Service, on page 1021
- Information About MPLS Quality of Service, on page 1022
- How to Configure MPLS Quality of Service, on page 1026
- Configuration Examples for MPLS Quality of Service, on page 1032
- Additional References for MPLS Quality of Service, on page 1038
- Feature Information for MPLS Quality of Service, on page 1039

Prerequisites for MPLS Quality of Service

To use MPLS CoS to full advantage in your network, the following functionality must be supported:

- Multiprotocol Label Switching (MPLS)—MPLS is the standardized label switching protocol defined by the Internet Engineering Task Force (IETF).
- Cisco Express Forwarding—Cisco Express Forwarding is an advanced Layer 3 IP switching technology that optimizes performance and scalability in networks that handle large volumes of traffic and that exhibit dynamic traffic patterns.
- Asynchronous Transfer Mode (ATM)—ATM signaling support is required if you are using ATM interfaces in your network.

  If you are using only packet interfaces in your network, ATM functionality is not needed.
- QoS features:
  - Weighted fair queueing (WFQ)—Used on non-GSR platforms, WFQ is a dynamic scheduling method that allocates bandwidth fairly to all network traffic.

    WFQ applies priorities, or weights, to traffic to classify the traffic into flows and determine how much bandwidth to allow each flow. WFQ moves interactive traffic to the front of a queue to reduce response time and fairly shares the remaining bandwidth among high-bandwidth flows.
  - Weighted random early detection (WRED)—WRED is a congestion avoidance mechanism that extends RED functionality by allowing different RED parameters to be configured per IP precedence value.

IP precedence bits, contained in the type of service (ToS) octet in the IP packet header, are used to denote the relative importance or priority of an IP packet. WRED uses these IP precedence values to classify packets into different discard priorities or classes of service.

- Modified deficit round robin (MDRR)—Used only on GSR platforms, MDRR is a traffic class prioritization mechanism that incorporates emission priority as a facet of quality of service. MDRR is similar in function to WFQ on non-GSR platforms.

  In MDRR, IP traffic is mapped to different classes of service queues. A group of queues is assigned to each traffic destination. On the transmit side of the platform, a group of queues is defined on a per-interface basis; on the receive side of the platform, a group of queues is defined on a per-destination basis. IP packets are then mapped to these queues, based on their IP precedence value.

  These queues are serviced on a round-robin basis, except for a queue that has been defined to run in either of two ways: strict priority mode or alternate priority mode.

  In strict priority mode, the high priority queue is serviced whenever it is not empty; this ensures the lowest possible delay for high priority traffic. In this mode, however, the possibility exists that other traffic might not be serviced for long periods of time if the high priority queue is consuming most of the available bandwidth.

  In alternate priority mode, the traffic queues are serviced in turn, alternating between the high priority queue and the remaining queues.

- Committed access rate (CAR)—CAR is a QoS feature that limits the input or output transmission rate on an interface and classifies packets by setting the IP precedence value or the QoS group in the IP packet header.

Information About MPLS Quality of Service

MPLS Quality of Service Overview

MPLS CoS functionality enables network administrators to provide differentiated services across an MPLS network. Network administrators can satisfy a wide range of networking requirements by specifying the class of service applicable to each transmitted IP packet. Different classes of service can be established for IP packets by setting the IP precedence bit in the header of each packet.

MPLS CoS supports the following differentiated services in an MPLS network:

- Packet classification
- Congestion avoidance
- Congestion management

The table below describes the MPLS CoS services and functions.

Table 110: MPLS CoS Services and Functions

Service	CoS Function	Description
Packet classification	Committed access rate (CAR). Packets are classified at the edge of the network before labels are assigned.	CAR uses the type of service (ToS) bits in the IP header to classify packets according to input and output transmission rates. CAR is often configured on interfaces at the edge of a network in order to control traffic flowing into or out of the network. You can use CAR classification commands to classify or reclassify a packet.
Congestion avoidance	Weighted random early detection (WRED). Packet classes are differentiated based on drop probability.	WRED monitors network traffic to anticipate and prevent congestion at common network and internetwork bottlenecks. WRED can selectively discard lower priority traffic when an interface becomes congested; WRED can also provide differentiated performance characteristics for different classes of service.
Congestion management	Weighted fair queueing WFQ) for non-GSR platform. Packet classes are differentiated based on bandwidth requirements and finite delay characteristics. Modified deficit round robin (MDRR) for GSR platforms.	WFQ is an automated scheduling system that ensures fair bandwidth allocation to all network traffic. WFQ uses weights (priorities) to determine how much bandwidth each class of traffic is allocated. MDRR, similar in function to WFQ for non-GSR platforms, is a traffic prioritization scheme that maps IP traffic to different classes of service queues, based on the IP precedence value of each packet. The queues are then serviced on a round-robin basis.

