duplicates if another style binding in the list has the same\n *\n * `TStyleValue`.\n *\n */

```

NOTE: this function is intended to be called twice once with `isPrevDir` set to `true` and once with it set to `false` to search both the previous as well as next items in the list.

No duplicate case

```
[style.color] [style.width.px] <<- index [style.height.px]
[style.width.px] to the existing [style.color] produces no duplicates because `width` is not found in any other part of the linked list. Duplicate case [style.color] [style.width.em] [style.width.px] <<- index In the above case adding [style.width.px] will produce a duplicate with [style.width.em] because `width` is found in the chain. Map case 1 [style.width.px] [style.color] [style] <<- index In the above case adding [style] will produce a duplicate with any other bindings because [style] is a Map and as such is fully dynamic and could produce `color` or `width`. Map case 2 [style] [style.width.px] [style.color] <<- index In the above case adding [style.color] will produce a duplicate because there is already a [style] binding which is a Map and as such is fully dynamic and could produce `color` or `width`. NOTE: Once [style] (Map) is added into the system all things are mapped as duplicates. NOTE: We use `style` as example, but same logic is applied to `class`es as well. @param tData TData where the linked list is stored. @param tStylingKey TStylingKeyPrimitive which contains the value to compare to other keys in the linked list. @param index Starting location in the linked list to search from @param isPrevDir Direction - `true` for previous (lower priority); - `false` for next (higher priority).
```

```

Update text content with a lone bound value

```

Used when a text node has 1 interpolated value in it, an no additional text
surrounds that interpolated value:
`<div>{v0}</div>`
Its compiled representation is:
`ts`
textInterpolate(v0);
returns itself,
so that it may be chained.
@see textInterpolateV
@codeGenApi
function textInterpolate(v0:
any): typeof textInterpolate {
  textInterpolate1(" ", v0, "");
  return textInterpolate;
}

```

Update text content with single bound value surrounded by other text

```

Used when a text node has 1 interpolated value in it:
`<div>prefix{v0}suffix</div>`
Its compiled representation is:
`ts`
textInterpolate1('prefix', v0, 'suffix');
returns itself, so that it may be chained.
@see textInterpolateV
@codeGenApi
function textInterpolate1(prefix: string, v0: any, suffix: string):
typeof textInterpolate1 {
  const IView = getLView();

```

```

`previousTNodes` list\n * `tNode.insertBeforeIndex`.\n *\n * Things to keep in mind:\n * 1. All i18n text nodes are
encoded as `TNodeType.Element`
and are created eagerly by the\n * `i18nStart` instruction.\n * 2. All `TNodeType.Placeholder` `TNodes` are
elements which will be created later by\n * `elementStart` instruction.\n * 3. `elementStart` instruction will create
`TNode`s in the ascending `TNode.index` order. (So a\n * smaller index `TNode` is guaranteed to be created
before a larger one)\n *\n * We use the above three invariants to determine `TNode.insertBeforeIndex`.\n *\n * In an
ideal world `TNode.insertBeforeIndex` would always be `TNode.next.index`. However,\n * this will not work
because `TNode.next.index` may be larger than `TNode.index` which means that\n * the next node is not yet created
and therefore we can't insert in front of it.\n *\n * Rule1: `TNode.insertBeforeIndex = null` if `TNode.next === null`
(Initial condition, as we don't\n * know if there will be further `TNode`s inserted after.)\n * Rule2: If
`previousTNode` is created after the `tNode` being inserted, then\n *
`previousTNode.insertBeforeNode = tNode.index` (So when a new `tNode` is added we check\n * previous
to see if we can update its `insertBeforeTNode`)\n *\n * See `TNode.insertBeforeIndex` for more context.\n *\n *
@param previousTNodes A list of previous TNodes so that we can easily traverse `TNode`s in\n * reverse order.

 *
 * This file re-exports all symbols contained in this directory.
 * Why is this file not `index.ts`?
 * There seems to be an inconsistent path resolution of an `index.ts` file
 * when only the parent directory is referenced. This could be due to the
 * node module resolution configuration differing from rollup
 * and/or typescript.
 * With commit
 * https://github.com/angular/angular/commit/d5e3f2c64bd13ce83e7c70788b7fc514ca4a9918
 * the `instructions.ts` file was moved to `instructions/instructions.ts`
 * and an `index.ts` file was used to re-export everything. Having
 * had file names that were importing from `instructions` directly
 * (not the from the sub file or the `index.ts` file) caused strange
 * CI issues. `index.ts` had to be renamed to `all.ts` for this to
 * work.
 * Jira Issue = FW-1184

/**
 * Resolves the providers which are defined in the DirectiveDef.
 * When inserting the tokens and the factories in their respective arrays,
 * we can assume that this method is called first for the component (if any),
 * and then for other directives on the same node.
 * As a consequence, the providers are always processed in that order:
 * 1) The view providers of the component
 * 2) The providers of the component
 * 3) The providers of the other directives
 * This matches the structure of the injectables arrays of a view (for each node).
 * So the tokens and the factories can be pushed at the end of the arrays,
 * except in one case for multi providers.
 * @param def the directive definition
 * @param providers: Array of `providers`
 * @param viewProviders: Array of `viewProviders`
 *
 * @ngexport function providersResolver<T>(

* Retrieves directive instances associated
with a given DOM node. Does not include component instances. @usageNotes
* Given the following
DOM structure:
<html>
<app-root>
<button my-button></button>
<my-comp></my-comp>
</app-root>
Calling `getDirectives` on `<button>` will return an array with an instance of the
`MyButton` directive that is associated with the DOM node.
Calling `getDirectives` on `<my-comp>`
will return an empty array.
@param node DOM node for which to get the directives. @returns Array of
directives associated with the node. @publicApi @globalApi ng
function getDirectives(node: Node): Directive[] {
  // Skip text nodes because we can't have directives associated with them.

Subject, Subscription} from 'rxjs';\n\n/**\n * Use in components with the `@Output` directive to emit custom
events\n * synchronously or asynchronously, and register handlers for those events\n * by subscribing to an
instance.\n * @usageNotes\n * Extends\n * [RxJS `Subject`](https://rxjs.dev/api/index/class/Subject)\n * for
Angular by adding the `emit()` method.\n * In the following example, a component defines two output
properties\n
 * that create event emitters. When the title is clicked, the emitter\n * emits an open or close event to toggle the
current visibility state.\n * ```html\n * @Component({\n *   selector: 'zippy',\n *   template: `
\n * <div
class="zippy">\n *   <div (click)="toggle()">Toggle</div>\n *   <div [hidden]="!visible">\n *     <ng-
content></ng-content>\n *   </div>\n * </div>`})\n * export class Zippy {\n *   visible: boolean = true;\n *
@Output() open: EventEmitter<any> = new EventEmitter();\n *   @Output() close: EventEmitter<any> = new
EventEmitter();\n *   toggle() {\n *     this.visible = !this.visible;\n *     if (this.visible) {\n *
this.open.emit(null);\n *     } else {\n *       this.close.emit(null);\n *     }\n *   }\n * }\n * ```\n *
Access the event object with the `$event` argument passed to the output event\n * handler:\n * ```html\n * <zippy
(open)="onOpen($event)" (close)="onClose($event)"></zippy>\n * ```\n * @see [Observables

        }
      }
    }
  }
  return result;
}

Refreshes a query by combining matches from all active views and removing matches from deleted views.
@returns `true` if a query got dirty during change detection or if this is a static query resolving in creation mode, `false` otherwise.
@codeGenApi
export function queryRefresh(queryList: QueryList<any>): boolean {
  const IView = getLView();
  const tView = getTView();
  const queryIndex = getCurrentQueryIndex();
  setCurrentQueryIndex(queryIndex + 1);
  const tQuery = getTQuery(tView, queryIndex);
  if (queryList.dirty && (isCreationMode(IView) === ((tQuery.metadata.flags & QueryFlags.isStatic) === QueryFlags.isStatic))) {
    if (tQuery.matches === null) {
      queryList.reset([]);
    } else {
      const result = tQuery.crossesNgTemplate ? collectQueryResults(tView, IView, queryIndex, []) : materializeViewResults(tView, IView, tQuery, queryIndex);
      queryList.reset(result, unwrapElementRef);
      queryList.notifyOnChanges();
    }
    return true;
  }
  return false;
}

Creates new QueryList, stores the reference in LView and returns QueryList.
@param predicate The type for which the query will search
@param flags Flags associated with the query
@param read What to save in the query
@codeGenApi
export function viewQuery<T>(predicate: ProviderToken<unknown>|string[], flags: QueryFlags, read?: any): void {
  ngDevMode && assertNumber(flags, 'Expecting flags');

```

this returned function will be passed through to the `fn` function in the parameters when it is called.

```

@publicApi
export function fakeAsync(fn: Function): (...args: any[]) => any {
  if (fakeAsyncTestModule)
    return fakeAsyncTestModule.fakeAsync(fn);
  throw new
  Error(fakeAsyncTestModuleNotLoadedErrorMessage);
}

```

**Simulates the asynchronous passage of time for the timers in the `fakeAsync` zone.**

The microtasks queue is drained at the very start of this function and after any timer callback has been executed.

**millis** The number of milliseconds to advance the virtual timer.

**tickOptions** The options to pass to the `tick` function.

**usageNotes**

The `tick` option is a flag called `processNewMacroTasksSynchronously`, which determines whether or not to invoke new macroTasks.

If you provide a `tickOptions` object, but do not specify a `processNewMacroTasksSynchronously` property (tick(100, {})), then `processNewMacroTasksSynchronously` defaults to true.

If you omit the `tickOptions` parameter (tick(100)), then `tickOptions` defaults to {processNewMacroTasksSynchronously: true}.

