## Configuration Examples for Flex Links

### Configuring Flex Links: Examples

This example shows how to verify the configuration after you configure an interface with a backup interface:

```
Switch# show interface switchport backup

Switch Backup Interface Pairs:
Active Interface Backup Interface State
-----
GigabitEthernet1/0/1 GigabitEthernet1/0/2 Active Up/Backup Standby
```

This example shows how to verify the configuration after you configure the preemption mode as forced for a backup interface pair:

```
Switch# show interface switchport backup detail

Switch Backup Interface Pairs:

Active Interface Backup Interface State
-----
GigabitEthernet1/0/211 GigabitEthernet1/0/2 Active Up/Backup Standby
Interface Pair : Gil/0/1, Gil/0/2
Preemption Mode : forced
Preemption Delay : 50 seconds
Bandwidth : 100000 Kbit (Gil/0/1), 100000 Kbit (Gil/0/2)
Mac Address Move Update Vlan : auto
```

### Configuring VLAN Load Balancing on Flex Links: Examples

In the following example, VLANs 1 to 50, 60, and 100 to 120 are configured on the switch:

```
Switch(config)# interface gigabitethernet 2/0/6
Switch(config-if)# switchport backup interface gigabitethernet 2/0/8 prefer vlan 60,100-120
```

When both interfaces are up, Gi2/0/8 forwards traffic for VLANs 60 and 100 to 120 and Gi2/0/6 forwards traffic for VLANs 1 to 50.

```
Switch# show interfaces switchport backup
Switch Backup Interface Pairs:
Active Interface      Backup Interface      State
-----
GigabitEthernet2/0/6  GigabitEthernet2/0/8  Active Up/Backup Standby
Vlans Preferred on Active Interface: 1-50
Vlans Preferred on Backup Interface: 60, 100-120
```

When a Flex Links interface goes down (LINK\_DOWN), VLANs preferred on this interface are moved to the peer interface of the Flex Links pair. In this example, if interface Gi2/0/6 goes down, Gi2/0/8 carries all VLANs of the Flex Links pair.

```
Switch# show interfaces switchport backup
Switch Backup Interface Pairs:
Active Interface      Backup Interface      State
-----
GigabitEthernet2/0/6  GigabitEthernet2/0/8  Active Down/Backup Up
Vlans Preferred on Active Interface: 1-50
Vlans Preferred on Backup Interface: 60, 100-120
```

When a Flex Links interface comes up, VLANs preferred on this interface are blocked on the peer interface and moved to the forwarding state on the interface that has just come up. In this example, if interface Gi2/0/6 comes up, VLANs preferred on this interface are blocked on the peer interface Gi2/0/8 and forwarded on Gi2/0/6.

```
Switch# show interfaces switchport backup
Switch Backup Interface Pairs:
Active Interface      Backup Interface      State
-----
GigabitEthernet2/0/6  GigabitEthernet2/0/8  Active Up/Backup Standby
Vlans Preferred on Active Interface: 1-50
Vlans Preferred on Backup Interface: 60, 100-120
```

```
Switch# show interfaces switchport backup detail
Switch Backup Interface Pairs:
Active Interface      Backup Interface      State
-----
FastEthernet1/0/3     FastEthernet1/0/4    Active Down/Backup Up
Vlans Preferred on Active Interface: 1-2,5-4094
Vlans Preferred on Backup Interface: 3-4
Preemption Mode      : off
Bandwidth : 10000 Kbit (Fa1/0/3), 100000 Kbit (Fa1/0/4)
Mac Address Move Update Vlan : auto
```

## Configuring Multicast Fast Convergence with Flex Links Failover: Examples

These are configuration examples for learning the other Flex Links port as the mrouter port when Flex Links is configured on GigabitEthernet1/0/11 and GigabitEthernet1/0/12, and output for the **show interfaces switchport backup** command:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface GigabitEthernet1/0/11
Switch(config-if)# switchport trunk encapsulation dot1q
Switch(config-if)# switchport mode trunk
Switch(config-if)# switchport backup interface GigabitEthernet1/0/12
Switch(config-if)# exit
Switch(config)# interface GigabitEthernet1/0/12
Switch(config-if)# switchport trunk encapsulation dot1q
Switch(config-if)# switchport mode trunk
Switch(config-if)# end
Switch# show interfaces switchport backup detail
```

```
Switch Backup Interface Pairs:
Active Interface Backup Interface State
GigabitEthernet1/0/11 GigabitEthernet1/0/12 Active Up/Backup Standby
Preemption Mode : off
Multicast Fast Convergence : Off
Bandwidth : 100000 Kbit (Gi1/0/11), 100000 Kbit (Gi1/0/12)
Mac Address Move Update Vlan : auto
```

This output shows a querier for VLANs 1 and 401, with their queries reaching the switch through GigabitEthernet1/0/11:

```
Switch# show ip igmp snooping querier

Vlan   IP Address      IGMP Version   Port
-----
1      1.1.1.1         v2             Gi1/0/11
401    41.41.41.1     v2             Gi1/0/11
```

This example is output for the **show ip igmp snooping mrouter** command for VLANs 1 and 401:

```
Switch# show ip igmp snooping mrouter

Vlan   ports
----   -
1      Gi1/0/11(dynamic), Gi1/0/12(dynamic)
401    Gi1/0/11(dynamic), Gi1/0/12(dynamic)
```

Similarly, both Flex Links ports are part of learned groups. In this example, GigabitEthernet2/0/11 is a receiver/host in VLAN 1, which is interested in two multicast groups:

```
Switch# show ip igmp snooping groups

Vlan   Group      Type   Version   Port List
-----
1      228.1.5.1  igmp   v2        Gi1/0/11, Gi1/0/12, Gi2/0/11
1      228.1.5.2  igmp   v2        Gi1/0/11, Gi1/0/12, Gi2/0/11
```

When a host responds to the general query, the switch forwards this report on all the mrouter ports. In this example, when a host sends a report for the group 228.1.5.1, it is forwarded only on GigabitEthernet1/0/11, because the backup port GigabitEthernet1/0/12 is blocked. When the active link, GigabitEthernet1/0/11, goes down, the backup port, GigabitEthernet1/0/12, begins forwarding.

As soon as this port starts forwarding, the switch sends proxy reports for the groups 228.1.5.1 and 228.1.5.2 on behalf of the host. The upstream router learns the groups and starts forwarding multicast data. This is the default behavior of Flex Links. This behavior changes when the user configures fast convergence using the **switchport backup interface gigabitEthernet 1/0/12 multicast fast-convergence** command. This example shows turning on this feature:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface gigabitEthernet 1/0/11
Switch(config-if)# switchport backup interface gigabitEthernet 1/0/12 multicast
fast-convergence
Switch(config-if)# exit
Switch# show interfaces switchport backup detail

Switch Backup Interface Pairs:
Active      Interface      Backup Interface State
-----
GigabitEthernet1/0/11 GigabitEthernet1/0/12 Active Up/Backup Standby
Preemption Mode : off
Multicast Fast Convergence : On
Bandwidth : 100000 Kbit (Gi1/0/11), 100000 Kbit (Gi1/0/12)
Mac Address Move Update Vlan : auto
```

This output shows a querier for VLAN 1 and 401 with their queries reaching the switch through GigabitEthernet1/0/11:

```
Switch# show ip igmp snooping querier

Vlan    IP Address      IGMP Version    Port
-----
1       1.1.1.1         v2              Gi1/0/11
401     41.41.41.1     v2              Gi1/0/11
```

This is output for the **show ip igmp snooping mrouter** command for VLAN 1 and 401:

```
Switch# show ip igmp snooping mrouter

Vlan    ports
-----
1       Gi1/0/11(dynamic), Gi1/0/12(dynamic)
401     Gi1/0/11(dynamic), Gi1/0/12(dynamic)
```

Similarly, both the Flex Links ports are a part of the learned groups. In this example, GigabitEthernet2/0/11 is a receiver/host in VLAN 1, which is interested in two multicast groups:

```
Switch# show ip igmp snooping groups

Vlan    Group          Type    Version    Port List
-----
1       228.1.5.1     igmp   v2         Gi1/0/11, Gi1/0/12, Gi2/0/11
1       228.1.5.2     igmp   v2         Gi1/0/11, Gi1/0/12, Gi2/0/11
```

Whenever a host responds to the general query, the switch forwards this report on all the mrouter ports. When you turn on this feature through the command-line port, and when a report is forwarded by the switch on GigabitEthernet1/0/11, it is also leaked to the backup port GigabitEthernet1/0/12. The upstream router learns the groups and starts forwarding multicast data, which is dropped at the ingress because GigabitEthernet1/0/12 is blocked. When the active link, GigabitEthernet1/0/11, goes down, the backup port, GigabitEthernet1/0/12, begins forwarding. You do not need to send any proxy reports as the multicast data is already being forwarded by the upstream router. By leaking reports to the backup port, a redundant multicast path has been set up, and the time taken for the multicast traffic convergence is very minimal.

### Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

### Restrictions for Configuring UDLD

The following are restrictions for configuring UniDirectional Link Detection (UDLD):

- A UDLD-capable port cannot detect a unidirectional link if it is connected to a UDLD-incapable port of another switch.
- When configuring the mode (normal or aggressive), make sure that the same mode is configured on both sides of the link.

**Caution**

Loop guard works only on point-to-point links. We recommend that each end of the link has a directly connected device that is running STP.

## Information About UDLD

UniDirectional Link Detection (UDLD) is a Layer 2 protocol that enables devices connected through fiber-optic or twisted-pair Ethernet cables to monitor the physical configuration of the cables and detect when a unidirectional link exists. All connected devices must support UDLD for the protocol to successfully identify and disable unidirectional links. When UDLD detects a unidirectional link, it disables the affected port and alerts you. Unidirectional links can cause a variety of problems, including spanning-tree topology loops.

### Modes of Operation

UDLD supports two modes of operation: normal (the default) and aggressive. In normal mode, UDLD can detect unidirectional links due to misconnected ports on fiber-optic connections. In aggressive mode, UDLD can also detect unidirectional links due to one-way traffic on fiber-optic and twisted-pair links and to misconnected ports on fiber-optic links.

In normal and aggressive modes, UDLD works with the Layer 1 mechanisms to learn the physical status of a link. At Layer 1, autonegotiation takes care of physical signaling and fault detection. UDLD performs tasks that autonegotiation cannot perform, such as detecting the identities of neighbors and shutting down misconnected ports. When you enable both autonegotiation and UDLD, the Layer 1 and Layer 2 detections work together to prevent physical and logical unidirectional connections and the malfunctioning of other protocols.

A unidirectional link occurs whenever traffic sent by a local device is received by its neighbor but traffic from the neighbor is not received by the local device.

### Normal Mode

In normal mode, UDLD detects a unidirectional link when fiber strands in a fiber-optic port are misconnected and the Layer 1 mechanisms do not detect this misconnection. If the ports are connected correctly but the traffic is one way, UDLD does not detect the unidirectional link because the Layer 1 mechanism, which is supposed to detect this condition, does not do so. In this case, the logical link is considered undetermined, and UDLD does not disable the port.

When UDLD is in normal mode, if one of the fiber strands in a pair is disconnected, as long as autonegotiation is active, the link does not stay up because the Layer 1 mechanisms detects a physical problem with the link. In this case, UDLD does not take any action and the logical link is considered undetermined.

#### Related Topics

- [Enabling UDLD Globally \(CLI\), on page 673](#)
- [Enabling UDLD on an Interface \(CLI\), on page 674](#)

### Aggressive Mode

In aggressive mode, UDLD detects a unidirectional link by using the previous detection methods. UDLD in aggressive mode can also detect a unidirectional link on a point-to-point link on which no failure between the two devices is allowed. It can also detect a unidirectional link when one of these problems exists:

- On fiber-optic or twisted-pair links, one of the ports cannot send or receive traffic.
- On fiber-optic or twisted-pair links, one of the ports is down while the other is up.

- One of the fiber strands in the cable is disconnected.

In these cases, UDLD disables the affected port.

In a point-to-point link, UDLD hello packets can be considered as a heart beat whose presence guarantees the health of the link. Conversely, the loss of the heart beat means that the link must be shut down if it is not possible to reestablish a bidirectional link.

If both fiber strands in a cable are working normally from a Layer 1 perspective, UDLD in aggressive mode detects whether those fiber strands are connected correctly and whether traffic is flowing bidirectionally between the correct neighbors. This check cannot be performed by autonegotiation because autonegotiation operates at Layer 1.

### Related Topics

[Enabling UDLD Globally \(CLI\), on page 673](#)

[Enabling UDLD on an Interface \(CLI\), on page 674](#)

## Methods to Detect Unidirectional Links

UDLD operates by using two methods:

- Neighbor database maintenance
- Event-driven detection and echoing

### Related Topics

[Enabling UDLD Globally \(CLI\), on page 673](#)

[Enabling UDLD on an Interface \(CLI\), on page 674](#)

## Neighbor Database Maintenance

UDLD learns about other UDLD-capable neighbors by periodically sending a hello packet (also called an advertisement or probe) on every active port to keep each device informed about its neighbors.

When the switch receives a hello message, it caches the information until the age time (hold time or time-to-live) expires. If the switch receives a new hello message before an older cache entry ages, the switch replaces the older entry with the new one.

Whenever a port is disabled and UDLD is running, whenever UDLD is disabled on a port, or whenever the switch is reset, UDLD clears all existing cache entries for the ports affected by the configuration change. UDLD sends at least one message to inform the neighbors to flush the part of their caches affected by the status change. The message is intended to keep the caches synchronized.

## Event-Driven Detection and Echoing

UDLD relies on echoing as its detection operation. Whenever a UDLD device learns about a new neighbor or receives a resynchronization request from an out-of-sync neighbor, it restarts the detection window on its side of the connection and sends echo messages in reply. Because this behavior is the same on all UDLD neighbors, the sender of the echoes expects to receive an echo in reply.

If the detection window ends and no valid reply message is received, the link might shut down, depending on the UDLD mode. When UDLD is in normal mode, the link might be considered undetermined and might not be shut down. When UDLD is in aggressive mode, the link is considered unidirectional, and the port is disabled.

