    * @import { LocalizeFn } from './localize';
    * @import { MessageId,
    ParsedTranslation,
    parseTranslation,
    TargetMessage,
    translate as _translate } from
    './utils';
    * We augment the `Localize` object to also store the translations.
    * Note that because the
    TRANSLATIONS are attached to a global object, they will be shared between
    all applications that are running
    in a single page of the browser.
    * declare const Localize: LocalizeFn & { TRANSLATIONS: Record<MessageId,
    ParsedTranslation> };
    * Load translations for use by `Localize`, if doing runtime translation.
    * If the
    `Localize` tagged strings are not going to be replaced at compiled time, it is possible
    to load a set of translations
    that will be applied to the `Localize` tagged strings at runtime,
    in the browser.
    * Loading a new translation
    will overwrite a previous translation if it has the same `MessageId`.
    * Note that `Localize` messages are only
    processed once, when the tagged string is first
    encountered, and does not provide dynamic language changing
    without refreshing the browser.
    * Loading new translations later
    in the application life-cycle will not change the translated text
    of messages that have already been translated.
    * The message IDs and translations are in the same format as that rendered to
    simple JSON
    translation
    files when extracting messages. In particular, placeholders in messages are rendered
    using the
    `${PLACEHOLDER_NAME}` syntax. For example the message from the following template:
    <div i18n>pre<span>inner-pre<b>bold</b>inner-post</span>post</div>
    would have the following
    form in the `translations` map:
    {
    "2932901491976224757":
    "pre${START_TAG_SPAN}inner-pre${START_BOLD_TEXT}bold${CLOSE_BOLD_TEXT}inner-
    post${CLOSE_TAG_SPAN}post"
    }
    * @param translations A map from message ID to translated
    message.
    * These messages are processed and added to a lookup based on their `MessageId`.
    * @see
    `clearTranslations()` for removing translations loaded using this function.

ts\n *

```

\$localize `some string to localize`\n \* ```\n

\*\n \* \*\*Providing meaning, description and id\*\*\n \*\n \* You can optionally specify one or more of `meaning`, `description` and `id` for a localized\n \* string by pre-pending it with a colon delimited block of the form:\n \*\n \* ```\n \* \$localize`:meaning|description@`@id:source message text`;\n \*\n \* \$localize`:meaning|:source message text`;\n \*\n \* \$localize`:description:source message text`;\n \*\n \* \$localize`:@`@id:source message text`;\n \* ```\n \*\n \* This format is the same as that used for `i18n` markers in Angular templates. See the\n \* [Angular i18n guide](guide/i18n-common-prepare#mark-text-in-component-template).\n \*\n \* \*\*Naming placeholders\*\*\n \*\n \* If the template literal string contains expressions, then the expressions will be automatically\n \* associated with placeholder names for you.\n \*\n \* For example:\n \*\n \* ```\n \* \$localize `Hi \${name}! There are \${items.length} items.`;\n \* ```\n \*\n \* will generate a message-source of `Hi {PH}! There are {PH\_1} items`. \n \*\n \* The recommended practice is to name the placeholder associated with each expression though.\n \*\n \* Do this by providing the placeholder name wrapped in `` characters directly after the\n \* expression. These placeholder names are stripped out of the rendered localized string.\n \*\n \* For example, to name the `items.length` expression placeholder `itemCount` you write:\n \*\n \* ```\n \* \$localize `There are \${items.length}:itemCount: items`;\n \* ```\n \*\n \* \*\*Escaping colon markers\*\*\n \*\n \* If you need to use a `` character directly at the start of a tagged string that has no\n \* metadata block, or directly after a substitution expression that has no name you must escape\n \* the `` by preceding it with a backslash.\n \*\n \* For example:\n \*\n \* ```\n \* // message has a metadata block so no need to escape colon\n \* \$localize `:some description::this message starts with a colon (:)`;\n \* // no metadata block so the colon must be escaped\n \* \$localize `\\:this message starts with a colon (:)`;\n \* ```\n \*\n \* ```\n \* // named substitution so no need to escape colon\n \* \$localize `\${label}:label:: \${}`\n \* // anonymous substitution so colon must be escaped\n \* \$localize `\${label}\\: \${}`\n \* ```\n \*\n \* \*\*Processing localized strings\*\*\n \*\n \* There are three scenarios:\n \*\n \* \*\*compile-time inlining\*\*\n \* the `\$localize` tag is transformed at compile time by a\n \* transpiler, removing the tag and replacing the template literal string with a translated\n \* literal string from a collection of translations provided to the transpilation tool.\n \*\n \* \*\*run-time evaluation\*\*\n \* the `\$localize` tag is a run-time function that replaces and\n \* reorders the parts (static strings and expressions) of the template literal string with strings\n \* from a collection of translations loaded at run-time.\n \*\n \* \*\*pass-through evaluation\*\*\n \* the `\$localize` tag is a run-time function that simply evaluates\n \* the original template literal string without applying any translations to the parts. This\n \* version is used during development or where there is no need to translate the localized\n \* template literals.\n \*\n \* @param messageParts a collection of the static parts of the template string.\n \* @param expressions a collection of the values of each placeholder in the template string.\n \* @returns the translated string, with the `messageParts` and `expressions` interleaved together.\n \*\n \* @globalApi\n \* @publicApi\n \*/\nexport const \$localize: LocalizeFn = function(\n messageParts: TemplateStringsArray, ...expressions: readonly any[]) {\n if (\$localize.translate) {\n // Don't use array expansion here to avoid the compiler adding `\_\_read()` helper unnecessarily.\n const translation = \$localize.translate(messageParts, expressions);\n messageParts = translation[0];\n expressions = translation[1];\n }\n let message = stripBlock(messageParts[0], messageParts.raw[0]);\n for (let i = 1; i < messageParts.length; i++) {\n message += expressions[i - 1] + stripBlock(messageParts[i], messageParts.raw[i]);\n }\n return message;\n};\n\nconst BLOCK\_MARKER = ':';\n\n/\*\*\n \* Strip a delimited "block" from the start of the `messagePart`, if it is found.\n \*\n \* If a marker character (:) actually appears in the content at the start of a tagged string or\n \* after a substitution expression, where a block has not been provided the character must be\n \* escaped with a backslash, `\\:`. This function checks for this by looking at the `raw`\n \* messagePart, which should still contain the backslash.\n \*\n \* @param messagePart The cooked message part to process.\n \* @param rawMessagePart The raw message part to check.\n \* @returns the message part with the placeholder name stripped, if found.\n \* @throws an error if the block is unterminated\n \*/\nfunction stripBlock(messagePart: string, rawMessagePart: string) {\n return rawMessagePart.charAt(0) === BLOCK\_MARKER ?\n messagePart.substring(findEndOfBlock(messagePart, rawMessagePart) + 1) :\n messagePart;\n}\n\n"/\*\*\n \* @license\n \* Copyright Google LLC All Rights Reserved.\n \*\n \* Use of this source code is governed by an MIT-style license that can be\n \* found in the LICENSE file at

```
 * The character used to mark the start and end of a `block` in a `localize` tagged string. A block can indicate  
metadata about the message or specify a name of a placeholder for substitution expressions. For  
example: `ts` `localize` Hello, ${title}:title!; `localize`:meaning|description@id:source message  
text; ` ` `next` export const BLOCK_MARKER = `;` ` ` The marker used to separate a message's  
`meaning` from its `description` in a metadata block. For example: `ts` `localize  
:correct|Indicates that the user got the answer correct: Right!; `localize`:movement|Button label for moving to  
the right: Right!; ` ` `next` export const MEANING_SEPARATOR = `|` ` ` The marker used to separate  
a message's custom `id` from its `description` in a metadata block. For example: `ts` `localize  
:A welcome message on the home page@@myApp-homepage-welcome: Welcome!; ` ` `next`  
export const ID_SEPARATOR = `@@` ` ` The marker used to separate legacy message ids from the rest of a  
metadata block. For example: `ts` `localize`:@@custom-  
id2df64767cd895a8fabe3e18b94b5b6b6f9e2e3f0: Welcome!; ` ` ` Note that this character is the ` ` symbol  
for the unit separator` ` ` not the `unit separator` character` itself, since that has no visual representation. See  
https://graphemica.com/%E2%90%9F. Here is some background for the original `unit separator  
character`: ` ` https://stackoverflow.com/questions/8695118/whats-the-file-group-record-unit-separator-control-  
characters-and-its-usage ` `next` export const LEGACY_ID_INDICATOR = `\\u241F` ` `, ` ` ` @license\n *

undefined) {\n associatedMessageIds[placeholderName] = associatedMessageId;\n }\n
cleanedMessageParts.push(messagePart);\n
}\n const messageId = metadata.customId || computeMsgId(messageString, metadata.meaning || '');\n const
legacyIds = metadata.legacyIds ? metadata.legacyIds.filter(id => id !== messageId) : [];\n return {\n id:
messageId,\n legacyIds,\n substitutions,\n substitutionLocations,\n text: messageString,\n customId:
metadata.customId,\n meaning: metadata.meaning || '',\n description: metadata.description || '',\n messageParts:
cleanedMessageParts,\n messagePartLocations,\n placeholderNames,\n associatedMessageIds,\n location,\n
};\n}\n\n\n/**\n * Parse the given message part (`cooked` + `raw`) to extract the message metadata from the text.\n
*\n * If the message part has a metadata block this function will extract the `meaning`,\n * `description`, `customId`

```

and `legacyId` (if provided) from the block. These metadata properties are serialized in the string delimited by `|`, `@` and `` respectively.

(Note that `` is the `LEGACY\_ID\_INDICATOR` - see `constants.ts`.)

For example:

```

:meaning|description@@custom-id:`
:meaning|@custom-id:`
:meaning|description:`
:description@@custom-id:`
:meaning|:`
:description:`
:@custom-id:`
:meaning|description@@custom-idlegacy-id-1legacy-id-2:`

```

The cooked version of the message part to parse.

The raw version of the message part to parse.

Returns A object containing any metadata that was parsed from the message part.

```

export function parseMetadata(cooked: string, raw: string): MessageMetadata {
  const {text: messageString, block} = splitBlock(cooked, raw);
  if (block === undefined) {
    return {text: messageString};
  } else {
    const [meaningDescAndId, ...legacyIds] = block.split(LEGACY_ID_INDICATOR);
    const [meaningAndDesc, customId] = meaningDescAndId.split(ID_SEPARATOR, 2);
    let [meaning, description]: (string|undefined)[] = meaningAndDesc.split(MEANING_SEPARATOR, 2);
    if (description === undefined) {
      description = meaning;
      meaning = undefined;
    }
    if (description === "") {
      description = undefined;
    }
    return {text: messageString, meaning, description, customId, legacyIds};
  }
}

```

Parse the given message part (`cooked` + `raw`) to extract any placeholder metadata from the text.

If the message part has a metadata block this function will extract the `placeholderName` and `associatedMessageId` (if provided) from the block.

These metadata properties are serialized in the string delimited by `@@`.

For example:

```

placeholder-name@@associated-id:`

```

The cooked version of the message part to parse.

The raw version of the message part to parse.

Returns A object containing the metadata (`placeholderName` and `associatedMessageId`) of the preceding placeholder, along with the static text that follows.

```

export function parsePlaceholder(cooked: string, raw: string): {
  messagePart: string;
  placeholderName?: string;
  associatedMessageId?: string;
} {
  const {text: messagePart, block} = splitBlock(cooked, raw);
  if (block === undefined) {
    return {messagePart};
  } else {
    const [placeholderName, associatedMessageId] = block.split(ID_SEPARATOR);
    return {messagePart, placeholderName, associatedMessageId};
  }
}

```

Split a message part (`cooked` + `raw`) into an optional delimited "block" off the front and the rest of the text of the message part.

Blocks appear at the start of message parts. They are delimited by a colon `:` character at the start and end of the block.

If the block is in the first message part then it will be metadata about the whole message: meaning, description, id. Otherwise it will be metadata about the immediately preceding substitution: placeholder name.

Since blocks are optional, it is possible that the content of a message block actually starts with a block marker. In this case the marker must be escaped `:`.

The cooked version of the message part to parse.

The raw version of the message part to parse.

Returns An object containing the `text` of the message part and the text of the `block`, if it exists.

Throws an error if the `block` is unterminated.

```

export function splitBlock(cooked: string, raw: string): {text: string, block?: string} {
  if (raw.charAt(0) !== BLOCK_MARKER) {
    return {text: cooked};
  } else {
    const endOfBlock = findEndOfBlock(cooked, raw);
    return {
      block: cooked.substring(1, endOfBlock),
      text: cooked.substring(endOfBlock + 1),
    };
  }
}

```

function computePlaceholderName(index: number) {
 return index === 1 ? 'PH' : `PH\_\${index - 1}`;
}

Find the end of a "marked block" indicated by the first non-escaped colon.

The cooked string (where escaped chars have been processed).

The raw string (where escape sequences are still in place).

Returns the index of the end of block marker.

Throws an error if the block is unterminated.

```

export function findEndOfBlock(cooked: string, raw: string): number {
  for (let cookedIndex = 1, rawIndex = 1; cookedIndex < cooked.length; cookedIndex++, rawIndex++) {
    if (raw[rawIndex] === '\\') {
      rawIndex++;
    } else if (cooked[cookedIndex] === BLOCK_MARKER) {
      return cookedIndex;
    }
  }
  throw new Error(`Unterminated $localize metadata block in "${raw}"`);
}

```

`description`\n * and `id` for a localized\n * string by pre-pending it with a colon delimited block of the form:\n
*\n * ``ts\n * $localize `:meaning|description@@id:source message text`;\n *\n * $localize `:meaning|:source message
text`;\n *\n * $localize `:description:source message text`;\n *\n * $localize `:@id:source message text`;\n *\n *
```\n *\n * This format is the same as that used for `i18n` markers in Angular templates. See the\n * [Angular i18n
guide](guide/i18n-common-prepare#mark-text-in-component-template).\n *\n * **Naming placeholders**\n *\n * If
the template literal string contains expressions, then the expressions will be automatically\n * associated with
placeholder names for you.\n *\n * For example:\n *\n * ``ts\n * $localize `Hi ${name}! There are ${items.length}
items.`;\n *\n * ```\n *\n * will generate a message-source of `Hi {SPH}! There are {SPH_1} items`.\n *\n * The
recommended practice is to name the placeholder associated with each expression though.\n *\n * Do this by
providing the placeholder name wrapped in `` characters directly after the\n * expression. These placeholder names
are stripped out of the rendered localized string.\n *\n * For example, to name the `items.length` expression
placeholder `itemCount` you write:\n *\n * ``ts\n * $localize `There are ${items.length}:itemCount: items.`;\n *\n
* ```\n *\n * **Escaping colon markers**\n *\n * If you need to use a `` character directly at the start of a tagged
string that has no\n * metadata block, or directly after a substitution expression that has no name you must escape\n
* the `` by preceding it with a backslash:\n *\n * For example:\n *\n * ``ts\n * // message has a metadata block so
no need to escape colon\n * $localize `:some description::this message starts with a colon (:)`;\n *\n * // no metadata
block so the colon must be escaped\n * $localize `\\:this message starts with a colon

```

(:);\n \* ```\n \*\n \* ```\ts\n \* // named substitution so no need to escape colon\n \* \$localize `\${label}:label:: \${}`\n \*  
 // anonymous substitution so colon must be escaped\n \* \$localize `\${label}\\: \${}`\n \* ```\n \*\n \* \*\*Processing  
 localized strings:\*\*\n \*\n \* There are three scenarios:\n \*\n \* \*\*compile-time inlining\*\*\n \* the `\$localize` tag is  
 transformed at compile time by a\n \* transpiler, removing the tag and replacing the template literal string with a  
 translated\n \* literal string from a collection of translations provided to the transpilation tool.\n \*\n \* \*\*run-time  
 evaluation\*\*\n \* the `\$localize` tag is a run-time function that replaces and\n \* reorders the parts (static strings and  
 expressions) of the template literal string with strings\n \* from a collection of translations loaded at run-time.\n \*\n \* \*\*pass-through evaluation\*\*\n \* the `\$localize` tag is a run-time function that simply evaluates\n \* the original  
 template literal string without applying any translations to

the parts. This\n \* version is used during development or where there is no need to translate the localized\n \*  
 template literals.\n \*\n \* @param messageParts a collection of the static parts of the template string.\n \* @param  
 expressions a collection of the values of each placeholder in the template string.\n \* @returns the translated string,  
 with the `messageParts` and `expressions` interleaved together.\n \*\n \* @globalApi\n \* @publicApi\n \* ^\nexport  
 const \$localize: LocalizeFn = function(\n messageParts: TemplateStringsArray, ...expressions: readonly any[]) {\n  
 if (\$localize.translate) {\n // Don't use array expansion here to avoid the compiler adding `\_\_read()` helper  
 unnecessarily.\n const translation = \$localize.translate(messageParts, expressions);\n messageParts =  
 translation[0];\n expressions = translation[1];\n }\n let message = stripBlock(messageParts[0],  
 messageParts.raw[0]);\n for (let i = 1; i < messageParts.length; i++) {\n message += expressions[i  
 - 1] + stripBlock(messageParts[i], messageParts.raw[i]);\n }\n return message;\n};\n\nconst BLOCK\_MARKER =  
 ':';\n\n/\*\*\n \* Strip a delimited `block` from the start of the `messagePart`, if it is found.\n \*\n \* If a marker  
 character (:) actually appears in the content at the start of a tagged string or\n \* after a substitution expression, where  
 a block has not been provided the character must be\n \* escaped with a backslash, `\\`. This function checks for this  
 by looking at the `raw`\n \* messagePart, which should still contain the backslash.\n \*\n \* @param messagePart The  
 cooked message part to process.\n \* @param rawMessagePart The raw message part to check.\n \* @returns the  
 message part with the placeholder name stripped, if found.\n \* @throws an error if the block is unterminated\n \*  
 ^\nfunction stripBlock(messagePart: string, rawMessagePart: string) {\n return rawMessagePart.charAt(0) ===  
 BLOCK\_MARKER ?\n messagePart.substring(findEndOfBlock(messagePart, rawMessagePart)  
 + 1) :\n messagePart;\n}\n\n"/\*\*\n \* @license\n \* Copyright Google LLC All Rights Reserved.\n \*\n \* Use of

```
{"version":3,"file":"init.mjs","sources":["../..../..../packages/localize/init/index.ts"],"sourcesContent":["/**\n *  
 * @license\n * Copyright Google LLC All Rights Reserved.\n * \n * Use of this source code is governed by an MIT-  
 * style license that can be\n * found in the LICENSE file at https://angular.io/license\n * \nimport { $localize as  
 $localize, _global as _global, LocalizeFn as LocalizeFn, TranslateFn as TranslateFn } from  
'@angular/localize';\n\nexport { $localize, LocalizeFn, TranslateFn }; \n\n// Attach $localize to the global context, as a  
 * side-effect of this module.\n * _global.$localize = $localize;\n * \n// `declare global` allows us to escape the current  
 * module and place types on the global namespace\n * \ndeclare global { \n * /**\n * * Tag a template literal string for  
 * localization.\n * \n * \n * For example:\n * \n * ``ts\n * $localize `some string to localize`\n * ``\n * \n * **Providing meaning, description  
 * \n * and id*\n * \n * You can optionally specify one or more of `meaning`, `description` and `id` for a localized\n * * string by pre-pending it with a colon delimited block of the form:\n * \n * ``ts\n * *\n * $localize`meaning|description@@id:source message text`;\n * \n * $localize`meaning|:source message text`;\n * \n * $localize`:description:source message text`;\n * \n * $localize`:@id:source message text`;\n * \n * This  
 * format is the same as that used for `i18n` markers in Angular templates. See the\n * [Angular i18n  
 * guide](guide/i18n-common-prepare#mark-text-in-component-template).\n * \n * **Naming placeholders**\n * \n * \n * If the template literal string contains expressions, then the expressions will be automatically\n * associated with
```

placeholder names for you.  
 For example:  
`$localize `Hi ${name}! There are ${items.length} items.``  
 will generate a message-source of ``Hi {SPH}! There are {SPH_1} items``.  
 The recommended practice is to name the placeholder associated with each expression though.  
 Do this by providing the placeholder name wrapped in ``:`` characters directly after the expression. These placeholder names are stripped out of the rendered localized string.  
 For example, to name the ``items.length`` expression placeholder ``itemCount`` you write:  
`$localize `There are ${items.length}:itemCount: items``  
 Escaping colon markers  
 If you need to use a ``:`` character directly at the start of a tagged string that has no metadata block, or directly after a substitution expression that has no name you must escape the ``:`` by preceding it with a backslash.  
 For example:  
`// message has a metadata block so no need to escape colon $localize `:some description::this message starts with a colon (:)``  
`// no metadata block so the colon must be escaped $localize `\:this message starts with a colon (:)``  
`// named substitution so no need to escape colon $localize `${label}:label: ${}``  
`// anonymous substitution so colon must be escaped $localize `${label}\: ${}``  
 Processing localized strings  
 There are three scenarios:  
 compile-time inlining: the ``$localize`` tag is transformed at compile time by a transpiler, removing the tag and replacing the template literal string with a translated literal string from a collection of translations provided to the transpilation tool.  
 run-time evaluation: the ``$localize`` tag is a run-time function that replaces and reorders the parts (static strings and expressions) of the template literal string with strings from a collection of translations loaded at run-time.  
 pass-through evaluation: the ``$localize`` tag is a run-time function that simply evaluates the original template literal string without applying any translations to the parts. This version is used during development or where there is no need to translate the localized template literals.  
 @param messageParts a collection of the static parts of the template string.  
 @param expressions a collection of the values of each placeholder in the template string.  
 @returns the translated string, with the ``messageParts`` and ``expressions`` interleaved together.  
`const $localize: LocalizeFn;
names:["_global","$localize"],"mappings":":;:::;AAAA;:::;AAMG;AAKH;AACAA,QAAO,CAAC,SAAS,GAAGC,UAAS"}`

import { AnimationMetadata, AnimationOptions }
from './animation_metadata';
import { AnimationPlayer } from './players/animation_player';

```

An injectable service that produces an animation sequence programmatically within an Angular component or directive. Provided by the `BrowserAnimationsModule` or `NoopAnimationsModule`.

**@usageNotes**

To use this service, add it to your component or directive as a dependency. The service is instantiated along with your component. Apps do not typically need to create their own animation players, but if you do need to, follow these steps:

- Use the `[AnimationBuilder.build](api/animations/AnimationBuilder#build)` method to create a programmatic animation. The method returns an `AnimationFactory` instance.
- Use the factory object to create an `AnimationPlayer` and attach it to a DOM element.
- Use the player object to control the animation programmatically.

For example:

```

// import the service from BrowserAnimationsModule
import { AnimationBuilder } from '@angular/animations';
// require the service as a dependency
class MyCmp {
  constructor(private _builder: AnimationBuilder) {}
  makeAnimation(element: any) {
    // first define a reusable animation
    const myAnimation =
      this._builder.build([
        style({ width: 0 }),
        animate(1000, style({ width: '100px' })),
      ]);
    // use the returned factory object to create a player
    const player = myAnimation.create(element);
    player.play();
  }
}

```

**@publicApi**

**AnimationBuilder** abstract class

Builds a factory for producing a defined animation.

**@param** animation A reusable animation definition.

**@returns** A factory object that can create a player for the defined animation.

**@see** `animate()`

**AnimationBuilder** abstract

```

build(animation: AnimationMetadata|AnimationMetadata[]): AnimationFactory;

```

A factory object returned from the

```

[AnimationBuilder.build](api/animations/AnimationBuilder#build)()

```

method.

**AnimationFactory** abstract class

Creates an `AnimationPlayer` instance for the reusable animation defined by the

```

[AnimationBuilder.build](api/animations/AnimationBuilder#build)()

```

method that created this factory and attaches the new player a DOM element.

**@param** element The DOM element to which to attach the player.

**@param** options A set of options that can include a time delay and additional developer-defined parameters.

**AnimationFactory** abstract

```

create(element: any, options?: AnimationOptions):
  AnimationPlayer;

```

**@license** Copyright Google LLC All Rights Reserved. Use of this source code is governed by an MIT-style license that can be found in the LICENSE file at <https://angular.io/license>

**StyleData** interface

Represents a set of CSS styles for use in an animation style as a generic.

```

interface StyleData {
  [key: string]: string|number;
}

```

**StyleDataMap** type

Represents a set of CSS styles for use in an animation style as a Map.