**Example**

```

@example core/testing/ts/fake_async.ts region='basic'

```

The following example includes a nested timeout (new macroTask), and the `tickOptions` parameter is allowed to default. In this case, `processNewMacroTasksSynchronously` defaults to true, and the nested function is executed on each tick.

```

it('test with nested setTimeout', fakeAsync(() => {
  let nestedTimeoutInvoked = false;
  function funcWithNestedTimeout() {
    setTimeout(() => {
      nestedTimeoutInvoked = true;
    });
    setTimeout(funcWithNestedTimeout);
    tick();
    expect(nestedTimeoutInvoked).toBe(true);
  });
  In the following case, `processNewMacroTasksSynchronously` is explicitly set to false, so the nested timeout function is not invoked.
  it('test with nested setTimeout', fakeAsync(() => {
    let nestedTimeoutInvoked = false;
    function funcWithNestedTimeout() {
      setTimeout(() => {
        nestedTimeoutInvoked = true;
      });
    };
    setTimeout(funcWithNestedTimeout);
    tick(0, {
      processNewMacroTasksSynchronously: false;
    });
    expect(nestedTimeoutInvoked).toBe(false);
  });
}

```

**tick**

```

@publicApi
export function tick(
  millis: number = 0, tickOptions:
  {processNewMacroTasksSynchronously:
  boolean} = {
    processNewMacroTasksSynchronously: true
  }): void {
  if (fakeAsyncTestModule) {
    return fakeAsyncTestModule.tick(millis, tickOptions);
  }
  throw new
  Error(fakeAsyncTestModuleNotLoadedErrorMessage);
}

```

**Flushes any pending microtasks and simulates the asynchronous passage of time for the timers in the `fakeAsync` zone by draining the macrotask queue until it is empty.**

**maxTurns** The maximum number of times the scheduler attempts to clear its queue before throwing an error.

**returns** The simulated time elapsed, in milliseconds.

```

@publicApi
export function flush(maxTurns?: number): number {
  if (fakeAsyncTestModule) {
    return
    fakeAsyncTestModule.flush(maxTurns);
  }
  throw new
  Error(fakeAsyncTestModuleNotLoadedErrorMessage);
}

```

**Discard all remaining periodic tasks.**

```

@publicApi
export function discardPeriodicTasks(): void {
  if (fakeAsyncTestModule)
    return
    fakeAsyncTestModule.discardPeriodicTasks();
  throw new
  Error(fakeAsyncTestModuleNotLoadedErrorMessage);
}

```

**Flush any pending microtasks.**

```

@publicApi
export function flushMicrotasks(): void {
  if (fakeAsyncTestModule) {
    return
    fakeAsyncTestModule.flushMicrotasks();
  }
  throw new
  Error(fakeAsyncTestModuleNotLoadedErrorMessage);
}

```

`Function.prototype.name` behaves differently between IE and other browsers. In most browsers
return the name of the function itself, no matter how many other functions it inherits from. On IE the function
doesn't have its own `name` property, but it takes it from the lowest level in the prototype chain. E.g. if we have
`class Foo extends Parent` most browsers will evaluate `Foo.name` to `Foo` while IE will return `Parent`. We work around
the issue by converting the function to a string and parsing its name out that way via a regex.
if (type.hasOwnProperty('name')) {
  return type.name;
}
const match = (" + type).match(/^(function\s*([^\s(]+));/);

    * @publicApi
    * ^\nexport function inject<T>(token: ProviderToken<T>, options: InjectOptions): T|null;
    * ^\n
    * Injects a token from the currently active injector.
    * `inject` is only supported during instantiation of a dependency by the DI system. It can be used
    * during:
    * - Construction (via the `constructor`) of a class being instantiated by the DI system, such
    * as an `@Injectable` or `@Component`.
    * - In the initializer for fields of such classes.
    * - In the factory function specified for `useFactory` of a `Provider` or an `@Injectable`.
    * - In the `factory` function specified for an `InjectionToken`.
    * @param token A token that represents a dependency that should be injected.
    * @param flags Optional flags that control how injection is executed.
    * The flags correspond to injection strategies that can be specified with
    * parameter decorators `@Host`, `@Self`, `@SkipSelf`, and `@Optional`.
    * @returns the injected value if operation is successful, `null` otherwise.
    * @throws if called outside of a supported context.
    * @usageNotes
    * In practice the `inject()` calls are allowed in a constructor, a constructor parameter and a
    * field initializer:
    * ```typescript
    * @Injectable({providedIn: 'root'})
    * export class Car {
    *   radio: Radio|undefined;
    *   // OK: field initializer
    *   spareTyre = inject(Tyre);
    *   constructor() {
    *     // OK: constructor body
    *     this.radio = inject(Radio);
    *   }
    * }
    * ```
    * It is also legal to call `inject` from a provider's factory:
    * ```typescript
    * providers: [
    *   {provide: Car, useFactory: () => {
    *     // OK: a class factory
    *     const engine = inject(Engine);
    *     return new Car(engine);
    *   }}
    * ]
    * ```
    * Calls to the `inject()` function outside of the class creation context will result in error. Most
    * notably, calls to `inject()` are disallowed after a class instance was created, in methods
    * (including lifecycle hooks):
    * ```typescript
    * @Component({ ... })
    * export class CarComponent {
    *   ngOnInit() {
    *     // ERROR: too late, the component instance was already created
    *     const engine = inject(Engine);
    *     engine.start();
    *   }
    * }
    * ```
    * @publicApi
    * ^\nexport function inject<T>(
    token: ProviderToken<T>, flags: InjectFlags|InjectOptions =

```

```\n *\n * is described as:\n * ```\n * {\n * publicInput1: 'publicInput1',\n * declaredInput2:
['publicInput2', 'declaredInput2'],\n * }\n * ```\n *\n * Which

```

the minifier may translate to:

```

minifiedDeclaredInput2: ['publicInput2', 'declaredInput2'],

```

This allows the render to re-construct the minified, public, and declared names of properties.

NOTE: - Because declared and public name are usually same we only generate the array `['public', 'declared']` format when they differ.

- The reason why this API and `outputs` API is not the same is that `NgOnChanges` has inconsistent behavior in that it uses declared names rather than minified or public. For this reason `NgOnChanges` will be deprecated and removed in future version and this API will be simplified to be consistent with `output`.

inputs?: {[P in keyof T]: string | [string, string];}

A map of output names.

The format is in: {[actualPropertyName: string]: string}.

Which the minifier may translate to: {[minifiedPropertyName: string]: string}.

This allows the render to re-construct the minified and non-minified names of properties.

outputs?: {[P in keyof T]: string};

Function executed by the parent template to allow child directive to apply host bindings.

hostBindings?: HostBindingsFunction<T>;

The number of bindings in this directive `hostBindings` (including pure fn bindings).

Used to calculate the length of the component's LView array, so we can pre-fill the array and set the host binding start index.

hostVars?: number;

Assign static attribute values to a host element.

This property will assign static attribute values as well as class and style values to a host element. Since attribute values can consist of different types of values, the `hostAttrs` array must include the values in the following format:

```

= [
  // static attributes (like `title`, `name`, `id`...)
  attr1, value1, attr2, value,
  // a single namespace value (like `x:id`)
  NAMESPACE_MARKER, namespaceUri1, name1, value1,
  // another single namespace value (like `x:name`)
  NAMESPACE_MARKER, namespaceUri2, name2, value2,
  // a series of CSS classes that will be applied to the element (no spaces)
  CLASSES_MARKER, class1, class2, class3,
  // a series of CSS styles (property + value) that will be applied to the element
  STYLES_MARKER, prop1, value1, prop2, value2
]

```

All non-class and non-style attributes must be defined at the start of the list first before all class and style values are set. When there is a change in value type (like when classes and styles are introduced) a marker must be used to separate the entries. The marker values themselves are set via entries found in the [AttributeMarker]

```

enum

```

Function to create instances of content queries associated with a given directive.

contentQueries?: ContentQueriesFunction<T>;

Defines the name that can be used in the template to assign this directive to a variable.

See: {@link Directive.exportAs}

exportAs?: string[];

Template function use for rendering DOM.

This function has following structure.

```

function Template<T>(ctx:T, creationMode: boolean) {
  if (creationMode) {
    // Contains creation mode instructions.
  }
  // Contains binding update instructions.
}

```

Common instructions are:

- Creation mode instructions:
  - `elementStart`, `elementEnd`
  - `text`
  - `container`
  - `listener`
- Binding update instructions:
  - `bind`
  - `elementAttribute`
  - `elementProperty`
  - `elementClass`
  - `elementStyle`

template: ComponentTemplate<T>;

Constants for the nodes in the component's view.

Includes attribute arrays, local definition arrays etc.

consts?: TConstantsOrFactory;

An array of `ngContent[selector]` values that were found in the template.

ngContentSelectors?: string[];

Additional set of instructions specific to view query processing. This could be seen as a set of instruction to be inserted into the template function.

Query-related instructions need to be pulled out to a specific function as a timing of execution is different as compared to all other instructions (after change detection hooks but before view hooks).

viewQuery?: ViewQueriesFunction<T>| null;

A list of optional features to apply.

See: {@link NgOnChangesFeature}, {@link ProvidersFeature}

features?: ComponentDefFeature[];

Defines template and style encapsulation options available for Component's {@link Component}.

encapsulation?: ViewEncapsulation;

Defines arbitrary developer-defined data to be stored on a renderer instance.

This is useful for renderers that delegate to other renderers.

see: animation

```

and it is not present in `* production`. Its presence is purely to help debug issue in development, and should not be relied on in production application.

`*^ debug?: LViewDebug;`

The node into which this ``LView`` is inserted.

`*^ [HOST]: RElement|null;`

The static data for this view.

We need a reference to this so we can easily walk up the `* node tree` in DI and get the `TView.data` array associated with a node (where the `* directive defs` are stored).

`*^ readonly[TVIEW]: TView;`

Flags for this view. See `LViewFlags` for more info.

`*^ [FLAGS]: LViewFlags;`

This may store an `{ @link LView }` or `{ @link LContainer }`.

`*^ `LView`` - The parent view. This is needed when we exit the view and must restore the previous `* LView`. Without this, the render method would have to keep a stack of `* views` as it is recursively rendering templates.

`*^ `LContainer`` - The current view is part of a container, and is an embedded view.