**UDLD Reset Options**

If an interface becomes disabled by UDLD, you can use one of the following options to reset UDLD:

- The **udld reset** interface configuration command.
- The **shutdown** interface configuration command followed by the **no shutdown** interface configuration command restarts the disabled port.
- The **no udld {aggressive | enable}** global configuration command followed by the **udld {aggressive | enable}** global configuration command reenables the disabled ports.
- The **no udld port** interface configuration command followed by the **udld port [aggressive]** interface configuration command reenables the disabled fiber-optic port.
- The **errdisable recovery cause udld** global configuration command enables the timer to automatically recover from the UDLD error-disabled state, and the **errdisable recovery interval *interval*** global configuration command specifies the time to recover from the UDLD error-disabled state.

# How to Configure UDLD

## Enabling UDLD Globally (CLI)

Follow these steps to enable UDLD in the aggressive or normal mode and to set the configurable message timer on all fiber-optic ports on the switch.

### SUMMARY STEPS

1. **configure terminal**
2. **udld {aggressive | enable | message time *message-timer-interval*}**
3. **end**

### DETAILED STEPS

|        | Command or Action                                                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                                                                                 | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Step 2 | <b>udld {aggressive   enable   message time <i>message-timer-interval</i>}</b><br><br><b>Example:</b><br>Switch(config)# <b>udld enable</b><br><b>message time 10</b> | Specifies the UDLD mode of operation: <ul style="list-style-type: none"> <li>• <b>aggressive</b>—Enables UDLD in aggressive mode on all fiber-optic ports.</li> <li>• <b>enable</b>—Enables UDLD in normal mode on all fiber-optic ports on the switch. UDLD is disabled by default.<br/>An individual interface configuration overrides the setting of the <b>udld enable</b> global configuration command.</li> <li>• <b>message time <i>message-timer-interval</i></b>—Configures the period of time between UDLD probe messages on ports that are in the advertisement phase and are detected to be bidirectional. The range is from 1 to 90 seconds; the default value is 15.</li> </ul> <p><b>Note</b> This command affects fiber-optic ports only. Use the <b>udld</b> interface configuration command to enable UDLD on other port types.</p> <p>Use the <b>no</b> form of this command, to disable UDLD.</p> |
| Step 3 | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b>                                                                                                       | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

- [Configuration Examples for Configuring the Switch for Access Point Discovery, page 686](#)

### Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

### Prerequisites for Configuring the Switch for Access Point Discovery

- Ensure that the Control and Provisioning of Wireless Access Points (CAPWAP) UDP ports 5246 and 5247 (similar to the Lightweight Access Point Protocol (LWAPP) UDP ports 12222 and 12223) are enabled and are not blocked by an intermediate device that could prevent an access point from joining the switch.
- If access control lists (ACLs) are in the control path between the switch and its access points, you must open new protocol ports to prevent access points from being stranded.
- If an access point is in the UP state and its IP address changes, the access point tears down the existing CAPWAP tunnel and rejoins the switch.

- Access points must be discovered by a switch before they can become an active part of the network. The lightweight access points support the following switch discovery processes:
  - Layer 3 CAPWAP discovery—You can enable this feature on different subnets from the access point. This feature uses IP addresses and UDP packets rather than the MAC addresses used by Layer 2 discovery.
  - Locally stored switch IP address discovery—If the access point was previously associated to a switch, the IP addresses of the primary, secondary, and tertiary switches are stored in the access point's nonvolatile memory. This process of storing switch IP addresses on an access point for later deployment is called *priming the access point*.
  - DHCP server discovery—This feature uses DHCP option 43 to provide switch IP addresses to the access points. Cisco switches support a DHCP server option that is typically used for this capability.
  - DNS discovery—The access point can discover switches through your domain name server (DNS). You must configure your DNS to return switch IP addresses in response to `CISCO-CAPWAP-CONTROLLER.localdomain`, where *localdomain* is the access point domain name. When an access point receives an IP address and DNS information from a DHCP server, it contacts the DNS to resolve `CISCO-CAPWAP-CONTROLLER.localdomain`. When the DNS sends a list of switch IP addresses, the access point sends discovery requests to the switches.

## Restrictions for Configuring the Switch for Access Point Discovery

- Ensure that the switches are configured with the correct date and time. If the date and time configured on the switch precedes the creation and installation date of certificates on the access points, the access point fails to join the switch.
- During the discovery process, access points that are supported by the Cisco switch, such as the 1140, 1260, 3500, 1040, 1600, 2600, or 3600 query only for Cisco switches.

## Information About Configuring the Switch for Access Point Discovery

In a CAPWAP environment, a lightweight access point discovers a switch by using CAPWAP discovery mechanisms and then sends a CAPWAP join request to the switch. The switch sends a CAPWAP join response to the access point that allows the access point to join the switch. When the access point joins the switch, the switch manages its configuration, firmware, control transactions, and data transactions.

### Access Point Communication Protocols

Cisco lightweight access points use the IETF standard CAPWAP to communicate with the switch and other lightweight access points on the network.

CAPWAP, which is based on LWAPP, is a standard, interoperable protocol that enables a switch to manage a collection of wireless access points. CAPWAP is implemented in switch for these reasons:

- To provide an upgrade path from Cisco products that use LWAPP to next-generation Cisco products that use CAPWAP
- To manage RFID readers and similar devices

- To enable switches to interoperate with third-party access points in the future

## Viewing Access Point Join Information

Join statistics for an access point that sends a CAPWAP discovery request to the switch at least once are maintained on the switch even if the access point is rebooted or disconnected. These statistics are removed only when the switch is rebooted or when you choose to clear the statistics.

## Troubleshooting the Access Point Join Process

Access points can fail to join a switch for many reasons such as a RADIUS authorization is pending, self-signed certificates are not enabled on the switch, the access point and switch's regulatory domains do not match, and so on.

You can configure the access points to send all CAPWAP-related errors to a syslog server. You do not need to enable any debug commands on the switch because all of the CAPWAP error messages can be viewed from the syslog server itself.

The state of the access point is not maintained on the switch until it receives a CAPWAP join request from the access point, so it can be difficult to determine why the CAPWAP discovery request from a certain access point was rejected. In order to troubleshoot such joining issues without enabling CAPWAP debug commands on the switch, the switch collects information for all access points that send a discovery message to this switch and maintains information for any access points that have successfully joined this switch.

The switch collects all join-related information for each access point that sends a CAPWAP discovery request to the switch. Collection begins when the first discovery message is received from the access point and ends when the last configuration payload is sent from the switch to the access point.

When the switch is maintaining join-related information for the maximum number of access points, it does not collect information for any more access points.

You can also configure a DHCP server to return a syslog server IP address to the access point using option 7 on the server. The access point then starts sending all syslog messages to this IP address.

You can configure the syslog server IP address through the access point CLI, if the access point is not connected to the switch by entering the **capwap ap log-server *syslog\_server\_IP\_address*** command.

When the access point joins a switch for the first time, the switch pushes the global syslog server IP address (the default is 255.255.255.255) to the access point. After that, the access point sends all syslog messages to this IP address, until it is overridden by one of the following scenarios:

- The access point is still connected to the same switch, and you changed the global syslog server IP address configuration on the switch by using the **ap syslog host *Syslog\_Server\_IP\_Address*** command. In this case, the switch pushes the new global syslog server IP address to the access point.
- The access point is still connected to the same switch, and you configured a specific syslog server IP address for the access point on the switch by using the **ap name *Cisco\_AP* syslog host *Syslog\_Host\_IP\_Address*** command. In this case, the switch pushes the new specific syslog server IP address to the access point.
- The access point gets disconnected from the switch, and you configured the syslog server IP address from the access point CLI by using the **capwap ap log-server *syslog\_server\_IP\_address*** command. This command works only if the access point is not connected to any switch.
- The access point gets disconnected from the switch and joins another switch. In this case, the new switch pushes its global syslog server IP address to the access point.

Whenever a new syslog server IP address overrides the existing syslog server IP address, the old address is erased from persistent storage, and the new address is stored in its place. The access point also starts sending all syslog messages to the new IP address, if the access point can reach the syslog server IP address.

## How to Configure Access Point Discovery

### Configuring the Syslog Server for Access Points (GUI)

- 
- Step 1** Choose **Configuration > Wireless > Access Points > All APs**.  
The **All APs** page is displayed showing a list of access points that are associated with the switch and their current settings.
- Step 2** From the **Show** drop-down list, choose **Quick Filter**.  
The filter options (text boxes) appear in each of the column header in the table.
- Step 3** Enter a keyword in the corresponding text boxes to specify the filter criteria based on which you want to search, and click the **Filter** icon.
- 

### Configuring the Syslog Server for Access Points (CLI)

#### SUMMARY STEPS

1. `show ap config global`
2. `show ap name Cisco_AP config general`

#### DETAILED STEPS

|               | Command or Action                                                                                                    | Purpose                                                                                |
|---------------|----------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| <b>Step 1</b> | <code>show ap config global</code><br><br><b>Example:</b><br>Switch# show ap config global                           | Displays the global syslog server settings for all access points that join the switch. |
| <b>Step 2</b> | <code>show ap name Cisco_AP config general</code><br><br><b>Example:</b><br>Switch# show ap name AP03 config general | Displays the syslog server settings for a specific access point.                       |

## Monitoring Access Point Join Information (CLI)

**Note** The procedure to perform this task using the switch GUI is not currently available.

### SUMMARY STEPS

1. **enable**
2. **show ap join stats summary**
3. **show ap mac-address *mac\_address* join stats summary**
4. **show ap mac-address *mac\_address* join stats detailed**
5. **clear ap join statistics**

### DETAILED STEPS

|               | Command or Action                                                                                                                                            | Purpose                                                                                                                                                                                                                    |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><br><b>Example:</b><br>Switch# enable                                                                                                       | Enters privileged EXEC mode.                                                                                                                                                                                               |
| <b>Step 2</b> | <b>show ap join stats summary</b><br><br><b>Example:</b><br>Switch# show ap join stats summary                                                               | Displays the MAC addresses of all the access points that are joined to the switch or that have tried to join.                                                                                                              |
| <b>Step 3</b> | <b>show ap mac-address <i>mac_address</i> join stats summary</b><br><br><b>Example:</b><br>Switch# show ap mac-address<br>000.2000.0400 join stats summary   | Displays all the statistics for the AP including the last join error detail.                                                                                                                                               |
| <b>Step 4</b> | <b>show ap mac-address <i>mac_address</i> join stats detailed</b><br><br><b>Example:</b><br>Switch# show ap mac-address<br>000.2000.0400 join stats detailed | Displays all join-related statistics collected for a specific access point.                                                                                                                                                |
| <b>Step 5</b> | <b>clear ap join statistics</b><br><br><b>Example:</b><br>Switch# clear ap join statistics                                                                   | Clears the join statistics for all access points.<br><b>Note</b> To clear the join statistics that correspond to specific access points, enter the <b>clear ap mac-address <i>mac_address</i> join statistics</b> command. |

## Searching for Access Point Radios (GUI)

- 
- Step 1** Choose **Monitor > Wireless > Access Points** and click **802.11a/n/ac Statistics** or **802.11b/g/n Statistics**.  
The 802.11 Radio pages are displayed. These pages show all of the 802.11a/n/ac or 802.11b/g/n access point radios that are associated with the switch and their current settings.
- Note** In a Cisco converged access environment, the 802.11a/n/ac and 802.11b/g/n radios should not be differentiated based on their Base Radio MAC addresses, because they might have the same addresses. Instead, the radios should be differentiated based on their physical addresses.
- Step 2** From the **Show** drop-down list, choose **Quick Filter**.  
The filter options (text boxes) appear in each of the column header in the table.
- Step 3** Enter a keyword in the corresponding text boxes to specify the filter criteria based on which you want to search, and click the **Filter** icon.
- 

## Monitoring the Interface Details (GUI)

- 
- Step 1** Choose **Configuration > Wireless > Access Points > All APs**.  
The **All APs** page is displayed showing a list of access points that are associated with the switch.
- Step 2** Click the access point name.  
The **AP > Edit** page is displayed.
- Step 3** Click the **Interface** tab.  
The interface details are displayed.
- 

# Configuration Examples for Configuring the Switch for Access Point Discovery

## Displaying the MAC Addresses of all Access Points: Example

This example shows how to display MAC addresses of all the access points that are joined to the switch:

```
Switch# show ap join stats summary
Number of APs..... 4

Base Mac           EthernetMac       AP Name IP Address      Status
-----
00:0b:85:57:bc:c0 00:0b:85:57:bc:c0 AP1130 10.10.163.217   Joined
00:1c:0f:81:db:80 00:1c:63:23:ac:a0 AP1140 10.10.163.216   Not joined
00:1c:0f:81:fc:20 00:1b:d5:9f:7d:b2 AP1     10.10.163.215   Joined
00:21:1b:ea:36:60 00:0c:d4:8a:6b:c1 AP2     10.10.163.214   Not joined
```

This example shows how to display the last join error details for a specific access point:

```
Switch# show ap mac-address 000.2000.0400 join stats summary
Is the AP currently connected to controller..... Yes
Time at which the AP joined this
controller last time..... Aug 21 12:50:36.061
Type of error
that occurred last..... AP got or has been disconnected
Reason for error
that occurred last..... The AP has been reset by the controller
Time at which the last join error occurred..... Aug 21 12:50:34.374
```

This example shows how to display all join-related statistics collected for a specific access point:

```
Switch# show ap mac-address 000.2000.0400 join stats detailed
Discovery phase statistics
- Discovery requests received..... 2
- Successful discovery responses sent..... 2
- Unsuccessful discovery request processing..... 0
- Reason for last unsuccessful discovery attempt..... Not applicable
- Time at last successful discovery attempt..... Aug 21 12:50:23.335
- Time at last unsuccessful discovery attempt..... Not applicable

Join phase statistics
- Join requests received..... 1
- Successful join responses sent..... 1
- Unsuccessful join request processing..... 1
- Reason for last unsuccessful join attempt..... RADIUS authorization
is pending
for the AP
- Time at last successful join attempt..... Aug 21 12:50:34.481
- Time at last unsuccessful join attempt..... Aug 21 12:50:34.374

Configuration phase statistics
- Configuration requests received..... 1
- Successful configuration responses sent..... 1
- Unsuccessful configuration request processing..... 0
- Reason for last unsuccessful configuration attempt.. Not applicable
- Time at last successful configuration attempt..... Aug 21 12:50:34.374
- Time at last unsuccessful configuration attempt..... Not applicable

Last AP message decryption failure details
- Reason for last message decryption failure..... Not applicable

Last AP disconnect details
- Reason for last AP connection failure..... The AP has been reset by
the controller

Last join error summary
- Type of error that occurred last..... AP got or has been
disconnected
- Reason for error that occurred last..... The AP has been reset
by the controller
- Time at which the last join error occurred..... Aug 21 12:50:34.374
```

## DHCP Option 43 for Lightweight Cisco Aironet Access Points Configuration Example

For more information about the AP join process, see *DHCP OPTION 43 for Lightweight Cisco Aironet Access Points Configuration Example* at [http://www.cisco.com/en/US/tech/tk722/tk809/technologies\\_configuration\\_example09186a00808714fe.shtml](http://www.cisco.com/en/US/tech/tk722/tk809/technologies_configuration_example09186a00808714fe.shtml).