```

type StyleDataMap = Map<string, string|number>;

```

**AnimateTimings** type

Represents animation-step timing parameters for an animation step.

**@see** `animate()`

**AnimateTimings** type

declare type AnimateTimings = {

**duration:** number

The full duration of an animation step. A number and optional time unit, such as `"1s"` or `"10ms"` for one second and 10 milliseconds, respectively. The default unit is milliseconds.

**delay:** number

The delay in applying an animation step. A number and optional time unit. The default unit is milliseconds.

**easing:** string | null

An easing style that controls how an animations step accelerates and decelerates during its run time. An easing function such as `cubic-bezier()` or one of the following constants:

- `"ease-in"`
- `"ease-out"`
- `"ease-in-and-out"`

**@description** Options that control animation styling and timing.

The following animation functions accept `AnimationOptions` data:

- `transition()`
- `sequence()`
- `@link animations/group group()`
- `query()`
- `animation()`
- `useAnimation()`
- `animateChild()`

Programmatic animations built using the `AnimationBuilder` service also make use of `AnimationOptions`.

**AnimationOptions** interface

Sets a time-delay for initiating an animation action.

**delay:** number

A number and optional time unit, such as `"1s"` or `"10ms"` for one second and 10 milliseconds, respectively. The default unit is milliseconds. Default value is 0, meaning no delay.

```

animation steps.

`animation: AnimationMetadata|AnimationMetadata[];`

Creates a named animation trigger, containing a list of `state()` and `transition()` entries to be evaluated when the expression bound to the trigger changes.

`@param name` An identifying string.

`@param definitions` An animation definition object, containing an array of `state()` and `transition()` declarations.

`@return` An object that encapsulates the trigger data.

`@usageNotes` Define an animation trigger in the `animations` section of `@Component` metadata. In the template, reference the trigger by name and bind it to a trigger expression that evaluates to a defined animation state, using the following format:

```
[@triggerName]="expression"
```

Animation trigger bindings convert all values to strings, and then match the previous and current values against any linked transitions.

Booleans can be specified as `1` or `true` and `0` or `false`.

### Usage Example

The following example creates an animation trigger reference based on the provided name value. The provided animation value is expected to be an array consisting of state and transition declarations.

```
typescript
@Component({
  selector: 'my-component',
  templateUrl: 'my-component-tpl.html',
  animations: [
    trigger('myAnimationTrigger', [
      state(...),
      state(...),
      transition(...),
      transition(...)
    ])
  ]
})
class MyComponent {
  myStatusExp = 'something';
}
```

The template associated with this component makes use of the defined trigger by binding to an element within its template code.

```
html
<!-- somewhere inside of my-component-tpl.html -->
<div [@myAnimationTrigger]="myStatusExp">...</div>
```

### Using an inline function

The `transition` animation method also supports reading an inline function which can decide if its associated animation should be run.

```
typescript
// this method is run each time the `myAnimationTrigger` trigger value changes.
function myInlineMatcherFn(fromState: string, toState: string, element: any, params: {[key: string]: any}): boolean {
  // notice that `element` and `params` are also available here
  return toState === 'yes-please-animate';
}
@Component({
  selector: 'my-component',
  templateUrl: 'my-component-tpl.html',
  animations: [
    trigger('myAnimationTrigger', [
      transition(myInlineMatcherFn, // the animation sequence code
    ])
  ])
})
class MyComponent {
  myStatusExp = 'yes-please-animate';
}
```

### Disabling Animations

When true, the special animation control binding `@.disabled` binding prevents all animations from rendering. Place the `@.disabled` binding on an element to disable animations on the element itself, as well as any inner animation triggers within the element.

The following example shows how to use this feature:

```
typescript
@Component({
  selector: 'my-component',
  template: `
<div [@.disabled]="isDisabled">
  <div [@childAnimation]="exp"></div>
</div>`,
  animations: [
    trigger('childAnimation', [
      // ...
    ])
  ]
})
class MyComponent {
  isDisabled = true;
  exp = '...';
}
```

When `@.disabled` is true, it prevents the `@childAnimation` trigger from animating, along with any inner animations.

### Disable animations application-wide

When an area of the template is set to have animations disabled, all inner components have their animations disabled as well. This means that you can disable all animations for an app

by placing a host binding set on `@.disabled` on the topmost Angular component.

```
typescript
import {Component, HostBinding} from '@angular/core';
@Component({
  selector: 'app-component',
  templateUrl: 'app.component.html',
})
class AppComponent {
  @HostBinding('@.disabled')
  public animationsDisabled = true;
}
```

### Overriding disablement of inner animations

Despite inner animations being disabled, a parent animation can `query()` for inner elements located in disabled areas of the template and still animate them if needed. This is also the case for when a sub animation is queried by a parent and then later animated using `animateChild()`.

### Detecting when an animation is disabled

If a region of the DOM (or the entire application) has its animations disabled, the animation trigger callbacks still fire, but for zero seconds. When the callback fires, it provides an instance of an `AnimationEvent`. If animations are disabled, the `.disabled` flag on the event is true.

`@publicApi`

```
export function trigger(name: string, definitions: AnimationMetadata[]): AnimationTriggerMetadata {
  return {
    type: AnimationMetadataType.Trigger,
    name,
    definitions,
    options: {}
  };
}
```

Defines an animation step

that combines styling information with timing information.

`@param timings` Sets `AnimateTimings`` for the parent animation.

A string in the format `"duration [delay] [easing]"`.

- Duration and delay are expressed as a number and optional time unit, such as `"1s"` or `"10ms"` for one second and 10 milliseconds, respectively.
- The default unit is milliseconds.
- The easing value controls how the animation accelerates and decelerates during its runtime. Value is one of `"ease"`, `"ease-in"`, `"ease-out"`, `"ease-in-out"`, or a `"cubic-bezier()"` function call.
- If not supplied, no easing is applied.

For example, the string `"1s 100ms ease-out"` specifies a duration of 1000 milliseconds, and delay of 100 ms, and the `"ease-out"` easing style, which decelerates near the end of the duration.

`@param styles` Sets `AnimationStyles` for the parent animation.

A function call to either `style()` or `keyframes()` that returns a collection of CSS style entries to be applied to the parent animation.

- When null, uses the styles from the destination state.
- This is useful when describing an animation step that will complete an animation; see `"Animating to the final state"` in `transitions()`.

`@returns` An object that encapsulates the animation step.

`@usageNotes`

Call within an animation `sequence()`, `{@link animations/group group()}``, or `transition()` call to specify an animation step that applies given style data to the parent animation for a given amount of time.

### Syntax Examples

#### Timing examples

The following examples show various `timings`` specifications.

- `animate(500)`` : Duration is 500 milliseconds.
- `animate("1s")`` : Duration is 1000 milliseconds.
- `animate("100ms 0.5s")`` : Duration is 100 milliseconds, delay is 500 milliseconds.
- `animate("5s ease-in")`` : Duration is 5000 milliseconds, easing in.
- `animate("5s 10ms cubic-bezier(.17,.67,.88,.1)")`` : Duration is 5000 milliseconds, delay is 10 milliseconds, easing according to a bezier curve.

#### Style examples

The following example calls `style()` to set a single CSS style.

```

<<typescript
animate(500, style({ background: "red" }));

```

The following example calls `keyframes()` to set a CSS style to different values for successive keyframes.

```

<<typescript
animate(500, keyframes([
  style({ background: "blue" }),
  style({ background: "red" })
]));

```

`@publicApi`

```

export function animate(timings: string|number,
  styles: AnimationStyleMetadata|AnimationKeyframesSequenceMetadata|null
  = null): AnimationAnimateMetadata {
  return {type: AnimationMetadataType.Animate, styles,
    timings};
}

```

`@description` Defines a list of animation steps to be run in parallel.

`@param steps` An array of animation step objects.

- When steps are defined by `style()` or `animate()` function calls, each call within the group is executed instantly.
- To specify offset styles to be applied at a later time, define steps with `keyframes()`, or use `animate()` calls with a delay value.

For example:

```

<<typescript
group([
  animate("1s", style({ background: "black" })),
  animate("2s", style({ color: "white" }))]
);

```

`@param options` An options object containing a delay and developer-defined parameters that provide styling defaults and can be overridden on invocation.

`@return` An object that encapsulates the group data.

`@usageNotes`

Grouped animations are useful when a series of styles must be animated at different starting times and closed off at different ending times.

When called within a `sequence()` or a `transition()` call, does not continue to the next instruction until all of the inner animation steps have completed.

`@publicApi`

```

export function group(steps: AnimationMetadata[], options: AnimationOptions|null = null): AnimationGroupMetadata {
  return {type: AnimationMetadataType.Group, steps, options};
}

```

Defines a list of animation steps to be run sequentially, one by one.

`@param steps` An array of animation step objects.

- Steps defined by `style()` calls apply the styling data immediately.
- Steps defined by `animate()` calls apply the styling data over time as specified by the timing data.

```

<<typescript
sequence([
  style({ opacity: 0 }),
  animate("1s", style({ opacity: 1 }))]
);

```

`@param options`

An options object containing a delay and developer-defined parameters that provide styling defaults and can be overridden on invocation.

`@return` An object that encapsulates the sequence data.

`@usageNotes`

When you pass an array of steps to a `transition()` call, the steps run sequentially by default. Compare this to the `{@link animations/group group()}`` call, which runs animation steps in parallel.

When a sequence is used within a `{@link animations/group group()}`` or a `transition()` call, execution continues to the next

instruction only after each of the inner animation steps have completed.

```

@publicApi
export function sequence(steps: AnimationMetadata[], options: AnimationOptions | null = null): AnimationSequenceMetadata {
  return {type: AnimationMetadataType.Sequence, steps, options};
}

```

Declares a key/value object containing CSS properties/styles that can then be used for an animation

```

[ state` ](api/animations/state),

```

within an animation sequence, or as styling data for calls to `animate()` and `keyframes()`.

`@param tokens` A set of CSS styles or HTML styles associated with an animation state. The value can be any of the following:

- A key-value style pair associating a CSS property with a value.
- An array of key-value style pairs.
- An asterisk (\*), to use auto-styling, where styles are derived from the element being animated and applied to the animation when it starts.
- Auto-styling can be used to define a state that depends on layout or other environmental factors.

`@return` An object that encapsulates the style data.

`@usageNotes`

The following examples create animation styles that collect a set of CSS property values:

```

typescript
// string values for CSS properties
style({ background: "red", color: "blue" })
// numerical pixel values
style({ width: 100, height: 0 })

```

The following example uses auto-styling to allow an element to animate from a height of 0 up to its full height:

```

style({ height: 0 }), animate("1s", style({ height: "*" }))

```

`@publicApi`

```

export function style(tokens: {[key: string]: string | number} | Array<*[key: string]: string | number>): AnimationStyleMetadata {
  return {type: AnimationMetadataType.Style, styles: tokens, offset: null};
}

```

Declares an animation state within a trigger attached to an element.

`@param name` One or more names for the defined state in a comma-separated string. The following reserved state names can be supplied to define a style for specific use cases:

- `void`` You can associate styles with this name to be used when the element is detached from the application. For example, when an `ngIf`` evaluates to false, the state of the associated element is `void``.
- `void`` (asterisk) Indicates the default state. You can associate styles with this name to be used as the fallback when the state that is being animated is not declared within the trigger.

`@param styles` A set of CSS styles associated with this state, created using the `style()`` function. This set of styles persists on the element once the state has been reached.

`@param options` Parameters that can be passed to the state when it is invoked. 0 or more key-value pairs.

`@return` An object that encapsulates the new state data.

`@usageNotes`

Use the `trigger()`` function to register states to an animation trigger. Use the `transition()`` function to animate between states. When a state is active within a component, its associated styles persist on the element, even when the animation ends.

`@publicApi`

```

export function state(name: string, styles: AnimationStyleMetadata, options?: {params: {[name: string]: any}}): AnimationStateMetadata {
  return {type: AnimationMetadataType.State, name, styles, options};
}

```

Defines a set of animation styles, associating each style with an optional `offset`` value.

`@param steps` A set of animation styles with optional offset data. The optional `offset`` value for a style specifies a percentage of the total animation time at which that style is applied.

`@returns` An object that encapsulates the keyframes data.

`@usageNotes`

Use with the `animate()`` call. Instead of applying animations from the current state to the destination state, keyframes describe how each style entry is applied and at what point within the animation arc. Compare [CSS Keyframe Animations](https://www.w3schools.com/css/css3\_animations.asp).

### Usage

In the following example, the offset values describe when each `backgroundColor`` value is applied. The color is red at the start, and changes to blue when 20% of the total time has elapsed.

```

typescript
// the provided offset values
animate("5s", keyframes([
  style({ backgroundColor: "red", offset: 0 }),
  style({ backgroundColor: "blue", offset: 0.2 }),
  style({ backgroundColor: "orange", offset: 0.3 }),
  style({ backgroundColor: "black", offset: 1 })
]))

```

If there are no `offset`` values specified in the style entries, the offsets are calculated automatically.

```

typescript
animate("5s", keyframes([
  style({ backgroundColor: "red" }) // offset = 0
  style({ backgroundColor: "blue" }) // offset = 0.33
  style({ backgroundColor: "orange" }) // offset = 0.66
  style({ backgroundColor: "black" }) // offset = 1
]))

```

`@publicApi`

```

export function keyframes(steps:

```

AnimationStyleMetadata[]): AnimationKeyframesSequenceMetadata {  
 return {type: AnimationMetadataType.Keyframes, steps};  
 }  
 \* Declares an animation transition which is played when a certain specified condition is met.  
 \* @param stateChangeExpr A string with a specific format or a function that specifies when the animation transition should occur (see [State Change Expression](#state-change-expression)).  
 \* @param steps One or more animation objects that represent the animation's instructions.  
 \* @param options An options object that can be used to specify a delay for the animation or provide custom parameters for it.  
 \* @returns An object that encapsulates the transition data.  
 \* @usageNotes  
 ### State Change Expression  
 The State Change Expression instructs Angular when to run the transition's animations, it can either be  
 - a string with a specific syntax  
 - or a function that compares the previous and current state (value of the expression bound to the element's trigger) and returns `true` if the transition should occur or `false` otherwise  
 The string format can be:  
 - `fromState => toState`, which indicates that the transition's animations should occur then the expression bound to the trigger's element goes from `fromState` to `toState`  
 \_Example:\_  

```

<code>transition('open => closed', animate('.5s ease-out', style({ height: 0 })))
</code>
  - `fromState <=> toState`, which indicates that the transition's animations should occur then the expression bound to the trigger's element goes from `fromState` to `toState` or vice versa  

  _Example:_  

```

<code>transition('enabled <=> disabled', animate('1s cubic-bezier(0.8,0.3,0,1)'))
</code>
  - `:enter`/`:leave`, which indicates that the transition's animations should occur when the element enters or exists the DOM  

  _Example:_  

```

<code>transition(':enter', [style({ opacity: 0 }), animate('500ms', style({ opacity: 1 }))]
</code>
  - `:increment`/`:decrement`, which indicates that the transition's animations should occur when the numerical expression bound to the trigger's element has increased in value or decreased  

  _Example:_  

```

<code>transition(':increment', query('@counter', animateChild()))
</code>
  - a sequence of any of the above divided by commas, which indicates that transition's animations should occur whenever one of the state change expressions matches  

  _Example:_  

```

<code>transition(':increment, => enabled, :enter', animate('1s ease', keyframes([style({ transform: 'scale(1)', offset: 0}), style({ transform: 'scale(1.1)', offset: 0.7}), style({ transform: 'scale(1)', offset: 1 })]))
</code>
  Also note that in such context:  

  - `void` can be used to indicate the absence of the element  

  - asterisks can be used as wildcards that match any state  

  - (as a consequence of the above, `void => *` is equivalent to `:enter` and `* => void` is equivalent to `:leave`)  

  - `true` and `false` also match expression values of `1` and `0` respectively (but do not match _truthy_ and _falsy_ values)  

  <div class="alert is-helpful">  

  * Be careful about entering end leaving elements as their transitions present a common pitfall for developers.  

  * Note that when an element with a trigger enters the DOM its `:enter` transition always gets executed, but its `:leave` transition will not be executed if the element is removed alongside its parent (as it will be removed "without warning" before its transition has a chance to be executed, the only way that such transition can occur is if the element is exiting the DOM on its own).  

  ### Animating to a Final State  

  If the final step in a transition is a call to animate() that uses a timing value with no style data, that step is automatically considered the final animation arc for the element to reach the final state, in such case Angular automatically adds or removes CSS styles to ensure that the element is in the correct final state.  

  ### Usage Examples  

  - Transition animations applied based on the trigger's expression value  

  _HTML_  

```

<code><div [@myAnimationTrigger]="myStatusExp"> ... </div>
</code>
  _typescript_  

```

<code>trigger("myAnimationTrigger", [ ..., // states
transition("on => off, open => closed", animate(500)),
transition(" * <=> error", query('.indicator', animateChild()))
])
</code>
  - Transition animations applied based on custom logic dependent on the trigger's expression value and provided parameters  

  _HTML_  

```

<code><div [@myAnimationTrigger]="{ value: stepName, params: { target: currentTarget } }"
</code>
  
```

```

```

```

```

```

```

```

```

})>\n * ... \n * </div>\n * ```\n *\n * ```typescript\n * trigger('myAnimationTrigger', [\n * ..., //
states\n * transition(\n * (fromState, toState, _element, params) =>\n * ['firststep',
'laststep'].includes(fromState.toLowerCase()))\n * && toState === params?.['target'],\n * animate('1s')\n *
)\n * ])\n * ```\n *\n * @publicApi\n **/\nexport function transition(\n stateChangeExpr: string|\n
((fromState: string, toState: string, element?: any, params?: {[key: string]: any}) => boolean),\n steps:
AnimationMetadata|AnimationMetadata[],\n options: AnimationOptions|null = null):
AnimationTransitionMetadata {\n return {type: AnimationMetadataType.Transition, expr: stateChangeExpr,
animation: steps, options};\n}\n\n/**\n * Produces a reusable animation that can be invoked in another animation or
sequence,\n * by calling the `useAnimation()` function.\n *\n * @param steps One or more animation objects, as
returned
by the `animate()`\n * or `sequence()` function, that form a transformation from one state to another.\n * A
sequence is used by default when you pass an array.\n * @param options An options object that can contain a delay
value for the start of the\n * animation, and additional developer-defined parameters.\n * Provided values for
additional parameters are used as defaults,\n * and override values can be passed to the caller on invocation.\n *
@returns An object that encapsulates the animation data.\n *\n * @usageNotes\n * The following example defines a
reusable animation, providing some default parameter\n * values.\n *\n * ```typescript\n * var fadeAnimation =
animation([\n * style({ opacity: '{{ start }}' }),\n * animate('{{ time }}',\n * style({ opacity: '{{ end }}'))\n *
],\n * { params: { time: '1000ms', start: 0, end: 1 }});\n * ```\n *\n * The following invokes the defined animation
with a call to `useAnimation()`\n * passing in override parameter values.\n
*\n * ```js\n * useAnimation(fadeAnimation, {\n * params: {\n * time: '2s',\n * start: 1,\n * end: 0\n *
}\n * })\n * ```\n *\n * If any of the passed-in parameter values are missing from this call,\n * the default values are
used. If one or more parameter values are missing before a step is\n * animated, `useAnimation()` throws an error.\n
*\n * @publicApi\n **/\nexport function animation(\n steps: AnimationMetadata|AnimationMetadata[],\n
options: AnimationOptions|null = null): AnimationReferenceMetadata {\n return {type:
AnimationMetadataType.Reference, animation: steps, options};\n}\n\n/**\n * Executes a queried inner animation
element within an animation sequence.\n *\n * @param options An options object that can contain a delay value for
the start of the\n * animation, and additional override values for developer-defined parameters.\n * @return An
object that encapsulates the child animation data.\n *\n * @usageNotes\n * Each time an animation is triggered in
Angular, the parent animation\n * has priority and any child animations are blocked. In order\n * for a child
animation to run, the parent animation must query each of the elements\n * containing child animations, and run
them using this function.\n *\n * Note that this feature is designed to be used with `query()` and it will only work\n *
with animations that are assigned using the Angular animation library. CSS keyframes\n * and transitions are not
handled by this API.\n *\n * @publicApi\n **/\nexport function animateChild(options: AnimateChildOptions|null =
null):\n AnimationAnimateChildMetadata {\n return {type: AnimationMetadataType.AnimateChild,
options};\n}\n\n/**\n * Starts a reusable animation that is created using the `animation()` function.\n *\n * @param
animation The reusable animation to start.\n * @param options An options object that can contain a delay value for
the start of\n * the animation, and additional override values for developer-defined parameters.\n * @return
An object that contains the animation parameters.\n *\n * @publicApi\n **/\nexport function useAnimation(\n
animation: AnimationReferenceMetadata,\n options: AnimationOptions|null = null):
AnimationAnimateRefMetadata {\n return {type: AnimationMetadataType.AnimateRef, animation,
options};\n}\n\n/**\n * Finds one or more inner elements within the current element that is\n * being animated
within a sequence. Use with `animate()`.\n *\n * @param selector The element to query, or a set of elements that
contain Angular-specific\n * characteristics, specified with one or more of the following tokens.\n * -
`query(':enter()')` or `query(':leave()')` : Query for newly inserted/removed elements (not\n * all elements can be
queried via these tokens, see\n * [Entering and Leaving Elements](#entering-and-leaving-elements))\n * -
`query(':animating()')` : Query all currently animating elements.\n * - `query('@triggerName')` : Query elements
that contain an animation trigger.\n

```

\* - `query('@*')` : Query all elements that contain an animation triggers.

\* - `query(':self')` : Include the current element into the animation sequence.

\* `@param animation` One or more animation steps to apply to the queried element or elements.

\* An array is treated as an animation sequence.

\* `@param options` An options object. Use the 'limit' field to limit the total number of items to collect.

\* `@return` An object that encapsulates the query data.

\* `@usageNotes`

### Multiple Tokens

\* Tokens can be merged into a combined query selector string. For example:

```
typescript
query(':self, .record:enter, .record:leave, @subTrigger', [...])
```

\* The `query()` function collects multiple elements and works internally by using `element.querySelectorAll`. Use the `limit` field of an options object to limit the total number of items to be collected. For example:

```
js
query('div', [animate(...), animate(...)], { limit: 1 })
```

\* By default, throws an error when zero items are found. Set the `optional` flag to ignore this error. For example:

```
js
query('.some-element-that-may-not-be-there', [animate(...), animate(...)], { optional: true })
```

### Entering and Leaving Elements

\* Not all elements can be queried via the `:enter` and `:leave` tokens, the only ones that can are those that Angular assumes can enter/leave based on their own logic (if their insertion/removal is simply a consequence of that of their parent they should be queried via a different token in their parent's `:enter`/`:leave` transitions).

\* The only elements Angular assumes can enter/leave based on their own logic (thus the only ones that can be queried via the `:enter` and `:leave` tokens) are:

- Those inserted dynamically (via `ViewContainerRef`)
- Those that have a structural directive (which, under the hood, are a subset of the above ones)

\* `<div class="alert is-helpful">` Note that elements will be successfully queried via `:enter`/`:leave` even if their insertion/removal is not done manually via `ViewContainerRef` or caused by their structural directive (e.g. they enter/exit alongside their parent).

\* `</div>`

\* `<div class="alert is-important">` There is an exception to what previously mentioned, besides elements entering/leaving based on their own logic, elements with an animation trigger can always be queried via `:leave` when their parent is also leaving.

```
</div>
```

### Usage Example

\* The following example queries for inner elements and animates them individually using `animate()`.

```
typescript
@Component({
  selector: 'inner',
  template: `
    <div [@queryAnimation]="exp">
      <h1>Title</h1>
      <div class="content">
        Blah blah blah
      </div>
    </div>`,
  animations: [
    trigger('queryAnimation', [
      transition('* => goAnimate', [
        // hide the inner elements
        query('h1', style({ opacity: 0 })),
        query('.content', style({ opacity: 0 })),
        // animate the inner elements in, one by one
        query('h1', animate(1000, style({ opacity: 1 }))),
        query('.content', animate(1000, style({ opacity: 1 })))
      ])
    ])
  ],
  class: Cmp,
  exports: [goAnimate]
})
export function query(selector: string, animation: AnimationMetadata|AnimationMetadata[], options: AnimationQueryOptions|null = null): AnimationQueryMetadata {
  return { type: AnimationMetadataType.Query, selector, animation, options };
}
```

\* Use within an animation `query()` call to issue a timing gap after each queried item is animated.

\* `@param timings` A delay value.

\* `@param animation` One or more animation steps.

\* `@returns` An object that encapsulates the stagger data.

\* `@usageNotes` In the following example, a container element wraps a list of items stamped out by an `ngFor`. The container element contains an animation trigger that will later be set to query for each of the inner items. Each time items are added, the opacity fade-in animation runs, and each removed item is faded out. When either of these animations occur, the stagger effect is applied after each item's animation is started.

```
html
<!-- list.component.html -->
<button (click)="toggle()">Show / Hide Items</button>
<div [@listAnimation]="items.length">
  <div *ngFor="let item of items">
    {{ item }}
  </div>
</div>
```

\* Here is the component code:

```
typescript
import { trigger, transition, style, animate, query, stagger } from '@angular/animations';
@Component({
  templateUrl: 'list.component.html',
  animations: [
    trigger('listAnimation', [
      ...
    ])
  ],
  class: ListComponent,
  items = [],
  showItems() {
    this.items = [0,1,2,3,4];
  },
  hideItems() {
    this.items = [];
  },
  toggle() {
    this.items.length ?