`*^ [PARENT]: LView|LContainer|null;`

The next sibling `LView` or `LContainer`.

`*^` Allows us to propagate between sibling view states that aren't in the same `* container`. Embedded views already have a `node.next`, but it is only set for `* views` in the same container.

We need a way to link component views and views `* across containers` as well.

`*^ [NEXT]:`

`LView|LContainer|null;`

Queries active for this view - nodes from a view are reported to those queries.

`*^ [QUERIES]: LQueries|null;`

Store the ``TNode`` of the location where the current ``LView`` is inserted into.

`*^ Given:`

```

<div>
  <ng-template><span></span></ng-template>
</div>

```

We end up with two ``TView`s`.

- ``parent` `TView`` which contains `<div><!-- anchor --></div>`
- ``child` `TView`` which contains `<span></span>`

Typically the ``child`` is inserted into the declaration location of the ``parent``, but it can be `* inserted` anywhere. Because it can be inserted anywhere it is not possible to store the `* insertion` information in the ``TView`` and instead we must store it in the ``LView[T_HOST]``.

So to determine where is our insertion parent we would execute:

```

const parentLView = IView[PARENT];
const parentTNode = IView[T_HOST];
const insertionParent = parentLView[parentTNode.index];

```

If `null``, this is the root view of an application (root component is in this view) and it has `* no parents`.

`*^ [T_HOST]: TNode|null;`

When a view is destroyed, listeners need to be released and outputs need to be `* unsubscribed`. This context array stores both listener functions wrapped with `* their context` and output subscription instances for a particular view.

These change per `LView` instance, so they cannot be stored on `TView`. Instead, `* TView.cleanup` saves an index to the necessary context in this array.

After ``LView`` is created it is possible to attach additional instance specific functions at the `* end` of the ``IView[CLEANUP]`` because we know that no more ``T`` level cleanup functions will be `* added` here.

`*^ [CLEANUP]: any[]|null;`

- For dynamic views, this is the context with which to render the template (e.g. `* `NgForContext``), or ``{}`` if not defined explicitly.
- For root view of the root component it's a reference to the component instance itself.
- For components, the context is a reference to the component instance itself.
- For inline views, the context is `null``.

`*^ [CONTEXT]: T;`

An optional Module Injector to be used as fall back after Element Injectors are consulted.

`*^ readonly[INJECTOR]: Injector|null;`

Factory to be used for creating Renderer.

`*^ [RENDERER_FACTORY]: RendererFactory;`

Renderer to be used for this view.

`*^ [RENDERER]: Renderer;`

An optional custom sanitizer.

`*^ [SANITIZER]: Sanitizer|null;`

Reference to the first `LView` or `LContainer` beneath this `LView` in `* the hierarchy`.

`*^` Necessary to store this so views can traverse through their nested views `* to remove listeners` and call `onDestroy` callbacks.

`*^ [CHILD_HEAD]: LView|LContainer|null;`

The last `LView` or `LContainer` beneath this `LView` in the hierarchy.

`*^` The tail allows us to quickly add a new state to the end of the view list `* without having to propagate` starting from the first child.

`*^ [CHILD_TAIL]:`

`LView|LContainer|null;`

View where this view's template was declared.

`*^` The template for a dynamically created view may be declared in a different view than `* it is inserted`. We already track the ``"insertion view"`` (view where the template was `* inserted`) in `LView[PARENT]`, but we also need access to the ``"declaration view"`` (view where the template was declared). Otherwise, we wouldn't be able to call the `* view's` template function with the proper contexts. Context should be inherited from `* the declaration view tree`, not the insertion view tree.

`*^` Example (AppComponent template):

```

<ng-template #foo></ng-

```

template>

```
<-- declared here -->\n * <some-comp [tpl]="foo"></some-comp> <-- inserted inside this component -->\n *\n * The <ng-template> above is declared in the AppComponent template, but it will be passed into\n * SomeComp and inserted there. In this case, the declaration view would be the AppComponent,\n * but the insertion view would be SomeComp. When we are removing views, we would want to\n * traverse through the insertion view to clean up listeners. When we are calling the\n * template function during change detection, we need the declaration view to get inherited\n * context.\n */\n [DECLARATION_VIEW]: LView|null;\n\n /**\n * Points to the declaration component view, used to track transplanted `LView`s.\n */\n * See:\n * `DECLARATION_VIEW` which points to the actual `LView` where it was declared, whereas\n * `DECLARATION_COMPONENT_VIEW` points to the component which may not be same as\n * `DECLARATION_VIEW`.\n */\n * Example:\n * ```\n * <#VIEW #myComp>\n * <div *ngIf="true">\n * <ng-template #myTpl>...</ng-template>\n * </div>\n * </#VIEW>\n * ```\n * In the above case `DECLARATION_VIEW` for `myTpl` points to the\n * `LView` of `ngIf` whereas\n * `DECLARATION_COMPONENT_VIEW` points to `LView` of the `myComp`\n * which owns the template.\n */\n * The reason for this is that all embedded views are always check-always whereas\n * the component\n * view can be check-always or on-push. When we have a transplanted view it is important to\n * determine if we have transplanted a view from check-always declaration to on-push insertion\n * point. In such a case the transplanted view needs to be added to the `LContainer` in the\n * declared `LView` and CD during the declared view CD (in addition to the CD at the insertion\n * point.) (Any transplanted views which are intra Component are of no interest because the CD\n * strategy of declaration and insertion will always be the same, because it is\n * the same\n * component.)\n */\n * Queries already track moved views in\n * `LView[DECLARATION_LCONTAINER]` and\n * `LContainer[MOVED_VIEWS]`. However the queries also track\n * `LView`s which moved within the same\n * component `LView`. Transplanted views are a subset of moved views, and we use\n * `DECLARATION_COMPONENT_VIEW` to differentiate them. As in this example.\n */\n * Example showing intra component `LView` movement.\n * ```\n * <#VIEW #myComp>\n * <div *ngIf="condition; then thenBlock else elseBlock"></div>\n * <ng-template #thenBlock>Content to render when condition is true.</ng-template>\n * <ng-template #elseBlock>Content to render when condition is false.</ng-template>\n * </#VIEW>\n * ```\n * The `thenBlock` and `elseBlock` is moved but not transplanted.\n */\n * Example showing inter component `LView` movement (transplanted view).\n * ```\n * <#VIEW #myComp>\n * <ng-template #myTpl>...</ng-template>\n * <insertion-component [template]="myTpl"></insertion-component>\n * </#VIEW>\n * ```\n * In the above example `myTpl` is passed into a different component. If `insertion-component`\n * instantiates `myTpl` and `insertion-component` is on-push then the `LContainer` needs to be\n * marked as containing transplanted views and those views need to be CD as part of the\n * declaration CD.\n */\n *\n * When change detection runs, it iterates over\n * `[MOVED_VIEWS]` and CDs any child `LView`s where\n * the `DECLARATION_COMPONENT_VIEW` of the current component and the child `LView`\n * does not match\n * (it has been transplanted across components.)\n */\n *\n * Note: `DECLARATION_COMPONENT_VIEW` points to itself if the LView is a component view (the\n * simplest / most common case).\n */\n * see also:\n * - https://hackmd.io/@mhevery/rJUsvv9H write up of the problem\n * - `LContainer[HAS_TRANSPLANTED_VIEWS]` which marks which `LContainer` has transplanted views.\n * - `LContainer[TRANSPLANT_HEAD]` and `LContainer[TRANSPLANT_TAIL]` storage for transplanted\n * -\n * `LView[DECLARATION_LCONTAINER]` similar problem for queries\n * - `LContainer[MOVED_VIEWS]` similar problem for queries\n */\n [DECLARATION_COMPONENT_VIEW]: LView;\n\n /**\n * A declaration point of embedded views (ones instantiated based on the content of a\n * <ng-template>), null for other types of views.\n */\n * We need to track all embedded views created from a given declaration point so we can prepare\n * query matches in a proper order (query matches are ordered based on their declaration point and\n * _not_ the insertion point).\n */\n [DECLARATION_LCONTAINER]: LContainer|null;\n\n /**\n * More flags for this
```