## Configuring Data Encryption

- [Finding Feature Information, page 689](#)
- [Prerequisites for Configuring Data Encryption, page 689](#)
- [Restrictions for Configuring Data Encryption, page 689](#)
- [Information About Data Encryption, page 690](#)
- [How to Configure Data Encryption, page 690](#)
- [Configuration Examples for Configuring Data Encryption, page 691](#)

### Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

### Prerequisites for Configuring Data Encryption

- Cisco 1260, 3500, 3600, 801, 1140, 1310, and 1520 series access points support Datagram Transport Layer Security (DTLS) data encryption.
- You can use the switch to enable or disable DTLS data encryption for a specific access point or for all access points.
- Non-Russian customers who use the Cisco switch do not need a data DTLS license.

### Restrictions for Configuring Data Encryption

- Encryption limits throughput at both the switch and the access point, and maximum throughput is desired for most enterprise networks.

- If your switch does not have a data DTLS license and if the access point associated with the switch has DTLS enabled, the data path will be unencrypted.
- In images that do not have a DTLS license, the DTLS commands are not available.

## Information About Data Encryption

The switch enables you to encrypt Control and Provisioning of Wireless Access Points (CAPWAP) control packets (and optionally, CAPWAP data packets) that are sent between the access point and the switch using DTLS. DTLS is a standards-track Internet Engineering Task Force (IETF) protocol based on TLS. CAPWAP control packets are management packets exchanged between a switch and an access point while CAPWAP data packets encapsulate forwarded wireless frames. CAPWAP control and data packets are sent over separate UDP ports: 5246 (control) and 5247 (data). If an access point does not support DTLS data encryption, DTLS is enabled only for the control plane, and a DTLS session for the data plane is not established.

## How to Configure Data Encryption

### Configuring Data Encryption (CLI)

#### SUMMARY STEPS

1. **configure terminal**
2. **ap link-encryption**
3. **end**
4. **show ap link-encryption**
5. **show wireless dtls connections**

#### DETAILED STEPS

|               | Command or Action                                                                             | Purpose                                                                                                                                                                                                                     |
|---------------|-----------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>         | Enters global configuration mode.                                                                                                                                                                                           |
| <b>Step 2</b> | <b>ap link-encryption</b><br><br><b>Example:</b><br>Switch(config)# <b>ap link-encryption</b> | Enables data encryption for all access points or a specific access point by entering this command. The default value is disabled.<br><br>Changing the data encryption mode requires the access points to rejoin the switch. |
| <b>Step 3</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b>                               | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode.                                                                                                         |

|               | Command or Action                                                                                      | Purpose                                                                                                                                                                                                                                                                                          |
|---------------|--------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 4</b> | <b>show ap link-encryption</b><br><br><b>Example:</b><br>Switch# show ap link-encryption               | Displays the encryption state of all access points or a specific access point. This command also shows authentication errors, which track the number of integrity check failures and replay errors. Relay errors help in tracking the number of times the access point receives the same packet. |
| <b>Step 5</b> | <b>show wireless dtls connections</b><br><br><b>Example:</b><br>Switch# show wireless dtls connections | Displays a summary of all active DTLS connections.<br><br><b>Note</b> If you experience any problems with DTLS data encryption, enter the <b>debug dtls ap {all   event   trace}</b> command to debug all DTLS messages, events, or traces.                                                      |

## Configuring Data Encryption (GUI)

- 
- Step 1** Choose **Configuration > Wireless > Access Points > All APs**.  
The All APs page is displayed.
  - Step 2** Click the name of the access point for which you want to enable data encryption.  
The **AP > Edit** page is displayed.
  - Step 3** Click the **Advanced** tab.
  - Step 4** Select or unselect the **Data Encryption** check box.  
**Note** Changing the data encryption mode requires the access points to reassociate with the switch.
  - Step 5** Click **Apply**.
  - Step 6** Click **Save Configuration**.
- 

## Configuration Examples for Configuring Data Encryption

### Displaying Data Encryption States for all Access Points: Examples

This example shows how to display the encryption state of all access points or a specific access point. This command also shows authentication errors, which track the number of integrity check failures and replay errors. Relay errors help in tracking the number of times the access point receives the same packet:

```
Switch# show ap link-encryption
      Encryption  Dnstream  Upstream  Last
AP Name         State      Count     Count     Update
-----
3602a           Enabled    0         0         Never
```

This example shows how to display a summary of all active DTLS connections:

```
Switch# show wireless dtls connections
AP Name          Local Port  Peer IP      Peer Port  Ciphersuite
-----
3602a            Capwap_Ctrl 10.10.21.213 46075      TLS_RSA_WITH_AES_128_CBC_SHA
3602a            Capwap_Data 10.10.21.213 46075      TLS_RSA_WITH_AES_128_CBC_SHA
```

## Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for Configuring the Access Point Retransmission Interval and Retry Count

- You can configure the retransmission intervals and retry count both at a global and a specific access point level. A global configuration applies these configuration parameters to all the access points. Alternatively, when you configure the retransmission level and retry count at a specific access point level, the values are applied to that particular access point. The access point specific configuration has a higher precedence than the global configuration.

## Information About Retransmission Interval and Retry Count

The switch and the access points exchange packets using the Control and Provisioning of Wireless Access Points (CAPWAP) reliable transport protocol. For each request, a response is defined. This response is used to acknowledge the receipt of the request message. Response messages are not explicitly acknowledged; therefore, if a response message is not received, the original request message is retransmitted after the retransmit interval. If the request is not acknowledged after a maximum number of retransmissions, the session is closed and the access points reassociate with another switch.

## How to Configure Access Point Retransmission Interval and Retry Count

### Configuring the Access Point Retransmission Interval and Retry Count (CLI)

#### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ap capwap retransmit interval** *interval\_time*
4. **ap capwap retransmit count** *count\_value*
5. **end**
6. **ap name** *Cisco\_AP* **capwap retransmit interval** *interval\_time*
7. **ap name** *Cisco\_AP* **capwap retransmit count** *count\_value*
8. **show ap capwap retransmit**

#### DETAILED STEPS

|               | Command or Action                                                                                                                          | Purpose                                                                                                                                                   |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><br><b>Example:</b><br>Switch# <b>enable</b>                                                                              | Enters privileged EXEC mode.                                                                                                                              |
| <b>Step 2</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                                                      | Enters global configuration mode.                                                                                                                         |
| <b>Step 3</b> | <b>ap capwap retransmit interval</b> <i>interval_time</i><br><br><b>Example:</b><br>Switch(config)# <b>ap capwap retransmit interval</b> 2 | Configures the control packet retransmit interval for all access points globally.<br><br><b>Note</b> The range for the interval parameter is from 2 to 5. |

|               | Command or Action                                                                                                                                                 | Purpose                                                                                                                                                                                                                                                  |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 4</b> | <b>ap capwap retransmit count</b> <i>count_value</i><br><br><b>Example:</b><br>Switch(config)# ap capwap retransmit count 3                                       | Configures the control packet retry count for all access points globally.<br><br><b>Note</b> The range for the count is from 3 to 8.                                                                                                                     |
| <b>Step 5</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config)# end                                                                                                          | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode.                                                                                                                                      |
| <b>Step 6</b> | <b>ap name</b> <i>Cisco_AP</i> <b>capwap retransmit interval</b> <i>interval_time</i><br><br><b>Example:</b><br>Switch# ap name AP02 capwap retransmit interval 2 | Configures the control packet retransmit interval for the individual access point that you specify.<br><br><b>Note</b> The range for the interval is from 2 to 5.<br><b>Note</b> You must be in privileged EXEC mode to use the <b>ap name</b> commands. |
| <b>Step 7</b> | <b>ap name</b> <i>Cisco_AP</i> <b>capwap retransmit count</b> <i>count_value</i><br><br><b>Example:</b><br>Switch# ap name AP02 capwap retransmit count 3         | Configures the control packet retry count for the individual access point that you specify.<br><br><b>Note</b> The range for the retry count is from 3 to 8.                                                                                             |
| <b>Step 8</b> | <b>show ap capwap retransmit</b><br><br><b>Example:</b><br>Switch# show ap capwap retransmit                                                                      | Displays the CAPWAP retransmit details.                                                                                                                                                                                                                  |

## Configuring the Access Point Retransmission Interval and Retry Count (GUI)

- Global configuration applicable to all APs:
  - a) Choose **Configuration > Wireless > Access Points > Global AP Configuration**. The **Global Configuration** page is displayed.
  - b) In the **AP Retransmit Config Parameters** area, enter the values for the following parameters:
    - **AP Retransmit Count**—Number of times you want the access point to retransmit the request to the switch. The valid range is between 3 and 8.
    - **AP Retransmit Interval**—Duration between the retransmission of requests. The valid range is between 2 and 5.
  - c) Click **Apply**.
  - d) Click **Save Configuration**.
- Configuration that is applicable to a specific AP:
  - a) Choose **Configuration > Wireless > Access Points > All APs**.

The **All APs** page is displayed with a list of access points.

- b) Click the access point name.  
The **AP > Edit** page is displayed.
- c) Click the **Advanced** tab.
- d) In the **AP Retransmit Config Parameters** area, enter the values for the following **AP Retransmit Count** and **AP Retransmit Interval** parameters:
  - **AP Retransmit Count**—Number of times you want the access point to retransmit the request to the switch. The valid range is between 3 and 8.
  - **AP Retransmit Interval**—Duration between the retransmission of requests. The valid range is between 2 and 5.
- e) Click **Apply**.
- f) Click **Save Configuration**.

## Viewing CAPWAP Maximum Transmission Unit Information (CLI)

### SUMMARY STEPS

1. `enable`
2. `show ap name Cisco_AP config general`

### DETAILED STEPS

|               | Command or Action                                                                                                                                     | Purpose                                                                                                                                                        |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <code>enable</code><br><br><b>Example:</b><br><code>Switch# enable</code>                                                                             | Enters privileged EXEC mode.                                                                                                                                   |
| <b>Step 2</b> | <code>show ap name Cisco_AP config general</code><br><br><b>Example:</b><br><code>Switch# show ap name Maria-1250 config general   include MTU</code> | Displays the maximum transmission unit (MTU) for the CAPWAP path on the switch. The MTU specifies the maximum size of any packet (in bytes) in a transmission. |

## Viewing CAPWAP Maximum Transmission Unit Information (GUI)

- 
- Step 1** Choose **Configuration > Wireless > Access Points > All APs**.

The **All APs** page is displayed.

**Step 2** Click the AP name.  
The **AP > Edit** page is displayed.

**Step 3** Click the **Advanced** tab.  
The **CAPWAP MTU** field shows the CAPWAP maximum retransmission unit information.

## Configuration Examples for Configuring Access Point Retransmission Interval and Retry Count

### Viewing the CAPWAP Retransmission Details: Example

Enter the following command:

```
Switch# show ap capwap retransmit
Global control packet retransmit interval : 3
Global control packet retransmit count : 5
```

| AP Name | Retransmit Interval | Retransmit Count |
|---------|---------------------|------------------|
| 3602a   | 5                   | 3                |

### Viewing Maximum Transmission Unit Information: Example

This example shows how to view the maximum transmission unit (MTU) for the CAPWAP path on the switch. The MTU specifies the maximum size of any packet (in bytes) in a transmission:

```
Switch# show ap name cisco-ap-name config general | include MTU
CAPWAP Path MTU..... 1500
```

# CHAPTER 37

## Configuring Adaptive Wireless Intrusion Prevention System

---

- [Finding Feature Information, page 699](#)
- [Prerequisites for Configuring wIPS, page 699](#)
- [How to Configure wIPS on Access Points, page 700](#)
- [Monitoring wIPS Information, page 702](#)
- [Configuration Examples for Configuring wIPS on Access Points, page 703](#)

### Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

### Prerequisites for Configuring wIPS

- The regular local mode access point has been extended with a subset of Wireless Intrusion Prevention System (wIPS) capabilities. This feature enables you to deploy your access points to provide protection without needing a separate overlay network.