```

```
this.hideItems() : this.showItems();\n *  }\n *  }\n *  ``\n *  Here is the animation trigger code:\n *  ``\n *  typescript\n *  trigger('listAnimation', [\n *    transition('* => *', [ // each time the binding value changes\n *      query(':leave', [\n *        stagger(100, [\n *          animate('0.5s', style({ opacity: 0 })))\n *        ])\n *      ]),\n *      query(':enter', [\n *        style({ opacity: 0 })),\n *        stagger(100, [\n *          animate('0.5s', style({ opacity: 1 })))\n *        ])\n *      ])\n *    ])\n *  ``\n *  @publicApi\n *  ^\n *  export function stagger(timings: string|number,\n *    animation: AnimationMetadata|AnimationMetadata[]):\n *    AnimationStaggerMetadata {
```

```
\n *   return {type: AnimationMetadataType.Stagger, timings, animation};\n * }\n * }", /**\n * @license\n * Copyright Google LLC All Rights Reserved.\n * Use of this source code is governed by an MIT-\n * style license that can be\n * found in the LICENSE file at https://angular.io/license\n * ^\n * export function\n * scheduleMicroTask(cb: () => any) {\n *   Promise.resolve().then(cb);\n * }\n * }", /**\n * @license\n * Copyright Google\n * LLC All Rights Reserved.\n * Use of this source code is governed by an MIT-style license that can be\n * found\n * in the LICENSE file at https://angular.io/license\n * ^\n * import {scheduleMicroTask} from './util';\n * }
```

Provides programmatic control of a reusable animation sequence, built using the

```
<code>[AnimationBuilder.build](api/animations/AnimationBuilder#build)</code>\n * method which returns an\n * `AnimationFactory`, whose\n * <code>[create](api/animations/AnimationFactory#create)</code> method\n * instantiates
```

```

\* Represents a set of CSS styles for use in an animation style as a generic.

\* Represents a set of CSS styles for use in an animation style as a Map.

\* Represents animation-step timing parameters for an animation step.

\* @see `animate()`

\* @publicApi

\* declare type AnimateTimings = {

\* The full duration of an animation step. A number and optional time unit,

\* such as `"1s"` or `"10ms"` for one second and 10 milliseconds, respectively.

\* The default unit is milliseconds.

\* duration: number,

\* The delay in applying an animation step. A number and optional time unit.

\* The default unit is milliseconds.

\* delay: number,

\* An easing style that controls how an animations step accelerates and decelerates during its run time. An easing function such as `cubic-bezier`,

\* or one of the following constants:

\* - `ease-in`

\* - `ease-out`

\* - `ease-in-and-out`

\* easing: string | null;

\* @description Options that control animation styling and timing.

\* The following animation functions accept `AnimationOptions`

\* - `transition()`

\* - `sequence()`

\* - `{@link animations/group group()}`

\* - `query()`

\* - `animation()`

\* - `useAnimation()`

\* - `animateChild()`

\* Programmatic animations built using the `AnimationBuilder` service also make use of `AnimationOptions`.

\* @publicApi

\* declare interface AnimationOptions {

\* Sets a time-delay for initiating an animation action.

\* A number and optional time unit, such as `"1s"` or `"10ms"` for one second and 10 milliseconds, respectively. The default unit is milliseconds.

\* Default value is 0, meaning no delay.

\* delay?: number|string;

\* A set of developer-defined parameters that modify styling and timing when an animation action starts. An array of key-value pairs, where the provided value is used as a default.

\* params?: {[name: string]: any};

\* Adds duration options to control animation styling and timing for a child animation.

\* @see `animateChild()`

\* @publicApi

\* declare interface AnimateChildOptions extends AnimationOptions {

\* duration?: number|string;

\* @description Constants for the categories of parameters that can be defined for animations.

\* A corresponding function defines a set of parameters for each category, and collects them into a corresponding `AnimationMetadata` object.

\* @publicApi

\* declare const enum AnimationMetadataType {

\* Associates a named animation state with a set of CSS styles.

\* See `state()(api/animations/state)`

\* State = 0,

\* Data for a transition from one animation state to another.

\* See `transition()`

\* Transition = 1,

\* Contains a set of animation steps.

\* See `sequence()`

\* Sequence = 2,

\* Contains a set of animation steps.

\* See `{@link animations/group group()}`

\* Group = 3,

\* Contains an animation step.

\* See `animate()`

\* Animate = 4,

\* Contains a set of animation steps.

\* See `keyframes()`

\* Keyframes = 5,

\* Contains a set of CSS property-value pairs into a named style.

\* See `style()`

\* Style = 6,

\* Associates an animation with an entry trigger that can be attached to an element.

\* See `trigger()`

\* Trigger = 7,

\* Contains a re-usable animation.

\* See `animation()`

\* Reference = 8,

\* Contains data to use in executing child animations returned by a query.

\* See `animateChild()`

\* AnimateChild = 9,

\* Contains animation parameters for a re-usable animation.

\* See `useAnimation()`

\* AnimateRef = 10,

\* Contains child-animation query data.

\* See `query()`

\* Query = 11,

\* Contains data for staggering an animation sequence.

\* See `stagger()`

\* Stagger = 12

\* Specifies automatic styling.

\* @publicApi

\* declare const AUTO\_STYLE = '\*';

\* Base for animation data structures.

\* @publicApi

\* declare interface AnimationMetadata {

\* type: AnimationMetadataType;

\* Contains an animation trigger. Instantiated and returned by the `trigger()` function.

\* @publicApi

\* declare interface AnimationTriggerMetadata extends AnimationMetadata {

\* The trigger name, used to associate it with an element. Unique within the component.

\* name: string;

\* An animation definition object, containing an array of state and transition declarations.

\* definitions: AnimationMetadata[];

\* An options object containing a delay and developer-defined

parameters that provide styling defaults and\n \* can be overridden on invocation. ```

*\n * @publicApi\n */\nexport interface AnimationSequenceMetadata extends AnimationMetadata {\n /**\n *
An array of animation step objects.\n */\n steps: AnimationMetadata[];\n /**\n * An options object containing a
delay and\n * developer-defined parameters that provide styling defaults and\n * can be overridden on invocation.
Default delay is 0.\n */\n options: AnimationOptions|null;\n}\n\n/**\n * Encapsulates an animation group.\n *
Instantiated and returned by the `@link animations/group group()` function.\n */\n * @publicApi\n */\nexport
interface AnimationGroupMetadata extends AnimationMetadata {\n /**\n * One or more animation or style steps
that form this group.\n */\n steps: AnimationMetadata[];\n /**\n * An options object containing a delay and\n *
developer-defined parameters that provide styling defaults and\n * can be overridden on invocation. Default delay
is 0.\n */\n options: AnimationOptions|null;\n}\n\n/**\n * Encapsulates animation
query options.\n * Passed to the `query()` function.\n */\n * @publicApi\n */\nexport declare interface
AnimationQueryOptions extends AnimationOptions {\n /**\n * True if this query is optional, false if it is required.
Default is false.\n * A required query throws an error if no elements are retrieved when\n * the query is executed.
An optional query does not.\n */\n optional?: boolean;\n /**\n * A maximum total number of results to
return from the query.\n * If negative, results are limited from the end of the query list towards the beginning.\n *
By default, results are not limited.\n */\n limit?: number;\n}\n\n/**\n * Encapsulates parameters for staggering the
start times of a set of animation steps.\n * Instantiated and returned by the `stagger()` function.\n */\n *
@publicApi\n */\nexport interface AnimationStaggerMetadata extends AnimationMetadata {\n /**\n * The
timing data for the steps.\n */\n timings: string|number;\n /**\n * One or more
animation steps.\n */\n animation: AnimationMetadata|AnimationMetadata[];\n}\n\n/**\n * Creates a named
animation trigger, containing a list of [ `state()` ](api/animations/state)\n * and `transition()` entries to be evaluated
when the expression\n * bound to the trigger changes.\n */\n * @param name An identifying string.\n * @param
definitions An animation definition object, containing an array of\n * [ `state()` ](api/animations/state) and
`transition()` declarations.\n */\n * @return An object that encapsulates the trigger data.\n */\n * @usageNotes\n *
Define an animation trigger in the `animations` section of `@Component` metadata.\n * In the template, reference
the trigger by name and bind it to a trigger expression that\n * evaluates to a defined animation state, using the
following format:\n */\n * `[@triggerName]="expression"`\n * Animation trigger bindings convert all values to
strings, and then match the\n * previous and current values against any linked transitions.\n
* Booleans can be specified as `1` or `true` and `0` or `false`.\n */\n * ### Usage Example\n */\n * The following
example creates an animation trigger reference based on the provided\n * name value.\n * The provided animation
value is expected to be an array consisting of state and\n * transition declarations.\n */\n * ```typescript\n *
@Component({\n * selector: "my-component",\n * templateUrl: "my-component-tpl.html",\n * animations:\n *
trigger("myAnimationTrigger", [\n * state(...),\n * state(...),\n * transition(...),\n *
transition(...)\n * ])\n * })\n * class MyComponent {\n * myStatusExp = "something";\n * }\n * ```\n */\n
* The template associated with this component makes use of the defined trigger\n * by binding to an element within
its template code.\n */\n * ```html\n * <!-- somewhere inside of my-component-tpl.html -->\n * <div
[@myAnimationTrigger]="myStatusExp">...</div>\n * ```\n */\n * ### Using an inline function\n
* The `transition` animation method also supports reading an inline function which can decide\n * if its associated
animation should be run.\n */\n * ```typescript\n * // this method is run each time the `myAnimationTrigger` trigger
value changes.\n * function myInlineMatcherFn(fromState: string, toState: string, element: any, params: {[key:\n
string]: any}): boolean {\n * // notice that `element` and `params` are also available here\n * return toState ==
'yes-please-animate';\n * }\n * }\n * @Component({\n * selector: 'my-component',\n * templateUrl: 'my-
component-tpl.html',\n * animations: [\n * trigger('myAnimationTrigger', [\n *
transition(myInlineMatcherFn, [\n * // the animation sequence code\n * ]),\n * ])\n * ])\n * })\n * class
MyComponent {\n * myStatusExp = "yes-please-animate";\n * }\n * ```\n */\n * ### Disabling Animations\n *
When true, the special animation control binding `@.disabled` binding prevents\n * all animations from
rendering.\n * Place the `@.disabled` binding on an element to disable\n * animations on the element itself, as well
as any inner animation triggers\n * within the element.\n */\n * The following example shows how to use this
feature:\n */\n * ```typescript\n * @Component({\n * selector: 'my-component',\n * template: `
<div

```

```

[@.disabled]=\isDisabled\>\n * <div [@childAnimation]=\exp"></div>\n * </div>\n * `,\n *
animations: [\n * trigger("childAnimation", [\n * // ... \n * ])\n * ]\n * }\n * class MyComponent {\n *
isDisabled = true;\n * exp = '...';\n * }\n * ``\n * \n * When `@.disabled` is true, it prevents the `@childAnimation`
trigger from animating,\n * along with any inner animations.\n * \n * ### Disable animations application-wide\n *
When an area of the template is set to have animations disabled,\n * **all** inner components have their animations
disabled as well.\n * This means that you can disable all animations for an app\n
* by placing a host binding set on `@.disabled` on the topmost Angular component.\n * \n * ``typescript\n * import
{Component, HostBinding} from '@angular/core';\n * \n * @Component({\n * selector: 'app-component',\n *
templateUrl: 'app.component.html',\n * })\n * class AppComponent {\n * @HostBinding('@.disabled')\n * public
animationsDisabled = true;\n * }\n * ``\n * \n * ### Overriding disablement of inner animations\n * Despite inner
animations being disabled, a parent animation can `query()`\n * for inner elements located in disabled areas of the
template and still animate\n * them if needed. This is also the case for when a sub animation is\n * queried by a
parent and then later animated using `animateChild()`.\n * \n * ### Detecting when an animation is disabled\n * If a
region of the DOM (or the entire application) has its animations disabled, the animation\n * trigger callbacks still
fire, but for zero seconds. When the callback fires, it provides\n * an instance of an
`AnimationEvent`. If animations are disabled,\n * the `.disabled` flag on the event is true.\n * \n * @publicApi\n
*\n * export function trigger(name: string, definitions: AnimationMetadata[]): AnimationTriggerMetadata {\n * return
{type: AnimationMetadataType.Trigger, name, definitions, options: {}};\n * }\n * \n * \n * Defines an animation step
that combines styling information with timing information.\n * \n * @param timings Sets `AnimateTimings` for the
parent animation.\n * A string in the format `"duration [delay] [easing]"`.\n * - Duration and delay are expressed as
a number and optional time unit,\n * such as `"1s"` or `"10ms"` for one second and 10 milliseconds, respectively.\n *
The default unit is milliseconds.\n * - The easing value controls how the animation accelerates and decelerates\n *
during its runtime. Value is one of `ease`, `ease-in`, `ease-out`,\n * `ease-in-out`, or a `cubic-bezier()` function
call.\n * If not supplied, no easing is applied.\n * \n * For example, the string
`"1s 100ms ease-out"` specifies a duration of\n * 1000 milliseconds, and delay of 100 ms, and the `"ease-out"`
easing style,\n * which decelerates near the end of the duration.\n * @param styles Sets AnimationStyles for the
parent animation.\n * A function call to either `style()` or `keyframes()`\n * that returns a collection of CSS style
entries to be applied to the parent animation.\n * When null, uses the styles from the destination state.\n * This is
useful when describing an animation step that will complete an animation;\n * see `"Animating to the final state"` in
`transitions()`.\n * @returns An object that encapsulates the animation step.\n * \n * @usageNotes\n * Call within an
animation `sequence()`, `{ @link animations/group group()}`, or\n * `transition()` call to specify an animation step\n
* that applies given style data to the parent animation for a given amount of time.\n * \n * ### Syntax Examples\n *
**Timing examples**\n * \n * The following examples show various `timings`
specifications.\n * - `animate(500)` : Duration is 500 milliseconds.\n * - `animate("1s")` : Duration is 1000
milliseconds.\n * - `animate("100ms 0.5s")` : Duration is 100 milliseconds, delay is 500 milliseconds.\n * -
`animate("5s ease-in")` : Duration is 5000 milliseconds, easing in.\n * - `animate("5s 10ms cubic-
bezier(.17,.67,.88,.1)")` : Duration is 5000 milliseconds, delay is 10\n * milliseconds, easing according to a bezier
curve.\n * \n * **Style examples**\n * \n * The following example calls `style()` to set a single CSS style.\n *
``typescript\n * animate(500, style({ background: "red" }));\n * ``\n * \n * The following example calls `keyframes()`
to set a CSS style\n * to different values for successive keyframes.\n * ``typescript\n * animate(500, keyframes([\n *
style({ background: "blue" }),\n * style({ background: "red" })\n * ]));\n * ``\n * \n * @publicApi\n
*\n * export function animate(\n * timings: string|number,\n * styles:
AnimationStyleMetadata|AnimationKeyframesSequenceMetadata|null
= \n * null): AnimationAnimateMetadata {\n * return {type: AnimationMetadataType.Animate, styles,
timings};\n * }\n * \n * \n * @description Defines a list of animation steps to be run in parallel.\n * \n * @param steps
An array of animation step objects.\n * - When steps are defined by `style()` or `animate()`\n * function calls, each
call within the group is executed instantly.\n * - To specify offset styles to be applied at a later time, define steps
with\n * `keyframes()`, or use `animate()` calls with a delay value.\n * For example:\n * \n * ``typescript\n *

```

group([n \* animate("1s", style({ background: "black" })),n \* animate("2s", style({ color: "white" }))]n \* )n \* ``n \* n \* @param options An options object containing a delay andn \* developer-defined parameters that provide styling defaults andn \* can be overridden on invocation.n \* n \* @return An object that encapsulates the group data.n \* n \* @usageNotesn \* Grouped animations are useful when a series of styles must be n \* animated at different starting times and closed off at different ending times.n \* n \* When called within a `sequence()` or a n \* `transition()` call, does not continue to the nextn \* instruction until all of the inner animation steps have completed.n \* n \* @publicApi\n \* \nexport function group(n \* steps: AnimationMetadata[], options: AnimationOptions|null = null): AnimationGroupMetadata {n \* return {type: AnimationMetadataType.Group, steps, options};\n \* }\n \* \n/\*\*n \* Defines a list of animation steps to be run sequentially, one by one.n \* n \* @param steps An array of animation step objects.n \* n \* - Steps defined by `style()` calls apply the styling data immediately.n \* n \* - Steps defined by `animate()` calls apply the styling data over time n \* as specified by the timing data.n \* n \* ``typescriptn \* sequence([n \* style({ opacity: 0 }),n \* animate("1s", style({ opacity: 1 }))]n \* )n \* ``n \* n \* @param options An options object containing a delay andn \* developer-defined parameters that provide styling defaults andn \* can be overridden on invocation.n \* n \* @return An object that encapsulates the sequence data.n \* n \* @usageNotes\n \* n \* When you pass an array of steps to a n \* `transition()` call, the steps run sequentially by default.n \* Compare this to the `{@link animations/group group()}` call, which runs animation steps in n \* parallel.n \* n \* When a sequence is used within a `{@link animations/group group()}` or a `transition()` call, n \* execution continues to the next instruction only after each of the inner animation n \* steps have completed.n \* n \* @publicApi\n \* \nexport function sequence(n \* steps: AnimationMetadata[], options: AnimationOptions|null = null): AnimationSequenceMetadata {n \* return {type: AnimationMetadataType.Sequence, steps, options};\n \* }\n \* \n/\*\*n \* Declares a key/value object containing CSS properties/styles that n \* can then be used for an animation [ state`](api/animations/state), within an animation n \* `sequence`, or as styling data for calls to `animate()` and `keyframes()`.n \* n \* @param tokens A set of CSS styles or HTML styles associated with an animation state.n \* The value can be any of the following:n \* n \* - A key-value style pair associating a CSS property with a value.n \* n \* - An array of key-value style pairs.n \* n \* - An asterisk (\*), to use auto-styling, where styles are derived from the element n \* being animated and applied to the animation when it starts.n \* n \* Auto-styling can be used to define a state that depends on layout or other n \* environmental factors.n \* n \* @return An object that encapsulates the style data.n \* n \* @usageNotes\n \* n \* The following examples create animation styles that collect a set of n \* CSS property values:n \* n \* ``typescriptn \* // string values for CSS propertiesn \* style({ background: "red", color: "blue" })n \* n \* // numerical pixel valuesn \* style({ width: 100, height: 0 })n \* ``n \* n \* The following example uses auto-styling to allow an element to animate from n \* a height of 0 up to its full height:n \* n \* ``n \* style({ height: 0 }),n \* animate("1s", style({ height: "\*" }))]n \* ``n \* n \* @publicApi\n \* \nexport function style(tokens: '\*|'[[key: string]: string | number]|\n \* Array<'\*'|{[key: string]: string | number}>): AnimationStyleMetadata {n \* return {type: AnimationMetadataType.Style, styles: tokens, offset: null};\n \* }\n \* \n/\*\*n \* Declares an animation state within a trigger attached to an element.n \* n \* @param name One or more names for the defined state in a comma-separated string.n \* The following reserved state names can be supplied to define a style for specific use n \* cases:n \* n \* - `void` You can associate styles with this name to be used when n \* the element is detached from the application. For example, when an `ngIf` evaluates n \* to false, the state of the associated element is void.n \* n \* - `\*` (asterisk) Indicates the default state. You can associate styles with this name n \* to be used as the fallback when the state that is being animated is not declared n \* within the trigger.n \* n \* @param styles A set of CSS styles associated with this state, created using the n \* `style()` function.n \* This set of styles persists on the element once the state has been reached.n \* n \* @param options Parameters that can be passed to the state when it is invoked.n \* 0 or more key-value pairs.n \* n \* @return An object that encapsulates the new state data.n \* n \* @usageNotes\n \* n \* Use the `trigger()` function to register states to an animation trigger.n \* Use the `transition()` function to animate between states.n \* n \* When a state is active within a component, its associated styles persist on the element, n \* even when the animation

ends.

```

@publicApi
export function state(
  name: string,
  styles: AnimationStyleMetadata,
  options?: {
    params: {
      [name: string]: any
    }
  }): AnimationStateMetadata

```

{\n return {type: AnimationMetadataType.State, name, styles, options};\n}\n\n\*\*\n \* Defines a set of animation styles, associating each style with an optional `offset` value.\n \* \n \* @param steps A set of animation styles with optional offset data.\n \* The optional `offset` value for a style specifies a percentage of the total animation\n \* time at which that style is applied.\n \* @returns An object that encapsulates the keyframes data.\n \* \n \* @usageNotes\n \* Use with the `animate()` call. Instead of applying animations\n \* from the current state\n \* to the destination state, keyframes describe how each style entry is applied and at what point\n \* within the animation arc.\n \* Compare [CSS Keyframe Animations](https://www.w3schools.com/css/css3\_animations.asp).\n \* \n \* ### Usage\n \* In the following example, the offset values describe\n \* when each `backgroundColor` value is applied. The color is red at the start, and changes to\n \* blue when 20% of the total time has elapsed.\n

```