view. See PreOrderHookFlags for more info.\n \*^n [PREORDER\_HOOK\_FLAGS]: PreOrderHookFlags;\n\n /\*\*\n \* The number of direct transplanted views which need a refresh or have descendants themselves\n \* that need a refresh but have not marked their ancestors as Dirty. check. These indices have\n * already been adjusted for the HEADER_OFFSET.\n * \n * \n components:
number[]|null;\n\n /**\n * A collection of queries tracked in a given view.\n * \n queries: TQueries|null;\n\n
/**\n * An array
of indices pointing to directives with content queries alongside with the\n * corresponding query index. Each entry
in this array is a tuple of:\n * - index of the first content query index declared by a given directive;\n * - index of a
directive.\n * \n * We are storing those indexes so we can refresh content queries as part of a view refresh\n *
process.\n * \n contentQueries: number[]|null;\n\n /**\n * Set of schemas that declare elements to be allowed
inside the view.\n * \n schemas: SchemaMetadata[]|null;\n\n /**\n * Array of constants for the view. Includes
attribute arrays, local definition arrays etc.\n * \n Used for directive matching, attribute bindings, local definitions and
more.\n * \n consts: TConstants|null;\n\n /**\n * Indicates that there was an error before we managed to
complete the first create pass of the\n * view. This means that the view is likely corrupted and we should try to
recover it.\n * \n incompleteFirstPass: boolean;\n}\n\n/**
Single hook callback function. \n\nexport type HookFn = () => void;\n\n/**\n * Information necessary to call a
hook. E.g. the callback that\n * needs to be invoked and the index at which to find its context.\n * \n\nexport type
HookEntry = number|HookFn;\n\n/**\n * Array of hooks that should be executed for a view and their directive
indices.\n * \n * For each node of the view, the following data is stored:\n * 1) Node index (optional)\n * 2) A series
of number/function pairs where:\n * - even indices are directive indices\n * - odd indices are hook functions\n * \n *
Special cases:\n * - a negative directive index flags an init hook (ngOnInit, ngAfterContentInit, ngAfterViewInit)\n
*\n\nexport type HookData = HookEntry[];\n\n/**\n * Array of destroy hooks that should be executed for a view and
their directive indices.\n * \n * The array is set up as a series of number/function or number/(number|function)[]:\n *
- Even indices represent the context with which hooks should be called.\n
* - Odd indices are the hook functions themselves. If a value at an odd index is an array,\n * it represents the
destroy hooks of a `multi` provider where:\n * - Even indices represent the index of the provider for which we've
registered a destroy hook,\n * inside of the `multi` provider array.\n * - Odd indices are the destroy hook
functions.\n * For example:\n * LView: `[0, 1, 2, AService, 4, [BService, CService, DService]]`\n * destroyHooks:
`[3, AService.ngOnDestroy, 5, [0, BService.ngOnDestroy, 2, DService.ngOnDestroy]]`\n * \n * In the example
above `AService` is a type provider with an `ngOnDestroy`, whereas `BService`,\n * `CService` and `DService` are
part of a `multi` provider where only `BService` and `DService`\n * have an `ngOnDestroy` hook.\n * \n\nexport type
DestroyHookData = (HookEntry|HookData)[];\n\n/**\n * Static data that corresponds to the instance-specific data
array on an LView.\n * \n * Each node's static data is stored in tData at the same index
that it's stored\n * in the data array. Any nodes that do not have static data store a null value in\n * tData to avoid a
sparse array.\n * \n * Each pipe's definition is stored here at the same index as its pipe instance in\n * the data
array.\n * \n * Each host property's name is stored here at the same index as its value in the\n * data array.\n * \n *
Each property binding name is stored here at the same index as its value in\n * the data array. If the binding is an
interpolation, the static string values\n * are stored parallel to the dynamic values. Example:\n * \n * id="prefix { {
v0 } } a { { v1 } } b { { v2 } } suffix"\n * \n * LView | TView.data\n * -----*\n * v0 value | 'a'\n *
v1 value | 'b'\n * v2 value | id prefix suffix\n * \n * Injector bloom filters are also stored here.\n * \n\nexport type

TStylingKey|ProviderToken<any>|TI18n|I18nUpdateOpCodes|Ticu|null|string)[];\n\n//
Note: This hack is necessary so we don't erroneously get a circular dependency\n// failure based on types.\n\nexport
const unusedValueExportToPlacateAjd = 1;\n\n/**\n * Human readable version of the `LView`.\n * \n * `LView` is

```

a data structure used internally to keep track of views. The `LView` is designed for efficiency and so at times it is difficult to read or write tests which assert on its values. For this reason when `ngDevMode` is true we patch a `LView.debug` property which points to `LViewDebug` for easier debugging and test writing. It is the intent of `LViewDebug` to be used in tests.

```

export interface LViewDebug<T = unknown> {
  /**
   * Flags associated with the `LView` unpacked into a more readable state.
   * See `LViewFlags` for the flag meanings.
   * readonly flags: {
    initPhaseState: number,
    creationMode: boolean,
    firstViewPass: boolean,
    checkAlways: boolean,
    dirty: boolean,
    attached: boolean,
    destroyed: boolean,
    isRoot: boolean,
    indexWithinInitPhase: number,
  };
  /**
   * Associated TView
   * readonly tView: TView;
  /**
   * Parent view (or container)
   * readonly parent: LViewDebug|LContainerDebug|null;
  /**
   * Next sibling to the `LView`.
   * readonly next: LViewDebug|LContainerDebug|null;
  /**
   * The context used for evaluation of the `LView`
   * (Usually the component)
   * readonly context: T;
  /**
   * Hierarchical tree of nodes.
   * readonly nodes: DebugNode[];
  /**
   * Template structure (no instance data).
   * (Shows how TNodes are connected)
   * readonly template: string;
  /**
   * HTML representation of the `LView`.
   * This is only approximate to actual HTML as child `LView`s are removed.
   * readonly html: string;
  /**
   * The host element to which this `LView` is attached.
   * readonly hostHTML: string|null;

  /**
   * Child `LView`s
   * readonly childViews: Array<LViewDebug|LContainerDebug>;
  /**
   * Sub range of `LView` containing decls (DOM elements).
   * readonly decls: LViewDebugRange;
  /**
   * Sub range of `LView` containing vars (bindings).
   * readonly vars: LViewDebugRange;
  /**
   * Sub range of `LView` containing expando (used by DI).
   * readonly expando: LViewDebugRange;
}

```

The `LContainer` is a data structure used internally to keep track of child views. The `LContainer` is designed for efficiency and so at times it is difficult to read or write tests which assert on its values. For this reason when `ngDevMode` is true we patch a `LContainer.debug` property which points to `LContainerDebug` for easier debugging and test writing. It is the intent of `LContainerDebug` to be used in tests.

```

export interface LContainerDebug {
  /**
   * Child `LView`s.
   * readonly views: LViewDebug[];
  /**
   * Parent: LViewDebug|null;
  /**
   * movedViews: LView[]|null;
  /**
   * host: RElement|RComment|LView;
  /**
   * next: LViewDebug|LContainerDebug|null;
  /**
   * hasTransplantedViews: boolean;
}

```

The `LView` is subdivided to ranges where the actual data is stored. Some of these ranges such as `decls` and `vars` are known at compile time. Other such as `i18n` and `expando` are runtime only concepts.

```

export interface LViewDebugRange {
  /**
   * The starting index in `LView` where the range begins. (Inclusive)
   * start: number;
  /**
   * The ending index in `LView` where the range ends. (Exclusive)
   * end: number;
  /**
   * The length of the range
   * length: number;
  /**
   * The merged content of the range. `t` contains data from `TView.data` and `l` contains `LView` data at an index.
   * content: LViewDebugRangeContent[];
}

```

For convenience the static and instance portions of `TView` and `LView` are merged into a single object in `LViewRange`.

```

export interface LViewDebugRangeContent {
  /**
   * Index into original `LView` or `TView.data`.
   * index: number;
  /**
   * Value from the `TView.data[index]` location.
   * t: any;
  /**
   * Value from the `LView[index]` location.
   * l: any;
}

```

A logical node which comprise into `LView`s.

```

export interface DebugNode {

 /**
 * Are we currently in i18n block as denoted by `elementStart` and
 `elementEnd`.
 *
 * This information is needed because while we are in i18n block all elements must be pre-
 declared
 * in the translation. (i.e. `Hello #2World/#2!` pre-declares element at `#2` location.)
 * This allocates
 `TNodeType.Placeholder` element at location `2`. If translator removes `#2`
 * from translation than the runtime
 must also ensure the element at `2` does not get inserted
 *
 * into the DOM. The translation does not carry information about deleted elements. Therefor the
 * only way to
 know that an element is deleted is that it was not pre-declared in the translation.
 *
 * This flag works by
 ensuring that elements which are created without pre-declaration
 * (`TNodeType.Placeholder`) are not inserted
 into the DOM render tree. (It does mean that the
 * element still gets instantiated along with all of its behavior
 [directives])
 *

requires complex logic as we need to deal with 2 constraints.\n * 1. Init hooks (ngOnInit, ngAfterContentInit,  
ngAfterViewInit) must all be executed once and only once, across many change detection cycles. This must be  
true even if some hooks throw, or if some recursively trigger a change detection cycle. To solve that, it is  
required to track the state of the execution of these init hooks. This is done by storing  
and maintaining flags in the view: the { @link InitPhaseState}, and the index within that phase. They can be  
seen as a cursor in the following structure: [[onInit1, onInit2], [afterContentInit1], [afterViewInit1,  
afterViewInit2, afterViewInit3]] They are are stored as flags in LView[FLAGS].\n * 2. Pre-order hooks can  
be executed in batches, because of the select instruction. To be able to pause and resume their execution, we also  
need some state about the hook's array that is being processed: - the index of the next hook to be executed\n
```

\* - the number of init hooks already found in the processed part of the array\n \* They are stored as flags in LView[PREORDER\_HOOK\_FLAGS].\n \* ^\n\n\n\*\*\n \* Executes pre-order check hooks ( OnChanges, DoChanges) given a view where all the init hooks were\n \* executed once. }
Factory for creating instances of injectors in the NodeInjector.
This factory is complicated by the fact that it can resolve `multi` factories as well.
NOTE: Some of the fields are optional which means that this class has two hidden classes.
- One without `multi` support (most common)
- One with `multi` values, (rare).
Since VMs can cache up to 4 inline hidden classes this is OK.
- Single factory: Only `resolving` and `factory` is defined.
- `providers` factory: `componentProviders` is a number and `index = -1`.
- `viewProviders` factory: `componentProviders` is a number and `index` points to `providers`.
export class
NodeInjectorFactory {
  /**
   * The inject implementation to be activated when using the factory.
   */
  injectImpl: null|(<T>(token: ProviderToken<T>, flags?: InjectFlags) => T);
  /**
   * Marker set to true during factory invocation to see if we get into recursive loop.
   * Recursive loop causes an error to be displayed.
   */
  resolving = false;
  /**
   * Marks that the token can see other Tokens declared in `viewProviders` on the same node.
   */
  canSeeViewProviders: boolean;
  /**
   * An array of factories to use in case of `multi` provider.
   */
  multi?: Array<() => any>;
  /**
   * Number of `multi`-providers which belong to the component.
   * This is needed because when multiple components and directives declare the `multi` provider they have to be concatenated in the correct order.
   * Example:
   * If we have a component and directive active on a single element as declared here:
   * component: {
   *   providers: [ { provide: String, useValue: 'component', multi: true } ],
   *   viewProviders: [ { provide: String, useValue: 'componentView', multi: true } ],
   *   directive: {
   *     providers: [ { provide: String, useValue: 'directive', multi: true } ],
   *   }
   * }
   * Then the expected results are:
   * providers: ['component', 'directive']
   * viewProviders: ['component', 'componentView', 'directive']
   * The way to think about it is that the `viewProviders` have been inserted after the component but before the directives, which is why we need to know how many `multi`s have been declared by the component.
   */
  componentProviders?: number;
  /**
   * Current index of the Factory in the `data`. Needed for `viewProviders` and `providers` merging.
   * See `providerFactory`.
   */
  index?: number;
}
* Because the same `multi` provider can be declared in `providers` and `viewProviders` it is possible for `viewProviders` to shadow the `providers`. For this reason we store the `provideFactory` of the `providers` so that `providers` can be extended with `viewProviders`.
Example:
Given:
providers: [ { provide: String, useValue: 'all', multi: true } ],
viewProviders: [ { provide: String, useValue: 'viewOnly', multi: true } ],
We have to return `[all]` in case of content injection, but `[all, 'viewOnly']` in case of view injection. We further have to make sure that the shared instances (in our case `all`) are the exact same instance in both the content as well as the view injection. (We have to make sure that we don't