MPLS CoS enables you to duplicate Cisco IP CoS (Layer 3) features as closely as possible in MPLS devices, including label edge switch routers (edge LSRs) and label switch routers (LSRs). MPLS CoS functions map nearly one-for-one to IP CoS functions on all types of interfaces.

Tag Switching and MPLS Terminology

The table below lists the existing legacy tag switching terms and the new, equivalent Multiprotocol Label Switching (MPLS) IETF terms used in this document and other related Cisco publications.

Table 111: Tag Switching Terms and Equivalent MPLS Terms

Old Designation	New Designation
Tag switching	Multiprotocol Label Switching
Tag (short for tag switching)	MPLS
Tag (item or packet)	Label
TDP (Tag Distribution Protocol)	LDP (Label Distribution Protocol). Cisco TDP and LDP (MPLS Label Distribution Protocol) closely parallel each other in function, but differ in detail, such as message formats and the commands required to configure the respective protocols and to monitor their operation
Tag switched	Label switched
TFIB (tag forwarding information base)	LFIB (label forwarding information base)
TSR (tag switching router)	LSR (label switching router)
TVC (tag VC, tag virtual circuit)	LVC (label VC, label virtual circuit)
TSP (tag switch path)	LSP (label switch path)

LSRs Used at the Edge of an MPLS Network

Label switching routers (LSRs) used at the edge of a Multiprotocol Label Switching (MPLS) network backbone are devices running MPLS software. The edge LSRs can be at the ingress or the egress of the network.

At the ingress of an MPLS network, devices process packets as follows:

1. IP packets enter the edge of the MPLS network at the edge LSR.
2. The edge LSR uses a classification mechanism such as the Modular Quality of Service Command-Line Interface (CLI) (MQC) to classify incoming IP packets and set the IP precedence value. Alternatively, IP packets can be received with the IP precedence value already set.
3. For each packet, the device performs a lookup on the IP address to determine the next-hop LSR.
4. The appropriate label is inserted into the packet, and the IP precedence bits are copied into the MPLS EXP bits in the label header.
5. The labeled packets are forwarded to the appropriate output interface for processing.
6. The packets are differentiated by class according to one of the following:
   - Drop probability—Weighted random early detection (WRED)
   - Bandwidth allocation and delay—Class-based weighted fair queueing (CBWFQ)

In either case, LSRs enforce the defined differentiation by continuing to employ WRED or CBWFQ on every ingress device.

At the egress of an MPLS network, devices process packets as follows:

1. MPLS-labeled packets enter the edge LSR from the MPLS network backbone.
2. The MPLS labels are removed and IP packets may be (re)classified.
3. For each packet, the device performs a lookup on the IP address to determine the packet's destination and forwards the packet to the destination interface for processing.
4. The packets are differentiated by the IP precedence values and treated appropriately, depending on the WRED or CBWFQ drop probability configuration.

LSRs Used at the Core of an MPLS Network

Label switching routers (LSRs) used at the core of a Multiprotocol Label Switching (MPLS) network are devices running MPLS software. These devices at the core of an MPLS network process packets as follows:

1. MPLS labeled packets coming from the edge devices or other core devices enter the core device.
2. A lookup is done at the core device to determine the next hop LSR.
3. An appropriate label is placed (swapped) on the packet and the MPLS EXP bits are copied.
4. The labeled packet is then forwarded to the output interface for processing.
5. The packets are differentiated by the MPLS EXP field marking and treated appropriately, depending on the weighted early random detection (WRED) and class-based weighted fair queueing (CBWFQ) configuration.