```typescript
// the provided offset values
animate("5s", keyframes([
  style({ backgroundColor: "red", offset: 0 }),
  style({ backgroundColor: "blue", offset: 0.2 }),
  style({ backgroundColor: "orange", offset: 0.3 }),
  style({ backgroundColor: "black", offset: 1 })
]))

```

If there are no `offset` values specified in the style entries, the offsets\n \* are calculated automatically.\n \* \n \* ```typescript\n \* animate("5s", keyframes([\n \* style({ backgroundColor: "red" }) // offset = 0\n \* style({ backgroundColor: "blue" }) // offset = 0.33\n \* style({ backgroundColor: "orange" }) // offset = 0.66\n \* style({ backgroundColor: "black" }) // offset = 1\n \* ]))\n \* \n \* @publicApi\n \* \n \* export function keyframes(
 steps: AnimationStyleMetadata[]): AnimationKeyframesSequenceMetadata {
 return {
 type: AnimationMetadataType.Keyframes,
 steps
 };
}

\*\*\n \* Declares an animation transition which is played when a certain specified condition is met.\n \* \n \* @param stateChangeExpr A string with a specific format or a function that specifies when the\n \* animation transition should occur (see [State Change Expression](#state-change-expression)).\n \* \n \* @param steps One or more animation objects that represent the animation's instructions.\n \* \n \* @param options An options object that can be used to specify a delay for the animation or provide\n \* custom parameters for it.\n \* \n \* @returns An object that encapsulates the transition data.\n \* \n \* @usageNotes\n \* \n \* ### State Change Expression\n \* The State Change Expression instructs Angular when to run the transition's animations, it can\n \* either be\n \* - a string with a specific syntax\n \* - or a function that compares the previous and current state (value of the expression bound to\n \* the element's trigger) and returns `true` if the transition should occur or `false` otherwise\n \* \n \* The string format can be:\n \* - `fromState => toState`, which indicates that the transition's animations should occur then the\n \* expression bound to the trigger's element goes from `fromState` to `toState`\n \* \n \* \_Example:\_\n \* ```typescript\n \* transition('open => closed', animate('.5s ease-out', style({ height: 0 })))\n \* \n \* - `fromState <=> toState`, which indicates that the transition's animations should occur then\n \* the expression bound to the trigger's element goes from `fromState` to `toState` or vice versa\n \* \n \* \_Example:\_\n \* ```typescript\n \* transition('enabled <=> disabled', animate('1s cubic-bezier(0.8,0.3,0,1)'))\n \* \n \* - `:enter`/:leave`, which indicates that the transition's animations should occur when the\n \* element enters or exists the DOM\n \* \n \* \_Example:\_\n \* ```typescript\n \* transition(':enter', [\n \* style({ opacity: 0 }),\n \* animate('500ms', style({ opacity: 1 }))]
 )\n \* \n \* - `:increment`/:decrement`, which indicates that the transition's animations should occur when\n \* the numerical expression bound to the trigger's element has increased in value or decreased\n \* \n \* \_Example:\_\n \* ```typescript\n \* transition(':increment', query('@counter', animateChild()))\n \* \n \* - a sequence of any of the above divided by commas, which indicates that transition's animations\n \* should occur whenever one of the state change expressions matches\n \* \n \* \_Example:\_\n \* ```typescript\n \* transition(':increment, => enabled, :enter', animate('1s ease', keyframes([\n \* style({ transform: 'scale(1)', offset: 0}),\n \* style({ transform: 'scale(1.1)', offset: 0.7}),\n \* style({ transform: 'scale(1)', offset: 1 })
 ]))\n \* \n \* \n \* Also note that in such context:\n \* - `void` can be used to indicate the absence of the element\n \* - asterisks can be used as wildcards that match

any state\n \* - (as a consequence of the above, `void => \*` is equivalent to `:enter` and `\* => void` is\n \* equivalent to `:leave`)\n \* - `true` and `false` also match expression values of `1` and `0` respectively (but do not match\n \* `_truthy_` and `_falsy_` values)\n \* `<div class=\"alert is-helpful\">`\n \* Be careful about entering end leaving elements as their transitions present a common\n \* pitfall for developers.\n \* Note that when an element with a trigger enters the DOM its `:enter` transition always\n \* gets executed, but its `:leave` transition will not be executed if the element is removed\n \* alongside its parent (as it will be removed `"without warning"` before its transition has\n \* a chance to be executed, the only way that such transition can occur is if the element\n \* is exiting the DOM on its own).\n \* `</div>`\n \* `### Animating to a Final State`\n \* If the final step in a transition is a call to `animate()` that uses a timing

value\n \* with no `style` data, that step is automatically considered the final animation arc,\n \* for the element to reach the final state, in such case Angular automatically adds or removes\n \* CSS styles to ensure that the element is in the correct final state.\n \* `### Usage Examples`\n \* - Transition animations applied based on\n \* the trigger's expression value\n \* `HTML`\n \* `<div [@myAnimationTrigger]="myStatusExp">` ...  
`</div>`\n \* `typescript`\n \* `trigger("myAnimationTrigger", [ ... , // states\n * transition("\n * => off, open => closed", animate(500)),\n * transition("\n * <=> error", query('.indicator', animateChild()))\n * ])\n *` \n \* - Transition animations applied based on custom logic dependent\n \* on the trigger's expression value and provided parameters\n \* `HTML`\n \* `<div [@myAnimationTrigger]="{ value:`

`stepName,`\n \* `params: { target: currentTarget } }\n * >`\n \* ...  
`</div>`\n \* `typescript`\n \* `trigger("myAnimationTrigger", [ ... , // states\n * transition(\n * (fromState, toState, _element, params) =>\n * ['firststep', 'laststep'].includes(fromState.toLowerCase())\n * && toState === params?.['target'],\n * animate('1s')\n * )\n * ])\n *` \n \* `@publicApi`\n \* `export function transition(\n * stateChangeExpr: string\n * ((fromState: string, toState: string, element?: any, params?: {[key: string]: any}) => boolean),\n * steps: AnimationMetadata|AnimationMetadata[],\n * options: AnimationOptions|null = null):`

`AnimationTransitionMetadata` {\n \* return {type: AnimationMetadataType.Transition, expr: stateChangeExpr, animation: steps, options};}\n \* `Produces a reusable animation that can be invoked in another animation or sequence,\n * by calling the useAnimation() function.\n * @param steps One or more animation objects, as returned`

by the `animate()`\n \* or `sequence()` function, that form a transformation from one state to another.\n \* A sequence is used by default when you pass an array.\n \* @param options An options object that can contain a delay value for the start of the\n \* animation, and additional developer-defined parameters.\n \* Provided values for additional parameters are used as defaults,\n \* and override values can be passed to the caller on invocation.\n \* @returns An object that encapsulates the animation data.\n \* `@usageNotes`\n \* The following example defines a reusable animation, providing some default parameter\n \* values.\n \* `typescript`\n \* `var fadeAnimation = animation([\n * style({ opacity: '{ start }' }),\n * animate('{ time }',\n * style({ opacity: '{ end }' })),\n * ],\n * { params: { time: '1000ms', start: 0, end: 1 } });\n *` \n \* The following invokes the defined animation with a call to `useAnimation()`,\n \* passing in override parameter values.\n \* `js`\n \* `useAnimation(fadeAnimation, {\n * params: {\n * time: '2s',\n * start: 1,\n * end: 0\n * } }\n * )\n *` \n \* If any of the passed-in parameter values are missing from this call,\n \* the default values are used. If one or more parameter values are missing before a step is\n \* animated, `useAnimation()` throws an error.\n \* `@publicApi`\n \* `export function animation(\n * steps: AnimationMetadata|AnimationMetadata[],\n * options: AnimationOptions|null = null): AnimationReferenceMetadata` {\n \* return {type:

`AnimationMetadataType.Reference, animation: steps, options};}\n * Executes a queried inner animation element within an animation sequence.\n * @param options An options object that can contain a delay value for the start of the\n * animation, and additional override values for developer-defined parameters.\n * @return An object that encapsulates the child animation data.\n * @usageNotes\n * Each time an animation is triggered in Angular, the parent animation\n * has priority and any child animations are blocked. In order\n * for a child animation to run, the parent animation must query each of the elements\n * containing child animations, and run`

`AnimationReferenceMetadata` {\n \* return {type: AnimationMetadataType.Reference, animation: steps, options};}\n \* `Executes a queried inner animation element within an animation sequence.\n * @param options An options object that can contain a delay value for the start of the\n * animation, and additional override values for developer-defined parameters.\n * @return An object that encapsulates the child animation data.\n * @usageNotes`\n \* Each time an animation is triggered in Angular, the parent animation\n \* has priority and any child animations are blocked. In order\n \* for a child animation to run, the parent animation must query each of the elements\n \* containing child animations, and run

`AnimationReferenceMetadata` {\n \* return {type: AnimationMetadataType.Reference, animation: steps, options};}\n \* `Executes a queried inner animation element within an animation sequence.\n * @param options An options object that can contain a delay value for the start of the\n * animation, and additional override values for developer-defined parameters.\n * @return An object that encapsulates the child animation data.\n * @usageNotes`\n \* Each time an animation is triggered in Angular, the parent animation\n \* has priority and any child animations are blocked. In order\n \* for a child animation to run, the parent animation must query each of the elements\n \* containing child animations, and run

them using this function. Note that this feature is designed to be used with `query()` and it will only work with animations that are assigned using the Angular animation library. CSS keyframes and transitions are not handled by this API.

```

@publicApi
export function animateChild(options: AnimationChildOptions|null = null): AnimationAnimateChildMetadata {
  return {type: AnimationMetadataType.AnimateChild, options};
}

```

Starts a reusable animation that is created using the `animation()` function.

```

@param animation The reusable animation to start.
@param options An options object that can contain a delay value for the start of the animation, and additional override values for developer-defined parameters.
@return An object that contains the animation parameters.
@publicApi
export function useAnimation(animation: AnimationReferenceMetadata, options: AnimationOptions|null = null): AnimationAnimateRefMetadata {
  return {type: AnimationMetadataType.AnimateRef, animation, options};
}

```

Finds one or more inner elements within the current element that is being animated within a sequence. Use with `animate()`.

```

@param selector The element to query, or a set of elements that contain Angular-specific characteristics, specified with one or more of the following tokens.
- `query(':enter')` or `query(':leave')` : Query for newly inserted/removed elements (not all elements can be queried via these tokens, see [Entering and Leaving Elements](#entering-and-leaving-elements))
- `query(':animating')` : Query all currently animating elements.
- `query('@triggerName')` : Query elements that contain an animation trigger.
- `query('@*)` : Query all elements that contain an animation triggers.
- `query(':self')` : Include the current element into the animation sequence.

```

One or more animation steps to apply to the queried element or elements. An array is treated as an animation sequence.

```

@param options An options object. Use the 'limit' field to limit the total number of items to collect.
@return An object that encapsulates the query data.
@usageNotes
### Multiple Tokens
Tokens can be merged into a combined query selector string. For example:
`typescript`
query(':self, .record:enter, .record:leave, @subTrigger', [...])
`js`
The `query()` function collects multiple elements and works internally by using `element.querySelector`. Use the `limit` field of an options object to limit the total number of items to be collected. For example:
`js`
query('div', [animate(...), animate(...)], { limit: 1 })
By default, throws an error when zero items are found. Set the `optional` flag to ignore this error. For example:
`js`
query('.some-element-that-may-not-be-there', [animate(...), animate(...)], { optional: true })

```

### Entering and Leaving Elements

Not all elements can be queried via the `:enter` and `:leave` tokens, the only ones that can are those that Angular assumes can enter/leave based on their own logic (if their insertion/removal is simply a consequence of that of their parent they should be queried via a different token in their parent's `:enter`/:`leave` transitions).

The only elements Angular assumes can enter/leave based on their own logic (thus the only ones that can be queried via the `:enter` and `:leave` tokens) are:

- Those inserted dynamically (via `ViewContainerRef`)
- Those that have a structural directive (which, under the hood, are a subset of the above ones)

```

<div class="alert is-helpful">

```

Note that elements will be successfully queried via `:enter`/:`leave` even if their insertion/removal is not done manually via `ViewContainerRef` or caused by their structural directive (e.g. they enter/exit alongside their parent).

```

</div>
<div class="alert is-important">

```

There is an exception to what previously mentioned, besides elements entering/leaving based on their own logic, elements with an animation trigger can always be queried via `:leave` when their parent is also leaving.

```

</div>

```

### Usage Example

The following example queries for inner elements and animates them individually using `animate()`.

```

`typescript`
@Component({
  selector: 'inner',
  template: `
    <div [@queryAnimation]=["exp"]>
      <h1>Title</h1>
      <div class="content">
        Blah blah blah
      </div>
    </div>
  `,
  animations: [
    trigger('queryAnimation', [
      transition('* => goAnimate', [
        // hide the inner elements
        query('h1', style({ opacity: 0 })),
        query('.content', style({ opacity: 0 })),
        // animate the inner elements in, one by one
        query('h1', animate(1000, style({ opacity: 1 }))),
        query('.content', animate(1000, style({ opacity: 1 }))),
      ]),
    ]),
  ]),
})
class Cmp {
  exp =

```

```

";\n * goAnimate() {\n *   this.exp = 'goAnimate';\n * } \n * }\n * ``\n * @publicApi\n * ^\nexport
function query(\n selector: string, animation: AnimationMetadata|AnimationMetadata[],\n options:
AnimationQueryOptions|null = null): AnimationQueryMetadata {\n return {type: AnimationMetadataType.Query,
selector, animation, options};\n}\n\n/**\n * Use within an animation `query()` call to issue a timing gap after\n *
each queried item is animated.\n * @param timings
A delay value.\n * @param animation One ore more animation steps.\n * @returns An object that encapsulates the
stagger data.\n * @usageNotes\n * In the following example, a container element wraps a list of items stamped
out\n * by an `ngFor`. The container element contains an animation trigger that will later be set\n * to query for each
of the inner items.\n * Each time items are added, the opacity fade-in animation runs,\n * and each removed item
is faded out.\n * When either of these animations occur, the stagger effect is\n * applied after each item's animation
is started.\n * ``html\n * <!-- list.component.html -->\n * <button (click)="toggle()">Show / Hide
Items</button>\n * <hr />\n * <div [@listAnimation]="items.length">\n * <div *ngFor="let item of items">\n *

 * [Validation]\n * The visitor code below will traverse the animation AST generated by the animation verb
functions\n * (the output is a tree of objects) and attempt to perform a series of validations on the data. The\n *
following corner-cases will be validated:\n * 1. Overlap of animations\n * Given that a CSS property cannot be
animated in more than one place at the same time, it's\n
 * important that this behavior is detected and validated. The way in which this occurs is that\n * each time a style
property is examined, a string-map containing the property will be updated with\n * the start and end times for when
the property is used within an animation step.\n * If there are two or more parallel animations that are currently
running (these are invoked by the\n * group()) on the same element then the validator will throw an error. Since the
start/end timing\n * values are collected for each property then if the current animation step is animating the same\n
 * property and its timing values fall anywhere into the window of time that the property is\n * currently being
animated within then this is what causes an error.\n * 2. Timing values\n * The validator will validate to see if a
timing value of `duration delay easing` or\n * `durationNumber` is valid or not.\n * (note that upon validation
the code below will replace the timing data with an object containing\n
 * {duration,delay,easing}).\n * 3. Offset Validation\n * Each of the style() calls are allowed to have an offset
value when placed inside of keyframes().\n * Offsets within keyframes() are considered valid when:\n * - No
offsets are used at all\n * - Each style() entry contains an offset value\n * - Each offset is between 0 and 1\n * -
Each offset is greater to or equal than the previous one\n * Otherwise an error will be thrown.\n */\n\nexport

 'leave';\nconst LEAVE_TOKEN_REGEX = new RegExp(LEAVE_TOKEN, 'g');\n\n/* The code within this file
 aims to generate web-animations-compatible keyframes from Angular's\n * animation DSL code.\n * The code
 below will be converted from:\n * \n * ``\n * sequence([\n *   style({ opacity: 0 } ),\n *   animate(1000, style({
 opacity: 0 } ))\n * ])\n * \n * To:\n * ``\n * keyframes = [{ opacity: 0, offset:
 0 }, { opacity: 1, offset: 1 }]\n * duration = 1000\n * delay = 0\n * easing = "\n * ``\n * \n * For this operation to
 cover the combination of animation verbs (style, animate, group, etc...) a\n * combination of AST traversal and
 merge-sort-like algorithms are used.\n * \n * [AST Traversal]\n * Each of the animation verbs, when executed, will
 return an string-map object representing what\n * type of action it is (style, animate, group, etc...) and the data
 associated with it. This means\n * that when functional composition mix of these functions is evaluated (like in the
 example above)\n * then it will end up producing a tree of objects representing the animation itself.\n * \n * When
 this animation object tree is processed by the visitor code below it will visit each of the\n * verb statements within
 the visitor. And during each visit it will build the context of the\n * animation keyframes by interacting with the
 `TimelineBuilder`.\n * \n * [TimelineBuilder]\n * This class is responsible
 for tracking the styles and building a series of keyframe objects for a\n * timeline between a start and end time. The
 builder starts off with an initial timeline and each\n * time the AST comes across a `group()`, `keyframes()` or a
 combination of the two within a\n * `sequence()` then it will generate a sub timeline for each step as well as a new
 one after\n * they are complete.\n * \n * As the AST is traversed, the timing state on each of the timelines will be
 incremented. If a sub\n * timeline was created (based on one of the cases above) then the parent timeline will
 attempt to\n * merge the styles used within the sub timelines into itself (only with group() this will happen).\n * This
 happens with a merge operation (much like how the merge works in mergeSort) and it will only\n * copy the most
 recently used styles from the sub timelines into the parent timeline. This ensures\n * that if the styles are used later
 on in another phase of the animation then they will be the most\n
 * up-to-date values.\n * \n * [How Missing Styles Are Updated]\n * Each timeline has a `backFill` property which is
 responsible for filling in new styles into\n * already processed keyframes if a new style shows up later within the
 animation sequence.\n * \n * ``\n * sequence([\n *   style({ width: 0 } ),\n *   animate(1000, style({ width: 100 }
)),\n *   animate(1000, style({ width: 200 })),\n *   animate(1000, style({ width: 300 })),\n *   animate(1000, style({
 width: 400, height: 400 }))] // notice how `height` doesn't exist anywhere\n * else\n * ])\n * \n * What is
 happening here is that the `height` value is added later in the sequence, but is missing\n * from all previous
 animation steps. Therefore when a keyframe is created it would also be missing\n * from all previous keyframes up
 until where it is first used. For the timeline keyframe generation\n * to properly fill in the style it will place the
 previous value (the value from the parent\n * timeline) or a default value
 of `` into the backFill map. The `copyStyles` method in util.ts\n * handles propagating that backfill map to the
 styles object.\n * \n * When a sub-timeline is created it will have its own backFill property. This is done so that\n
 * styles present within the sub-timeline do not accidentally seep into the previous/future timeline\n * keyframes\n * \n
 * [Validation]\n * The code in this file is not responsible for validation. That functionality happens with within\n
 * the `AnimationValidatorVisitor` code.\n */\nexport function buildAnimationTimelines(\n  driver:

 * [Validation]\n * The visitor code below will traverse the animation AST generated by the animation verb
functions\n * (the output is a tree of objects) and attempt to perform a series of validations on the data. The\n *
following corner-cases will be validated:\n * 1. Overlap of animations\n * Given that a CSS property cannot be
animated in more than one place at the same time, it's\n
 * important that this behavior is detected and validated. The way in which this occurs is that\n * each time a style
property is examined, a string-map containing the property will be updated with\n * the start and end times for when
the property is used within an animation step.\n * If there are two or more parallel animations that are currently
running (these are invoked by the\n * group()) on the same element then the validator will throw an error. Since the
start/end timing\n * values are collected for each property then if the current animation step is animating the same\n
 * property and its timing values fall anywhere into the window of time that the property is\n * currently being
animated within then this is what causes an error.\n * 2. Timing values\n * The validator will validate to see if a
timing value of `duration delay easing` or\n * `durationNumber` is valid or not.\n * (note that upon validation
the code below will replace the timing data with an object containing\n
 * {duration,delay,easing}).\n * 3. Offset Validation\n * Each of the style() calls are allowed to have an offset
value when placed inside of keyframes().\n * Offsets within keyframes() are considered valid when:\n * - No
offsets are used at all\n * - Each style() entry contains an offset value\n * - Each offset is between 0 and 1\n * -
Each offset is greater to or equal than the previous one\n * Otherwise an error will be thrown.\n */\n\nexport

```

\* The code within this file aims to generate web-animations-compatible keyframes from Angular's animation DSL code.

\* The code below will be converted from:

```

sequence([
  style({ opacity: 0 }),
  animate(1000, style({ opacity: 0 }))]
)
To:
keyframes = [{ opacity: 0, offset: 0 }, { opacity: 1, offset: 1 }]
duration = 1000
delay = 0
easing = ''

```

\* For this operation to cover the combination of animation verbs (style, animate, group, etc...) a combination of AST traversal and merge-sort-like algorithms are used.

\* [AST Traversal]

\* Each of the animation verbs, when executed, will return an string-map object representing what type of action it is (style, animate, group, etc...) and the data associated with it. This means that when functional composition mix of these functions is evaluated (like in the example above) then it will end up producing a tree of objects representing the animation itself.

\* When this animation object tree is processed by the visitor code below it will visit each of the verb statements within the visitor. And during each visit it will build the context of the animation keyframes by interacting with the `TimelineBuilder`.

\* [TimelineBuilder]

\* This class is responsible for tracking the styles and building a series of keyframe objects for a timeline between a start and end time. The builder starts off with an initial timeline and each time the AST comes across a `group()`, `keyframes()` or a combination of the two within a `sequence()` then it will generate a sub timeline for each step as well as a new one after they are complete.

\* As the AST is traversed, the timing state on each of the timelines will be incremented. If a sub timeline was created (based on one of the cases above) then the parent timeline will attempt to merge the styles used within the sub timelines into itself (only with group() this will happen).

\* This happens with a merge operation (much like how the merge works in mergeSort) and it will only copy the most recently used styles from the sub timelines into the parent timeline. This ensures that if the styles are used later on in another phase of the animation then they will be the most up-to-date values.

\* [How Missing Styles Are Updated]

\* Each timeline has a `backFill` property which is responsible for filling in new styles into already processed keyframes if a new style shows up later within the animation sequence.

```

sequence([
  style({ width: 0 }),
  animate(1000, style({ width: 100 })),
  animate(1000, style({ width: 200 })),
  animate(1000, style({ width: 300 })),
  animate(1000, style({ width: 400, height: 400 }))]
// notice how `height` doesn't exist anywhere
else

```

\* What is happening here is that the `height` value is added later in the sequence, but is missing from all previous animation steps. Therefore when a keyframe is created it would also be missing from all previous keyframes up until where it is first used. For the timeline keyframe generation to properly fill in the style it will place the previous value (the value from the parent timeline) or a default value of `\*` into the backFill map. The `copyStyles` method in util.ts handles propagating that backfill map to the styles object.

\* When a sub-timeline is created it will have its own backFill property. This is done so that styles present within the sub-timeline do not accidentally seep into the previous/future timeline keyframes.

\* [Validation]

\* The code in this file is not responsible for validation. That functionality happens with within the `AnimationValidatorVisitor` code.

import { StyleDataMap } from
 '@angular/animations';
import { eraseStyles, setStyles } from './util';

Returns an instance of
`SpecialCasedStyles` if and when any special (non animateable) styles are
detected.

In CSS there exist
properties that cannot be animated within a keyframe animation
(whether it be via CSS keyframes or web-
animations) and the animation implementation
will ignore them. This function is designed to detect those special
cased styles and
return a container that will be executed at the start and end of the animation.

@returns
an instance of `SpecialCasedStyles` if any special styles are detected otherwise
`null`

export

`import {Type} from '../interface/type';  
import {getClosureSafeProperty} from '../util/property';  
import {ClassProvider, ConstructorProvider, ExistingProvider, FactoryProvider, StaticClassProvider, ValueProvider} from './provider';`  

Information about how a type or `InjectionToken` interfaces with the DI system.  
At a minimum, this includes a `factory` which defines how to create the given type `T`, possibly requesting injection of other types if necessary.  
Optionally, a `providedIn` parameter specifies that the given type belongs to a particular `Injector`, `NgModule`, or a special scope (e.g. `'root'`). A value of `null` indicates that the injectable does not belong to any scope.  
`@codeGenApi`  
`@publicApi` The ViewEngine compiler emits code with this type for injectables. This code is deployed to npm, and should be treated as public api.  
`export interface InjectableDeclaration<T> {  
 /** Specifies that the given type belongs to a particular injector: InjectorType such as NgModule, 'root' the root injector, 'any' all injectors, null, does not belong to any injector. Must be explicitly listed in the injector providers.  
 providedIn: InjectorType<any>|'root'|'platform'|'any'|'environment'|null;  
 /** The token to which this definition belongs.  
 Note that this may not be the same as the type that the factory will create.  
 token: unknown;  
 /** Factory method to execute to create an instance of the injectable.  
 factory: (t?: Type<any>) => T;  
 /** In a case of no explicit injector, a location where the instance of the injectable is stored.  
 value: T|undefined;  
 /** Information about the providers to be included in an Injector as well as how the given type which carries the information should be created by the DI system.  
 An InjectorDef can import other types which have InjectorDefs, forming a deep nested structure of providers with a defined priority (identically to how NgModule's also have an import/dependency structure).  
 NOTE: This is a private type and should not be exported.  
 @codeGenApi  
 @publicApi  
 @export interface InjectorDef<T> {  
 // TODO(alxhub): Narrow down the type here once decorators properly change the return type of the class they are decorating (to add the prov property for example).  
 providers: (Type<any>|ValueProvider|ExistingProvider|FactoryProvider|ConstructorProvider|StaticClassProvider|ClassProvider|any[])[];  
 imports: (InjectorType<any>|InjectorTypeWithProviders<any>|any)[];  
 }  
 /** A Type which has a prov: InjectableDeclaration static field.  
 InjectableTypes contain their own Dependency Injection metadata and are usable in an InjectorDef-based StaticInjector.  
 @publicApi  
 @export interface InjectableType<T> extends Type<T> {  
 /** Opaque type whose structure is highly version dependent. Do not rely on any properties.  
 prov: unknown;  
 }  
 /** A type which has an InjectorDef static field.  
 InjectableTypes can be used to configure a StaticInjector.  
 This is an opaque type whose structure is highly version dependent. Do not rely on any properties.  
 @publicApi  
 @export interface InjectorType<T> extends Type<T> {  
 fac?: unknown;  
 inj: unknown;  
 }  
 /** Describes the InjectorDef equivalent of a ModuleWithProviders, an InjectorType with an associated array of providers.  
 Objects of this type can be listed in the imports section of an InjectorDef.  
 NOTE: This is a private type and should not be exported.  
 @export interface InjectorTypeWithProviders<T> {  
 ngModule: InjectorType<T>;  
 providers?: (Type<any>|ValueProvider|ExistingProvider|FactoryProvider|ConstructorProvider|StaticClassProvider|ClassProvider|any[])[];  
 }  
 /** Construct an injectable definition which defines how a token will be constructed by the DI system, and in which injectors (if any) it will be available.  
 This should be assigned to a static prov field on a type, which will then be an InjectableType.  
 Options: providedIn determines which injectors will include the injectable, by either associating it with an @NgModule or other InjectorType, or`

by specifying that this injectable should be provided in the `root` injector, which will be the application-level injector in most apps. The factory gives the zero argument function which will create an instance of the injectable. The factory can call `inject` to access the `Injector` and request injection of dependencies.

```

@codeGenApi
@publicApi
This instruction has been emitted by ViewEngine for some time and is deployed to npm.

export function defineInjectable<T>(opts: { token: unknown, providedIn?: Type<any> | 'root' | 'platform' | 'any' | 'environment' | null, factory: () => T }): unknown {
  token: opts.token,
  providedIn: opts.providedIn as any || null,
  factory: opts.factory,
  value: undefined,
} as InjectableDeclaration<T>;
}

@deprecated in v8, delete after v10. This API should be used only by generated code, and that code should now use defineInjectable instead.

@publicApi
export
const defineInjectable = defineInjectable;

Construct an `InjectorDef` which configures an injector.

This should be assigned to a static injector def (`inj`) field on a type, which will then be an `InjectorType`.