```

double instantiate.) For this reason the `viewProviders` has a pointer to the shadowed `providers` factory so that it can instantiate the `providers`

```

(['all']) and then extend it with `viewProviders` (['all'] + ['viewOnly'] = ['all', 'viewOnly']).
providerFactory?: NodeInjectorFactory|null;

/**
 * TNodeType corresponds to the {@link TNode} `type` property.
 */
NOTE: type IDs are such that we use each bit to denote a type. This is done so that we can easily check if the `TNode` is of more than one type.
if (tNode.type === TNodeType.Text || tNode.type === TNodeType.Element)
  can be written as:
  if (tNode.type & (TNodeType.Text | TNodeType.Element))
  However any given `TNode` can only be of one type.
export const enum TNodeType {
  /**
   * The TNode contains information about a DOM element aka {@link RText}.
   */
  Text = 0b1,
  /**
   * The TNode contains information about a DOM element aka {@link RElement}.
   */
  Element = 0b10,
  /**
   * The TNode contains information about an {@link LContainer} for embedded views.
   */
  Container = 0b100,
  /**
   * The TNode contains information about an <ng-container> element {@link RNode}.
   */
  ElementContainer = 0b1000,
  /**
   * The TNode contains information about an <ng-content> projection
   */
  Projection = 0b10000,
  /**
   * The TNode contains information about an ICU comment used in `i18n`.
   */
  Icu = 0b100000,
  /**
   * Special node type representing a placeholder for future `TNode` at this location.
   */
  I18n = 0b1000000,
}
I18n translation blocks are created before the element nodes which they contain. (I18n blocks can span over many elements.) Because i18n `TNode`s (representing text) are created first they often may need to point to element `TNode`s which are not yet created. In such a case we create a `Placeholder` `TNode`. This allows the i18n to structurally link the `TNode`s together without knowing any information about the future nodes which will be at that location.
On `firstCreatePass` When element instruction executes it will try to create a `TNode` at that location. Seeing a `Placeholder` `TNode` already there tells the system that it should reuse existing `TNode` (rather than create a new one) and just update the missing information.
Placeholder = 0b1000000,
// Combined Types These should never be used for `TNode.type` only as a useful way to check if `TNode.type` is one of several choices.
// See:
https://github.com/microsoft/TypeScript/issues/35875 why we can't refer to existing enum.
AnyRNode = 0b11,

    * \n * If index is -1, this is a dynamically
created container node or embedded view node.
    * /\n index: number;
    * \n /**\n * Insert before existing DOM
node index.
    * \n * When DOM nodes are being inserted, normally they are being appended as they are created.
    * \n * Under i18n case, the translated text nodes are created ahead of time as part of the
    * `i18nStart` instruction
which means that this `TNode` can't just be appended and instead
    * needs to be inserted using
`insertBeforeIndex` semantics.
    * \n * Additionally sometimes it is necessary to insert
new text nodes as a child of this `TNode`. In
    * such a case the value stores an array of text nodes to insert.
    * \n * Example:
    * ``\n * <div i18n>
    * Hello <span>World</span>
    * </div>
    * ``\n * In the above
example the `i18nStart` instruction can create `Hello`, `World` and `!` text
    * nodes. It can also insert `Hello`
and `!` text node as a child of `

`, but it can't
    * insert `World` because the `` node has not yet been
created. In such a case the
    * `` `TNode` will have an array which will direct the `` to not only
insert
    * itself in front of `!` but also to insert the `World` (created by `i18nStart`) into
    * `` itself.
    * \n * Pseudo code:
    * ``\n * if (insertBeforeIndex === null) {
    * // append as normal
    * } else if
(Array.isArray(insertBeforeIndex)) {
    * // First insert current `TNode` at correct location
    * const
currentNode = IView[this.index];
    * parentNode.insertBefore(currentNode,
IView[this.insertBeforeIndex[0]]);
    * // Now append all of the children
    * for(let i=1;
i<this.insertBeforeIndex; i++) {
    * currentNode.appendChild(IView[this.insertBeforeIndex[i]]);
    * }
    * } else {
    * parentNode.insertBefore(IView[this.index], IView[this.insertBeforeIndex])
    * }
    * ``\n * -
null: Append as normal using `parentNode.appendChild`
    * - `number`: Append using
    * `parentNode.insertBefore(IView[this.index], IView[this.insertBeforeIndex])`
    * \n * *Initialization*
    * \n * Because `i18nStart` executes before nodes are created, on `TView.firstCreatePass` it is not
    * possible for
`i18nStart` to set the `insertBeforeIndex` value as the corresponding `TNode`
    * has not yet been created. For this
reason the `i18nStart` creates a `TNodeType.Placeholder`
    * `TNode` at that location. See
`TNodeType.Placeholder` for more information.
    * /\n insertBeforeIndex: InsertBeforeIndex;
    * \n
    * \n /**\n * The index of the closest injector in this node's LView.
    * \n * If the index === -1, there is no injector
on this node or any ancestor node in this view.
    * \n * If the index !== -1, it is the index of this node's injector OR

```

the index of a parent injector in the same view. We pass the parent injector index down the node tree of a view so it's possible to find the parent injector without walking a potentially deep node tree. Injector indices are not set across view boundaries because there could be multiple component hosts. If `tNode.injectorIndex === tNode.parent.injectorIndex`, then the index belongs to a parent injector.

`injectorIndex: number;`  
 Stores starting index of the directives. NOTE: The first directive is always component (if present).  
`directiveStart: number;`  
 Stores final exclusive index of the directives. The area right behind the `directiveStart-directiveEnd` range is used to allocate the `HostBindingFunction`vars`` (or null if no bindings.) Therefore `directiveEnd` is used to set `LFrame.bindingRootIndex`` before `HostBindingFunction`` is executed.  
`directiveEnd: number;`  
 Stores the last directive which had a styling instruction. Initial value of this is `-1`` which means that no `hostBindings`` styling instruction has executed. As `hostBindings`` instructions execute they set the value to the index of the `DirectiveDef`` which contained the last `hostBindings`` styling instruction. Valid values are:  
`-1`` No `hostBindings`` instruction has executed.  
`directiveStart <= directiveStylingLast < directiveEnd``: Points to the `DirectiveDef`` of the last styling instruction which executed in the `hostBindings``. This data is needed so that styling instructions know which static styling data needs to be collected from the `DirectiveDef.hostAttrs``. A styling instruction needs to collect all data since last styling instruction.  
`directiveStylingLast: number;`  
 Stores indexes of property bindings. This field is only set in the `ngDevMode` and holds indexes of property bindings so  `TestBed`  can get bound property metadata for a given node.  
`propertyBindings: number[]|null;`  
 Stores if `Node` is `Component`, `isProjected`, `hasContentQuery`, `hasClassInput` and `hasStyleInput` etc.  
`flags: TNodeFlags;`  
 This number stores two values using its bits:  
 - the index of the first provider on that node (first 16 bits)  
 - the count of view providers from the component on this node (last 16 bits)  
 // TODO(misko): break this into actual vars.  
`providerIndexes: TNodeProviderIndexes;`  
 The value name associated with this node. if type:  
`TNodeType.Text``: text value  
`TNodeType.Element``: tag name  
`TNodeType.ICUContainer``: `TIcu`` value: any;  
 Attributes associated with an element. We need to store attributes to support various use-cases (attribute injection, content projection with selectors, directives matching). Attributes are stored statically because reading them from the DOM would be way too slow for content projection and queries. Since `attrs` will always be calculated first, they will never need to be marked undefined by other instructions. For regular attributes a name of an attribute and its value alternate in the array. e.g. `['role', 'checkbox']`. This array can contain flags that will indicate "special attributes" (attributes with namespaces, attributes extracted from bindings and outputs).  
`TAttributes|null;`  
 Same as `TNode.attrs`` but contains merged data across all directive host bindings. We need to keep `attrs`` as unmerged so that it can be used for attribute selectors. We merge `attrs` here so that it can be used in a performant way for initial rendering. The `attrs`` are merged in first pass in following order:  
 - Component's `hostAttrs``  
 - Directives' `hostAttrs``  
 - Template `TNode.attrs`` associated with the current `TNode``.  
`mergedAttrs: TAttributes|null;`  
 A set of local names under which a given element is exported in a template and visible to queries. An entry in this array can be created for different reasons:  
 - an element itself is referenced, ex.: `<div #foo>`  
 - a component is referenced, ex.: `<my-cmpt #foo>`  
 - a directive is referenced, ex.: `<my-cmpt #foo="directiveExportAs">`.  
 A given element might have different local names and those names can be associated with a directive. We store local names at even indexes while odd indexes are reserved for directive index in a view (or `-1`` if there is no associated directive).  
 Some examples:  
 - `<div #foo>` => `["foo", -1]`  
 - `<my-cmpt #foo>` => `["foo", myCmptIdx]`  
 - `<my-cmpt #foo #bar="directiveExportAs">` => `["foo", myCmptIdx, "bar", directiveIdx]`  
 - `<div #foo #bar="directiveExportAs">` => `["foo", -1, "bar", directiveIdx]`  
`localNames: (string|number)[]|null;`  
 Information about input properties that need to be set once from attribute data.  
`initialInputs: InitialInputData|null|undefined;`  
 Input data for all