Benefits of MPLS CoS in IP Backbones

You realize the following benefits when you use MPLS CoS in a backbone consisting of IP devices running Multiprotocol Label Switching (MPLS):

- Efficient resource allocation—Weighted fair queueing (WFQ) is used to allocate bandwidth on a per-class and per-link basis, thereby guaranteeing a percentage of link bandwidth for network traffic.
- Packet differentiation—When IP packets traverse an MPLS network, packets are differentiated by mapping the IP precedence bits of the IP packets to the MPLS CoS bits in the MPLS EXP field. This mapping of bits enables the service provider to maintain end-to-end network guarantees and meet the provisions of customer service level agreements (SLAs).
- Future service enhancements—MPLS CoS provides building blocks for future service enhancements (such as virtual leased lines) by meeting bandwidth requirements.

How to Configure MPLS Quality of Service

Configuring WRED

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type number*
4. **random-detect**
5. **random-detect precedence** *min-threshold max-threshold mark-probability*
6. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**interface** *type number* **Example:** `Device(config)# gigabitethernet0/0/0`	Specifies the interface type and number, and enters interface configuration mode.
Step 4	**random-detect** **Example:** `Device(config-if)# random-detect`	Configures the interface to use weighted random early detection/distributed weighted random early detection (WRED/DWRED).
Step 5	**random-detect precedence** *min-threshold max-threshold mark-probability* **Example:** `Device(config-if)# random-detect precedence 0 32 256 100`	Configures WRED/DWRED parameters per precedence value.
Step 6	**end** **Example:** `Device(config-if)# end`	Returns to privileged EXEC mode.

Verifying WRED

To verify weighted random early detection (WRED), use a command of the form shown in the following table. This example is based on "Device2" in the network topology shown in the figure in the configuration examples section.

SUMMARY STEPS

1. **show queueing interface** *subinterface*

DETAILED STEPS

Procedure

show queueing interface *subinterface*

Example:

```
Device2# show queueing interface gigabitethernet6/0/0
```

Verifies the WRED configuration on the specified interface.

```
Device2# show queueing interface gigabitethernet6/0/0

Interface Gige6/0/0 queueing strategy:random early detection (WRED)
     Exp-weight-constant:9 (1/512)
     Mean queue depth:0

     Class    Random       Tail    Minimum    Maximum     Mark
               drop       drop  threshold  threshold  probability
       0         85          0         20         40     1/10
       1         22          0         22         40     1/10
       2          0          0         24         40     1/10
       3          0          0         26         40     1/10
       4          0          0         28         40     1/10
       5          0          0         31         40     1/10
       6          0          0         33         40     1/10
       7          0          0         35         40     1/10
     rsvp         0          0         37         40     1/10
```

Configuring CAR

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *name*
4. **rate-limit input** [**access-group** [**rate-limit**] *acl-index*] *bps burst-normal burst-max* **conform-action** *conform-action* **exceed-action** *exceed-action*
5. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**interface** *name* **Example:** `Device(config)# interface gigabitethernet`	Designates the input interface, and enters interface configuration mode.
Step 4	**rate-limit input** [**access-group** [**rate-limit**] *acl-index*] *bps burst-normal burst-max* **conform-action** *conform-action* **exceed-action** *exceed-action* **Example:** `Device(config-if)# rate-limit input access-group 101 496000 32000 64000 conform-action set-prec-transmit 4`	Specifies the action to take on packets during label imposition.
Step 5	**end** **Example:** `Device(config-if)# end`	Returns to privileged EXEC mode.

Verifying the CAR Configuration

SUMMARY STEPS

1. **show interfaces** *slot/port* **rate-limit**

DETAILED STEPS

Procedure

show interfaces *slot/port* **rate-limit**

Example:

```
Device2# show interfaces fe1/1/1 rate-limit
```

Verifies the CAR configuration, use a command of the following form.

```
Device2# show interfaces fe1/1/1 rate-limit

FastEthernet1/1/1
   Input
     matches:access-group 101
       params: 496000 bps, 32000 limit, 64000 extended limit
       conformed 2137 packets, 576990 bytes; action:set-prec-transmit 4
       exceeded 363 packets, 98010 bytes; action:set-prec-transmit 0
       last packet:11788ms ago, current burst:39056 bytes
       last cleared 00:01:18 ago, conformed 58000 bps, exceeded 10000 bps
```