# How to Configure WIPS on Access Points

## Configuring WIPS on an Access Point (CLI)

### SUMMARY STEPS

1. **ap name *Cisco\_AP* mode local**
2. **ap name *Cisco\_AP* dot11 5ghz shutdown**
3. **ap name *Cisco\_AP* dot11 24ghz shutdown**
4. **ap name *Cisco\_AP* mode monitor submode wips**
5. **ap name *Cisco\_AP* monitor-mode wips-optimized**
6. **show ap dot11 24ghz monitor**
7. **ap name *Cisco\_AP* no dot11 5ghz shutdown**
8. **ap name *Cisco\_AP* no dot11 24ghz shutdown**

### DETAILED STEPS

|               | Command or Action                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                      |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>ap name <i>Cisco_AP</i> mode local</b><br><br><b>Example:</b><br>Switch# ap name AP01 mode local                                  | Configures an access point for monitor mode.<br><br>A message appears that indicates that changing the AP's mode causes the access point to reboot. This message also displays a prompt that enables you to specify whether or not you want to continue with changing the AP mode. Enter <b>y</b> at the prompt to continue. |
| <b>Step 2</b> | <b>ap name <i>Cisco_AP</i> dot11 5ghz shutdown</b><br><br><b>Example:</b><br>Switch# ap name AP01 dot11 5ghz shutdown                | Disables the 802.11a radio on the access point.                                                                                                                                                                                                                                                                              |
| <b>Step 3</b> | <b>ap name <i>Cisco_AP</i> dot11 24ghz shutdown</b><br><br><b>Example:</b><br>Switch# ap name AP02 dot11 24ghz shutdown              | Disables the 802.11b radio on the access point.                                                                                                                                                                                                                                                                              |
| <b>Step 4</b> | <b>ap name <i>Cisco_AP</i> mode monitor submode wips</b><br><br><b>Example:</b><br>Switch# ap name AP01 mode monitor<br>submode wips | Configures the WIPS submode on the access point.<br><br><b>Note</b> To disable WIPS on the access point, enter the <b>ap name <i>Cisco_AP</i> modemonitor submode none</b> command.                                                                                                                                          |
| <b>Step 5</b> | <b>ap name <i>Cisco_AP</i> monitor-mode wips-optimized</b>                                                                           | Enables WIPS optimized channel scanning for the access point.<br><br>The access point scans each channel for 250 milliseconds. It derives the list of channels to be scanned from the monitor configuration. You can choose the following options:                                                                           |

|               | Command or Action                                                                                                                 | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | <b>Example:</b><br><pre>Switch# ap name AP01 monitor-mode wips-optimized</pre>                                                    | <ul style="list-style-type: none"> <li>• <b>All</b>—All channels supported by the access point's radio.</li> <li>• <b>Country</b>—Only the channels supported by the access point's country of operation.</li> <li>• <b>DCA</b>—Only the channel set used by the dynamic channel assignment (DCA) algorithm, which by default includes all of the nonoverlapping channels allowed in the access point's country of operation.</li> </ul> |
| <b>Step 6</b> | <b>show ap dot11 24ghz monitor</b><br><br><b>Example:</b><br><pre>Switch# show ap dot11 24ghz monitor</pre>                       | Displays the monitor configuration channel set.<br><br><b>Note</b> The 802.11b Monitor Channels value in the output of the command indicates the monitor configuration channel set.                                                                                                                                                                                                                                                      |
| <b>Step 7</b> | <b>ap name Cisco_AP no dot11 5ghz shutdown</b><br><br><b>Example:</b><br><pre>Switch# ap name AP01 no dot11 5ghz shutdown</pre>   | Enables the 802.11a radio on the access point.                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Step 8</b> | <b>ap name Cisco_AP no dot11 24ghz shutdown</b><br><br><b>Example:</b><br><pre>Switch# ap name AP01 no dot11 24ghz shutdown</pre> | Enables the 802.11b radio on the access point.                                                                                                                                                                                                                                                                                                                                                                                           |

## Configuring WIPS on an Access Point (GUI)

- 
- Step 1** Choose **Configuration > Wireless > Access Points > All APs**.  
The **All APs** page is displayed.
- Step 2** Click the access point name.  
The **AP > Edit** page is displayed.
- Step 3** From the **AP Mode** drop-down list, choose one of the following options to configure the AP mode parameters:
- **Local**
  - **Monitor**
- Step 4** From the **AP Sub Mode** drop-down list, choose **WIPS**.
- Step 5** Click **Apply**.
- Step 6** Click **Save Configuration**.
-

## Monitoring WIPS Information

**Note**

The procedure to perform this task using the switch GUI is not currently available.

### SUMMARY STEPS

1. **show ap name *Cisco\_AP* config general**
2. **show ap monitor-mode summary**
3. **show wireless wps wips summary**
4. **show wireless wps wips statistics**
5. **clear wireless wips statistics**

### DETAILED STEPS

|               | Command or Action                                                                                                     | Purpose                                                                         |
|---------------|-----------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>show ap name <i>Cisco_AP</i> config general</b><br><br><b>Example:</b><br>Switch# show ap name AP01 config general | Displays information on the WIPS submode on the access point.                   |
| <b>Step 2</b> | <b>show ap monitor-mode summary</b><br><br><b>Example:</b><br>Switch# show ap monitor-mode summary                    | Displays the WIPS optimized channel scanning configuration on the access point. |
| <b>Step 3</b> | <b>show wireless wps wips summary</b><br><br><b>Example:</b><br>Switch# show wireless wps wips summary                | Displays the WIPS configuration forwarded by NCS or Prime to the switch.        |

| <b>Step 5</b> | <b>clear wireless wips statistics</b><br><br><b>Example:</b><br>Switch# clear wireless wips statistics                | Clears the WIPS statistics on the switch.                                       |

# Configuration Examples for Configuring wIPS on Access Points

## Displaying the Monitor Configuration Channel Set: Example

This example shows how to display the monitor configuration channel set:

```
Switch# show ap dot11 24ghz monitor
Default 802.11b AP monitoring
802.11b Monitor Mode..... enable
802.11b Monitor Channels..... Country channels
802.11b AP Coverage Interval..... 180 seconds
802.11b AP Load Interval..... 60 seconds
802.11b AP Noise Interval..... 180 seconds
802.11b AP Signal Strength Interval..... 60 seconds
```

## Displaying wIPS Information: Examples

This example shows how to display information on the wIPS submode on the access point:

```
Switch# show ap name AP01 config general
Cisco AP Identifier..... 3
Cisco AP Name..... AP1131:46f2.98ac
...
AP Mode ..... Monitor
Public Safety ..... Disabled Disabled
AP SubMode ..... WIPS
```

This example shows how to display the wIPS optimized channel scanning configuration on the access point:

```
Switch# show ap monitor-mode summary
AP Name      Ethernet MAC   Status      Scanning
              Channel
              List
-----
AP1131:4f2.9a 00:16:4:f2:9:a WIPS        1,6,NA,NA
```

This example shows how to display the wIPS configuration forwarded by WCS to the switch:

```
Switch# show wireless wps wips summary
Policy Name..... Default
Policy Version..... 3
```

This example shows how to display the current state of wIPS operation on the switch:

```
Switch# show wireless wps wips statistics
Policy Assignment Requests..... 1
Policy Assignment Responses..... 1
Policy Update Requests..... 0
Policy Update Responses..... 0
Policy Delete Requests..... 0
Policy Delete Responses..... 0
Alarm Updates..... 13572
Device Updates..... 8376
Device Update Requests..... 0
Device Update Responses..... 0
Forensic Updates..... 1001
Invalid WIPS Payloads..... 0
Invalid Messages Received..... 0
CAPWAP Enqueue Failed..... 0
NMSP Enqueue Failed..... 0
NMSP Transmitted Packets..... 22950
NMSP Transmit Packets Dropped..... 0
NMSP Largest Packet..... 1377
```

## Configuring Authentication for Access Points

### Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

### Prerequisites for Configuring Authentication for Access Points

- You can set a global username, password, and enable password for all access points that are currently joined to the switch and any that join in the future inherit as they join the switch. If desired, you can override the global credentials and assign a unique username, password, and enable password for a specific access point.
- After an access point joins the switch, the access point enables console port security, and you are prompted for your username and password whenever you log into the access point's console port. When you log in, you are in nonprivileged mode, and you must enter the enable password in order to use the privileged mode.
- The global credentials that you configure on the switch are retained across switch and access point reboots. They are overwritten only if the access point joins a new switch that is configured with a global

username and password. If the new switch is not configured with global credentials, the access point retains the global username and password configured for the first switch.

- You must track the credentials used by the access points. Otherwise, you might not be able to log into an access point's console port. If you need to return the access points to the default *Cisco/Cisco* username and password, you must clear the switch's configuration and the access point's configuration to return them to factory-default settings. To reset the default access point configuration, enter the **ap name Cisco\_AP mgmtuser username Cisco password Cisco** command. Entering the command does not clear the static IP address of the access point. Once the access point rejoins a switch, it adopts the default *Cisco/Cisco* username and password.
- You can configure global authentication settings for all access points that are currently joined to the switch and any that join in the future. If desired, you can override the global authentication settings and assign unique authentication settings for a specific access point.
- This feature is supported on the following hardware:
  - All Cisco switches that support authentication.
  - Cisco Aironet 1140, 1260, 1310, 1520, 1600, 2600, 3500, and 3600 access points

## Restrictions for Configuring Authentication for Access Points

- The switch name in the AP configuration is case sensitive. Therefore, make sure to configure the exact system name on the AP configuration. Failure to do this results in the AP fallback not working.

## Information about Configuring Authentication for Access Points

Cisco IOS access points are shipped from the factory with *Cisco* as the default enable password. This password allows users to log into the nonprivileged mode and enter the **show** and **debug** commands that pose a security threat to your network. You must change the default enable password to prevent unauthorized access and to enable users to enter configuration commands from the access point's console port.

You can configure 802.1X authentication between a lightweight access point and a Cisco switch. The access point acts as an 802.1X supplicant and is authenticated by the switch where it uses EAP-FAST with anonymous PAC provisioning.

# How to Configure Authentication for Access Points

## Configuring Global Credentials for Access Points (CLI)

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ap mgmtuser username *user\_name* password 0 *passsword* secret 0 *secret\_value***
4. **end**
5. **ap name *Cisco\_AP* mgmtuser username *user\_name* password *password* secret *secret***
6. **show ap summary**
7. **show ap name *Cisco\_AP* config general**

### DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                                | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Switch# <b>enable</b>                                                                                                                                                                    | Enters privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                                                                                                                                            | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Step 3 | <b>ap mgmtuser username <i>user_name</i> password 0 <i>passsword</i> secret 0 <i>secret_value</i></b><br><br><b>Example:</b><br>Switch(config)# <b>ap mgmtuser apusr1 password appass 0 secret 0 appass1</b>                     | Configures the global username and password and enables the password for all access points that are currently joined to the switch and any access points that join the switch in the future. In the command, the parameter 0 specifies that an unencrypted password will follow and 8 specifies that an AES encrypted password will follow.                                                                                                                                                                                                                                        |
| Step 4 | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b>                                                                                                                                                                  | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Step 5 | <b>ap name <i>Cisco_AP</i> mgmtuser username <i>user_name</i> password <i>password</i> secret <i>secret</i></b><br><br><b>Example:</b><br>Switch(config)# <b>ap name TSIM_AP-2 mgmtuser apusr1 password appass secret secret</b> | Overrides the global credentials for a specific access point and assigns a unique username and password and enables password to this access point.<br><br>The credentials that you enter in this command are retained across switch and access point reboots and if the access point joins a new switch.<br><b>Note</b> If you want to force this access point to use the switch's global credentials, enter the <b>ap name <i>Cisco_AP</i> no mgmtuser</b> command. The following message appears after you execute this command: "AP reverted to global username configuration." |

|               | Command or Action                                                                                              | Purpose                                                                                                                                                                                                                                                                                                                      |
|---------------|----------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 6</b> | <b>show ap summary</b><br><br><b>Example:</b><br>Switch# show ap summary                                       | Displays a summary of all connected Cisco APs.                                                                                                                                                                                                                                                                               |
| <b>Step 7</b> | <b>show ap name Cisco_AP config general</b><br><br><b>Example:</b><br>Switch# show ap name AP02 config general | Displays the global credentials configuration for a specific access point.<br><br><b>Note</b> If this access point is configured for global credentials, the AP User Mode text boxes shows “Automatic.” If the global credentials have been overwritten for this access point, the AP User Mode text box shows “Customized.” |

## Configuring Global Credentials for Access Points (GUI)

**Step 1** Choose **Configuration > Wireless > Access Points > Global AP Configuration**. The **Global Configuration** page is displayed.

**Step 2** In the **Login Credentials** area, enter the following parameters:

- **User Name**
- **Password**
- **Confirm Password**
- **Secret Password**
- **Confirm Secret Password**

The password should contain characters from at least three of the following classes: lowercase letters, uppercase letters, digits, and special characters. No character in the password can be repeated more than three times consecutively. The password should not contain the management username or the reverse of the username. The password should not contain words like Cisco, oscic, admin, nimda or any variant obtained by changing the capitalization of letters by substituting l, |, or ! or substituting 0 for o or substituting \$ for s.

**Step 3** Click **Apply**.  
The global username and password are applied to all the access points that are associated with the switches

**Step 4** Click **Save Configuration**.

**Step 5** (Optional) You can override the global credentials for a specific access point and assign a unique username and password by following these steps:

- a) Choose **Configuration > Wireless > Access Points > All APs**.  
The **All APs** page is displayed.
- b) Click the name of an access point.  
The **AP > Edit** page is displayed.

- c) Click the **Credentials** tab.
- d) In the **Login Credentials** area, select the **Over-ride Global Credentials** check box.
- e) Enter the values for the following parameters:
  - **Username**
  - **Password**
  - **Enable Password**
- f) Click **Apply**.
- g) Click **Save Configuration**.