directives on this node. `null` means that there are no directives with\n \* inputs on this node.\n \* /\n inputs: PropertyAliases|null;\n\n /\*\*\n \* Output data for all directives on this node. `null` means that there are no directives with\n \* outputs on this node.\n \* /\n outputs: PropertyAliases|null;\n\n /\*\*\n \* The TView or TViews attached to this node.\n \* \n \* If this TNode corresponds to an LContainer with inline views, the container will\n \* need to store separate static data for each of its view blocks (TView[]). Otherwise,\n \* nodes in inline views with the same index as nodes in their parent views will overwrite\n \* each other, as they are in the same template.\n \* \n \* Each index in this array corresponds to the static data for a certain\n \* view. So if you had V(0) and V(1) in a container, you might have:\n \* \n \* [\n \* [{tagName: 'div', attrs: ...}, null], // V(0) TView\n \* [{tagName: 'button', attrs ...}, null] // V(1) TView\n \* \n \* If this TNode corresponds to an LContainer with a template (e.g. structural\n \* directive), the template's TView will be stored here.\n \* \n \* If this TNode corresponds to an element, tViews will be null.\n \* /\n tViews: TView|TView[]|null;\n\n /\*\*\n \* The next sibling node. Necessary so we can propagate through the root nodes of a view\n \* to insert them or remove them from the DOM.\n \* /\n next: TNode|null;\n\n /\*\*\n \* The next projected sibling. Since in Angular content projection works on the node-by-node\n \* basis the act of projecting nodes might change nodes relationship at the insertion point\n \* (target view). At the same time we need to keep initial relationship between nodes as\n \* expressed in content view.\n \* /\n projectionNext: TNode|null;\n\n /\*\*\n \* First child of the current node.\n \* \n \* For component nodes, the child will always be a ContentChild (in same view).\n \* \n \* For embedded view nodes, the child will be in their child view.\n \* /\n child: TNode|null;\n\n /\*\*\n \* Parent node (in the same view only).\n \* \n \* We need a reference to a node's parent so we can append the node to its parent's native\n \* element at the appropriate time.\n \* \n \* If the parent would be in a different view (e.g. component host), this property will be null.\n \* \n \* It's important that we don't try to cross component boundaries when retrieving the parent\n \* \n \* because the parent will change (e.g. index, attrs) depending on where the component was\n \* used (and thus shouldn't be stored on TNode). In these cases, we retrieve the parent through\n \* LView.node instead (which will be instance-specific).\n \* \n \* If this is an inline view node (V), the parent will be its container.\n \* /\n parent: TElementNode|TContainerNode|null;\n\n /\*\*\n \* List of projected TNodes for a given component host element OR index into the said nodes.\n \* \n \* For easier discussion assume this example:\n \* \n \* <parent>'s view definition:\n \* \n \* <child id="c1">content1</child>\n \* \n \* <child id="c2"><span>content2</span></child>\n \* \n \* <child>'s view definition:\n \* \n \* <ng-content id="cont1"></ng-content>\n \* \n \* \n \* If `Array.isArray(projection)` then `TNode` is a host element:\n \* \n \* - `projection` stores the content nodes which are to be projected.\n \* \n \* - The nodes represent categories defined by the selector: For example:\n \* \n \* <ng-content/><ng-content select="abc"/>` would represent the heads for `<ng-content/>\n \* \n \*` and `<ng-content select="abc"/>` respectively.\n \* \n \* - The nodes we store in `projection` are heads only, we used `.next` to get their\n \* \n \* siblings.\n \* \n \* - The nodes `.next` is sorted/rewritten as part of the projection setup.\n \* \n \* - `projection` size is equal to the number of projections `<ng-content>`. The size of\n \* \n \* `c1` will be `1` because `<child>` has only one `<ng-content>`. \n \* \n \* - we store `projection` with the host (`c1`, `c2`) rather than the `<ng-content>` (`cont1`)\n \* \n \* because the same component (`<child>`) can be used in multiple locations (`c1`, `c2`) and\n \* \n \* as a result have different set of nodes to project.\n \* \n \* - without `projection` it would be difficult to efficiently traverse nodes to be projected.\n \* \n \* \n \* If `typeof projection == 'number'` then `TNode` is a `<ng-content>` element:\n \* \n \* - `projection` is an index of the host's `projection`Nodes.\n \* \n \* - This would return the first head node to project:\n \* \n \* `getHost(currentTNode).projection[currentTNode.projection]`.\n \* \n \* - When projecting nodes the parent node retrieved may be a `<ng-content>` node, in which case\n \* \n \* the process is recursive in nature.\n \* \n \* \n \* If `projection` is of type `RNode[]` then we have a collection of native nodes passed as\n \* \n \* projectable nodes during dynamic component creation.\n \* \n \* /\n projection: (TNode|RNode[]|number|null);\n\n /\*\*\n \* A collection of all `style` static values for an element (including from host).\n \* \n \* This field will be populated if and when:\n \* \n \* \n \* - There are one or more initial `style`s on an element (e.g. `<div style="width:200px;">`)\n \* \n \* - There are one or more initial `style`s on a directive/component host\n \* \n \* (e.g. `@Directive({host: {style: "width:200px;" } })`)\n

```

*/\n styles: string|null;\n\n /**\n * A collection
of all `style` static values for an element excluding host sources.\n *\n * Populated when there are one or more
initial `style`s on an element\n * (e.g. `

```

\* If this is a component TNode with projection, this will be an array of projected TNodes or native nodes (see TNode.projection for more info). If it's a regular element node or a component without projection, it will be null.

\* projection: (TNode|RNode[])|null;

\* Stores TagName

\* value: string;

Static data for a text node

\* export interface TTextNode extends TNode {

\* Index in the data[] array

index: number;

child: null;

\* Text nodes will have parents unless they are the first node of a component or embedded view (which means their parent is in a different view and must be retrieved using LView.node).

\* parent: TElementNode|TElementContainerNode|null;

tViews: null;

projection: null;

Static data for an LContainer

\* export interface TContainerNode extends TNode {

\* Index in the data[] array.

\* If it's -1, this is a dynamically created container node that isn't stored in data[] (e.g. when you inject ViewContainerRef).

index: number;

child: null;

\* Container nodes will have parents unless:

\* - They are the first node of a component or embedded view

\* - They are dynamically created

\* parent: TElementNode|TElementContainerNode|null;

tViews: TView|TView[]|null;

projection: null;

value: null;

Static data for an <ng-container>

\* export interface TElementContainerNode extends TNode {

\* Index in the LView[] array.

index: number;

child: TElementNode|TTextNode|TContainerNode|TElementContainerNode|TProjectionNode|null;

parent: TElementNode|TElementContainerNode|null;

tViews: null;

projection: null;

Static data for an ICU expression

\* export interface TIcuContainerNode extends TNode {

\* Index in the LView[] array.

index: number;

child: null;

parent: TElementNode|TElementContainerNode|null;

tViews: null;

projection: null;

value: TIcu;

Static data for an LProjectionNode

\* export interface TProjectionNode extends TNode {

\* Index in the data[] array

child: null;

\* Projection nodes will have parents unless they are the first node of a component or embedded view (which means their parent is in a different view and must be retrieved using LView.node).

\* parent: TElementNode|TElementContainerNode|null;

tViews: null;

\* Index of the projection node. (See TNode.projection for more info.)

projection: number;

value: null;

A union type representing all TNode types that can host a directive.

\* export type TDirectiveHostNode = TElementNode|TContainerNode|TElementContainerNode;

\* This mapping is necessary so we can set input properties and output listeners properly at runtime when property names are minified or aliased.

\* Key: unminified / public input or output name

\* Value: array containing minified / internal name and related directive index

\* The value must be an array to support inputs and outputs with the same name on the same node.

\* export type PropertyAliases = {

// This uses an object map because using the Map type would be too slow

[key: string]: PropertyAliasValue;

};

\* Store the runtime input or output names for all the directives.

\* i+0: directive instance index

\* i+1: privateName

\* e.g. [0, 'change-minified']

\* export type PropertyAliasValue = (number|string)[];

\* This array contains information about input properties that need to be set once from attribute data. It's ordered by directive index (relative to element) so it's simple to look up a specific directive's initial input data.

\* Within each sub-array:

\* i+0: attribute name

\* i+1: minified/internal input name

\* i+2: initial value

\* If a directive on a node does not have any input properties that should be set from attributes, its index is set to null to avoid a sparse array.

\* e.g. [null, ['role-min', 'minified-input', 'button']]

\* export type InitialInputData = (InitialInputs|null)[];

\* Used by InitialInputData to store input properties that should be set once from attributes.

\* i+0: attribute name

\* i+1: minified/internal input name

\* i+2: initial value

\* e.g. ['role-min', 'minified-input', 'button']

\* export type InitialInputs = string[];

Note: This hack is necessary so we don't erroneously get a circular dependency failure based on types.

\* export const unusedValueExportToPlacateAjd = 1;

\* Type representing a set of TNodes that can have local refs (#foo) placed on them.

\* export type TNodeWithLocalRefs = TContainerNode|TElementNode|TElementContainerNode;

\* Type for a function that extracts a value for a local refs.