Configuring CBWFQ

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **class-map** *class-map-name*
4. **match** *type number*
5. **policy-map** *policy-map-name*
6. **class** *class-map-name*
7. **bandwidth** *number*
8. **interface** *type number*
9. **service-policy output** *policy-map-name*
10. **end**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**class-map** *class-map-name* **Example:** `Device(config)# class-map class-map-1`	Creates a class map, and enters class-map configuration mode.
Step 4	**match** *type number* **Example:** `Device(config-cmap)# match ip precedence 0 1`	Specifies the traffic on which the class map is to match.

	Command or Action	Purpose
Step 5	**policy-map** *policy-map-name* **Example:** `Device(config-cmap)# policy-map outputmap`	Creates a policy map, and enters policy-map configuration mode.
Step 6	**class** *class-map-name* **Example:** `Device(config-pmap)# class class-map-1`	Associates the class map with the policy map.
Step 7	**bandwidth** *number* **Example:** `Device(config-pmap-c)# bandwidth 10000`	Associates the bandwidth (CBWFQ) action to act on traffic matched by the class map, and enters policy-map class configuration mode.
Step 8	**interface** *type number* **Example:** `Device(config-pmap-c)# interface gigabitethernet0/0/0`	Specifies the interface type and number, and enters interface configuration mode.
Step 9	**service-policy output** *policy-map-name* **Example:** `Device(config-if)# service-policy output outputmap`	Assigns the policy map to an interface.
Step 10	**end** **Example:** `Device(config-if)# end`	Returns to privileged EXEC mode.

Verifying the CBWFQ Configuration

SUMMARY STEPS

1. **show policy-map interface** *type number*

DETAILED STEPS

Procedure

show policy-map interface *type number*

Example:

```
Device5# show policy-map interface fe5/1/0
```

Verifies the class-based weighted fair queueing (CBWFQ) configuration, use a command of the following form. This example is based on “Device 5” in the network topology shown in the figure in the configuration examples section.

```
Device5# show policy-map interface fe5/1/0
```

```
FastEthernet5/1/0
 service-policy output:outputmap
   class-map:prec_01 (match-all)
     522 packets, 322836 bytes

Configuration Examples for MPLS Quality of Service

The configuration examples are based on the sample network topology shown in the figure below.

Figure 69: Sample Network Topology for Configuring MPLS CoS on Device Interfaces

Example: Configuring Cisco Express Forwarding

Cisco Express Forwarding must be running on all devices in the Multiprotocol Label Switching (MPLS) network for MPLS CoS to work. To enable Cisco Express Forwarding, use one of the following commands:

```
Device(config)# ip cef
```

or

```
Device(config)# ip cef distributed
```

Example: Running IP on Device 1

The following commands enable IP routing on Device 1. All devices in the figure must have IP enabled. Device 1 is not part of the Multiprotocol Label Switching (MPLS) network.

```
!
ip routing
!
hostname R1
!
interface Loopback0
 ip address 10.1.1.1 255.255.255.255
!
interface FastEthernet0/0/1
 ip address 10.0.0.1 255.0.0.0
!
router ospf 100
 network 10.0.0.0 0.255.255.255 area 100
 network 10.0.0.1 0.255.255.255 area 100
```

Example: Running MPLS on Device 2

Device 2 is a label edge router. Cisco Express Forwarding and Multiprotocol Label Switching (MPLS) must be enabled on this device. Committed access rate (CAR) is also configured on Device 2 and Fast Ethernet interface 1/1/3. The CAR policy used at Fast Ethernet interface 1/1/0 acts on incoming traffic matching access-list 101. If the traffic rate is less than the committed information rate (in this example, 496000), the traffic will be sent with IP precedence 4. Otherwise, this traffic will be sent with IP precedence 0.

```
!
ip routing
!
hostname R2
!
ip cef
mpls ip
tag-switching advertise-tags
!
interface Loopback0
 ip address 10.10.10.10 255.255.255.255
!
interface FastEthernet1/1/0
 ip address 10.0.0.2 255.0.0.0