## Configuring Authentication for Access Points (CLI)

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ap dot1x username *user\_name\_value* password 0 *password\_value***
4. **end**
5. **ap name *Cisco\_AP* dot1x-user username *username\_value* password *password\_value***
6. **configure terminal**
7. **no ap dot1x username *user\_name\_value* password 0 *password\_value***
8. **end**
9. **show ap summary**
10. **show ap name *Cisco\_AP* config general**

### DETAILED STEPS

|        | Command or Action                                                                     | Purpose                                                                                                                                                                                                                                        |
|--------|---------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Switch# <b>enable</b>                         | Enters privileged EXEC mode.                                                                                                                                                                                                                   |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b> | Enters global configuration mode.                                                                                                                                                                                                              |
| Step 3 | <b>ap dot1x username <i>user_name_value</i> password 0 <i>password_value</i></b>      | Configures the global authentication username and password for all access points that are currently joined to the switch and any access points that join the switch in the future. This command contains the following keywords and arguments: |

|                      | Command or Action                                                                                                                                                                                                                               | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      | <p><b>Example:</b><br/> Switch(config)# ap dot1x username<br/> AP3 password 0<br/> password</p>                                                                                                                                                 | <ul style="list-style-type: none"> <li>• <b>username</b>—Specifies an 802.1X username for all access points.</li> <li>• <i>user-id</i>—Username.</li> <li>• <b>password</b>—Specifies an 802.1X password for all access points.</li> <li>• <b>0</b>—Specifies an unencrypted password.</li> <li>• <b>8</b>—Specifies an AES encrypted password.</li> <li>• <i>passwd</i>—Password.</li> </ul> <p><b>Note</b> You must enter a strong password for the password parameter. Strong passwords are at least eight characters long, contain a combination of uppercase and lowercase letters, numbers, and symbols, and are not a word in any language.</p>                                                                                                                                                                                                      |
| <p><b>Step 4</b></p> | <p><b>end</b></p> <p><b>Example:</b><br/> Switch(config)# <b>end</b></p>                                                                                                                                                                        | <p>Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <p><b>Step 5</b></p> | <p><b>ap name</b> <i>Cisco_AP</i> <b>dot1x-user</b><br/> <b>username</b> <i>username_value</i> <b>password</b><br/> <i>password_value</i></p> <p><b>Example:</b><br/> Switch# ap name AP03 dot1x-user<br/> username apuser1 password appass</p> | <p>Overrides the global authentication settings and assigns a unique username and password to a specific access point. This command contains the following keywords and arguments:</p> <ul style="list-style-type: none"> <li>• <b>username</b>—Specifies to add a username.</li> <li>• <i>user-id</i>—Username.</li> <li>• <b>password</b>—Specifies to add a password.</li> <li>• <b>0</b>—Specifies an unencrypted password.</li> <li>• <b>8</b>—Specifies an AES encrypted password.</li> <li>• <i>passwd</i>—Password.</li> </ul> <p><b>Note</b> You must enter a strong password for the password parameter. See the note in Step 2 for the characteristics of strong passwords. The authentication settings that you enter in this command are retained across switch and access point reboots and whenever the access point joins a new switch.</p> |
| <p><b>Step 6</b></p> | <p><b>configure terminal</b></p> <p><b>Example:</b><br/> Switch# <b>configure terminal</b></p>                                                                                                                                                  | <p>Enters global configuration mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <p><b>Step 7</b></p> | <p><b>no ap dot1x username</b> <i>user_name_value</i><br/> <b>password 0</b> <i>password_value</i></p> <p><b>Example:</b><br/> Switch(config)# no ap dot1x<br/> username<br/> dot1xusr password 0 dot1xpass</p>                                 | <p>Disables 802.1X authentication for all access points or for a specific access point.</p> <p>The following message appears after you execute this command: “AP reverted to global username configuration.”</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|                | Command or Action                                                                                              | Purpose                                                                                                                                                                                                                                                                                                                                        |
|----------------|----------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                |                                                                                                                | <b>Note</b> You can disable 802.1X authentication for a specific access point only if global 802.1X authentication is not enabled. If global 802.1X authentication is enabled, you can disable 802.1X for all access points only.                                                                                                              |
| <b>Step 8</b>  | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b>                                                | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode.                                                                                                                                                                                                                            |
| <b>Step 9</b>  | <b>show ap summary</b><br><br><b>Example:</b><br>Switch# show ap summary                                       | Displays the authentication settings for all access points that join the switch.<br><br><b>Note</b> If global authentication settings are not configured, the Global AP Dot1x User Name text box shows "Not Configured."                                                                                                                       |
| <b>Step 10</b> | <b>show ap name Cisco_AP config general</b><br><br><b>Example:</b><br>Switch# show ap name AP02 config general | Displays the authentication settings for a specific access point.<br><br><b>Note</b> If this access point is configured for global authentication, the AP Dot1x User Mode text boxes shows "Automatic." If the global authentication settings have been overwritten for this access point, the AP Dot1x User Mode text box shows "Customized." |

## Configuring Authentication for Access Points (GUI)

- Step 1** Choose **Configuration > Wireless > Access Points > Global AP Configuration**. The **Global Configuration** page is displayed.
- Step 2** In the **802.1x Supplicant Credentials** area, select the **Credentials Required** check box.
- Step 3** Enter the username and password details.  
**Note** You must enter a strong password in these text boxes. Strong passwords have the following characteristics:
- They are at least eight characters long
  - They contain a combination of uppercase and lowercase letters, numbers, and symbols
  - They are not a word in any language
- Step 4** Click **Apply**.
- Step 5** Click **Save Configuration**.
- Step 6** (Optional) You can override the global configuration and assign a unique username and password to a specific access point by following these steps:
- a) Choose **Configuration > Wireless > Access Points > All APs**. The **All APs** page is displayed.
- Step 7** Click the name of an access point.

The **AP > Edit** is displayed.

- Step 8** Click the **Credentials** tab.
- Step 9** In the **802.1x Supplicant Credentials** area, select the **Over-ride Global Credentials** check box.
- Step 10** Enter the username and password details.
- Step 11** Click **Apply**.
- Step 12** Click **Save Configuration**.

## Configuring the Switch for Authentication (CLI)

**Note** The procedure to perform this task using the switch GUI is not currently available.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **dot1x system-auth-control**
4. **aaa new-model**
5. **aaa authentication dot1x default group radius**
6. **radius-server host *host\_ip\_adress* acct-port *port\_number* auth-port *port\_number* key 0**  
*unencrypted\_server\_key*
7. **interface TenGigabitEthernet1/0/1**
8. **switch mode access**
9. **dot1x pae authenticator**
10. **end**

### DETAILED STEPS

|               | Command or Action                                                                     | Purpose                           |

| <b>Step 4</b>  | <b>aaa new-model</b><br><br><b>Example:</b><br>Switch(config)# aaa new-model                                                                                                                                                                                      | Enables new access control commands and functions.                                                                            |
| <b>Step 5</b>  | <b>aaa authentication dot1x default group radius</b><br><br><b>Example:</b><br>Switch(config)# aaa authentication<br>dot1x default group radius                                                                                                                   | Sets the default authentications lists for IEEE 802.1X by using all the radius hosts in a server group.                       |
| <b>Step 6</b>  | <b>radius-server host <i>host_ip_adress</i> acct-port <i>port_number</i> auth-port <i>port_number</i> key 0 unencrypted_server_key</b><br><br><b>Example:</b><br>Switch(config)# radius-server host<br>10.1.1.1 acct-port 1813 auth-port 6225 key 0<br>encryptkey | Sets a clear text encryption key for the RADIUS authentication server.                                                        |
| <b>Step 7</b>  | <b>interface TenGigabitEthernet1/0/1</b><br><br><b>Example:</b><br>Switch(config)# interface<br>TenGigabitEthernet1/0/1                                                                                                                                           | Sets the 10-Gigabit Ethernet interface.<br><br>The command prompt changes from Controller(config)# to Controller(config-if)#. |
| <b>Step 8</b>  | <b>switch mode access</b><br><br><b>Example:</b><br>Switch(config-if)# switch mode access                                                                                                                                                                         | Sets the unconditional trunking mode access to the interface.                                                                 |
| <b>Step 9</b>  | <b>dot1x pae authenticator</b><br><br><b>Example:</b><br>Switch(config-if)# dot1x pae<br>authenticator                                                                                                                                                            | Sets the 802.1X interface PAE type as the authenticator.                                                                      |
| <b>Step 10</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config)# end                                                                                                                                                                                                          | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode.           |

# Configuration Examples for Configuring Authentication for Access Points

## Displaying the Authentication Settings for Access Points: Examples

This example shows how to display the authentication settings for all access points that join the switch:

```
Switch# show ap summary
Number of APs..... 1
Global AP User Name..... globalap
Global AP Dot1x User Name..... globalDot1x
```

This example shows how to display the authentication settings for a specific access point:

```
Switch# show ap name AP02 config dot11 24ghz general
Cisco AP Identifier..... 0
Cisco AP Name..... TSIM_AP2
...
AP Dot1x User Mode..... AUTOMATIC
AP Dot1x User Name..... globalDot1x
```

## Converting Autonomous Access Points to Lightweight Mode

### Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

### Prerequisites for Converting Autonomous Access Points to Lightweight Mode

- Access points that are converted to lightweight mode do not support Wireless Domain Services (WDS). Converted access points communicate only with Cisco wireless LAN switches and cannot communicate

with WDS devices. However, the switch provides functionality that is equivalent to WDS when the access point associates to it.

- All Cisco lightweight access points support 16 Basic Service Set Identifiers (BSSIDs) per radio and a total of 16 wireless LANs per access point. When a converted access point associates to a switch, only wireless LANs with IDs 1 through 16 are pushed to the access point unless the access point is a member of an access point group.
- Access points that are converted to lightweight mode must get an IP address and discover the switch using DHCP, DNS, or IP subnet broadcast.

## Information About Autonomous Access Points Converted to Lightweight Mode

You can convert autonomous Cisco Aironet access points to lightweight mode. When you upgrade the access points to lightweight mode, the access point communicates with the switch and receives a configuration and software image from the switch.

See the *Upgrading Autonomous Cisco Aironet Access Points to Lightweight Mode* document for instructions to upgrade an autonomous access point to lightweight mode:

[http://www.cisco.com/en/US/docs/wireless/access\\_point/conversion/lwapp/upgrade/guide/lwapnote.html](http://www.cisco.com/en/US/docs/wireless/access_point/conversion/lwapp/upgrade/guide/lwapnote.html)

### Reverting from Lightweight Mode to Autonomous Mode

After you convert an autonomous access point to lightweight mode, you can convert the access point from a lightweight unit back to an autonomous unit by loading a Cisco IOS release that supports autonomous mode (Cisco IOS Release 12.3(7)JA or earlier releases). If the access point is associated with a switch, you can use the switch to load the Cisco IOS release. If the access point is not associated to a switch, you can load the Cisco IOS release using TFTP. In either method, the access point must be able to access a TFTP server that contains the Cisco IOS release to be loaded.

### Using DHCP Option 43 and DHCP Option 60

Cisco Aironet access points use the type-length-value (TLV) format for DHCP option 43. You must program the DHCP servers to return the option based on the access point's DHCP Vendor Class Identifier (VCI) string (DHCP option 60).

For more information about DHCP VCI strings of access points, see [http://www.cisco.com/en/US/tech/tk722/tk809/technologies\\_configuration\\_example09186a00808714fe.shtml](http://www.cisco.com/en/US/tech/tk722/tk809/technologies_configuration_example09186a00808714fe.shtml).

See the product documentation for your DHCP server for instructions on configuring DHCP option 43. The *Upgrading Autonomous Cisco Aironet Access Points to Lightweight Mode* document contains example steps for configuring option 43 on a DHCP server.

If the access point is ordered with the Service Provider Option - AIR-OPT60-DHCP selected, the VCI string for that access point will be different than those strings listed in the previous table. The VCI string has the following suffix: ServiceProvider. For example, a 1260 with this option returns this VCI string: Cisco AP c1260-ServiceProvider.

**Note**

The switch IP address that you obtain from the DHCP server should be a unicast IP address. Do not configure the switch IP address as a multicast address when configuring DHCP option 43.

## How Converted Access Points Send Crash Information to the Switch

When a converted access point unexpectedly reboots, the access point stores a crash file on its local flash memory at the time of the crash. After the unit reboots, it sends the reason for the reboot to the switch. If the unit rebooted because of a crash, the switch pulls up the crash file using existing CAPWAP messages and stores it in the switch flash memory. The crash information copy is removed from the access point flash memory when the switch pulls it from the access point.

## Uploading Memory Core Dumps from Converted Access Points

By default, access points converted to lightweight mode do not send memory core dumps to the switch. This section provides instructions to upload access point core dumps using the switch GUI or CLI.

## Displaying MAC Addresses for Converted Access Points

There are some differences in the way that controllers display the MAC addresses of converted access points on information pages in the controller GUI:

- On the AP Summary page, the controller lists the Ethernet MAC addresses of converted access points.
- On the AP Detail page, the controller lists the BSS MAC addresses and Ethernet MAC addresses of converted access points.
- On the Radio Summary page, the switch lists converted access points by the radio MAC address.

## Configuring a Static IP Address for a Lightweight Access Point

If you want to specify an IP address for an access point rather than having one assigned automatically by a DHCP server, you can use the controller GUI or CLI to configure a static IP address for the access point. Static IP addresses are generally used only for deployments with a limited number of users.

An access point cannot discover the switch using domain name system (DNS) resolution if a static IP address is configured for the access point, unless you specify a DNS server and the domain to which the access point belongs. You can configure these parameters using either the switch CLI or the GUI.

**Note**

If you configure an access point to use a static IP address that is not on the same subnet on which the access point's previous DHCP address was, the access point falls back to a DHCP address after the access point reboots. If the access point falls back to a DHCP address, enter the **show ap config general Cisco\_AP** CLI command to show that the access point is using a fallback IP address. However, the GUI shows both the static IP address and the DHCP address, but it does not identify the DHCP address as a fallback address.

# How to Convert a Lightweight Access Point Back to an Autonomous Access Point

## Converting a Lightweight Access Point Back to an Autonomous Access Point (CLI)

### SUMMARY STEPS

1. `enable`
2. `ap name Cisco_AP tftp-downgrade tftp_server_ip_address tftp_server_image_filename`

### DETAILED STEPS

|               | Command or Action                                                                                                                                                                           | Purpose                                                                                                                                                                                                                 |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <code>enable</code><br><br><b>Example:</b><br>Switch# <code>enable</code>                                                                                                                   | Enters privileged EXEC mode.                                                                                                                                                                                            |
| <b>Step 2</b> | <code>ap name Cisco_AP tftp-downgrade tftp_server_ip_address tftp_server_image_filename</code><br><br><b>Example:</b><br>Switch# <code>ap name AP02 tftp-downgrade 10.0.0.1 tsrvname</code> | Converts the lightweight access point back to autonomous mode.<br><br><b>Note</b> After entering this command, you must wait until the access point reboots and then reconfigure the access point using the CLI or GUI. |

## Converting a Lightweight Access Point Back to an Autonomous Access Point (Using the Mode Button and a TFTP Server)

- 
- Step 1** Configure the PC on which your TFTP server software runs with a static IP address in the range of 10.0.0.2 to 10.0.0.30.
- Step 2** Make sure that the PC contains the access point image file (such as `c1140-k9w7-tar.123-7.JA.tar` for a 1140 series access point) in the TFTP server folder and that the TFTP server is activated.
- Step 3** Rename the access point image file in the TFTP server folder to `c1140-k9w7-tar.default` for a 1140 series access point.
- Step 4** Connect the PC to the access point using a Category 5 (CAT5) Ethernet cable.
- Step 5** Disconnect power from the access point.
- Step 6** Press and hold the **MODE** button while you reconnect power to the access point.
- Note** The **MODE** button on the access point must be enabled.

- Step 7** Hold the **MODE** button until the status LED turns red (approximately 20 to 30 seconds), and release the MODE button.
- Step 8** Wait until the access point reboots as indicated by all LEDs turning green followed by the Status LED blinking green.
- Step 9** After the access point reboots, reconfigure the access point using the GUI or the CLI.