\* Example:

\* - <div #nativeDivEl> - nativeDivEl should point to the native <div> element;

\* - <ng-template #tplRef> - tplRef should point to the TemplateRef instance;

\* export type LocalRefExtractor = (tNode: TNodeWithLocalRefs, currentView: LView) => any;

\* Returns true if the

```

`TNode` has a directive which has `@Input()` for `class` binding.\n *\n * ```\n * <div my-dir

`inject` should include `viewProviders` in its resolution.\n * This is set to true when we try to instantiate a
component. This value is reset in\n * `getNodeInjectable` to a value which matches the declaration location of the

```

```

token about to be instantiated. This is done so that if we are injecting a token which was declared outside of
`viewProviders` we don't accidentally pull `viewProviders` in. Example:
class MyService {
  constructor(public value: String) {}
  @Component({ providers: [MyService,
    { provide: String, value: 'providers' } ], viewProviders: [
    { provide: String, value: 'viewProviders' } ] })
  class MyComponent {
    constructor(myService: MyService, value: String) {
      // We expect that Component can see into `viewProviders`
      expect(value).toEqual('viewProviders');
      // `MyService` was not declared in `viewProviders` hence it can't see it.
      expect(myService.value).toEqual('providers');
    }
  }
}
**
let includeViewProviders = true;
export function setIncludeViewProviders(v: boolean): boolean {
  const oldValue = includeViewProviders;
  includeViewProviders = v;
  return oldValue;
}
**
The number of slots in each bloom filter (used by DI). The larger this number, the fewer directives that will share slots, and thus, the fewer false positives when checking for the existence of a directive.
const BLOOM_SIZE = 256;
const BLOOM_MASK = BLOOM_SIZE - 1;
**
The number of bits that is represented by a single bloom bucket. JS bit operations are 32 bits, so each bucket represents 32 distinct tokens which accounts for log2(32) = 5 bits of a bloom hash number.
const BLOOM_BUCKET_BITS = 5;
**
Counter used to generate unique IDs for directives.
let nextNgElementId = 0;
**
Value used when something wasn't found by an injector.
const NOT_FOUND = {};
**
Registers this directive as present in its node's injector by flipping the directive's corresponding bit in the injector's bloom filter.
@param injectorIndex The index of the node injector where this token should be registered
@param tView The TView for the injector's bloom filters
@param type The directive token to register
export function bloomAdd(injectorIndex: number, tView: TView, type: ProviderToken<any>|string): void {
  ngDevMode && assertEquals(tView.firstCreatePass, true, 'expected firstCreatePass to be true');
  let id: number|undefined;
  if (typeof type === 'string') {
    id = type.charCodeAt(0) || 0;
  } else if (type.hasOwnProperty(NG_ELEMENT_ID)) {
    id = (type as any)[NG_ELEMENT_ID];
  }
  // Set a unique ID on the directive type, so if something tries to inject the directive, we can easily retrieve the ID and hash it into the bloom bit that should be checked.
  if (id == null) {
    id = (type as any)[NG_ELEMENT_ID] = nextNgElementId++;
  }
  // We only have BLOOM_SIZE (256) slots in our bloom filter (8 buckets * 32 bits each), so all unique IDs must be modulo-ed into a number from 0 - 255 to fit into the filter.
  const bloomHash = id & BLOOM_MASK;
  // Create a mask that targets the specific bit associated with the directive. JS bit operations are 32 bits, so this will be a number between 2^0 and 2^31, corresponding to bit positions 0 - 31 in a 32 bit integer.
  const mask = 1 << bloomHash;
  // Each bloom bucket in `tData` represents `BLOOM_BUCKET_BITS` number of bits of `bloomHash`. Any bits in `bloomHash` beyond `BLOOM_BUCKET_BITS` indicate the bucket offset that the mask should be written to.
  (tView.data as number[])[injectorIndex + (bloomHash >> BLOOM_BUCKET_BITS)] |= mask;
}
**
Creates (or gets an existing) injector for a given element or container.

```

string will never cause an XSS vulnerability if used in a context that will cause a browser to load and execute a resource, e.g. when assigning to `script.src`.

`export function trustedScriptURLFromString(url: string): TrustedScriptURL {`  
 `return getPolicy()?.createScriptURL(url) || url;`  
`}`

Unsafely call the Function constructor with the given string arguments. It is only available in development mode, and should be stripped out of production code.

@security This is a security-sensitive function; any use of this function must go through security review. In particular, it must be assured that it is only called from development code, as use in production code can lead to XSS vulnerabilities.

`export function newTrustedFunctionForDev(...args: string[]): Function {`  
 `if (typeof ngDevMode === 'undefined') {`  
 `throw new Error('newTrustedFunctionForDev should never be called in production');`  
 `}`  
 `if (!global.trustedTypes) {`  
 `// In environments that don't support Trusted Types, fall back to the most straightforward implementation:`  
 `return new Function(...args);`  
 `}`  
 `// Chrome currently does not support passing TrustedScript to the Function constructor. The following implements the workaround proposed on the page below, where the Chromium bug is also referenced:`  
 `// https://github.com/w3c/webappsec-trusted-types/wiki/Trusted-Types-for-function-constructor`  
 `const fnArgs = args.slice(0, -1).join(',');`  
 `const fnBody = args[args.length - 1];`  
 `const body = `(function anonymous(${fnArgs}) { ${fnBody} })`;`  
 `// Using eval directly confuses the compiler and prevents this module from being stripped out of JS binaries even if not used. The global['eval'] indirection fixes that.`  
 `const fn = global['eval'](trustedScriptFromString(body) as string) as Function;`  
 `if (fn.bind === undefined) {`  
 `// Workaround for a browser bug that only exists in Chrome 83, where passing a TrustedScript to eval just returns the TrustedScript back without evaluating it. In that case, fall back to the most straightforward implementation:`  
 `return new Function(...args);`  
 `}`  
 `// To completely mimic the behavior of calling "new Function", two more things need to happen:`  
 `// 1. Stringifying the resulting function should return its source code`  
 `fn.toString = () => body;`  
 `// 2. When calling the resulting function, `this` should refer to `global``  
 `return fn.bind(global);`  
`}`

When Trusted Types support in Function constructors is widely available, the implementation of this function can be simplified to:

`return new Function(...args.map(a => trustedScriptFromString(a)));`

*\n\n\n /**\n * A pattern that
recognizes a commonly useful subset of URLs that are safe.\n *\n * This regular expression matches a subset of
URLs that will not cause script\n * execution if used in URL context within a HTML document. Specifically, this\n
* regular expression matches if (comment from here on and regex copied from\n * Soy's EscapingConventions):\n *
(1) Either an allowed protocol (http, https, mailto or ftp).\n * (2) or no protocol. A protocol must be followed by a
colon. The below\n * allows that by allowing colons only after one of the characters [/?#].\n * A colon after a
hash (#) must be in the fragment.\n * Otherwise, a colon after a (?) must be in a query.\n * Otherwise, a colon
after a single solidus (/) must be in a path.\n * Otherwise, a colon after a double solidus (//) must be in the
authority\n * (before port).\n *\n * The pattern disallows &, used in HTML entity declarations before\n * one of
the characters in [/?#]. This disallows HTML entities used in the\n *
protocol name, which should never happen, e.g. \"h&#116;tp\" for \"http\".\n * It also disallows HTML entities in
the first path part of a relative path,\n * e.g. \"foo&lt;bar/baz\". Our existing escaping functions should not
produce\n * that. More importantly, it disallows masking of a colon,\n * e.g. \"javascript&#58;...\".\n *\n * This

```

```

NB: This currently consciously doesn't support SVG. SVG sanitization has had several security\n// issues in the past,

```

so it seems safer to leave it out if possible. If support for binding SVG via innerHTML is required, SVG attributes should be added here. NB: Sanitization does not allow <form> elements or other active elements (<button> etc). Those can be sanitized, but they increase security surface area without a legitimate use case, so they are left out here.

```

/**
 * Creates a token that can be used in a DI Provider.
 * Use an `InjectionToken` whenever the type you are injecting is not reified (does not have a runtime representation) such as when injecting an interface, callable type, array or parameterized type.
 * `InjectionToken` is parameterized on `T` which is the type of object which will be returned by the `Injector`. This provides an additional level of type safety.
 * interface MyInterface {...}
 * const myInterface = injector.get(new InjectionToken<MyInterface>('SomeToken'));
 * // myInterface is inferred to be MyInterface.
 * When creating an `InjectionToken`, you can optionally specify a factory function which returns (possibly by creating) a default value of the parameterized type `T`. This sets up the `InjectionToken` using this factory as a provider as if it was defined explicitly in the application's root injector. If the factory function, which takes zero arguments, needs to inject dependencies, it can do so using the `inject` function.
 * As you can see in the Tree-shakable InjectionToken example below.
 * Additionally, if a `factory` is specified you can also specify the `providedIn` option, which overrides the above behavior and marks the token as belonging to a particular `@NgModule`. As mentioned above, `root` is the default value for `providedIn`.
 * @usageNotes
 * ### Basic Examples
 * ### Plain InjectionToken
 * @example core/di/ts/injector_spec.ts region='InjectionToken'
 * ### Tree-shakable InjectionToken
 * @example core/di/ts/injector_spec.ts region='ShakableInjectionToken'
 * @publicApi

/**
 * A ReflectiveDependency injection container used for instantiating
objects and resolving
 * dependencies.
 * An `Injector` is a replacement for a `new` operator, which can
automatically resolve the
 * constructor dependencies.
 * In typical use, application code asks for the
dependencies in the constructor and they are
 * resolved by the `Injector`.
 * @usageNotes
 * ### Example
 * The following example creates an `Injector` configured to create `Engine` and `Car`.
 * ```typescript
 * @Injectable()
 * class Engine {
 * }
 * @Injectable()
 * class Car {
 *   constructor(public engine: Engine)
 * }
 * var injector = ReflectiveInjector.resolveAndCreate([Car, Engine]);
 * var car = injector.get(Car);
 * expect(car instanceof Car).toBe(true);
 * expect(car.engine instanceof Engine).toBe(true);
 * ```
 * Notice,
we don't use the `new` operator because we explicitly want to have the `Injector`
 * resolve all of the object's
dependencies automatically.
 * TODO: delete in v14.
 * @deprecated

```

from v5 - slow and brings in a lot of code, Use `Injector.create` instead.