Options:
  providers: an optional array of providers to add to the injector. Each provider must either have a factory or point to a type which has a `prov` static property (the type must be an `InjectableType`).
  imports: an optional array of imports of other `InjectorType`s or `InjectorTypeWithModule`s whose providers will also be added to the injector. Locally provided types will override providers from imports.

@codeGenApi
export function defineInjector(options: { providers?: any[], imports?: any[] }): unknown {
  return { providers: options.providers || [], imports: options.imports || [] };
}

Read the injectable def (`prov`) for `type` in a way which is immune to accidentally reading inherited value.

@param type A type which may have its own (non-inherited) `prov`.

export function getInjectableDef<T>(type: any): InjectableDeclaration<T> | null {
  return getOwnDefinition(type, NG_PROV_DEF) || getOwnDefinition(type, NG_INJECTABLE_DEF);
}

export function isInjectable(type: any): boolean {
  return getInjectableDef(type) !== null;
}

Return definition only if it is defined directly on `type` and is not inherited from a base class of `type`.

export function getOwnDefinition<T>(type: any, field: string): InjectableDeclaration<T> | null {
  return type.hasOwnProperty(field) ? type[field] : null;
}

Read the injectable def (`prov`) for `type` or read the `prov` from one of its ancestors.

@param type A type which may have `prov`, via inheritance.

@deprecated Will be removed in a future version of Angular, where an error will occur in the scenario if we find the `prov` on an ancestor only.

export function getInheritedInjectableDef<T>(type: any): InjectableDeclaration<T> | null {
  const def = type && (type[NG_PROV_DEF] || type[NG_INJECTABLE_DEF]);
  if (def) {
    const typeName = getTypeName(type);
    // TODO(FW-1307): Re-add ngDevMode when closure can handle it
    // ngDevMode && console.warn(`DEPRECATED: DI is instantiating a token "${typeName}" that inherits its @Injectable decorator but does not provide one itself. This will become an error in a future version of Angular. Please add @Injectable() to the "${typeName}" class.`);
    return def;
  } else {
    return null;
  }
}

Gets the name of a type, accounting for some cross-browser differences.

export function getTypeName(type: any): string {
  // `Function.prototype.name` behaves differently between IE and other browsers. In most browsers it'll always return the name of the function itself, no matter how many other functions it inherits from. On IE the function doesn't have its own `name` property, but it takes it from the lowest level in the prototype chain. E.g. if we have `class Foo extends Parent` most browsers will evaluate `Foo.name` to `Foo` while IE will return `Parent`. We work around the issue by converting the function to a string and parsing its name out that way via a regex.
  if (type.hasOwnProperty('name')) {
    return type.name;
  }

will inline these when minifying so there shouldn't be a cost.\nexport const HOST = 0;\nexport const TVIEW = 1;\nexport const FLAGS = 2;\nexport const PARENT = 3;\nexport const NEXT = 4;\nexport const TRANSPLANTED\_VIEWS\_TO\_REFRESH = 5;\nexport const T\_HOST = 6;\nexport const CLEANUP = 7;\nexport const CONTEXT = 8;\nexport const INJECTOR = 9;\nexport const RENDERER\_FACTORY = 10;\nexport const RENDERER = 11;\nexport const SANITIZER = 12;\nexport const CHILD\_HEAD = 13;\nexport const CHILD\_TAIL = 14;\n// FIXME(misko): Investigate if the three declarations aren't all same thing.\nexport const DECLARATION\_VIEW = 15;\nexport const DECLARATION\_COMPONENT\_VIEW = 16;\nexport const DECLARATION\_LCONTAINER = 17;\nexport const PREORDER\_HOOK\_FLAGS = 18;\nexport const QUERIES = 19;\nexport const ID = 20;\nexport const EMBEDDED\_VIEW\_INJECTOR = 21;\n// Size of LView's header. Necessary to adjust for it when setting slots.\n \* IMPORTANT: `HEADER\_OFFSET` should only be referred to in the `\*` instructions to translate instruction index into `LView` index. All other indexes should be in the `LView` index space and there should be no need to refer to `HEADER\_OFFSET` anywhere else.\n \* ^\nexport const HEADER\_OFFSET = 22;\n\n\n// This interface replaces the real LView interface if it is an arg or a\n// return value of a public instruction. This ensures we don't need to expose the actual interface, which should be kept private.\nexport interface OpaqueViewState {\n \_\_brand\_\_: 'Brand for OpaqueViewState that nothing will match';\n}\n \* LView` stores all of the information needed to process the instructions as they are invoked from the template. Each embedded view and component view has its own `LView`. When processing a particular view, we set the `viewData` to that `LView`. When that view is done processing, the `viewData` is set back to whatever the original `viewData` was before (the parent `LView`).\n \* Keeping separate state for each view facilitates view insertion / deletion, so we don't have to edit the data array based on which views are present.\n \* ^\nexport interface LView<T = unknown> extends Array<any> {\n /\*\*\n \* Human readable representation of the `LView`.\n \*\n \* NOTE: This property only exists if `ngDevMode` is set to `true` and it is not present in production. Its presence is purely to help debug issue in development, and should not be relied on in production application.\n \*\n \* debug?: LViewDebug;\n \*\n \* The node into which this `LView` is inserted.\n \* ^\n [HOST]: RElement|null;\n \*\n \* The static data for this view. We need a reference to this so we can easily walk up the node tree in DI and get the TView.data array associated with a node (where the directive defs are stored).\n \*\n \* readonly[TVIEW]: TView;\n \*\n \* Flags for this view. See LViewFlags for more info. ^\n [FLAGS]: LViewFlags;\n \*\n \* This may store an {@link LView} or {@link LContainer}.\n \*\n \* `LView` - The parent view. This is needed when we exit the view and must restore the previous LView. Without this, the render method would have to keep a stack of views as it is recursively rendering templates.\n \*\n \* `LContainer` - The current view is part of a container, and is an embedded view.\n \* ^\n [PARENT]: LView|LContainer|null;\n \*\n \* The next sibling LView or LContainer.\n \*\n \* Allows us to propagate between sibling view states that aren't in the same container. Embedded views already have a node.next, but it is only set for views in the same container. We need a way to link component views and views across containers as well.\n \* ^\n [NEXT]: LView|LContainer|null;\n \*\n \* Queries active for this view - nodes from a view are reported to those queries. ^\n [QUERIES]: LQueries|null;\n \*\n \* Store the `TNode` of the location where the current `LView` is inserted into.\n \*\n \* Given:\n \* ```\n \* <div>\n \* <ng-template><span></span></ng-template>\n \* </div>\n \* ```\n \* We end up with two `TView`s - `parent` `TView` which contains `<div><!-- anchor --></div>` - `child` `TView` which contains `<span></span>`\n \*\n \* Typically the `child` is inserted into the declaration location of the `parent`, but it can be inserted anywhere. Because it can be inserted anywhere it is not possible to store the insertion information in the `TView` and instead we must store it in the `LView[T\_HOST]`.\n \*\n \* So to determine where is our insertion parent we would execute:\n \* ```\n \* const parentLView = IView[PARENT];\n \* const parentTNode = IView[T\_HOST];\n \* const insertionParent = parentLView[parentTNode.index];\n \* ```\n \*\n \* If `null`, this is the root view of an application (root component is in this view) and it has no parents.\n \* ^\n [T\_HOST]: TNode|null;\n \*\n \* When a view is destroyed, listeners need to be released and outputs need

to be unsubscribed. This context array stores both listener functions wrapped with their context and output subscription instances for a particular view. These change per LView instance, so they cannot be stored on TView. Instead, TView.cleanup saves an index to the necessary context in this array. After LView is created it is possible to attach additional instance specific functions at the end of the LView[CLEANUP] because we know that no more T level cleanup functions will be added here.

[CLEANUP]: any[] | null; - For dynamic views, this is the context with which to render the template (e.g. NgForContext), or {} if not defined explicitly. - For root view of the root component it's a reference to the component instance itself. - For components, the context is a reference to the component instance itself. - For inline views, the context is null.

[CONTEXT]: T; An optional Module Injector to be used as fall back after Element Injectors are consulted.

readonly[INJECTOR]: Injector | null; Factory to be used for creating Renderer.

[RENDERER\_FACTORY]: RendererFactory; Renderer to be used for this view.

[RENDERER]: Renderer; An optional custom sanitizer.

[SANITIZER]: Sanitizer | null; Reference to the first LView or LContainer beneath this LView in the hierarchy. Necessary to store this so views can traverse through their nested views to remove listeners and call onDestroy callbacks.

[CHILD\_HEAD]: LView | LContainer | null; The last LView or LContainer beneath this LView in the hierarchy. The tail allows us to quickly add a new state to the end of the view list without having to propagate starting from the first child.

[CHILD\_TAIL]: LView | LContainer | null; View where this view's template was declared. The template for a dynamically created view may be declared in a different view than it is inserted. We already track the "insertion view" (view where the template was inserted) in LView[PARENT], but we also need access to the "declaration view" (view where the template was declared). Otherwise, we wouldn't be able to call the view's template function with the proper contexts. Context should be inherited from the declaration view tree, not the insertion view tree.

Example (AppComponent template):

```
<ng-template #foo></ng-template>    <-- declared here -->
<some-comp [tpl]="foo"></some-comp>    <-- inserted inside this component -->
```

The <ng-template> above is declared in the AppComponent template, but it will be passed into SomeComp and inserted there. In this case, the declaration view would be the AppComponent, but the insertion view would be SomeComp. When we are removing views, we would want to traverse through the insertion view to clean up listeners. When we are calling the template function during change detection, we need the declaration view to get inherited context.

[DECLARATION\_VIEW]: LView | null; Points to the declaration component view, used to track transplanted LView's. See: DECLARATION\_VIEW which points to the actual LView where it was declared, whereas DECLARATION\_COMPONENT\_VIEW points to the component which may not be same as DECLARATION\_VIEW.

Example:

```
<#VIEW #myComp>
<div *ngIf="true">
<ng-template #myTpl>...</ng-template>
</div>
</#VIEW>
```

In the above case DECLARATION\_VIEW for myTpl points to the LView of ngIf whereas DECLARATION\_COMPONENT\_VIEW points to LView of the myComp which owns the template.

The reason for this is that all embedded views are always check-always whereas the component view can be check-always or on-push. When we have a transplanted view it is important to determine if we have transplanted a view from check-always declaration to on-push insertion point. In such a case the transplanted view needs to be added to the LContainer in the declared LView and CD during the declared view CD (in addition to the CD at the insertion point.) (Any transplanted views which are intra Component are of no interest because the CD strategy of declaration and insertion will always be the same, because it is the same component.)

Queries already track moved views in LView[DECLARATION\_LCONTAINER] and LContainer[MOVED\_VIEWS]. However the queries also track LView's which moved within the same component LView. Transplanted views are a subset of moved views, and we use DECLARATION\_COMPONENT\_VIEW to differentiate them. As in this example:

Example showing intra component LView movement:

```
<#VIEW #myComp>
<div
```

```

*ngIf="condition;
  then thenBlock else elseBlock"></div>\n * <ng-template #thenBlock>Content to render when condition is
true.</ng-template>\n * <ng-template #elseBlock>Content to render when condition is false.</ng-template>\n *
</#VIEW>\n * ```\n * The `thenBlock` and `elseBlock` is moved but not transplanted.\n * \n * Example
showing inter component `LView` movement (transplanted view).\n * ```\n * <#VIEW #myComp>\n * <ng-
template #myTpl>...</ng-template>\n * <insertion-component [template]="myTpl"></insertion-
component>\n * </#VIEW>\n * ```\n * In the above example `myTpl` is passed into a different component. If
`insertion-component`\n * instantiates `myTpl` and `insertion-component` is on-push then the `LContainer` needs
to be\n * marked as containing transplanted views and those views need to be CD as part of the\n * declaration
CD.\n * \n * \n * When change detection runs, it iterates over `[MOVED_VIEWS]` and CDs any child `LView`s
where\n *
the `DECLARATION_COMPONENT_VIEW` of the current component and the child `LView` does not match\n
* (it has been transplanted across components.)\n * \n * Note: `[DECLARATION_COMPONENT_VIEW]` points
to itself if the LView is a component view (the\n * simplest / most common case).\n * \n * see also:\n * -
https://hackmd.io/@mhevery/rJUJsvv9H write up of the problem\n * -
`LContainer[HAS_TRANSPLANTED_VIEWS]` which marks which `LContainer` has transplanted views.\n * -
`LContainer[TRANSPLANT_HEAD]` and `LContainer[TRANSPLANT_TAIL]` storage for transplanted\n * -
`LView[DECLARATION_LCONTAINER]` similar problem for queries\n * - `LContainer[MOVED_VIEWS]`
similar problem for queries\n * \n * \n * [DECLARATION_COMPONENT_VIEW]: LView;\n * \n * \n * A declaration
point of embedded views (ones instantiated based on the content of a\n * <ng-template>), null for other types of
views.\n * \n * We need to track all embedded views created from a given declaration
point so we can prepare\n * query matches in a proper order (query matches are ordered based on their declaration
point and\n * _not_ the insertion point).\n * \n * \n * [DECLARATION_LCONTAINER]: LContainer|null;\n * \n * \n *
More flags for this view. See PreOrderHookFlags for more info.\n * \n * \n * [PREORDER_HOOK_FLAGS]:
PreOrderHookFlags;\n * \n * \n * \n * The number of direct transplanted views which need a refresh or have
descendants themselves\n * that need a refresh but have not marked their ancestors as Dirty. This tells us that
during\n * change detection we should still descend to find those children to refresh, even if the parents\n * are
not `Dirty`/`CheckAlways`.\n * \n * \n * [TRANSPLANTED_VIEWS_TO_REFRESH]: number;\n * \n * \n * Unique ID of
the view. Used for `__ngContext__` lookups in the `LView` registry. \n * \n * \n * [ID]: number;\n * \n * \n *
Optional
injector assigned to embedded views that takes\n * precedence over the element and module injectors.\n * \n * \n
readonly[EMBEDDED_VIEW_INJECTOR]:
Injector|null;\n * \n * \n * \n * \n * \n * \n * \n * \n * \n * \n * \n * \n * \n * \n * \n * \n * \n * \n *

  *   `The binding start index is the index at which the data array starts to store bindings only. Saving this value ensures that we will begin reading bindings at the correct point in the array when we are in update mode.`
  *   `-1 means that it has not been initialized.`
  *   `bindingStartIndex: number;`
  *   `The index where the "expando" section of `LView` begins. The expando section contains injectors, directive instances, and host binding values. Unlike the "decls" and "vars" sections of `LView`, the length of this section cannot be calculated at compile-time because directives are matched at runtime to preserve locality.`
  *   `We store this start index so we know where to start checking host bindings in `setHostBindings`.`
  *   `expandoStartIndex: number;`
  *   `Whether or not there are any static view queries tracked on this view.`
  *   `We store this so we know whether or not we should do a view query refresh after creation mode to collect static query results.`
  *   `staticViewQueries: boolean;`
  *   `Whether or not there are any static content queries tracked on this view.`
  *   `We store this so we know whether or not we should do a content query refresh after creation mode to collect static query results.`
  *   `staticContentQueries: boolean;`
  *   `A reference to the first child node located in the view.`
  *   `firstChild: TNode|null;`
  *   `Stores the OpCodes to be replayed during change-detection to process the `HostBindings``
  *   `See `HostBindingOpCodes` for encoding details.`
  *   `hostBindingOpCodes: HostBindingOpCodes|null;`
  *   `Full registry of directives and components that may be found in this view.`
  *   `It's necessary to keep a copy of the full def list on the TVView so it's possible to render template functions without a host component.`
  *   `directiveRegistry: DirectiveDefList|null;`
  *   `Full registry of pipes that may be found in this view.`
  *   `The property is either an array of `PipeDefs` or a function which returns the array of `PipeDefs`. The function is necessary to be able to support forward declarations.`
  *   `It's necessary to keep a copy of the full def list on the TVView so it's possible to render template functions without a host component.`
  *   `pipeRegistry: PipeDefList|null;`
  *   `Array of ngOnInit, ngOnChanges and ngDoCheck hooks that should be executed for this view in creation mode.`
  *   `This array has a flat structure and contains TNode indices, directive indices (where an instance can be found in `LView`) and hook functions. TNode index is followed by the directive index and a hook function. If there are multiple hooks for a given TNode, the TNode index is not repeated and the next lifecycle hook information is stored right after the previous hook function. This is done so that at runtime the

```

system can efficiently iterate over all of the functions to invoke without having to make any decisions/lookups.

- `preOrderHooks: HookData`: Array of `ngOnChanges` and `ngDoCheck` hooks that should be executed for this view in update mode. This array has the same structure as the `preOrderHooks` one.
- `preOrderCheckHooks: HookData`: Array of `ngAfterContentInit` and `ngAfterContentChecked` hooks that should be executed for this view in creation mode.
- `Even indices: Directive index`
- `Odd indices: Hook function`
- `contentHooks: HookData`: Array of `ngAfterContentChecked` hooks that should be executed for this view in update mode.
- `Even indices: Directive index`
- `Odd indices: Hook function`
- `contentCheckHooks: HookData`: Array of `ngAfterViewInit` and `ngAfterViewChecked` hooks that should be executed for this view in creation mode.
- `Even indices: Directive index`
- `Odd indices: Hook function`
- `viewHooks: HookData`: Array of `ngAfterViewChecked` hooks that should be executed for this view in update mode.
- `Even indices: Directive index`
- `Odd indices: Hook function`
- `viewCheckHooks: HookData`: Array of `ngOnDestroy` hooks that should be executed when this view is destroyed.
- `Even indices: Directive index`
- `Odd indices: Hook function`
- `destroyHooks: DestroyHookData`: When a view is destroyed, listeners need to be released and outputs need to be unsubscribed. This cleanup array stores both listener data (in chunks of 4) and output data (in chunks of 2) for a particular view. Combining the arrays saves on memory (70 bytes per array) and on a few bytes of code size (for two separate for loops).
- If it's a native DOM listener or output subscription being stored:
  - 1st index is: event name `name = tView.cleanup[i+0]`
  - 2nd index is: index of native element or a function that retrieves global target (window, document or body) reference based on the native element:
    - `typeof idxOrTargetGetter === 'function'`: global target getter function
    - `typeof idxOrTargetGetter === 'number'`: index of native element
  - 3rd index is: index of listener function `listener = LView[CLEANUP][tView.cleanup[i+2]]`
  - 4th index is: `useCaptureOrIndex = tView.cleanup[i+3]`
    - `typeof useCaptureOrIndex === 'boolean'`: useCapture boolean
    - `typeof useCaptureOrIndex === 'number'`: `useCaptureOrIndex >= 0`removeListener = LView[CLEANUP][useCaptureOrIndex]`
    - `useCaptureOrIndex < 0`subscription = LView[CLEANUP][useCaptureOrIndex]`
- If it's an output subscription or query list destroy hook:
  - 1st index is: output unsubscribe function / query list destroy function
  - 2nd index is: index of function context in `LView.cleanupInstances[]`
- `tView.cleanup[i+0].call(LView[CLEANUP][tView.cleanup[i+1]])`: cleanup: any[]|null
- A list of element indices for child components that will need to be refreshed when the current view has finished its check. These indices have already been adjusted for the `HEADER_OFFSET`.
- components: number[]|null
- A collection of queries tracked in a given view.
- queries: TQueries|null
- An array of indices pointing to directives with content queries alongside with the corresponding query index. Each entry in this array is a tuple of:
  - index of the first content query index declared by a given directive;
  - index of a directive.
- We are storing those indexes so we can refresh content queries as part of a view refresh process.
- contentQueries: number[]|null
- Set of schemas that declare elements to be allowed inside the view.
- schemas: SchemaMetadata[]|null
- Array of constants for the view. Includes attribute arrays, local definition arrays etc.
- Used for directive matching, attribute bindings, local definitions and more.
- consts: TConstants|null
- Indicates that there was an error before we managed to complete the first create pass of the view. This means that the view is likely corrupted and we should try to recover it.
- incompleteFirstPass: boolean;
- Single hook callback function. `export type HookFn = () => void;`
- Information necessary to call a hook. E.g. the callback that needs to be invoked and the index at which to find its context.
- export type HookEntry = number|HookFn;
- Array of hooks that should be executed for a view and their directive indices.
- For each node of the view, the following data is stored:
  - Node index (optional)
  - 2) A series of number/function pairs where:
    -

even indices are directive indices\n \* - odd indices are hook functions\n \*\n \* Special cases:\n \* - a negative directive index flags an init hook (ngOnInit, ngAfterContentInit, ngAfterViewInit)\n \*/\nexport type HookData = HookEntry[];\n\n/\*\*\n \* Array of destroy hooks that should be executed for a view and their directive indices.\n \*\n \* The array is set up as a series of number/function or number/(number|function)[]:\n \* - Even indices represent the context with which hooks should be called.\n \* - Odd indices are the hook functions themselves. If a value at an odd index is an array,\n \* it represents the destroy hooks of a `multi` provider where:\n \* - Even indices represent the index of the provider for which we've registered a destroy hook,\n \* inside of the `multi` provider array.\n \* - Odd indices are the destroy hook functions.\n \* For example:\n \* LView: `[0, 1, 2, AService, 4, [BService, CService, DService]]`\n \* destroyHooks: `[3, AService.ngOnDestroy, 5, [0, BService.ngOnDestroy, 2, DService.ngOnDestroy]]`\n \*\n \* In the example above `AService` is a type provider with an `ngOnDestroy`, whereas `BService`, `CService` and `DService` are part of a `multi` provider where only `BService` and `DService` have an `ngOnDestroy` hook.\n \*/\nexport type DestroyHookData = (HookEntry|HookData)[];\n\n/\*\*\n \* Static data that corresponds to the instance-specific data array on an LView.\n \*\n \* Each node's static data is stored in tData at the same index that it's stored\n \* in the data array. Any nodes that do not have static data store a null value in\n \* tData to avoid a sparse array.\n \*\n \* Each pipe's definition is stored here at the same index as its pipe instance in\n \* the data array.\n \*\n \* Each host property's name is stored here at the same index as its value in the\n \* data array.\n \*\n \* Each property binding name is stored here at the same index as its value in\n \* the data array. If the binding is an interpolation, the static string values\n \* are stored parallel to the dynamic values. Example:\n \*\n \* id="prefix {{ v0 }}" a {{ v1 }} b {{ v2 }} suffix`\n \*\n \* LView | TView.data\n \*-----\n \* v0 value | 'a'\n \* v1 value | 'b'\n \* v2 value | id prefix suffix\n \*\n \* Injector bloom filters are also stored here.\n \*/\nexport type TData = (TNode|PipeDef<any>|DirectiveDef<any>|ComponentDef<any>|number|TStylingRange|\nTStylingKey|ProviderToken<any>|TI18n|I18nUpdateOpCodes|Ticu|null|string)[];\n\n// Note: This hack is necessary so we don't erroneously get a circular dependency\n// failure based on types.\nexport const unusedValueExportToPlacateAjd = 1;\n\n/\*\*\n \* Human readable version of the `LView`.\n \*\n \* `LView` is a data structure used internally to keep track of views. The `LView` is designed for\n \* efficiency and so at times it is difficult to read or write tests which assert on its values. For\n \* this reason when `ngDevMode` is true we patch a `LView.debug` property which points to\n \* `LViewDebug` for easier debugging and test writing. ```

Special location which allows easy identification of type. If we have an array which was retrieved from the `LView`` and that array has `true`` at `TYPE`` location, we know it is `LContainer``. `LContainer`` export const `TYPE = 1;`  
 Below are constants for `LContainer`` indices to help us look up `LContainer`` members without having to remember the specific indices.  
 Uglify will inline these when minifying so there shouldn't be a cost.  
 Flag to signify that this `LContainer`` may have transplanted views which need to be change detected. (see: `LView[DECLARATION_COMPONENT_VIEW]``). This flag, once set, is never unset for the `LContainer``. This means that when unset we can skip a lot of work in `refreshEmbeddedViews``. But when set we still need to verify that the `MOVED_VIEWS`` are transplanted and on-push.  
 export const `HAS_TRANSPLANTED_VIEWS = 2;`  
 PARENT, NEXT, TRANSPLANTED\_VIEWS\_TO\_REFRESH are indices 3, 4, and 5  
 As we already have these constants in `LView``, we don't need to re-create them.  
 T\_HOST is index 6  
 We already have this constants in `LView``, we don't need to re-create it.  
 export const `NATIVE = 7;`  
 export const `VIEW_REFS = 8;`  
 export const `MOVED_VIEWS = 9;`  
 Size of `LContainer``'s header. Represents the index after which all views in the container will be inserted. We need to keep a record of current views so we know which views are already in the DOM (and don't

need to be re-added) and so we can remove views from the DOM when they are no longer required.

```

const CONTAINER_HEADER_OFFSET = 10;