## Authorizing Access Points (CLI)

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ap auth-list ap-policy authorize-ap**
4. **username *user\_name* mac aaa attribute list *list\_name***
5. **aaa new-model**
6. **aaa authorization credential-download *auth\_list* local**
7. **aaa attribute list *list***
8. **aaa session-id common**
9. **aaa local authentication default authorization default**
10. **show ap name *Cisco\_AP* config general**

### DETAILED STEPS

|               | Command or Action                                                                                                                                                              | Purpose                                                |

| <b>Step 1</b> | <b>enable</b><br><br><b>Example:</b><br>Switch# <b>enable</b>                                                                                                                  | Enters privileged EXEC mode.                           |
| <b>Step 2</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                                                                                          | Enters global configuration mode.                      |
| <b>Step 3</b> | <b>ap auth-list ap-policy authorize-ap</b><br><br><b>Example:</b><br>Switch(config)# <b>ap auth-list ap-policy authorize-ap</b>                                                | Configures an access point authorization policy.       |
| <b>Step 4</b> | <b>username <i>user_name</i> mac aaa attribute list <i>list_name</i></b><br><br><b>Example:</b><br>Switch(config)# <b>username aaa.bbb.ccc mac aaa attribute list attrlist</b> | Configures the MAC address of an access point locally. |

|                | Command or Action                                                                                                                                                | Purpose                                                                             |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|
| <b>Step 5</b>  | <b>aaa new-model</b><br><br><b>Example:</b><br>Switch(config)# aaa new-model                                                                                     | Enables new access control commands and functions.                                  |
| <b>Step 6</b>  | <b>aaa authorization credential-download auth_list local</b><br><br><b>Example:</b><br>Switch(config)# aaa authorization credential-download auth_download local | Downloads EAP credentials from the local server.                                    |
| <b>Step 7</b>  | <b>aaa attribute list list</b><br><br><b>Example:</b><br>Switch(config)# aaa attribute list alist                                                                | Configures AAA attribute list definitions.                                          |
| <b>Step 8</b>  | <b>aaa session-id common</b><br><br><b>Example:</b><br>Switch(config)# aaa session-id common                                                                     | Configures the AAA common session ID.                                               |
| <b>Step 9</b>  | <b>aaa local authentication default authorization default</b><br><br><b>Example:</b><br>Switch(config)# aaa local authentication default authorization default   | Configures the local authentication method list.                                    |
| <b>Step 10</b> | <b>show ap name Cisco_AP config general</b><br><br><b>Example:</b><br>Switch(config)# show ap name AP01 config general                                           | Displays the configuration information that corresponds to a specific access point. |

## Authorizing Access Points (GUI)

- 
- Step 1** Choose **Configuration > Security > AAA > AP Policy**. The **AP Policy** page is displayed.
- Step 2** In the Policy Configuration area, enable or disable the following parameters:
- **Authorize LSC APs against Auth-List**
  - **AP with Self-Signed Certificate**
  - **Authorize MIC APs against AAA**

- AP with Manufacturing Installed Certificate

**Step 3** Click **Apply**.

**Step 4** Click **Save Configuration**.

## Disabling the Reset Button on Converted Access Points (CLI)

You can enable or disable the Reset button on access points that are converted to lightweight mode. The Reset button is labeled MODE on the outside of the access point.

**Note** The procedure to perform this task using the controller GUI is not currently available.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **no ap reset-button**
4. **end**
5. **ap name *Cisco\_AP* reset-button**

### DETAILED STEPS

| <b>Step 6</b> | <b>ap static-ip domain</b> <i>static_ip_domain</i><br><br><b>Example:</b><br>Switch(config)# ap static-ip domain<br>domain1                           | Configures the domain to which a specific access point or all access points belong.<br><br><b>Note</b> To undo the domain name configuration, enter the <b>no ap static-ip domain static_ip_domain</b> command.                                                 |
| <b>Step 7</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b>                                                                                       | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode.                                                                                                                                             |
| <b>Step 8</b> | <b>show ap name</b> <i>Cisco_AP</i> <b>config general</b><br><br><b>Example:</b><br>Switch# show ap name AP03 config<br>general                       | Displays the IP address configuration for the access point.                                                                                                                                                                                                     |

## Configuring a Static IP Address on an Access Point (GUI)

- 
- Step 1** Choose **Configuration > Wireless > Access Points > All APs**.  
The **All APs** page is displayed.
- Step 2** Click the name of the access point.  
The **AP > Edit** page is displayed.
- Step 3** In the **General** tab, in the **IP Config** area, select the **Static IP** check box if you want to assign a static IP address to the access point.
- Step 4** Enter the following details:
- **Static IP**

- Netmask
- Gateway

- Step 5** Click **Apply**.  
The access point reboots and rejoins the switch, and the static IP address that you specified is sent to the access point.
- Step 6** After the static IP address has been sent to the access point, configure the **DNS IP Address** and **Domain Name**.
- Step 7** Click **Apply**.
- Step 8** Click **Save Configuration**.
- 

## Recovering the Access Point Using the TFTP Recovery Procedure

---

- Step 1** Download the required recovery image from Cisco.com (ap3g2-k9w8-tar.152-2.JA.tar) and install it in the root directory of your TFTP server.
- Step 2** Connect the TFTP server to the same subnet as the target access point and power-cycle the access point. The access point boots from the TFTP image and then joins the switch to download the oversized access point image and complete the upgrade procedure.
- Step 3** After the access point has been recovered, you can remove the TFTP server.
- 

## Configuration Examples for Converting Autonomous Access Points to Lightweight Mode

### Displaying the IP Address Configuration for Access Points: Example

This example shows how to display the IP address configuration for the access point:

```
Switch# show ap name AP03 dot11 24ghz config general
Cisco AP Identifier..... 4
Cisco AP Name..... AP6
IP Address Configuration..... Static IP assigned
IP Address..... 10.10.10.118
IP NetMask..... 255.255.255.0
Gateway IP Addr..... 10.10.10.1
Domain..... Domain1
Name Server..... 10.10.10.205
...
```

## Displaying Access Point Crash File Information: Example

This example shows how to display access point crash file information. Using this command, you can verify whether the file is downloaded to the switch:

```
Switch# show ap crash-file
Local Core Files:
lrad_AP1130.rdump0 (156)
```

The number in parentheses indicates the size of the file. The size should be greater than zero if a core dump file is available.

## Using Cisco Workgroup Bridges

### Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

### Information About Cisco Workgroup Bridges and non-Cisco Workgroup bridges

A WGB is a mode that can be configured on an autonomous Cisco IOS access point to provide wireless connectivity to a lightweight access point on behalf of clients that are connected by Ethernet to the WGB access point. A WGB connects a wired network over a single wireless segment by learning the MAC addresses of its wired clients on the Ethernet interface and reporting them to the lightweight access point using Internet Access Point Protocol (IAPP) messaging. The WGB provides wireless access connectivity to wired clients by establishing a single wireless connection to the lightweight access point.

When a Cisco WGB is used, the WGB informs the access points of all the clients that it is associated with. The switch is aware of the clients that are associated with the access point. When non-Cisco WGBs are used, the switch has no information about the IP address of the clients on the wired segment behind the WGB. Without this information, the switch drops the following types of messages:

- ARP REQ from the distribution system for the WGB client.
- ARP RPLY from the WGB client.
- DHCP REQ from the WGB client.

- DHCP RPLY for the WGB client.

## Monitoring the Status of Workgroup Bridges

**Note**

The procedure to perform this task using the switch GUI is not currently available.

### SUMMARY STEPS

1. **enable**
2. **show wireless wgb summary**
3. **show wireless wgb mac-address *wgb\_mac\_address* detail**

### DETAILED STEPS

| <b>Step 8</b> | <b>debug dot11 state</b><br><br><b>Example:</b><br>Switch# debug dot11 state | Enables dot11/state debugging. Debug an IP assignment issue when static IP is used. |

## Configuration Examples for Configuring Workgroup Bridges

### WGB Configuration: Example

This example shows how to configure a WGB access point using static WEP with a 40-bit WEP key:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# dot11 ssid WGB_with_static_WEP
Switch(config-ssid)# authentication open
Switch(config-ssid)# guest-mode
Switch(config-ssid)# exit
Switch(config)# interface dot11Radio 0
Switch(config)# station-role workgroup-bridge
Switch(config-if)# encry mode wep 40
Switch(config-if)# encry key 1 size 40 0 1234567890
Switch(config-if)# ssid WGB_with_static_WEP
Switch(config-if)# end
```

Verify that the WGB is associated to an access point by entering this command on the WGB:

**show dot11 association**

Information similar to the following appears:

```
Switch# show dot11 associations
802.11 Client Stations on Dot11Radio0:
SSID [FCVTESTING] :
MAC Address      IP address      Device          Name           Parent          State
000b.8581.6aee  10.11.12.1     WGB-client     map1           -               Assoc
ap#
```

## Configuring Probe Request Forwarding

- [Finding Feature Information, page 731](#)
- [Information About Configuring Probe Request Forwarding, page 731](#)
- [How to Configure Probe Request Forwarding \(CLI\), page 731](#)

### Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

### Information About Configuring Probe Request Forwarding

Probe requests are 802.11 management frames that are sent by clients to request information about the capabilities of Service Set Identifiers (SSIDs). By default, access points forward acknowledged probe requests to the switch for processing. Acknowledged probe requests are probe requests for SSIDs that are supported by the access point. If desired, you can configure access points to forward both acknowledged and unacknowledged probe requests to the switch. The switch can use the information from unacknowledged probe requests to improve the location accuracy.

### How to Configure Probe Request Forwarding (CLI)

**Note**

---

The procedure to perform this task using the switch GUI is not currently available.

---

## SUMMARY STEPS

1. **configure terminal**
2. **wireless probe filter**
3. **wireless probe filter *num\_probes interval***
4. **end**
5. **show wireless probe**

## DETAILED STEPS

|        | Command or Action                                                                                                                  | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------|------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                                              | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Step 2 | <b>wireless probe filter</b><br><br><b>Example:</b><br>Switch(config)# <b>wireless probe filter</b>                                | Enables or disables the filtering of probe requests forwarded from an access point to the switch.<br><br><b>Note</b> If you enable probe filtering, the default filter setting, the access point forwards only acknowledged probe requests to the switch. If you disable probe filtering, the access point forwards both acknowledged and unacknowledged probe requests to the switch.                                                                                               |
| Step 3 | <b>wireless probe filter <i>num_probes interval</i></b><br><br><b>Example:</b><br>Switch(config)# <b>wireless probe filter 5 5</b> | Limits the number of probe requests sent to the switch per client per access point radio in a given interval. You must specify the following arguments with this command: <ul style="list-style-type: none"> <li>• <i>num_probes</i>—Number of probe requests forwarded to the switch per client per access point radio in a given interval. The range is from 1 to 100.</li> <li>• <i>interval</i>—Probe limit interval in milliseconds. The range is from 100 to 10000.</li> </ul> |
| Step 4 | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b>                                                                    | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode.                                                                                                                                                                                                                                                                                                                                                                  |
| Step 5 | <b>show wireless probe</b><br><br><b>Example:</b><br>Switch# <b>show wireless probe</b>                                            | Displays the advanced probe request configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                   |

### Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

### Optimizing RFID Tracking on Access Points

To optimize the monitoring and location calculation of RFID tags, you can enable tracking optimization on up to four channels within the 2.4-GHz band of an 802.11b/g access point radio. This feature allows you to scan only the channels on which tags are usually programmed to operate (such as channels 1, 6, and 11).

6. **show ap monitor-mode summary**

### DETAILED STEPS

|               | Command or Action                                                                                                                                                                                                                                   | Purpose                                                                                                                                                                                                                                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>ap name</b> <i>Cisco_AP</i> <b>mode monitor submode none</b><br><br><b>Example:</b><br>Switch# ap name 3602a mode monitor<br>submode none                                                                                                        | Specifies the monitor submode for the access point as none.<br><br><b>Note</b> A warning message indicates that changing the access point's mode will cause the access point to reboot and prompts you to specify whether you want to continue by entering <b>Y</b> .<br><br>After you enter <b>Y</b> , the access point reboots. |
| <b>Step 2</b> | <b>ap name</b> <i>Cisco_AP</i> <b>dot11 24ghz shutdown</b><br><br><b>Example:</b><br>Switch# ap name AP01 dot11 24ghz shutdown                                                                                                                      | Disables the access point radio.                                                                                                                                                                                                                                                                                                  |
| <b>Step 3</b> | <b>ap name</b> <i>Cisco_AP</i> <b>monitor-mode tracking-opt</b><br><br><b>Example:</b><br>Switch# ap name TSIM_AP1 monitor-mode<br>tracking-opt                                                                                                     | Configures the access point to scan only the Dynamic Channel Assignment (DCA) channels supported by its country of operation.<br><br><b>Note</b> To disable tracking optimization for an access point, enter the <b>ap name</b> <i>Cisco_AP</i> <b>monitor-mode tracking-opt no-optimization</b> command.                         |
| <b>Step 4</b> | <b>ap name</b> <i>Cisco_AP</i> <b>monitor-mode dot11b</b><br>{ <b>fast-channel</b> [ <i>first_channel second_channel third_channel fourth_channel</i> ]}<br><br><b>Example:</b><br>Switch# ap name AP01 monitor-mode dot11b<br>fast-channel 1 2 3 4 | Chooses up to four specific 802.11b channels to be scanned by the access point.<br><br><b>Note</b> In the United States, you can assign any value from 1 to 11 (inclusive) to the channel variable. Other countries support additional channels. You must assign at least one channel.                                            |

|               | Command or Action                                                                                                             | Purpose                                         |
|---------------|-------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------|
| <b>Step 5</b> | <b>ap name <i>Cisco_AP</i> no dot11 24ghz shutdown</b><br><br><b>Example:</b><br>Switch# ap name AP01 no dot11 24ghz shutdown | Enables the access point radio.                 |
| <b>Step 6</b> | <b>show ap monitor-mode summary</b><br><br><b>Example:</b><br>Switch# show ap monitor-mode summary                            | Displays all the access points in monitor mode. |

## Configuration Examples for Optimizing RFID Tracking

### Displaying all the Access Points in Monitor Mode: Example

This example shows how to display all the access points in monitor mode:

```
Switch# show ap monitor-mode summary

AP Name          Ethernet MAC    Status    Scanning
                Channel
                List
-----
AP1131:4f2.9a  00:16:4:f2:9:a Tracking 1,6,NA,NA
```

## Configuring Country Codes

- [Finding Feature Information, page 737](#)
- [Prerequisites for Configuring Country Codes, page 737](#)
- [Information About Configuring Country Codes, page 738](#)
- [How to Configure Country Codes \(CLI\), page 738](#)
- [Configuration Examples for Configuring Country Codes, page 741](#)

### Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

### Prerequisites for Configuring Country Codes

- Generally, you configure one country code per switch; you configure one code that matches the physical location of the switch and its access points. You can configure up to 20 country codes per switch. This multiple-country support enables you to manage access points in various countries from a single switch.
- When the multiple-country feature is used, all switches that are going to join the same RF group must be configured with the same set of countries, configured in the same order.
- Access points are capable of using all the available legal frequencies. However, access points are assigned to the frequencies that are supported in their relevant domains.
- The country list configured on the RF group leader determines which channels the members would operate on. This list is independent of which countries have been configured on the RF group members.
- For switches in the Japan regulatory domain, you must have had one or more Japan country codes (JP, J2, or J3) configured on your switch at the time you last booted your switch.

- For switches in the Japan regulatory domain, you must have at least one access point with a -J regulatory domain joined to your switch.

## Information About Configuring Country Codes

Controllers and access points are designed for use in many countries with varying regulatory requirements. The radios within the access points are assigned to a specific regulatory domain at the factory (such as -E for Europe), but the country code enables you to specify a particular country of operation (such as FR for France or ES for Spain). Configuring a country code ensures that each radio's broadcast frequency bands, interfaces, channels, and transmit power levels are compliant with country-specific regulations.

### Information About Japanese Country Codes

Country codes define the channels that can be used legally in each country. These country codes are available for Japan:

- JP—Allows only -J radios to join the controller
- J2—Allows only -P radios to join the controller
- J3—Uses the -U frequencies but allows -U, -P and -Q (other than 1550/1600/2600/3600) radios to join the controller
- J4—Allows 2.4G JPQU and 5G PQU to join the controller.

---

**Note** The 1550, 1600, 2600, and 3600 APs require J4.

---

See the *Channels and Maximum Power Settings for Cisco Aironet Lightweight Access Points* document for the list of channels and power levels supported by access points in the Japanese regulatory domains.

## How to Configure Country Codes (CLI)

---

**Note** The procedure to perform this task using the switch GUI is not currently available.

---

## SUMMARY STEPS

1. **enable**
2. **show wireless country supported**
3. **configure terminal**
4. **ap dot11 24ghz shutdown**
5. **ap dot11 5ghz shutdown**
6. **ap country *country\_code***
7. **end**
8. **show wireless country channels**
9. **configure terminal**
10. **no ap dot11 5ghz shutdown**
11. **no ap dot11 24ghz shutdown**
12. **end**
13. **ap name *Cisco\_AP* shutdown**
14. **configure terminal**
15. **ap country *country\_code***
16. **end**
17. **ap name *Cisco\_AP* no shutdown**

## DETAILED STEPS

|        | Command or Action                                                                                        | Purpose                                         |
|--------|----------------------------------------------------------------------------------------------------------|-------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Switch# enable                                                   | Enters privileged EXEC mode.                    |
| Step 2 | <b>show wireless country supported</b><br><br><b>Example:</b><br>Switch# show wireless country supported | Displays a list of all available country codes. |
| Step 3 | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                    | Enters global configuration mode.               |
| Step 4 | <b>ap dot11 24ghz shutdown</b><br><br><b>Example:</b><br>Switch(config)# ap dot11 5ghz shutdown          | Disables the 802.11a network.                   |
| Step 5 | <b>ap dot11 5ghz shutdown</b><br><br><b>Example:</b><br>Switch(config)# ap dot11 24ghz shutdown          | Disables the 802.11b/g network.                 |

|         | Command or Action                                                                                      | Purpose                                                                                                                                                                                              |
|---------|--------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 6  | <b>ap country</b> <i>country_code</i><br><br><b>Example:</b><br>Switch(config)# ap country IN          | Assigns access points to a specific country.<br><br><b>Note</b> Make sure that the country code you choose is compatible with the regulatory domain of at least one of the access point's radios.    |
| Step 7  | <b>end</b><br><br><b>Example:</b><br>Switch(config)# end                                               | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode.                                                                                  |
| Step 8  | <b>show wireless country channels</b><br><br><b>Example:</b><br>Switch# show wireless country channels | Displays the list of available channels for the country codes configured on your switch.<br><br><b>Note</b> Perform Steps 9 through 17 only if you have configured multiple country codes in Step 6. |
| Step 9  | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                         | Enters global configuration mode.                                                                                                                                                                    |
| Step 10 | <b>no ap dot11 5ghz shutdown</b><br><br><b>Example:</b><br>Switch(config)# no ap dot11 5ghz shutdown   | Enables the 802.11a network.                                                                                                                                                                         |
| Step 11 | <b>no ap dot11 24ghz shutdown</b><br><br><b>Example:</b><br>Switch(config)# no ap dot11 24ghz shutdown | Enables the 802.11b/g network.                                                                                                                                                                       |
| Step 12 | <b>end</b><br><br><b>Example:</b><br>Switch(config)# end                                               | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode.                                                                                  |
| Step 13 | <b>ap name</b> <i>Cisco_AP</i> <b>shutdown</b><br><br><b>Example:</b><br>Switch# ap name AP02 shutdown | Disables the access point.<br><br><b>Note</b> Ensure that you disable only the access point for which you are configuring country codes.                                                             |
| Step 14 | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                         | Enters global configuration mode.                                                                                                                                                                    |

|         | Command or Action                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------|----------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 15 | <p><b>ap country</b> <i>country_code</i></p> <p><b>Example:</b><br/>Switch# ap country IN</p>                        | <p>Assigns an access point to a specific country.</p> <p><b>Note</b> Ensure that the country code that you choose is compatible with the regulatory domain of at least one of the access point's radios.</p> <p><b>Note</b> If you enabled the networks and disabled some access points and then enter the <b>ap country</b> <i>country_code</i> command, the specified country code is configured on only the disabled access points. All other access points are ignored.</p> |
| Step 16 | <p><b>end</b></p> <p><b>Example:</b><br/>Switch(config)# <b>end</b></p>                                              | <p>Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode.</p>                                                                                                                                                                                                                                                                                                                                                      |
| Step 17 | <p><b>ap name</b> <i>Cisco_AP</i> <b>no shutdown</b></p> <p><b>Example:</b><br/>Switch# ap name AP02 no shutdown</p> | <p>Enables the access point.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Configuration Examples for Configuring Country Codes

### Displaying Channel List for Country Codes: Example

This example shows how to display the list of available channels for the country codes configured on your switch:

```
Switch# show wireless country channels

Configured Country.....: US - United States
KEY: * = Channel is legal in this country and may be configured manually.
A = Channel is the Auto-RF default in this country.
. = Channel is not legal in this country.
C = Channel has been configured for use by Auto-RF.
x = Channel is available to be configured for use by Auto-RF.
(-,-) = (indoor, outdoor) regulatory domain allowed by this country.
-----:+++++-----

### Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

### Prerequisites for Configuring Link Latency

- The switch displays the current round-trip time as well as a running minimum and maximum round-trip time. The minimum and maximum times continue to run as long as the switch is up or can be cleared and allowed to restart.
- You can configure link latency for a specific access point using the switch GUI or CLI or for all access points joined to the switch using the CLI.

## Restrictions for Configuring Link Latency

- Link latency calculates the Control and Provisioning of Wireless Access Points (CAPWAP) response time between the access point and the switch. It does not measure network latency or ping responses.

## Information About Configuring Link Latency

You can configure link latency on the switch to measure the link between an access point and the switch. You can use this feature with all access points that are joined to the switch where the link can be a slow or unreliable WAN connection.

### TCP MSS

If the client's maximum segment size (MSS) in a Transmission Control Protocol (TCP) three-way handshake is greater than the maximum transmission unit can handle, the client might experience reduced throughput and the fragmentation of packets. To avoid this problem, you can specify the MSS for all access points that are joined to the switch or for a specific access point.

When you enable this feature, the access point selects the MSS for TCP packets to and from wireless clients in its data path. If the MSS of these packets is greater than the value that you configured or greater than the default value for the CAPWAP tunnel, the access point changes the MSS to the new configured value.

### Link Tests

A link test is used to determine the quality of the radio link between two devices. Two types of link-test packets are transmitted during a link test: request and response. Any radio receiving a link-test request packet fills in the appropriate text boxes and echoes the packet back to the sender with the response type set.

The radio link quality in the client-to-access point direction can differ from that in the access point-to-client direction due to the asymmetrical distribution of the transmit power and receive sensitivity on both sides. Two types of link tests can be performed: a ping test and a CCX link test.

With the *ping link test*, the controller can test link quality only in the client-to-access point direction. The RF parameters of the ping reply packets received by the access point are polled by the controller to determine the client-to-access point link quality.

With the *CCX link test*, the switch can also test the link quality in the access point-to-client direction. The switch issues link-test requests to the client, and the client records the RF parameters (received signal strength indicator [RSSI], signal-to-noise ratio [SNR], and so on) of the received request packet in the response packet. Both the link-test requestor and responder roles are implemented on the access point and switch. Not only can the access point or switch initiate a link test to a CCX v4 or v5 client, but a CCX v4 or v5 client can initiate a link test to the access point or switch.

The switch shows the link-quality metrics for CCX link tests in both directions (out— the access point to the client; in— the client to the access point):

- Signal strength in the form of RSSI (minimum, maximum, and average)
- Signal quality in the form of SNR (minimum, maximum, and average)
- Total number of packets that are retried

- Maximum retry count for a single packet
- Number of lost packets
- Data rate of a successfully transmitted packet

The controller shows this metric regardless of direction:

- Link test request/reply round-trip time (minimum, maximum, and average)

The controller software supports CCX versions 1 through 5. CCX support is enabled automatically for every WLAN on the controller and cannot be disabled. The controller stores the CCX version of the client in its client database and uses it to limit the features for this client. If a client does not support CCXv4 or v5, the controller performs a ping link test on the client. If a client supports CCXv4 or v5, the controller performs a CCX link test on the client. If a client times out during a CCX link test, the controller switches to the ping link test automatically.

## How to Configure Link Latency

### Configuring Link Latency (CLI)

#### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ap link-latency**
4. **ap tcp-adjust-mss size size**
5. **show ap name Cisco\_AP config general**
6. **ap name Cisco\_AP link-latency [reset]**
7. **show ap name Cisco\_AP config general**

#### DETAILED STEPS

|        | Command or Action                                                                | Purpose                                                                                                                                                                                                                                        |
|--------|----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Switch# enable                           | Enters privileged EXEC mode.                                                                                                                                                                                                                   |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal   | Enters global configuration mode.                                                                                                                                                                                                              |
| Step 3 | <b>ap link-latency</b><br><br><b>Example:</b><br>Switch(config)# ap link-latency | Enables link latency for all access points that are currently associated with the switch.<br><br><b>Note</b> To disable link latency for all the access points that are associated with the switch, use the <b>no ap link-latency</b> command. |

|               | Command or Action                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               |                                                                                                                                       | <p><b>Note</b> These commands enable or disable link latency only for access points that are currently joined to the switch. You have to enable or disable link latency for the access points that join in the future.</p> <p><b>Note</b> To enable or disable link latency for specific access points that are associated with the switch, enter the following commands in Privileged EXEC mode:</p> <ul style="list-style-type: none"> <li>• <b>ap name <i>Cisco_AP</i> link-latency</b>—Enables link latency.</li> <li>• <b>ap name <i>Cisco_AP</i> no link-latency</b>—Disables link latency.</li> </ul>                                                                                                                                                                                                                                                                                                                     |
| <b>Step 4</b> | <p><b>ap tcp-adjust-mss size <i>size</i></b></p> <p><b>Example:</b><br/>Switch(config)# ap tcp-adjust-mss size 537</p>                | Configures TCP MSS adjust size for all access points. The range is from 536 to 1363.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Step 5</b> | <p><b>show ap name <i>Cisco_AP</i> config general</b></p> <p><b>Example:</b><br/>Switch(config)# show ap name AP02 config general</p> | <p>Displays the general configuration details of the access point. These configuration details contain the link latency results that correspond to the access point that you specify in the command.</p> <p>The output of this command contains the following link latency results:</p> <ul style="list-style-type: none"> <li>• <b>Current Delay</b>—The current round-trip time (in milliseconds) of CAPWAP heartbeat packets from the access point to the switch and back.</li> <li>• <b>Maximum Delay</b>—Since the time that link latency has been enabled or reset, the maximum round-trip time (in milliseconds) of CAPWAP heartbeat packets from the access point to the switch and back.</li> <li>• <b>Minimum Delay</b>—Since the time that link latency has been enabled or reset, the minimum round-trip time (in milliseconds) of CAPWAP heartbeat packets from the access point to the switch and back.</li> </ul> |
| <b>Step 6</b> | <p><b>ap name <i>Cisco_AP</i> link-latency [reset]</b></p> <p><b>Example:</b><br/>Switch(config)# ap name AP02 link-latency reset</p> | Clears the current, minimum, and maximum link latency statistics on the switch for a specific access point.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Step 7</b> | <p><b>show ap name <i>Cisco_AP</i> config general</b></p> <p><b>Example:</b><br/>Switch(config)# show ap name AP02 config general</p> | Displays the general configuration details of the access point. Use this command to see the result of the reset operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Configuring Link Latency (GUI)