```

    * @publicApi
    * ^\nexport abstract class ReflectiveInjector implements Injector {
    * /**
    * * Turns an array of provider definitions into an array of resolved providers.
    * * A resolution is a process of flattening multiple nested arrays and converting individual
    * * providers into an array of `ResolvedReflectiveProvider`s.
    * * @usageNotes
    * * ### Example
    * * ```typescript
    * * @Injectable()
    * * class Engine {}
    * * @Injectable()
    * * class Car {
    * *   constructor(public engine: Engine) {}

TStylingKeyPrimitive|TStylingStatic;\n\n/**\n * The primitive portion (`TStylingStatic` removed) of the value
stored in the `TData` which is\n * needed to re-concatenate the styling.\n * \n * - `string`: Stores the property name.
Used with `styleProp`/`classProp` instruction.\n * - `null`: Represents map, so there is no name. Used with
`styleMap`/`classMap`.\n * - `false`: Represents an ignore case. This happens when `styleProp`/`classProp`
instruction\n * is combined with directive which shadows its input `@Input('class')`. That way the binding\n *
should not participate in the styling resolution.\n * \nexport type TStylingKeyPrimitive = string|null|false;\n\n/**\n *

```

Store the static values for the styling binding. The `TStylingStatic` is just `KeyValueArray` where key (stored at location 0) contains the `TStylingKey` (stored at location 1). In other words this wraps the `TStylingKey` such that the contains the wrapped value. When instructions are resolving styling they may need to look forward or backwards in the linked list to resolve the value. For this reason we have to make sure that the linked list also contains the static values. However the list only has space for one item per styling instruction. For this reason we store the static values here as part of the `TStylingKey`. This means that the resolution function when looking for a value needs to first look at the binding value, and then at `TStylingKey` (if it exists). Imagine we have:

```

<div
class="TEMPLATE" my-dir>
  @Directive({
    host: {
      class: 'DIR',
      [class.dynamic]: 'exp' //
classProp('dynamic', ctx.exp);
    })
  // assume binding location: 10 for `classProp('dynamic', ctx.exp);
  tData[10] =
<TStylingStatic>
  ': 'dynamic', // This is the wrapped value of `TStylingKey`
  'DIR': true, // This is the
default static value of directive binding
];
  tData[10
+ 1] = 0; // We don't have prev/next
  IView[10] = undefined; // assume `ctx.exp` is `undefined`
  IView[10 + 1] = undefined; // Just normalized `IView[10]`
  // So when the function is resolving styling
value, it first needs to look into the linked list
(there is none) and then into the static `TStylingStatic` too see if
there is a default value for `dynamic` (there is not). Therefore it is safe to remove it.
  If setting `true`
case:
  IView[10] = true; // assume `ctx.exp` is `true`
  IView[10 + 1] = true; // Just normalized
`IView[10]`
  // So when the function is resolving styling value, it first needs to look into the linked list
(there is none) and then into `TNode.residualClass` (TNode.residualStyle) which contains
  tNode.residualClass =
  'TEMPLATE': true,
];
  // This means that it is safe to add class.
  export interface TStylingStatic extends KeyValueArray<any>
  {
    // This is a branded number which contains previous and next index.
    // When we come across
styling instructions we need to store the `TStylingKey` in the correct
order so that we can re-concatenate the
styling value in the desired priority.
    // The insertion can happen either at the
- end of template as in the
case of coming across additional styling instruction in the template
- in front of the template in the case of
coming across additional instruction in the
`hostBindings`.
    // We use `TStylingRange` to store the
previous and next index into the `TData` where the template
bindings can be found.
    // bit 0 is used to
mark that the previous index has a duplicate for current value.
    // bit 1 is used to mark that the next index has a
duplicate for the current value.
    // bits 2-16 are used to encode the next/tail of the template.
    // bits 17-32 are
used to encode the previous/head of template.
    // NODE: *duplicate* false implies
that it is statically known that this binding will not collide
with other bindings and therefore there is no need to
check other bindings. For example the
bindings in `<div [style.color]=`exp` [style.width]=`exp`>` will never
collide and will have
their bits set accordingly. Previous duplicate means that we may need to check previous if
the
current binding is `null`. Next duplicate means that we may need to check next bindings if the
current
binding is not `null`.
    // NOTE: `0` has special significance and represents `null` as in no additional pointer.
  }
  export interface TStylingRange {
    __brand__: 'TStylingRange';

The file exists because Ivy styling instruction execution order does not match\n \* that of the priority order. The purpose of this code is to create a linked list so\n \* that the\n \* instructions can be traversed in priority order when computing the styles.\n \* Assume we are dealing with the following code:\n \* ```\n \* @Component({\n \* template: `\n \* <my-cmp [style]=\" {color: '#001'} \"\n \* [style.color]=\" #002 \"\n \* dir-style-color-1\n \* dir-style-color-2>\n \* `)\n \* class ExampleComponent {\n \* static ngComp = ... {\n \* ... // Compiler ensures that `styleProp` is after

```

`styleMap`\n * styleMap({color: '#001'});\n * styleProp('color', '#002');\n * ... \n * } \n * } \n * } \n *
@Directive({\n * selector: `[dir-style-color-1]',\n * })\n * class Style1Directive {\n * @HostBinding('style') style
= {color: '#005'};\n * @HostBinding('style.color') color = '#006';\n * \n * static ngDir = ... {\n * ... \n * //
Compiler ensures that `styleProp` is after `styleMap`\n * styleMap({color: '#005'});\n * styleProp('color',
'#006');\n * ... \n * } \n *
} \n * \n * @Directive({\n * selector: `[dir-style-color-2]',\n * })\n * class Style2Directive {\n *
@HostBinding('style') style = {color: '#007'};\n * @HostBinding('style.color') color = '#008';\n * \n * static ngDir
= ... {\n * ... \n * // Compiler ensures that `styleProp` is after `styleMap`\n * styleMap({color: '#007'});\n *
styleProp('color', '#008');\n * ... \n * } \n * } \n * \n * @Directive({\n * selector: `my-cmp`,\n * })\n * class
MyComponent {\n * @HostBinding('style') style = {color: '#003'};\n * @HostBinding('style.color') color =
'#004';\n * \n * static ngComp = ... {\n * ... \n * // Compiler ensures that `styleProp` is after `styleMap`\n *
styleMap({color: '#003'});\n * styleProp('color', '#004');\n * ... \n * } \n * } \n * ```\n * \n * The Order of
instruction execution is:\n * \n * NOTE: the comment binding location is for illustrative purposes only.\n * \n * ```\n *
// Template: (ExampleComponent)\n * styleMap({color:
'#001'}); // Binding index: 10\n * styleProp('color', '#002'); // Binding index: 12\n * // MyComponent\n *
styleMap({color: '#003'}); // Binding index: 20\n * styleProp('color', '#004'); // Binding index: 22\n * //
Style1Directive\n * styleMap({color: '#005'}); // Binding index: 24\n * styleProp('color', '#006'); // Binding
index: 26\n * // Style2Directive\n * styleMap({color: '#007'}); // Binding index: 28\n * styleProp('color',
'#008'); // Binding index: 30\n * ```\n * \n * The correct priority order of concatenation is:\n * \n * ```\n * //
MyComponent\n * styleMap({color: '#003'}); // Binding index: 20\n * styleProp('color', '#004'); // Binding
index: 22\n * // Style1Directive\n * styleMap({color: '#005'}); // Binding index: 24\n * styleProp('color',
'#006'); // Binding index: 26\n * // Style2Directive\n * styleMap({color: '#007'}); // Binding index: 28\n *
styleProp('color',
'#008'); // Binding index: 30\n * // Template: (ExampleComponent)\n * styleMap({color: '#001'}); // Binding
index: 10\n * styleProp('color', '#002'); // Binding index: 12\n * ```\n * \n * What color should be rendered?\n * \n *
Once the items are correctly sorted in the list, the answer is simply the last item in the\n * concatenation list which
is `#002`.\n * \n * To do so we keep a linked list of all of the bindings which pertain to this element.\n * Notice that
the bindings are inserted in the order of execution, but the `TVView.data` allows\n * us to traverse them in the order
of priority.\n * \n * [Idx] TVView.data` LVView` | Notes\n * |---|-----|-----|-----|-----| \n * |...|
| \n * | \n * |10 | null` | {color: '#001'} | `styleMap('color', {color: '#001'})` \n * |11 | 30 | 12` | ... | \n *
|12 | `color` | `'#002` | `styleProp('color', '#002')` \n * |13 | 10 | 0` | ... | \n *
| \n * |... | \n * | \n * |20 | null` | {color: '#003'} | `styleMap('color', {color: '#003'})` \n * |21 | 0 | 22` | ...
| \n * | \n * |22 | `color` | `'#004` | `styleProp('color', '#004')` \n * |23 | 20 | 24` | ... | \n * |24 | null`
| {color: '#005'} | `styleMap('color', {color: '#005'})` \n * |25 | 22 | 26` | ... | \n * |26 | `color` | `'#006`
| `styleProp('color', '#006')` \n * |27 | 24 | 28` | ... | \n * |28 | null` | {color: '#007'} | `styleMap('color',
{color: '#007'})` \n * |29 | 26 | 30` | ... | \n * |30 | `color` | `'#008` | `styleProp('color', '#008')` \n * |31
| 28 | 10` | ... | \n *
\n * \n * The above data structure allows us to re-concatenate the styling no matter which data
binding\n * changes.\n * \n * NOTE: in addition to keeping track of next/previous index the `TVView.data` also stores
prev/next\n * duplicate bit. The duplicate bit if
true says there either is a binding with the same name or\n * there is a map (which may contain the name). This
information is useful in knowing if other\n * styles with higher priority need to be searched for overwrites.\n * \n *
NOTE: See `should support example in 'tnode_linked_list.ts' documentation` in\n * `tnode_linked_list_spec.ts` for
working example.\n * \n * \n * let __unused_const_as_closure_does_not_like_standalone_comment_blocks__:\n *
undefined;\n * \n * \n * Insert new `tStyleValue` at `TData` and link existing style bindings such that we maintain
linked\n * list of styles and compute the duplicate flag.\n * \n * Note: this function is executed during
`firstUpdatePass` only to populate the `TVView.data`.\n * \n * The function works by keeping track of `tStylingRange`
which contains two pointers pointing to\n * the head/tail of the template portion of the styles.\n * - if `isHost ===
false` (we are template) then insertion is at tail of `TStylingRange`\n * - if `isHost === true` (we are

```

```