```

The state associated with a container. This is an array so that its structure is closer to LView. This helps when traversing the view tree (which is a mix of containers and component views), so we can jump to viewOrContainer[NEXT] in the same way regardless of type.

```

export interface LContainer extends Array<any> {
  // The host element of this LContainer. The host could be an LView if this container is on a component node. In that case, the component LView is its HOST.
  readonly [HOST]: RElement|RComment|LView;
  // This is a type field which allows us to differentiate `LContainer` from `StylingContext` in an efficient way. The value is always set to `true`
  [TYPE]: true;
  // Flag to signify that this `LContainer` may have transplanted views which need to be change detected. (see: `LView[DECLARATION_COMPONENT_VIEW]`)
  // This flag, once set, is never unset for the `LContainer`.
  [HAS_TRANSPLANTED_VIEWS]: boolean;
  // Access to the parent view is necessary so we can propagate back up from inside a container to parent[NEXT].
  [PARENT]: LView;
  // This allows us to jump from a container to a sibling container or component view with the same parent, so we can remove listeners efficiently.
  [NEXT]: LView|LContainer|null;
  // The number of direct transplanted views which need a refresh or have descendants themselves

```

```

  // that need a refresh but have not marked their ancestors as Dirty. This tells us that during change detection we should still descend to find those children to refresh, even if the parents are not `Dirty`/`CheckAlways`.
  [TRANSPLANTED_VIEWS_TO_REFRESH]: number;
  // A collection of views created based on the underlying `<ng-template>` element but inserted into a different `LContainer`. We need to track views created from a given declaration point since queries collect matches from the embedded view declaration point and not the insertion point.
  [MOVED_VIEWS]: LView[]|null;
  // Pointer to the `TNode` which represents the host of the container.
  [T_HOST]: TNode;
  // The comment element that serves as an anchor for this LContainer.
  readonly [NATIVE]: RComment;
  // TODO(misko): remove as this value can be gotten by unwrapping `[HOST]`
  // Array of `ViewRef`s used by any `ViewContainerRef`s that point to this container.
  // This is lazily initialized by `ViewContainerRef` when the first view is inserted.
  // NOTE: This is stored as `any[]` because render3 should really not be aware of `ViewRef` and doing so creates circular dependency.
  [VIEW_REFS]: unknown[]|null;
}

```

Note: This hack is necessary so we don't erroneously get a circular dependency failure based on types.

```

has called the template function of a\n *      * component with `RenderFlags.Create`.\n *      * ^\n *      * TemplateCreateEnd,\n *      * \n *      * /**\n *      * Corresponds to the point in time before the runtime has called the template function of a\n *      * component
with `RenderFlags.Update`.\n *      * ^\n *      * TemplateUpdateStart,\n *      * \n *      * /**\n *      * Corresponds to the point in time after the

```

runtime has called the template function of a component with `RenderFlags.Update`.  
`TemplateUpdateEnd` corresponds to the point in time before the runtime has called a lifecycle hook of a component or directive.  
`LifecycleHookStart` corresponds to the point in time after the runtime has called a lifecycle hook of a component or directive.  
`LifecycleHookEnd` corresponds to the point in time before the runtime has evaluated an expression associated with an event or an output.  
`OutputStart` corresponds to the point in time after the runtime has evaluated an expression associated with an event or an output.  
`OutputEnd`  
Profiler function which the runtime will invoke before and after user code.  
export interface Profiler {  
 (event: ProfilerEvent, instance: {} | null, hookOrListener?: (e?: any) => any): void;  
 let profilerCallback: Profiler | null = null;  
 Sets the callback function which will be invoked before and after performing certain actions at runtime (for example, before and after running change detection).  
 Warning: this function is `INTERNAL` and should not be relied upon in application's code. The contract of the function might be changed in any release and/or the function can be removed completely.  
 @param profiler function provided by the caller or null value to disable profiling.  
 export const setProfiler = (profiler: Profiler | null) => {  
 profilerCallback = profiler;  
 };  
 Profiler function which wraps user code executed by the runtime.  
 @param event ProfilerEvent corresponding to the execution context  
 @param instance component instance  
 @param hookOrListener lifecycle hook function or output listener. The value depends on the execution context  
 @returns Profiler = function(  
 event: ProfilerEvent, instance: {} | null, hookOrListener?: (e?: any) => any) {  
 if (profilerCallback != null /\* both `null` and `undefined` \*/) {  
 profilerCallback(event, instance, hookOrListener);  
 }  
 };

 For efficiency reasons we often put several different data types (`RNode`, `LView`, `LContainer`) in same location in `LView`. This is because we don't want to pre-allocate space for it because the storage is sparse. This file contains utilities for dealing with such data types.  
 How do we know what is stored at a given location in `LView`?  
 - `Array.isArray(value) === false` => `RNode` (The normal storage value)  
 - `Array.isArray(value) === true` => then the `value[0]` represents the wrapped value.  
 - `typeof value[TYPE] === 'object'` => `LView`  
 - This happens when we have a component at a given location  
 - `typeof value[TYPE] === true` => `LContainer`  
 - This happens when we have `LContainer` binding at a given location.  
 NOTE: it is assumed that `Array.isArray` and `typeof` operations are very efficient.  
 Returns `RNode`.

interface LFrame {
  Parent LFrame;
  Child LFrame;
  child: LFrame|null;
  State of the current view being processed;
  An array of nodes (text, element, container, etc), pipes, their bindings, and any local variables that need to be stored between invocations;
  IView: LView;
  Current `TView` associated with the `LFrame.IView`.
  One can get `TView` from `LFrame[TVIEW]` however because it is so common it makes sense to store it in `LFrame` for perf reasons;
  tView: TView;
  Used to set the parent property when nodes are created and track query results;
  This is used in conjunction with `isParent`.
  currentTNode: TNode|null;
  If `isParent` is:
  - `true`: then `currentTNode` points to a parent node;
  - `false`: then `currentTNode` points to previous node (sibling);
  isParent: boolean;
  Index of currently selected element in LView;
  Used by binding instructions. Updated as part of advance instruction;
  selectedIndex: number;
  Current pointer to the binding index;
  bindingIndex: number;
  The last viewData retrieved by nextContext().
  Allows building nextContext() and reference() calls;
  e.g. const inner = x().$implicit; const outer = x().$implicit;
  contextLView: LView|null;
  Store the element depth count. This is used to identify the root elements of the template so that we can then attach patch data `LView` to only those elements. We know that those are the only places where the patch data could change, this way we will save on number of places where the patching occurs;
  elementDepthCount: number;
  Current namespace to be used when creating elements;
  currentNamespace: string|null;
  The root index from which pure function instructions should calculate their binding indices. In component views, this is TView.bindingStartIndex. In a host binding context, this is the TView.expandoStartIndex + any dirs/hostVars before the given dir;
  bindingRootIndex: number;
  Current index of a View or Content Query which needs to be processed next;
  We iterate over the list of Queries and increment current query index at every step;
  currentQueryIndex: number;
  When host binding is executing this points to the directive index;
  `TView.data[currentDirectiveIndex]` is `DirectiveDef`
  `LView[currentDirectiveIndex]` is directive instance;
  currentDirectiveIndex: number;
  Are we currently in i18n block as denoted by `elementStart` and `elementEnd`;
  This information is needed because while we are in i18n block all elements must be pre-declared in the translation. (i.e. `Hello #2World/#2!` pre-declares element at `#2` location.)
  This allocates `TNodeType.Placeholder` element at location `2`. If translator removes `#2` from translation than the runtime must also ensure the element at `2` does not get inserted into the DOM. The translation does not carry information about deleted elements.
}

```

Therefore the only way to know that an element is deleted is that it was not pre-declared in the translation.

This flag works by ensuring that elements which are created without pre-declaration (TNodeType.Placeholder) are not inserted into the DOM render tree. (It does mean that the element still gets instantiated along with all of its behavior [directives])

```
inI18n: boolean;
```

All implicit instruction state is stored here. It is useful to have a single object where all of the state is stored as a mental model (rather it being spread across many different variables).

PERF NOTE: Turns out that writing to a true global variable is slower than having an intermediate object with properties.

```
interface InstructionState {
  Current `LFrame`
  `null` if we have not called `enterView`
  IFrame: LFrame;
  Stores whether directives should be matched to elements.
  When template contains `ngNonBindable` then we need to prevent the runtime from matching directives on children of that element.
  Example:
  <my-comp my-directive> Should match component / directive.
  </my-comp> <div ngNonBindable> <my-comp my-directive> Should not match component / directive because we are in ngNonBindable.
  </my-comp>
  </div>
  bindingsEnabled: boolean;
}
const instructionState: InstructionState = {
  IFrame: createLFrame(null),
  bindingsEnabled: true,
};
```

In this mode, any changes in bindings will throw an ExpressionChangedAfterChecked error. Necessary to support ChangeDetectorRef.checkNoChanges().

The `checkNoChanges` function is invoked only in ngDevMode=true and verifies that no unintended changes exist in the change detector or its children.

```
let _isInCheckNoChangesMode = false;
```

Returns true if the instruction state stack is empty. Intended to be called from tests only (tree shaken otherwise).

```
export function specOnlyIsInstructionStateEmpty(): boolean {
  return instructionState.IFrame.parent === null;
}
export function getElementDepthCount() {
  return instructionState.IFrame.elementDepthCount;
}
export function increaseElementDepthCount() {
  instructionState.IFrame.elementDepthCount++;
}
export function decreaseElementDepthCount() {
  instructionState.IFrame.elementDepthCount--;
}
export function getBindingsEnabled(): boolean {
  return instructionState.bindingsEnabled;
}
```

Enables directive matching on elements.

Example:

```
<my-comp my-directive> Should match component / directive.
</my-comp> <div ngNonBindable> <!-- disableBindings() --> <my-comp my-directive> Should not match component / directive because we are in ngNonBindable.
</my-comp> <!-- enableBindings() --> </div>
```

@codeGenApi

```
export function enableBindings(): void {
  instructionState.bindingsEnabled = true;
}
export function disableBindings(): void {
  instructionState.bindingsEnabled = false;
}
```

Return the current `LView`.

```
export function getLView<T>(): LView<T> {
  return instructionState.IFrame.IView as LView<T>;
}
export function getTView(): TView {
  return instructionState.IFrame.tView;
}
```

Restores `contextViewData` to the given OpaqueViewState instance. Used in conjunction with the `getCurrentView` instruction to save a snapshot of the current view and restore it when listeners are invoked. This allows walking the declaration view tree in listeners to get vars from parent views.

@param viewToRestore The OpaqueViewState instance to restore.

@returns Context of the restored OpaqueViewState instance.

```
@codeGenApi
export function restoreView<T> = any>(viewToRestore: OpaqueViewState): T {
  instructionState.IFrame.contextLView = viewToRestore as any as LView;
  return (viewToRestore as any as LView)[CONTEXT] as unknown as T;
}
```

Clears the view set in `restoreView` from memory. Returns the passed in value so that it can be used as a return value of an instruction.

```
@codeGenApi
export function resetView<T>(value?: T): T|undefined {
  instructionState.IFrame.contextLView = null;
  return value;
}
export function getCurrentTNode(): TNode|null {

`const tNode = tView.data[index + NodeInjectorOffset.TNODE]`
NodeInjectorOffset {
  TNODE = 8,
  PARENT = 8,
  BLOOM_SIZE = 8,
  SIZE = 9,
}
Represents a relative location of parent injector.
The interfaces encodes number of parents `LView`s to traverse and index in the `LView` pointing to the parent injector.
interface RelativeInjectorLocation {
  __brand__: 'RelativeInjectorLocationFlags';
}
export const enum RelativeInjectorLocationFlags {
  InjectorIndexMask = 0b11111111111111,
  ViewOffsetShift = 16,
  NO_PARENT = -1,
}
export const NO_PARENT_INJECTOR:
  RelativeInjectorLocation = -1 as any;
Each injector is saved in 9 contiguous slots in `LView` and 9 contiguous slots in `TView.data`. This allows us to store information about the current node's tokens (which can be shared in `TView`) as well as the tokens of its ancestor nodes (which cannot be shared, so they live in `LView`). Each of these slots (aside from the last slot) contains a bloom filter. This bloom filter determines whether a directive is available on the associated node or not. This prevents us from searching the directives array at this level unless it's probable the directive is in it. See:
https://en.wikipedia.org/wiki/Bloom\_filter for more about bloom filters.
Because all injectors have been flattened into `LView` and `TViewData`, they cannot typed using interfaces as they were previously. The start index of each `LInjector` and `TInjector` will differ based on where it is flattened into the main array, so it's not possible to know the indices ahead of time and save their types here. The interfaces are still included here for documentation purposes.

  // Necessary to find directive indices for a particular node.
  [TNODE]: TElementNode|TElementContainerNode|TContainerNode;
}
Factory for creating instances of injectors in the NodeInjector.
This factory is complicated by the fact that it can resolve `multi` factories as well. NOTE: Some of the fields are optional which means that this class has two hidden classes.
- One without `multi` support (most common)
- One with `multi` values, (rare).
Since VMs can cache up to 4 inline hidden classes this is OK.
- Single factory: Only `resolving` and `factory` is defined.
- `providers` factory: `componentProviders` is a number and `index` points to `providers`.
export class NodeInjectorFactory {
  // The inject implementation to be activated when using the factory.
  injectImpl: null|(<T>(token: ProviderToken<T>, flags?: InjectFlags) => T);
  // Marker set to true during factory invocation to see if we get into recursive loop.
  // Recursive loop causes an error to be displayed.
  resolving = false;
  // Marks that

```

the token can see other Tokens declared in `viewProviders` on the same node.

```

    * canSeeViewProviders:
    boolean;
    /**
     * An array of factories to use in case of `multi` provider.
     * multi?: Array<() => any>;
    */
    * Number of `multi`-providers which belong to the component.
    * This is needed because when multiple components and directives declare the `multi` provider
    * they have to be concatenated in the correct order.
    * Example:
    * If we have a component and directive active on a single element as declared here
    * ``
    * component:
    * providers: [ {provide: String, useValue: 'component', multi: true} ],
    * viewProviders: [ {provide: String, useValue: 'componentView', multi: true} ],
    * directive:
    * providers: [ {provide: String, useValue: 'directive', multi: true} ],
    * ``
    * Then the expected results are:
    * providers: ['component', 'directive']
    * viewProviders:
    * ['component', 'componentView', 'directive']
    * ``
    * The way to think about it is that the `viewProviders` have been inserted after the component
    * but before the directives, which is why we need to know how many `multi`s have been declared by
    * the component.
    * componentProviders?: number;
    /**
     * Current index of the Factory in the `data`. Needed for `viewProviders` and `providers` merging.
     * See `providerFactory`.
    */
    * index?: number;
    /**
     * Because the same `multi` provider can be declared in `providers` and `viewProviders` it is
     * possible for `viewProviders` to shadow the `providers`. For this reason we store the
     * `provideFactory` of the `providers` so that `providers` can be extended with `viewProviders`.
    * Example:
    * Given:
    * providers: [ {provide: String, useValue: 'all', multi: true} ],
    * viewProviders: [ {provide: String, useValue: 'viewOnly', multi: true} ],
    * ``
    * We have to return `['all']` in case of content injection, but `['all', 'viewOnly']` in case
    * of view injection. We further have to make sure that the shared instances (in our case
    * `all`) are the exact same instance in both the content as well as the view injection. (We
    * have to make sure that we don't double instantiate.) For this reason the `viewProviders`
    * `Factory` has a pointer to the shadowed `providers` factory so that it can instantiate the
    * `providers` ( `['all']` ) and then extend it with `viewProviders` ( `['all'] + ['viewOnly']` ).
    * providerFactory?: NodeInjectorFactory|null;

See TNodeType. ^\n type: TNodeType;\n\n /\*\*\n \* Index of the TNode in TView.data and corresponding native element in LView. ^\n \* This is necessary to get from any TNode to its corresponding native element when traversing the node tree.\n \* \n \* If index is -1, this is a dynamically created container node or embedded view node.\n \* ^\n index: number;\n\n /\*\*\n \* Insert before existing DOM node index. ^\n \* When DOM nodes are being inserted, normally they are being appended as they are created. Under i18n case, the translated text nodes are created ahead of time as part of the `i18nStart` instruction which means that this `TNode` can't just be appended and instead needs to be inserted using `insertBeforeIndex` semantics. ^\n \* Additionally sometimes it is necessary to insert new text nodes as a child of this `TNode`. In such a case the value stores an

array of text nodes to insert.  
 Example:  
`<div i18n> Hello <span>World</span>! </div>`  
 In the above example the `i18nStart` instruction can create `Hello`, `World` and `!` text nodes. It can also insert `Hello` and `!` text node as a child of `<div>`, but it can't insert `World` because the `<span>` node has not yet been created. In such a case the `<span>` `TNode` will have an array which will direct the `<span>` to not only insert itself in front of `!` but also to insert the `World` (created by `i18nStart`) into `<span>` itself.

```

Pseudo code:
if (insertBeforeIndex === null) {
  // append as normal
} else if (Array.isArray(insertBeforeIndex)) {
  // First insert current TNode at correct location
  const currentNode = IView[this.index];
  parentNode.insertBefore(currentNode, IView[this.insertBeforeIndex[0]]);
  // Now append all of the children
  for(let i=1; i<this.insertBeforeIndex; i++) {
    currentNode.appendChild(IView[this.insertBeforeIndex[i]]);
  }
} else {
  parentNode.insertBefore(IView[this.index], IView[this.insertBeforeIndex]);
}

```

- null: Append as normal using `parentNode.appendChild`  
 - number: Append using `parentNode.insertBefore(IView[this.index], IView[this.insertBeforeIndex])`

**Initialization**  
 Because `i18nStart` executes before nodes are created, on `TView.firstCreatePass` it is not possible for `i18nStart` to set the `insertBeforeIndex` value as the corresponding `TNode` has not yet been created. For this reason the `i18nStart` creates a `TNodeType.Placeholder TNode` at that location. See `TNodeType.Placeholder` for more information.

**insertBeforeIndex: InsertBeforeIndex**  
 The index of the closest injector in this node's `LView`.  
 If the index `=== -1`, there is no injector on this node or any ancestor node in this view.  
 If the index `!=== -1`, it is the index of this node's injector OR the index of a parent injector in the same view. We pass the parent injector index down the node tree of a view so it's possible to find the parent injector without walking a potentially deep node tree.  
 Injector indices are not set across view boundaries because there could be multiple component hosts.  
 If `tNode.injectorIndex === tNode.parent.injectorIndex`, then the index belongs to a parent injector.

**injectorIndex: number**  
 Stores starting index of the directives.  
 NOTE: The first directive is always component (if present).  
**directiveStart: number**  
 Stores final exclusive index of the directives.  
 The area right behind the `directiveStart-directiveEnd` range is used to allocate the `HostBindingFunction`vars`` (or null if no bindings.) Therefore `directiveEnd` is used to set `LFrame.bindingRootIndex` before `HostBindingFunction` is executed.

**directiveEnd: number**  
 Stores the last directive which had a styling instruction.  
 Initial value of this is `-1` which means that no `hostBindings` styling instruction has executed. As `hostBindings` instructions execute they set the value to the index of the `DirectiveDef` which contained the last `hostBindings` styling instruction.  
 Valid values are:  
`-1` No `hostBindings` instruction has executed.  
`directiveStart <= directiveStylingLast < directiveEnd`: Points to the `DirectiveDef` of the last styling instruction which executed in the `hostBindings`.  
 This data is needed so that styling instructions know which static styling data needs to be collected from the `DirectiveDef.hostAttrs`. A styling instruction needs to collect all data since last styling instruction.

**directiveStylingLast: number**  
 Stores indexes of property bindings. This field is only set in the `ngDevMode` and holds indexes of property bindings so  `TestBed`  can get bound property metadata for a given node.  
**propertyBindings: number[]|null**  
 Stores if `Node` is `Component`, `isProjected`, `hasContentQuery`, `hasClassInput` and `hasStyleInput`  
 etc.  
**flags: TNodeFlags**  
 This number stores two values using its bits:  
 - the index of the first provider on that node (first 16 bits)  
 - the count of view providers from the component on this node (last 16 bits)  
 // TODO(misko): break this into actual vars.  
**providerIndexes: TNodeProviderIndexes**  
 The value name associated with this node.  
 if type: `TNodeType.Text`: text value  
`TNodeType.Element`: tag name  
`TNodeType.ICUContainer`: `TIcu` value  
 any;  
 Attributes associated with an element. We need to store attributes to support various use-cases (attribute injection, content projection with selectors, directives matching).  
 Attributes are stored statically because

reading them from the DOM would be way too slow for content projection and queries. Since attrs will always be calculated first, they will never need to be marked undefined by other instructions. For regular attributes a name of an attribute and its value alternate in the array. e.g. ['role', 'checkbox'] This array can contain flags that will indicate "special attributes" (attributes with namespaces, attributes extracted from bindings and outputs). attrs: TAttributes|null; Same as `TNode.attrs` but contains merged data across all directive host bindings. We need to keep `attrs` as unmerged so that it can be used for attribute selectors. We merge attrs here so that it can be used in a performant way for initial rendering. The `attrs` are merged in first pass in following order: Component's `hostAttrs` - Directives' `hostAttrs` - Template `TNode.attrs` associated with the current `TNode`. mergedAttrs: TAttributes|null; A set of local names under which a given element is exported in a template and visible to queries. An entry in this array can be created for different reasons: - an element itself is referenced, ex.: `

` - a component is referenced, ex.: `` - a directive is referenced, ex.: `

---

Open Source Used In webex\_teams\_security\_automation bwks-uap 864

\* For easier discussion assume this example:  

```

<parent>'s view definition:
<child id="c1">content1</child>
<child id="c2"><span>content2</span></child>
<child>'s view definition:
<ng-content id="cont1"></ng-content>

```

\* If `Array.isArray(projection)` then `TNode` is a host element:  
\* - `projection` stores the content nodes which are to be projected.  
\* - The nodes represent categories defined by the selector: For example:  

```

<ng-content/><ng-content select="abc"/>

```

would represent the heads for `<ng-content/>` and `<ng-content select="abc"/>` respectively.  
\* - The nodes we store in `projection` are heads only, we used `.next` to get their siblings.  
\* - The nodes `.next` is sorted/rewritten as part of the projection setup.  
\* - `projection` size is equal to the number of projections `<ng-content>`. The size of `c1` will be `1` because `<child>` has only one `<ng-content>`.  
\* - we store `projection` with the host (`c1`, `c2`) rather than the `<ng-content>` (`cont1`) because the same component (`<child>`) can be used in multiple locations (`c1`, `c2`) and as a result have different set of nodes to project.  
\* - without `projection` it would be difficult to efficiently traverse nodes to be projected.  
\* If `typeof projection === 'number'` then `TNode` is a `<ng-content>` element:  
\* - `projection` is an index of the host's `projection` Nodes.  
\* - This would return the first head node to project:  

```

getHost(currentTNode).projection[currentTNode.projection]

```

\* - When projecting nodes the parent node retrieved may be a `<ng-content>` node, in which case the process is recursive in nature.  
\* If `projection` is of type `RNode[]` than we have a collection of native nodes passed as projectable nodes during dynamic component creation.  

```

^ projection: (TNode|RNode[]|number|null);

```

\* A collection of all `style` static values for an element (including from host).  
\* This field will be populated if and when:  
\* - There are one or more initial `style`'s on an element (e.g. `<div style="width:200px;">`)  
\* - There are one or more initial `style`'s on a directive/component host (e.g. `@Directive({host: {style: "width:200px;"}})`)  
\* styles: `string|null`  
\* A collection of all `style` static values for an element excluding host sources.  
\* Populated when there are one or more initial `style`'s on an element (e.g. `<div style="width:200px;">`)  
\* Must be stored separately from `tNode.styles` to facilitate setting directive inputs that shadow the `style` property. If we used `tNode.styles` as is for shadowed inputs, we would feed host styles back into directives as `"inputs"`. If we used `tNode.attrs`, we would have to concatenate the attributes on every template pass. Instead, we process once on first create pass and store here.  

```

^ stylesWithoutHost: string|null;

```

\* A `KeyValueArray` version of residual `styles`.  
\* When there are styling instructions than each instruction stores the static styling which is of lower priority than itself. This means that there may be a higher priority styling than the instruction.  
\* Imagine:  

```

<div style="color: highest;" my-dir>
@Directive({
  host: {
    style: 'color: lowest;',
    '[styles.color]': 'exp // styleProp('color', ctx.exp);'
  })

```

\* In the above case: `color: lowest` is stored with `styleProp('color', ctx.exp);` instruction - `color: highest` is the residual and is stored here.  
\* - `undefined`: not initialized.  
\* - `null`: initialized but `styles` is `null`  
\* - `KeyValueArray`: parsed  

```

^ residualStyles: KeyValueArray<any>|undefined|null;

```

\* A collection of all class static values for an element (including from host).  
\* This field will be populated if and when:  
\* - There are one or more initial classes on an element (e.g. `<div class="one two three">`)  
\* - There are one or more initial classes on a directive/component host (e.g. `@Directive({host: {class: "SOME_CLASS"}})`)  
\* classes: `string|null`  
\* A collection of all class static values for an element excluding host sources.  
\* Populated when there are one or more initial classes on an element (e.g. `<div class="SOME_CLASS">`)  
\* Must be stored separately from `tNode.classes` to facilitate setting directive inputs that shadow the `class` property. If we used `tNode.classes` as is for shadowed inputs, we would feed host classes back into directives as `"inputs"`. If we used `tNode.attrs`, we would have to concatenate the attributes on every template pass. Instead, we process once on first create pass and store here.  

```

^ classesWithoutHost: string|null;

```

\* A `KeyValueArray` version of residual `classes`.  
\* Same as `TNode.residualStyles` but for classes.  
\* - `undefined`: not initialized.

```

`null`: initialized but `classes` is `null` \n * - `KeyValueArray`: parsed version of `classes`.\n */\n residualClasses:

`import {Type} from './interface/type';  
import {assertLessThan} from './util/assert';  
import {defineInjectable} from './interface/defs';  
/**  
 * Creates a token that can be used in a DI Provider.  
 * Use an `InjectionToken` whenever the type you are injecting is not reified (does not have a runtime representation) such as when injecting an interface, callable type, array or parameterized type.  
 * `InjectionToken` is parameterized on `T` which is the type of object which will be returned by the `Injector`. This provides an additional level of type safety.  
 *  
 * interface MyInterface {...}  
 * const myInterface = injector.get(new InjectionToken<MyInterface>('SomeToken'));  
 * // myInterface is inferred to be MyInterface.  
 *  
 * When creating an `InjectionToken`, you can optionally specify a factory function which returns (possibly by creating) a default value of the`

parameterized type `T`. This sets up the `InjectionToken` using this factory as a provider as if it was defined explicitly in the application's root injector. If the factory function, which takes zero arguments, needs to inject dependencies, it can do so using the `inject` function. As you can see in the Tree-shakable InjectionToken example below. Additionally, if a `factory` is specified you can also specify the `providedIn` option, which overrides the above behavior and marks the token as belonging to a particular `@NgModule`. As mentioned above, `root` is the default value for `providedIn`.

```
##### Basic Examples  
##### Plain InjectionToken  
 * { @example core/di/ts/injector_spec.ts region='InjectionToken'}  
##### Tree-shakable InjectionToken  
 * { @example core/di/ts/injector_spec.ts region='ShakableInjectionToken'}  
 *  
 * @publicApi  
 *  
 * export class InjectionToken<T> {  
 *   /** @internal */  
 *   readonly ngMetadataName = 'InjectionToken';  
 *   readonly prov: unknown;  
 *   /**  
 *    * @param _desc Description for the token,  
 *    * used only for debugging purposes,  
 *    * it should but does not need to be unique  
 *    * @param options Options for the token's usage, as described above  
 *    * @param constructor(protected _desc: string, options?: {  
 *    *   providedIn?: Type<any>|'root'|'platform'|any|null, factory: () => T  
 *    * }) {  
 *    *   this.prov = undefined;  
 *    *   if (typeof options == 'number') {  
 *    *     (typeof ngDevMode === 'undefined' || ngDevMode) &&  
 *    *     assertLessThan(options, 0, 'Only negative numbers are supported here');  
 *    *     // This is a special hack to assign __NG_ELEMENT_ID__ to this instance.  
 *    *     // See `InjectorMarkers` (this as any).__NG_ELEMENT_ID__ = options;  
 *    *   } else if (options !== undefined) {  
 *    *     this.prov = defineInjectable({  
 *    *       token: this,  
 *    *       providedIn: options.providedIn || 'root',  
 *    *       factory: options.factory,  
 *    *     });  
 *    *   }  
 *    * }  
 *    *  
 *    * @internal  
 *    * @param get multi(): InjectionToken<Array<T>> {  
 *    *   return this as InjectionToken<Array<T>>;  
 *    * }  
 *    * toString(): string {  
 *    *   return `InjectionToken ${this._desc}`;  
 *    * }  
 *    * }  
 *    *  
 *    * export interface InjectableDefToken<T> extends InjectionToken<T> {  
 *    *   prov: unknown;  
 *    *   /**  
 *    *    * @license  
 *    *    * Copyright Google LLC All Rights Reserved.  
 *    *    * Use of this source code is governed by an MIT-style license that can be  
 *    *    * found in the LICENSE file at https://angular.io/license  
 *    *    *  
 *    *    * import {InjectionToken} from './di/injection_token';  
 *    *    * import {ProviderToken} from './di/provider_token';  
 *    *    * import {makePropDecorator} from './util/decorators';  
 *    *    *  
 *    *    * A DI token that you can use to create a virtual [provider](guide/glossary#provider) that will populate the `entryComponents` field of components and NgModules based on its `useValue` property value. All components that are referenced in the `useValue` value (either directly  
 *    *    * or in a nested array or map) are added to the `entryComponents` property.  
 *    *    *  
 *    *    * @usageNotes  
 *    *    * The following example shows how the router can populate the `entryComponents` field of an NgModule based on a router configuration that refers to components.  
 *    *    *  
 *    *    * typescript // helper function inside the router  
 *    *    * function provideRoutes(routes) {  
 *    *   return [  
 *    *     {provide: ROUTES, useValue: routes},  
 *    *     {provide: ANALYZE_FOR_ENTRY_COMPONENTS, useValue: routes, multi: true}  
 *    *   ];  
 *    * }  
 *    *  
 *    * // user code  
 *    * let routes = [  
 *    *   {path: '/root', component: RootComp},  
 *    *   {path: '/teams', component: TeamsComp}  
 *    * ];  
 *    *  
 *    * @NgModule({  
 *    *   providers: [provideRoutes(routes)]  
 *    * })  
 *    * class ModuleWithRoutes {  
 *    * }  
 *    *  
 *    * @publicApi  
 *    * @deprecated Since 9.0.0. With Ivy, this property is no longer necessary.  
 *    *  
 *    * export const ANALYZE_FOR_ENTRY_COMPONENTS = new
```

```

content query.\n *\n * Use to get the `QueryList` of elements or directives from the content DOM.\n * Any time
a child element is added, removed, or moved, the query list will be\n * updated, and the changes observable of the
query list will emit a new value.\n *\n * Content queries are set before the `ngAfterContentInit` callback is
called.\n *\n * Does not retrieve elements or directives that are in other components' templates,\n * since a
component's template is always a black box to its ancestors.\n *\n * ***Metadata Properties***:\n *\n *
***selector*** - The directive type or the name used for querying.\n * ***descendants*** - If `true` include all
descendants of the element. If `false` then only\n * query direct children of the element.\n *\n *
***emitDistinctChangesOnly*** - The `QueryList#changes` observable will emit new values only\n * if the
QueryList result has changed. When `false` the `changes` observable might emit even\n * if the QueryList has not
changed.\n * *** Note: *** This config option is ***deprecated***, it will be permanently set to `true` and\n *
removed in future versions of Angular.\n *\n * ***read*** - Used to read a different token from the queried
elements.\n *\n * The following selectors are supported.\n * * Any class with the `@Component` or
`@Directive` decorator\n * * A template reference variable as a string (e.g. query `<my-component #cmp></my-
component>`\n * with `@ContentChildren('cmp')`\n * * Any provider defined in the child component tree of
the current component (e.g.\n * `@ContentChildren(SomeService) someService: SomeService)`\n * * Any
provider defined through a string token (e.g. `@ContentChildren('someToken')\n * someTokenVal: any)`\n * *
A `TemplateRef` (e.g. query `<ng-template></ng-template>` with\n * `@ContentChildren(TemplateRef)
template;`\n *)\n * In addition, multiple string selectors can be separated with a comma (e.g.\n *
`@ContentChildren('cmp1,cmp2')`\n *)\n *\n * The following values are supported by `read`:\n * * Any class with
the `@Component` or `@Directive` decorator\n * * Any provider defined on the injector of the component that is
matched by
the `selector` of\n * this query\n * * Any provider defined through a string token (e.g. `{provide: 'token',
useValue: 'val'}`)\n * * `TemplateRef`, `ElementRef`, and `ViewContainerRef`\n *\n * @usageNotes\n *\n *
Here is a simple demonstration of how the `ContentChildren` decorator can be used.\n *\n * {@example
core/di/ts/contentChildren/content_children_howto.ts region='HowTo'}\n *\n * ### Tab-pane example\n *\n *
Here is a slightly more realistic example that shows how `ContentChildren` decorators\n * can be used to
implement a tab pane component.\n *\n * {@example core/di/ts/contentChildren/content_children_example.ts
region='Component'}\n *\n * @Annotation\n */\n (selector: ProviderToken<unknown>|Function|string, opts?:
{\n descendants?: boolean,\n emitDistinctChangesOnly?: boolean,\n read?: any,\n }): any;\n new(selector:
ProviderToken<unknown>|Function|string,\n opts?: {descendants?: boolean, emitDistinctChangesOnly?:

```

```

boolean, read?: any}): Query;
}
Type of the ContentChildren metadata.
@Annotation
@publicApi
export type ContentChildren = Query;
ContentChildren decorator and metadata.
@Annotation
@publicApi
export const ContentChildren: ContentChildrenDecorator =
makePropDecorator(
  'ContentChildren', (selector?: any, data: any = {}) => ({
    selector,
    first: false,
    isViewQuery: false,
    descendants: false,
    emitDistinctChangesOnly: emitDistinctChangesOnlyDefaultValue,
    ...data
  })),
Query);
Type of the ContentChild decorator / constructor function.
@publicApi
export interface ContentChildDecorator {
  /**
   * @description
   * Property decorator that configures a content
   * query.
   * Use to get the first element or the directive
   * matching the selector from the content DOM.
   * If the content DOM changes, and a new child matches the
   * selector, the property will be updated.
   * Content queries are set before the `ngAfterContentInit`
   * callback is called.
   * Does not retrieve elements or directives that are in other components' templates,
   * since a component's template is always a black box to its ancestors.
   * **Metadata Properties**
   * **selector** - The directive type or the name used for querying.
   * **descendants** - If `true` (default) include
   * all descendants of the element. If `false` then only query direct children of the element.
   * **read** - Used
   * to read a different token from the queried element.
   * **static** - True to resolve query results before change
   * detection runs, false to resolve after change detection. Defaults to false.
   * The following selectors are
   * supported.
   * Any class with the `@Component`
   * or `@Directive` decorator
   * A template reference variable as a string (e.g. query `<my-component
   * #cmp></my-component>` with `@ContentChild('cmp')`)
   * Any provider defined in the child component
   * tree of the current component (e.g. `@ContentChild(SomeService) someService: SomeService`)
   * Any
   * provider defined through a string token (e.g. `@ContentChild('someToken') someTokenVal: any`)
   * A
   * `TemplateRef` (e.g. query `<ng-template></ng-template>` with `@ContentChild(TemplateRef) template;`)
   * The following values are supported by `read`:
   * Any class with the `@Component` or `@Directive`
   * decorator
   * Any provider defined on the injector of the component that is matched by the `selector` of
   * this query
   * Any provider defined through a string token (e.g. `{provide: 'token', useValue: 'val'}`)
   * `TemplateRef`, `ElementRef`, and `ViewContainerRef`
   * @usageNotes
   * {
   *   @example
   *   core/di/ts/contentChild/content_child_howto.ts
   *   region='HowTo'}
   *   ### Example
   *   {
   *     @example core/di/ts/contentChild/content_child_example.ts
   *     region='Component'}
   *     @Annotation
   *     (selector: ProviderToken<unknown>|Function|string,
   *     opts?: {descendants?: boolean, read?: any, static?: boolean}): any;
   *     new(selector:
   *     ProviderToken<unknown>|Function|string,
   *     opts?: {descendants?: boolean, read?: any, static?: boolean}):
   *     ContentChild;
   *   }
   *   Type of the ContentChild metadata.
   *   @publicApi
   *   export type
   *   ContentChild = Query;
   *   ContentChild decorator and metadata.
   *   @Annotation
   *   @publicApi
   *   export const ContentChild: ContentChildDecorator = makePropDecorator(
   *     'ContentChild',
   *     (selector?: any, data: any = {}) =>
   *       ({selector, first: true, isViewQuery: false, descendants: true, ...data}),
   *     Query);
   *   Type of the ViewChildren decorator / constructor function.
   *   @see `ViewChildren`.
   *   @publicApi
   *   export interface ViewChildrenDecorator {
   *     /**
   *      * @description
   *      * Property
   *      * decorator that configures a view query.
   *      * Use to get the `QueryList` of elements or directives from the view
   *      * DOM.
   *      * Any time a child element is added, removed, or moved, the query list will be updated,
   *      * and the
   *      * changes observable of the query list will emit a new value.
   *      * View queries are set before the
   *      * `ngAfterViewInit` callback is called.
   *      * **Metadata Properties**
   *      * **selector** - The directive
   *      * type or the name used for querying.
   *      * **read** - Used to read a different token from the queried elements.
   *      * **emitDistinctChangesOnly** - The `QueryList#changes` observable will emit new values only
   *      * if the
   *      * QueryList result has changed. When `false` the `changes` observable might emit even
   *      * if the QueryList has not
   *      * changed.
   *      * Note: This config option is deprecated, it will be permanently
   *      * set to `true` and
   *      * removed in future versions of Angular.
   *      * The following selectors are supported.
   *      * Any class with the `@Component` or `@Directive` decorator
   *      * A template reference variable as a string

```

(e.g. query ``<my-component #cmp></my-component>``\n \* with ``@ViewChild('cmp')``)\n \* \* Any provider defined in the child component tree of the current component (e.g.\n \* ``@ViewChild(SomeService) someService!: SomeService``)\n \* \* Any provider defined through a string token (e.g. ``@ViewChild('someToken')`\n \* `someTokenVal!: any``)\n \* \* A ``TemplateRef`` (e.g. query ``<ng-template></ng-template>`` with ``@ViewChild(TemplateRef)`\n \* `template;``)\n \* In addition, multiple string selectors can be separated with a comma (e.g.\n \* ``@ViewChild('cmp1,cmp2')``)\n \* The following values are supported by ``read``:\n \* \* Any class with the ``@Component`` or ``@Directive`` decorator\n \* \* Any provider defined on the injector of the component that is matched by the ``selector`` of\n \* this query\n \* \* Any provider defined through a string token (e.g. `{provide: 'token', useValue: 'val'}`)\n \* \* ``TemplateRef``, ``ElementRef``, and ``ViewContainerRef``\n \* `@usageNotes`\n \* `{@example core/di/ts/viewChildren/view_children_howto.ts region='HowTo'}`\n \* `### Another example`\n \* `{@example core/di/ts/viewChildren/view_children_example.ts region='Component'}`\n \* `@Annotation`\n \* `(selector: ProviderToken<unknown>|Function|string,\n * opts?: {read?: any, emitDistinctChangesOnly?: boolean}): any;\n * new(selector: ProviderToken<unknown>|Function|string,\n * opts?: {read?: any, emitDistinctChangesOnly?: boolean}): ViewChildren;`\n \* Type of the ViewChildren metadata.\n \* `@publicApi`\n \* `export type ViewChildren = Query;`\n \* ViewChildren decorator and metadata.\n \* `@Annotation`\n \* `@publicApi`\n \* `export const ViewChildren: ViewChildrenDecorator = makePropDecorator(\n * 'ViewChildren', (selector?: any, data: any = {}) => ({\n * selector,\n * first: false,\n * isViewQuery: true,\n * descendants: true,\n * emitDistinctChangesOnly: emitDistinctChangesOnlyDefaultValue,\n * ...data\n * })),\n * Query);`\n \* Type of the ViewChild decorator / constructor function.\n \* `@see 'ViewChild'`\n \* `@publicApi`\n \* `export interface ViewChildDecorator {\n * /**\n * @description\n * Property decorator that configures a view query.\n * The change detector looks for the first element or the directive matching the selector\n * in the view DOM. A set of interfaces which are shared between `@angular/core` and `@angular/compiler` to allow for late binding of `@angular/compiler` for JIT purposes.

This file has two copies. Please ensure that they are in sync:

- packages/compiler/src/compiler\_facade\_interface.ts (main)
- packages/core/src/compiler/compiler\_facade\_interface.ts (replica)

Please ensure that the two files are in sync using this command:

```
cp packages/compiler/src/compiler_facade_interface.ts \
packages/core/src/compiler/compiler_facade_interface.ts
```

```

`inject` is only supported during instantiation of a dependency by the DI system. It can be used\n *\n * during:\n *\n * -
Construction (via the `constructor`) of a class being instantiated by the DI system, such\n *\n * as an `@Injectable` or
`@Component`.\n *\n * - In the initializer for fields of such classes.\n *\n * - In the factory function specified for
`useFactory` of a `Provider` or an `@Injectable`.\n *\n * - In
the `factory` function specified for an `InjectionToken`.\n *\n * @param token A token that represents a
dependency that should be injected.\n *\n * @param flags Optional flags that control how injection is executed.\n *\n * The

```

```

flags correspond to injection strategies that can be specified with
`@Host`, `@Self`, `@SkipSelf`, and `@Optional`.
`@returns` the injected value if operation is successful, `null` otherwise.
`@throws` if called outside of a supported context.
In practice the `inject()` calls are allowed in a constructor, a constructor parameter and a field initializer:
typescript
@Injectable({providedIn: 'root'})
export class Car {
  radio: Radio; // OK: field initializer
  spareTyre = inject(Tyre); // OK: constructor body
  constructor() {
    // OK: constructor body
    this.radio = inject(Radio);
  }
}
It is also legal to call `inject` from a provider's factory:
typescript
providers: [
  {provide: Car, useFactory: () => {
    // OK: a class factory
    const engine = inject(Engine);
    return new Car(engine);
  }}
]
Calls to the `inject()` function outside of the class creation context will result in error. Most notably, calls to `inject()` are disallowed after a class instance was created, in methods (including lifecycle hooks):
typescript
@Component({ ... })
export class CarComponent {
  ngOnInit() {
    // ERROR: too late, the component instance was already created
    const engine = inject(Engine);
    engine.start();
  }
}
typescript
@publicApi
export function inject<T>(
  token: ProviderToken<T>, flags: InjectFlags|InjectOptions = InjectFlags.Default): T|null {
  if (typeof flags !== 'number') {
    // While TypeScript doesn't accept it without a cast, bitwise OR with false-y values in JavaScript is a no-op. We can use that for a very codesize-efficient conversion from `InjectOptions` to `InjectFlags`.
    flags = (InternalInjectFlags.Default | // comment to force a line break in the formatter
      ((flags.optional && InternalInjectFlags.Optional) as number) |
      ((flags.host && InternalInjectFlags.Host) as number) |
      ((flags.self && InternalInjectFlags.Self) as number) |
      ((flags.skipSelf && InternalInjectFlags.SkipSelf) as number)) as InjectFlags;
  }
  return inject(token, flags);
}
export function injectArgs(types: ProviderToken<any>|any[]): any[] {
  const args: any[] = [];
  for (let i = 0; i < types.length; i++) {
    const arg = resolveForwardRef(types[i]);
    if (Array.isArray(arg)) {
      if (arg.length === 0) {
        throw new RuntimeError(
          RuntimeErrorCode.INVALID_DIFFER_INPUT,
          ngDevMode && 'Arguments array must have arguments.');

Reserved.

Use of this source code is governed by an MIT-style license that can be found in the
LICENSE file at https://angular.io/license

import {Type} from './interface/type';
import {NgModuleType} from './metadata/ng_module_def';
import {getNgModuleDef} from './render3/definition';
import {stringify} from './util/stringify';

Map of module-id to the corresponding NgModule.

const modules = new Map<string, NgModuleType>();

Whether to check for duplicate NgModule registrations.

This can be disabled for testing.

let checkForDuplicateNgModules = true;

function assertSameOrNotExisting(id: string, type: Type<any>|null, incoming: Type<any>): void {
  if (type && type !== incoming && checkForDuplicateNgModules) {
    throw new Error(`Duplicate module registered for ${id} - ${stringify(type)} vs ${stringify(type.name)}`);
  }
}

Adds the given NgModule type to Angular's NgModule registry.

This is generated as a side-effect of NgModule compilation. Note that the `id` is passed in explicitly and not read from the NgModule definition. This is for two reasons: it avoids a megamorphic read, and in JIT there's a chicken-and-egg problem where the NgModule may not be fully resolved when it's registered.

@codeGenApi
export function registerNgModuleType(ngModuleType: NgModuleType, id: string): void {
  const existing = modules.get(id) || null;
  assertSameOrNotExisting(id, existing, ngModuleType);
  modules.set(id, ngModuleType);
}

export function clearModulesForTest(): void {
  modules.clear();
}

export function getRegisteredNgModuleType(id: string): NgModuleType|undefined {
  return modules.get(id);
}

Control whether the NgModule registration system enforces that each NgModule type registered has a unique id.

This is useful for testing as the NgModule registry cannot be properly reset between tests with Angular's current API.

export function setAllowDuplicateNgModuleIdsForTest(allowDuplicates: boolean): void {
  checkForDuplicateNgModules = !allowDuplicates;
}

A schema definition associated with an NgModule.

@param name The name of a defined schema.

@publicApi
export interface SchemaMetadata {
  name: string;
}

Defines a schema that allows an NgModule to contain the following:
- Non-Angular elements named with dash case (-).
- Element properties named with dash case (-).
Dash case is the naming convention for custom elements.

@publicApi
export const CUSTOM_ELEMENTS_SCHEMA: SchemaMetadata = {
  name: 'custom-elements'
};

Defines a schema that allows any property on any element.

This schema allows you to ignore the errors related to any unknown elements or properties in a template. The usage of this schema is generally discouraged because it prevents useful validation and may hide real errors in your template. Consider using the `CUSTOM_ELEMENTS_SCHEMA` instead.

@publicApi
export const NO_ERRORS_SCHEMA: SchemaMetadata = {
  name: 'no-errors-schema'
};

```

This should not exist, it is a bit of a hack. When we bootstrap a top level node and we need to support passing projectable nodes, so we cheat and put them in the TNode of the Host TView. (Yes we put instance info at the T Level). We can get away with it because we know that that TView is not shared and therefore it will not be a problem. This should be refactored and cleaned up.

*\n*\n */\n * A pattern that recognizes a commonly useful subset of URLs that are safe.\n *\n * This regular
expression
  matches a subset of URLs that will not cause script\n * execution if used in URL context within a HTML
document. Specifically, this\n * regular expression matches if (comment from here on and regex copied from\n *
Soy's EscapingConventions):\n * (1) Either an allowed protocol (http, https, mailto or ftp).\n * (2) or no protocol. A
protocol must be followed by a colon. The below\n * allows that by allowing colons only after one of the
characters [/?#].\n * A colon after a hash (#) must be in the fragment.\n * Otherwise, a colon after a (?) must be
in a query.\n * Otherwise, a colon after a single solidus (/) must be in a path.\n * Otherwise, a colon after a
double solidus (//) must be in the authority\n * (before port).\n *\n * The pattern disallows &, used in HTML
entity declarations before\n * one of the characters in [/?#]. This disallows HTML entities used in the\n * protocol
name, which should never happen, e.g. \"h&#116;tp\" for \"http\".\n * It also disallows
HTML entities in the first path part of a relative path,\n * e.g. \"foo&lt;bar/baz\". Our existing escaping functions
should not produce\n * that. More importantly, it disallows masking of a colon,\n * e.g. \"javascript&#58;...\".\n
*\n * This regular expression was taken from the Closure sanitization library.\n */\n const SAFE_URL_PATTERN =

```

Marker which indicates that a value has not yet been created from the factory function.

```
const NOT_YET = {};
```

Marker which indicates that the factory function for a token is in the process of being called.

If the injector is asked to inject a token with its value set to CIRCULAR, that indicates injection of a dependency has recursively attempted to inject the original token, and there is a circular dependency among the providers.

```
const CIRCULAR = {};
```

A lazily initialized

```
NullInjector.
let NULL_INJECTOR: Injector|undefined = undefined;
export function getNullInjector(): Injector {
  if (NULL_INJECTOR === undefined) {
    NULL_INJECTOR = new NullInjector();
  }
  return NULL_INJECTOR;
}
```

An entry in the injector which tracks information about the given token, including a possible current value.

```
interface Record<T> {
  factory: (() => T)|undefined;
  value: T|{};
  multi: any[]|undefined;
}
```

An `Injector` that's part of the environment injector hierarchy, which exists outside of the component tree.

```
@developerPreview

import { getCurrentTNode, getLView } from './render3/state';
import { getNativeByTNode } from './render3/util/view_utils';
/**
 * Creates an ElementRef from the most recent node.
 */
@returns The ElementRef instance to use
export function injectElementRef(): ElementRef {
  return createElementRef(getCurrentTNode(), getLView());
}
/**
 * Creates an ElementRef given a node.
 */
@param tNode The node for which you'd like an ElementRef
@param lView The view to which the node belongs
@returns The ElementRef instance to use
export function createElementRef(tNode: TNode, lView: LView): ElementRef {
  return new ElementRef(getNativeByTNode(tNode, lView) as RElement);
}
/**
 * A wrapper around a native element inside of a View.
 */
An `ElementRef` is backed by a render-specific element. In the browser, this is usually a DOM element.
@security Permitting direct access to the DOM can make your application more vulnerable to XSS attacks. Carefully review any use of `ElementRef` in your code. For more detail, see the [Security Guide](https://g.co/ng/security).
@publicApi
// Note: We don't expose things like `Injector`, `ViewContainer`, ... here, i.e. users have to ask for what they need. With that, we can build better analysis tools and could do better codegen in the future.
export class ElementRef<T = any> {
  /**
   * The underlying native element or `null` if direct access to native elements is not supported (e.g. when the application runs in a web worker).
   */
  <div class="callout is-critical">
    <header>Use with caution</header>
    <p>
      Use this API as the last resort when direct access to DOM is needed. Use templating and data-binding provided by Angular instead. Alternatively you can take a look at {@link Renderer2} which provides API that can safely be used even when direct access to native elements is not supported.
    </p>
    Relying on direct DOM access creates tight coupling between your application and rendering layers which will make it impossible to separate the two and deploy your application into a web worker.
    </div>

export const Renderer2Interceptor = new InjectionToken<Renderer2[]>('Renderer2Interceptor');
/**
 * Creates and initializes a custom renderer that implements the `Renderer2` base class.
 */
@publicApi
export abstract class RendererFactory2 {
  /**
   * Creates and initializes a custom renderer for a host DOM element.
   */
  @param hostElement The element to render.
  @param type The base class to implement.
  @returns The new custom renderer instance.
  abstract createRenderer(hostElement: any, type: RendererType2|null): Renderer2;
}

```

callback invoked when rendering has begun.  
`abstract begin?(): void;`  
 \* A callback invoked when rendering has completed.  
`abstract end?(): void;`  
 \* Use with animations test-only mode. Notifies the test when rendering has completed.  
 \* @returns The asynchronous result of the developer-defined function.  
`abstract whenRenderingDone?(): Promise<any>;`  
 \* Extend this base class to implement custom rendering. By default, Angular renders a template into DOM. You can use custom rendering to intercept rendering calls, or to render to something other than DOM.  
 \* Create your custom renderer using `RendererFactory2`.  
 \* Use a custom renderer to bypass Angular's templating and make custom UI changes that can't be expressed declaratively.  
 \* For example if you need to set a property or an attribute whose name is not statically known, use the `setProperty()` or `setAttribute()` method.  
 \* @publicApi  
`export abstract class Renderer2 {`  
 \* Use to store arbitrary developer-defined data on a renderer instance, as an object containing key-value pairs.  
 \* This is useful for renderers that delegate to other renderers.  
`abstract get data(): {[key: string]: any};`  
 \* Implement this callback to destroy the renderer or the host element.  
`abstract destroy(): void;`  
 \* Implement this callback to create an instance of the host element.  
 \* @param name An identifying name for the new element, unique within the namespace.  
 \* @param namespace The namespace for the new element.  
 \* @returns The new element.  
`abstract createElement(name: string, namespace?: string|null): any;`  
 \* Implement this callback to add a comment to the DOM of the host element.  
 \* @param value The comment text.  
 \* @returns The modified element.  
`abstract createComment(value: string): any;`  
 \* Implement this callback to add text to the DOM of the host element.  
 \* @param value The text string.  
 \* @returns The modified element.  
`abstract createText(value: string): any;`  
 \* If null or undefined, the view engine won't call it.  
 \* This is used as a performance optimization for production mode.  
 \* // TODO(issue/24571): remove '!'.  
`destroyNode!: ((node: any) => void)|null;`  
 \* Appends a child to a given parent node in the host element DOM.  
 \* @param parent The parent node.  
 \* @param newChild The new child node.  
`abstract appendChild(parent: any, newChild: any): void;`  
 \* Implement this callback to insert a child node at a given position in a parent node in the host element DOM.  
 \* @param parent The parent node.  
 \* @param newChild The new child nodes.  
 \* @param refChild The existing child node before which `newChild` is inserted.  
 \* @param isMove Optional argument which signifies if the current `insertBefore` is a result of a `move`. Animation uses this information to trigger move animations. In the past the Animation would always assume that any `insertBefore` is a move. This is not strictly true because with runtime `i18n` it is possible to invoke `insertBefore` as a result of `i18n` and it should not trigger an animation move.  
`abstract insertBefore(parent: any, newChild: any, refChild: any, isMove?: boolean): void;`  
 \* Implement this callback to remove a child node from the host element's DOM.  
 \* @param parent The parent node.  
 \* @param oldChild The child node to remove.  
 \* @param isHostElement Optionally signal to the renderer whether this element is a host element or not.  
`abstract removeChild(parent: any, oldChild: any, isHostElement?: boolean): void;`  
 \* Implement this callback to prepare an element to be bootstrapped as a root element, and return the element instance.  
 \* @param selectorOrNode The DOM element.  
 \* @param preserveContent Whether the contents of the root element should be preserved, or cleared upon bootstrap (default behavior).  
 \* Use with `ViewEncapsulation.ShadowDom` to allow simple native content projection via `<slot>` elements.  
 \* @returns The root element.  
`abstract selectRootElement(selectorOrNode: string|any, preserveContent?: boolean): any;`  
 \* Implement this callback to get the parent of a given node in the host element's DOM.  
 \* @param node The child node to query.  
 \* @returns The parent node, or null if there is no parent.  
 \* For WebWorkers, always returns true.  
 \* This is because the check is synchronous, and the caller can't rely on checking for null.  
`abstract parentNode(node: any): any;`  
 \* Implement this callback to get the next sibling node of a given node in the host element's DOM.  
 \* @returns The sibling node, or null if there is no sibling.  
 \* For WebWorkers, always returns a value.  
 \* This is because the check is synchronous, and the caller can't rely on checking for null.  
`abstract nextSibling(node: any): any;`  
 \* Implement this callback to set an attribute value for

```

interface. Injectors

are configured with [providers](guide/glossary#provider) that associate dependencies of various types with [injection tokens](guide/glossary#di-token).  
@see [DI Providers](guide/dependency-injection-providers).  
@see `StaticProvider`  
@usageNotes  
The following example creates a service injector instance.  
@example core/di/ts/provider\_spec.ts region='ConstructorProvider'  
### Usage  
example  
@example core/di/ts/injector\_spec.ts region='Injector'  
`Injector` returns itself when given `Injector` as a token:  
@example core/di/ts/injector\_spec.ts region='injectInjector'  
@publicApi  
export abstract class Injector {  
 static THROW\_IF\_NOT\_FOUND = THROW\_IF\_NOT\_FOUND;  
 static NULL: Injector = (/\* \_\_PURE\_\_ \*/ new NullInjector());  
 /\*\*  
 \* Retrieves an instance from the injector based on the provided token.  
 \* @returns The instance from the injector if defined, otherwise the `notFoundValue`.  
 \* @throws When the `notFoundValue` is `undefined` or `Injector.THROW\_IF\_NOT\_FOUND`.  
 \*/  
 abstract get<T>(token: ProviderToken<T>, notFoundValue?: T, flags?: InjectFlags): T;  
 /\*\*  
 \* @deprecated from v4.0.0 use ProviderToken<T>  
 \* @suppress {duplicate}  
 \*/  
 abstract get(token: any, notFoundValue?: any): any;  
 /\*\*  
 \* @deprecated from v5 use the new signature Injector.create(options)  
 \*/  
 static create(providers: StaticProvider[], parent?: Injector): Injector;  
 /\*\*  
 \* Creates a new injector instance that provides one or more dependencies, according to a given type or types of `StaticProvider`.  
 \* @param options An object with the following properties:  
 \* \* `providers`: An array of providers of the [StaticProvider type](api/core/StaticProvider).  
 \* \* `parent`: (optional) A parent injector.  
 \* \* `name`: (optional) A developer-defined identifying name for the new injector.  
 \* @returns The new injector instance.  
 \*/  
 static create(options: { providers: StaticProvider[], parent?: Injector, name?: string }): Injector;  
 static create(options: StaticProvider[] | { providers: StaticProvider[], parent?: Injector, name?: string }, parent?: Injector): Injector {

/**
 * Thrown when
```

```

trying to retrieve a dependency by key from { @link Injector}, but the
 * { @link Injector} does not have a { @link
Provider} for the given key.
 * @usageNotes
 * ### Example
 * ```typescript
 * class A {
 *   constructor(b:B) {}
 * }
 * expect(() => Injector.resolveAndCreate([A])).toThrowError();
 * ```
 * \nexport
function noProviderError(injector: ReflectiveInjector, key: ReflectiveKey): InjectionError {
 * return
 * injectionError(injector, key, function(keys: ReflectiveKey[]) {
 *   const first = stringify(keys[0].token);
 *   return
 *   `No provider for ${first}!${constructResolvingPath(keys)}`;
 * });
 * }
 * \n\n/**
 * Thrown when dependencies form a
cycle.
 * @usageNotes
 * ### Example
 * ```typescript
 * var injector = Injector.resolveAndCreate([
 *   { provide: 'one', useFactory: (two) => 'two', deps: [[new Inject('two')]] },
 *   { provide: 'two', useFactory:
(one) => 'one', deps: [[new Inject('one')]] }
 * ]);
 * expect(() => injector.get('one')).toThrowError();
 * ```
 * \n * Retrieving `A` or `B` throws a `CyclicDependencyError` as the graph above cannot be constructed.
 * \nexport
function cyclicDependencyError(injector: ReflectiveInjector, key: ReflectiveKey): InjectionError {
 * return
 * injectionError(injector, key, function(keys: ReflectiveKey[]) {
 *   return `Cannot instantiate cyclic
dependency!${constructResolvingPath(keys)}`;
 * });
 * }
 * \n\n/**
 * Thrown when a constructing type returns with
an Error.
 * \n * The `InstantiationError` class contains the original error plus the dependency graph which caused
 * this object to be instantiated.
 * @usageNotes
 * ### Example
 * ```typescript
 * class A {
 *   constructor() {
 *     throw new Error('message');
 *   }
 * }
 * var injector =
Injector.resolveAndCreate([A]);
 * try {
 *   injector.get(A);
 * } catch (e) {
 *   expect(e instanceof
InstantiationError).toBe(true);
 *   expect(e.originalException.message).toEqual('message');
 *   expect(e.originalStack).toBeDefined();
 * }
 * ```
 * \nexport
function instantiationError(injector:
ReflectiveInjector, originalException: any, originalStack: any,
 * key: ReflectiveKey): InjectionError {
 * return
 * injectionError(injector, key, function(keys: ReflectiveKey[]) {
 *   const first = stringify(keys[0].token);
 *   return
 *   `${originalException.message}: Error during instantiation of ${first}!${
 *   constructResolvingPath(keys)}`;
 * }, originalException);
 * }
 * \n\n/**
 * Thrown when an object other than { @link Provider} (or `Type`) is passed to
{ @link Injector}
 * creation.
 * @usageNotes
 * ### Example
 * ```typescript
 * expect(() =>
Injector.resolveAndCreate(['not a type'])).toThrowError();
 * ```
 * \nexport
function
invalidProviderError(provider: any) {
 * return
 * Error(`Invalid provider - only instances of Provider and Type
are allowed, got: ${provider}`);
 * }
 * \n\n/**
 * Thrown when the class has no annotation information.
 * \n * Lack of annotation information prevents the { @link Injector} from determining which dependencies
 * need
to be injected into the constructor.
 * @usageNotes
 * ### Example
 * ```typescript
 * class A {
 *   constructor(b) {}
 * }
 * expect(() => Injector.resolveAndCreate([A])).toThrowError();
 * ```
 * \n * This
error is also thrown when the class not marked with { @link Injectable} has parameter types.
 * ```typescript
 * class B {}
 * class A {
 *   constructor(b:B) {} // no information about the parameter types of A is available at
runtime.
 * }
 * expect(() => Injector.resolveAndCreate([A,B])).toThrowError();
 * ```
 * \nexport
function noAnnotationError(typeOrFunc: Type<any>|Function, params: any[][]): Error {
 * const signature: string[]
= [];
 * for (let i = 0, ii = params.length; i < ii; i++) {
 *   const parameter = params[i];
 *   if (!parameter ||
parameter.length == 0) {
 *     signature.push('?');
 *   } else {
 *     signature.push(parameter.map(stringify).join(' '));
 *   }
 * }
 * return
 * Error(`Cannot resolve all parameters
for ` + stringify(typeOrFunc) + `(` +
signature.join(', ') + `). ` +
 * `Make sure that all the parameters are
decorated with Inject or have valid type annotations and that ` +
stringify(typeOrFunc) + ` is decorated with
Injectable.`);
 * }
 * \n\n/**
 * Thrown when getting an object by index.
 * @usageNotes
 * ### Example
 * ```typescript
 * class A {
 * }
 * var injector = Injector.resolveAndCreate([A]);
 * expect(() =>
injector.getAt(100)).toThrowError();
 * ```
 * \nexport
function outOfBoundsError(index: number) {
 * return
 * Error(`Index ${index} is out-of-bounds.`);
 * }
 * \n\n// TODO: add a working example after alpha38 is released
 * \n/**
 * Thrown when a multi provider and a regular provider are bound to the same token.
 * @usageNotes
 * ###
Example
 * ```typescript
 * expect(() => Injector.resolveAndCreate([
 *   { provide: 'Strings', useValue: 'string1', multi: true },
 *   { provide: 'Strings', useValue: 'string2',
multi: false }
 * ])).toThrowError();
 * ```
 * \nexport
function
mixingMultiProvidersWithRegularProvidersError(provider1: any, provider2: any): Error {
 * return

```

```

ReflectiveDependency injection container used for instantiating objects and resolving\n * dependencies.\n * An
`Injector` is a replacement for a `new` operator, which can automatically resolve the\n * constructor dependencies.\n
*\n * In typical use, application code asks for the dependencies in the constructor and they are\n * resolved by the
`Injector`.\n *\n * @usageNotes\n * ### Example\n *\n * The following example creates an `Injector` configured to
create `Engine` and `Car`.\n *\n * ```typescript\n * @Injectable()\n * class Engine {\n * }\n *\n * @Injectable()\n *
class Car {\n * constructor(public engine:Engine) {\n * }\n *\n * var injector =
ReflectiveInjector.resolveAndCreate([Car, Engine]);\n * var car = injector.get(Car);\n * expect(car instanceof
Car).toBe(true);\n * expect(car.engine instanceof Engine).toBe(true);\n * ```\n *\n * Notice,
we don't use the `new` operator because we explicitly want to have the `Injector`\n * resolve all of the object's
dependencies automatically.\n *\n * TODO: delete in v14.\n *\n * @deprecated from v5 - slow and brings in a lot of
code, Use `Injector.create` instead.\n *\n * @publicApi\n */\n\nexport abstract class ReflectiveInjector implements

This file should not be necessary because node resolution should just default to `./di/index`!
However it does not seem to work and it breaks:
- //packages/animations/browser/test:test_web_chromium-local
- //packages/compiler-cli/test:extract_i18n
- //packages/compiler-cli/test:ngc
- //packages/compiler-cli/test:perform_watch
- //packages/compiler-cli/test/diagnostics:check_types
- //packages/compiler-cli/test/transformers:test
- //packages/compiler/test:test
- //tools/public_api_guard:core_api

Remove this file once the above is solved or wait until `ngc` is deleted and then it should be safe to delete this file.

export * from './di/index';

 */
import { InjectFlags, resolveForwardRef } from './di';
import { assertInjectImplementationNotEqual } from './di/inject_switch';
import { inject } from './di/injector_compatibility';
import { ProviderToken } from './di/provider_token';
import { getOrCreateInjectable } from './di';
import { TDirectiveHostNode } from './interfaces/node';
import { getCurrentTNode, getLView } from './state';

Returns the value associated to the given token from the injectors.
`directiveInject` is intended to be used for directive, component and pipe factories.
All other injection use `inject` which does not walk the node injector tree.

Usage example (in factory function):
class SomeDirective {
  constructor(directive: DirectiveA) {}
  static dir = defineDirective({
    type: SomeDirective,
    factory: () => new SomeDirective(directiveInject(DirectiveA))
  });
}

@param token the type or token to inject
@param flags Injection flags
@returns the value from the injector or `null` when not found

@codeGenApi
export function directiveInject<T>(token: ProviderToken<T>): T;
export function directiveInject<T>(token: ProviderToken<T>, flags: InjectFlags): T;
export function directiveInject<T>(token: ProviderToken<T>, flags = InjectFlags.Default): T | null {
  const lView = getLView();
  // Fall back to inject() if view hasn't been created. This situation can happen in tests // if inject utilities are used before bootstrapping.

```

```

    if (IView === null) {\n    // Verify that we will not get into infinite loop.\n    ngDevMode &&
assertInjectImplementationNotEqual(directiveInject);\n    return inject(token, flags);\n } \n const tNode =

TStylingKeyPrimitive|TStylingStatic;\n\n/n/**\n * The primitive portion (`TStylingStatic` removed) of the value
stored in the `TData` which is\n * needed to re-concatenate the styling.\n *\n * - `string`: Stores the property name.
Used with `styleProp`/`classProp` instruction.\n * - `null`: Represents map, so there is no name. Used with
`styleMap`/`classMap`.\n * - `false`: Represents an ignore case. This happens when `styleProp`/`classProp`
instruction\n * is combined with directive which shadows its input `@Input('class')`. That way the binding\n *
should not participate in the styling resolution.\n */\nexport type TStylingKeyPrimitive = string|null|false;\n\n/n/**\n *
Store the static values for the styling binding.\n *\n * The `TStylingStatic` is just `KeyValueArray` where key `\"\"`
(stored at location 0) contains the\n * `TStylingKey` (stored at location 1). In other words this wraps the
`TStylingKey` such that the\n * `\"\"` contains the wrapped value.\n *\n * When instructions are resolving styling
they may need to look forward or backwards in the linked\n * list to resolve the value. For this reason we have to
make sure that the linked list also contains\n * the static values. However the list only has space for one item per
styling instruction. For this\n * reason we store the static values here as part of the `TStylingKey`. This means that
the\n * resolution function when looking for a value needs to first look at the binding value, and then\n * at
`TStylingKey` (if it exists).\n *\n * Imagine we have:\n *\n * ``\n * <div class=\"TEMPLATE\" my-dir>\n *\n * @Directive({\n *   host: {\n *     class: 'DIR',\n *     '[class.dynamic]': 'exp' // classProp('dynamic', ctx.exp);\n *   }\n * })\n * ``\n *\n * In the above case the linked list will contain one item:\n *\n * ``\n * // assume binding location:
10 for `classProp('dynamic', ctx.exp)`;\n * tData[10] =

```

```

<TStylingStatic>{\n *   ": 'dynamic', // This is the wrapped value of `TStylingKey`\n *   'DIR': true, // This is the
default static value of directive binding.\n *   ];\n *   tData[10 + 1] = 0; // We don't have prev/next.\n *   \n *   IView[10] = undefined; // assume `ctx.exp` is `undefined`\n *   IView[10 + 1] = undefined; // Just normalized
`IView[10]`\n *   ```\n *   \n *   So when the function is resolving styling value, it first needs to look into the linked list\n
*   (there is none) and then into the static `TStylingStatic` too see if there is a default value for\n *   `dynamic` (there is
not). Therefore it is safe to remove it.\n *   \n *   If setting `true` case:\n *   ```\n *   IView[10] = true; // assume
`ctx.exp` is `true`\n *   IView[10 + 1] = true; // Just normalized `IView[10]`\n *   ```\n *   \n *   So when the function is
resolving styling value, it first needs to look into the linked list\n *   (there is none) and then into
`TNode.residualClass` (TNode.residualStyle) which contains\n
*   ```\n *   tNode.residualClass = [\n *   'TEMPLATE': true,\n *   ];\n *   ```\n *   \n *   This means that it is safe to add
class.\n *   \n *   ^\n *   \n *   export interface TStylingStatic extends KeyValueArray<any> { }\n *   \n *   /**\n *   \n *   This is a branded number
which contains previous and next index.\n *   \n *   \n *   When we come across styling instructions we need to store the
`TStylingKey` in the correct\n *   order so that we can re-concatenate the styling value in the desired priority.\n *   \n *   \n *
The insertion can happen either at the:\n *   - end of template as in the case of coming across additional styling
instruction in the template\n *   - in front of the template in the case of coming across additional instruction in the\n *
`hostBindings`.\n *   \n *   \n *   We use `TStylingRange` to store the previous and next index into the `TData` where the
template\n *   bindings can be found.\n *   \n *   \n *   - bit 0 is used to mark that the previous index has a duplicate for current
value.\n *   \n *   - bit 1 is used to mark that the next index has a duplicate
for the current value.\n *   \n *   - bits 2-16 are used to encode the next/tail of the template.\n *   \n *   - bits 17-32 are used to
encode the previous/head of template.\n *   \n *   \n *   NODE: *duplicate* false implies that it is statically known that this
binding will not collide\n *   with other bindings and therefore there is no need to check other bindings. For example
the\n *   bindings in `

detection tree.\n *\n * Detached views will not be checked during change detection runs until they are\n * re-
attached, even if they are dirty. `detach` can be used in combination with\n * { @link
ChangeDetectorRef#detectChanges detectChanges} to implement local change\n * detection checks.\n
*\n * <!-- TODO: Add a link to a chapter on detach/reattach/local digest -->\n * <!-- TODO: Add a live demo
once ref.detectChanges is merged into master -->\n * @usageNotes\n * ### Example\n *\n * The
following example defines a component with a large list of readonly data.\n * Imagine the data changes constantly,
many times per second. For performance reasons,\n * we want to check and update the list every five seconds. We
can do that by detaching\n * the component's change detector and doing a local check every five seconds.\n *\n *
```typescript\n * class DataProvider {\n * // in a real application the returned data will be different every time\n
* get data() {\n * return [1,2,3,4,5];\n * }\n * }\n *\n * @Component({\n * selector: 'giant-list',\n *
template: `\n * <li *ngFor="let d of dataProvider.data">Data {{ d }}</li>\n * `,\n * })\n * class GiantList
{\n * constructor(private ref: ChangeDetectorRef,\n * private dataProvider: DataProvider) {\n * ref.detach();\n *
setInterval(() => {\n * this.ref.detectChanges();\n * }, 5000);\n * }\n * }\n *\n * @Component({\n * selector: 'app',\n *
providers: [DataProvider],\n * template: `\n * <giant-list><giant-list>\n * `,\n * })\n * class App {\n *
}\n * ```\n *\n * detach(): void {\n * this._IView[FLAGS] &= ~LViewFlags.Attached;\n * }\n\n /**\n * Re-
attaches a view to the change detection tree.\n *\n * This can be used to re-attach views that were previously
detached from the tree\n * using { @link ChangeDetectorRef#detach detach}. Views are attached to the tree by
default.\n *\n * <!-- TODO: Add a link to a chapter on detach/reattach/local digest -->\n * @usageNotes\n
* ### Example\n *\n * The following example creates a component displaying `live` data. The component will
detach\n * its change detector from the main change detector tree when the component's
live property\n * is set to false.\n *\n * ```typescript\n * class DataProvider {\n * data = 1;\n *\n *
constructor() {\n * setInterval(() => {\n * this.data = this.data * 2;\n * }, 500);\n * }\n * }\n *\n *
@Component({\n * selector: 'live-data',\n * inputs: ['live'],\n * template: `Data: {{dataProvider.data}}`\n *
})\n * class LiveData {\n * constructor(private ref: ChangeDetectorRef, private dataProvider: DataProvider) {\n
*\n * set live(value) {\n * if (value) {\n * this.ref.reattach();\n * } else {\n * this.ref.detach();\n
* }\n * }\n * }\n *\n * @Component({\n * selector: 'app-root',\n * providers: [DataProvider],\n *
template: `\n * Live Update: <input type="checkbox" [(ngModel)]="live">\n * <live-data
[live]="live"><live-data>\n * `,\n * })\n * class AppComponent {\n * live = true;\n * }\n * ```\n *\n
reattach():\n
void {\n * this._IView[FLAGS] |= LViewFlags.Attached;\n * }\n\n /**\n * Checks the view and its children.\n
*\n * This can also be used in combination with { @link ChangeDetectorRef#detach detach} to implement\n *
local change detection checks.\n *\n * <!-- TODO: Add a link to a chapter on detach/reattach/local digest -->\n *
<!-- TODO: Add a live demo once ref.detectChanges is merged into master -->\n * @usageNotes\n * ###
Example\n *\n * The following example defines a component with a large list of readonly data.\n * Imagine, the
data changes constantly, many times per second. For performance reasons,\n * we want to check and update the list
every five seconds.\n *\n * We can do that by detaching the component's change detector and doing a local
change detection\n * check every five seconds.\n *\n * See { @link ChangeDetectorRef#detach detach} for more