- 
- Step 1** Choose **Configuration > Wireless > Access Points > All APs**.  
The **All APs** page appears with a list of access points.
- Step 2** Click the name of the access point.  
The **AP > Edit** page appears.
- Step 3** Click the **Advanced** tab.
- Step 4** In the **Link Latency** area, select or unselect the **Enable Link Latency** check box.  
**Note** You can select the **Enable Link Latency** check box to enable link latency for this access point or unselect it to prevent the access point from sending the round-trip time to the switch after every echo response is received. The default state is unselected.
- Step 5** Click **Apply**.
- Step 6** When a message box appears that indicates that AP Parameters are modified successfully, click **OK**.
- Step 7** When the **All APs** page is displayed, click the access point that you have modified earlier.  
The **AP > Edit** page appears.
- Step 8** Click the **Advanced** tab.  
In the **Link Latency** area, the following link latency and data latency results are displayed:
- **Current(mSec)**—The current round-trip time (in milliseconds) of CAPWAP heartbeat packets or data packets from the access point to the switch and back.
  - **Minimum(mSec)**—Since the time that link latency has been enabled or reset, the minimum round-trip time (in milliseconds) of CAPWAP heartbeat packets or data packets from the access point to the switch and back.
  - **Maximum(mSec)**—Since the time that link latency has been enabled or reset, the maximum round-trip time (in milliseconds) of CAPWAP heartbeat packets or data packets from the access point to the switch and back.
- Step 9** Click **Reset Link Latency** to clear the current, minimum, and maximum link latency and data latency statistics on the switch for this access point.  
**Note** After the page refreshes and the **All APs** page is displayed again, click the **Advanced** tab. The updated statistics appear in the **Minimum** and **Maximum** text boxes.
-

# How to Configure TCP MSS

## Configuring TCP MSS (CLI)

### SUMMARY STEPS

1. `configure terminal`
2. `ap tcp-adjust-mss size size_value`
3. `reload`
4. `show ap tcp-adjust-mss`

### DETAILED STEPS

|               | Command or Action                                                                                                                       | Purpose                                                                                                                                                                                                                                                                                                                                              |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <code>configure terminal</code><br><br><b>Example:</b><br>Switch# <code>configure terminal</code>                                       | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                    |
| <b>Step 2</b> | <code>ap tcp-adjust-mss size <i>size_value</i></code><br><br><b>Example:</b><br>Switch(config)# <code>ap tcp-adjust-mss size 537</code> | Enables the TCP MSS on the particular access point that you specify.<br><br><b>Note</b> To enable TCP MSS on all the access points that are associated with the switch, enter the <code>ap tcp-adjust-mss size <i>size_value</i></code> command, where the size parameter is from 536 to 1363 bytes. The default value varies for different clients. |
| <b>Step 3</b> | <code>reload</code><br><br><b>Example:</b><br>Switch# <code>reload</code>                                                               | Reboots the switch in order for your change to take effect.                                                                                                                                                                                                                                                                                          |
| <b>Step 4</b> | <code>show ap tcp-adjust-mss</code><br><br><b>Example:</b><br>Switch# <code>show ap tcp-adjust-mss</code>                               | Displays the current TCP MSS setting for all the access points that are associated with the switch.<br><br><b>Note</b> To display the TCP MSS settings that correspond to a specific access point, enter the <code>show ap name <i>Cisco_AP</i> tcp-adjust-mss</code> command.                                                                       |

## Configuring TCP MSS (GUI)

- 
- Step 1** Choose **Configuration > Wireless > Access Points > Global AP Configuration**.

The **Global Configuration** page is displayed.

- Step 2** In the **TCP MSS** area, select the **Global TCP Adjust MSS** check box and set the MSS for all access points that are associated with the switch. The valid range is from 536 to 1363 bytes.
- Step 3** Click **Apply**.
- Step 4** Click **Save Configuration**.

## Performing a Link Test (CLI)

**Note** The procedure to perform this task using the switch GUI is not currently available.

### SUMMARY STEPS

1. **test wireless linktest** *mac\_address*
2. **configure terminal**
3. **wireless linktest frame-size** *frame\_size*
4. **wireless linktest number-of-frames** *number\_of\_frames*
5. **end**

### DETAILED STEPS

|               | Command or Action                                                                                                                                    | Purpose                                                    |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------|
| <b>Step 1</b> | <b>test wireless linktest</b> <i>mac_address</i><br><br><b>Example:</b><br>Switch# test wireless linktest<br>00:0d:88:c5:8a:d1                       | Runs a link test.                                          |
| <b>Step 2</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                                                                | Enters global configuration mode.                          |
| <b>Step 3</b> | <b>wireless linktest frame-size</b> <i>frame_size</i><br><br><b>Example:</b><br>Switch(config)# wireless linktest<br>frame-size 41                   | Configures the link test frame size for each packet.       |
| <b>Step 4</b> | <b>wireless linktest number-of-frames</b> <i>number_of_frames</i><br><br><b>Example:</b><br>Switch(config)# wireless linktest<br>number-of-frames 50 | Configures the number of frames to send for the link test. |

|        | Command or Action                                                       | Purpose                                                                                                             |
|--------|-------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| Step 5 | <p><b>end</b></p> <p><b>Example:</b><br/>Switch(config)# <b>end</b></p> | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode. |

## Configuration Examples for Configuring Link Latency

### Running a Link Test: Example

This example shows how to run a link test:

```
Switch# test wireless linktest 00:0d:88:c5:8a:d1
```

When CCX v4 or later releases is enabled on both the controller and the client being tested, information similar to the following appears:

```
CCX Link Test to 00:0d:88:c5:8a:d1.
Link Test Packets Sent..... 20
Link Test Packets Received..... 10
Link Test Packets Lost (Total/AP to Client/Client to AP)... 10/5/5
Link Test Packets round trip time (min/max/average)..... 5ms/20ms/15ms
RSSI at AP (min/max/average)..... -60dBm/-50dBm/-55dBm
RSSI at Client (min/max/average)..... -50dBm/-40dBm/-45dBm
SNR at AP (min/max/average)..... 40dB/30dB/35dB
SNR at Client (min/max/average)..... 40dB/30dB/35dB
Transmit Retries at AP (Total/Maximum)..... 5/3
Transmit Retries at Client (Total/Maximum)..... 4/2
Transmit rate: 1M 2M 5.5M 6M 9M 11M 12M 18M 24M 36M 48M 54M 108M
Packet Count: 0 0 0 0 0 0 0 0 2 0 18 0
Transmit rate: 1M 2M 5.5M 6M 9M 11M 12M 18M 24M 36M 48M 54M 108M
Packet Count: 0 0 0 0 0 0 0 0 2 0 8 0
```

When CCX v4 or later releases is not enabled on either the controller or the client being tested, fewer details appear:

```
Ping Link Test to 00:0d:88:c5:8a:d1.
Link Test Packets Sent..... 20
Link Test Packets Received..... 20
Local Signal Strength..... -49dBm
Local Signal to Noise Ratio..... 39dB
```

### Displaying Link Latency Information: Example

This example shows how to display general configuration details of the access point. These configuration details contain the link latency results that correspond to the access point that you specify in the command.

```
Switch# show ap name AP01 config general
```

```
Cisco AP Name : AP01
Cisco AP Identifier : 55
Country Code : US - United States

- [How to Configure Power over Ethernet, page 754](#)
- [Configuration Examples for Configuring Power over Ethernet, page 756](#)

### Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

### Information About Configuring Power over Ethernet

When an access point that has been converted to lightweight mode (such as an AP1262) access point is powered by a power injector that is connected to a Cisco pre-Intelligent Power Management (pre-IPM) switch, you must configure Power over Ethernet (PoE), which is also known as *inline power*.

# How to Configure Power over Ethernet

## Configuring Power over Ethernet (CLI)

### SUMMARY STEPS

1. **ap name** *Cisco\_AP* **power injector installed**
2. **ap name** *Cisco\_AP* **power injector override**
3. **ap name** *Cisco\_AP* **power injector switch-mac-address** *switch\_mac\_address*
4. **show ap name** *Cisco\_AP* **config general**

### DETAILED STEPS

|               | Command or Action                                                                                                                                                                               | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>ap name</b> <i>Cisco_AP</i> <b>power injector installed</b><br><br><b>Example:</b><br>Switch# ap name AP02 power injector installed                                                          | Enables the PoE power injector state. The access point remembers that a power injector is connected to this particular switch port. If you relocate the access point, you must reenter this command after the presence of a new power injector is verified.<br><br><b>Note</b> Enter this command if your network contains any older Cisco 6-W switches that could be accidentally overloaded if connected directly to a 12-W access point. Make sure that the Cisco Discovery Protocol (CDP) is enabled before entering this command. Otherwise, this command will fail. |
| <b>Step 2</b> | <b>ap name</b> <i>Cisco_AP</i> <b>power injector override</b><br><br><b>Example:</b><br>Switch# ap name AP02 power injector override                                                            | Removes the safety checks and allows the access point to be connected to any switch port. You can use this command if your network does not contain any older Cisco 6-W switches that could be overloaded if connected directly to a 12-W access point. The access point assumes that a power injector is always connected. If you relocate the access point, it continues to assume that a power injector is present.                                                                                                                                                    |
| <b>Step 3</b> | <b>ap name</b> <i>Cisco_AP</i> <b>power injector switch-mac-address</b> <i>switch_mac_address</i><br><br><b>Example:</b><br>Switch# ap name AP02 power injector switch-mac-address 10a.2d.5c.3d | Sets the MAC address of the switch port that has a power injector.<br><br><b>Note</b> Enter this command if you know the MAC address of the connected switch port and do not want to automatically detect it using the installed option.                                                                                                                                                                                                                                                                                                                                  |
| <b>Step 4</b> | <b>show ap name</b> <i>Cisco_AP</i> <b>config general</b><br><br><b>Example:</b><br>Switch# show ap name AP02 config general                                                                    | Displays common information that includes the PoE settings for a specific access point.<br><br><b>Note</b> The Power Type/Mode text box shows “degraded mode” if the access point is not operating at full power.                                                                                                                                                                                                                                                                                                                                                         |

## Configuring Power over Ethernet (GUI)

- 
- Step 1** Choose **Configuration > Wireless > Access Points > All APs**.  
The **All APs** page appears with a list of access points that are associated with the switch.
- Step 2** Click the name of the access point.  
The **AP > Edit** page appears.
- Step 3** Click the **Advanced** tab.
- Step 4** In the **Power Over Ethernet Settings** area, select the **Pre-Standard 802.3af Switches** check box.  
Select this check box if the access point is being powered by a high-power 802.3af Cisco switch. This switch provides more than the traditional 6 Watts of power but does not support the intelligent power management (IPM) feature.
- Note** Unselect the **Pre-standard 802.3af Switches** check box if power is being provided by a power injector. This is the default value.
- Step 5** Select the **Power Injector State** check box.  
Select this check box if the attached switch does not support IPM and a power injector is being used. If the attached switch supports IPM, you do not need to select this check box.
- The **Power Injector Selection** drop-down list is displayed that contains parameters that enable you to protect your switch port from an accidental overload if the power injector is inadvertently bypassed.
- Step 6** From the **Power Injector Selection** drop-down list, choose an option to specify the desired level of protection. You can choose any one of the following three options:
- **Installed**—Examines and remembers the MAC address of the currently connected switch port and assumes that a power injector is connected. Choose this option if your network contains older Cisco 6-Watt switches and you want to avoid possible overloads by forcing a double-check of any relocated access points.  
If you want to configure the switch MAC address, enter the MAC address in the **Injector Switch MAC Address** text box. If you want the access point to find the switch MAC address, leave the **Injector Switch MAC Address** text box blank.
  - **Note** Each time that an access point is relocated, the MAC address of the new switch port fails to match the remembered MAC address, and the access point remains in low-power mode. You must then physically verify the existence of a power injector and reselect this option to cause the new MAC address to be remembered.
  - **Override**—Allows the access point to operate in high-power mode without first verifying a matching MAC address. You can use this option if your network does not contain any older Cisco 6-W switches that could be overloaded if connected directly to a 12-W access point. The advantage of this option is that if you relocate the access point, it continues to operate in high-power mode without any further configuration. The disadvantage of this option is that if the access point is connected directly to a 6-W switch, an overload occurs.
- Step 7** Click **Apply**.
- Step 8** Click **Save Configuration**.
- 

### What to Do Next

Manually reset the access point in order for the change to take effect.

## Configuration Examples for Configuring Power over Ethernet

### Displaying Power over Ethernet Information: Example

This example shows how to display common information that includes the PoE settings for a specific access point:

```
Switch# show ap name AP01 config general

Cisco AP Identifier..... 1
Cisco AP Name..... AP1
...
PoE Pre-Standard Switch..... Enabled
PoE Power Injector MAC Addr..... Disabled
Power Type/Mode..... PoE/Low Power (degraded mode)
...
```

### Overview

The switch delivers more services at access layer other than merely providing increased speeds and feeds. Wireless services is now integrated with the switch, which ensures that the access layer switch terminates the wireless users data plane, thereby delivering on the promise of Cisco's unified architecture. Unification implies that mobility services are provided to both wireless and wired stations.

The switch provides seamless roaming, which requires transparency of the network configuration and deployment options to the client.

From the end user's perspective, any mobility event must not change its IP address, its default router or DHCP server. This means that as stations roam, they must be able to

- Send an ARP to their default router, or
- Transmit a DHCP request to the server that had previously assigned their address.

From the infrastructure's perspective, as mobility events occur, the station's traffic must follow its current point of attachment, which can either be a mobility agent (MA) or mobility controller (MC). This must be true regardless of whether the station has moved to a network that is configured for a different subnet. The period from which the station is not receiving traffic following its mobility event must be as short as possible, even below 40 ms whenever possible, which includes any authentication procedures that are required.

From the infrastructure's perspective, the mobility management solution must have four main components, and all of these functions must be performed within the constraints of roaming:

- Initial Association—This function is used to identify the user's new point of attachment in the network.
- Context Transfer—This function is used to transfer state information associated with the station. This ensures that the station's static and real-time policies, including security and application ACLs, and services, remain the same across handoffs.
- Handoff—This function is used to signal that the station's point of attachment has changed, and control of the station should be relinquished by the previous access switch.
- Data Plane—This function is typically tied to the handoff process, and ensures that the station's traffic continues to be delivered and received from the station without any noticeable performance degradation.

## Wired and Wireless Mobility

One of the key features of the Converged access solution (applicable to both the Cisco Catalyst 3850 Switch and Cisco WLC 5700 Series Controller) is its ability to provide a device with an IP address and maintain its session persistence, across mobility events from ethernet connections to wireless and vice-versa. This feature allows users to remain on an ethernet network when possible, and make use of the freedom of mobility associated with wireless when necessary.

This feature leverages support from both the client and the infrastructure and uses the two factor authentication-device and user. The device authentication credentials is cached in the mobility controller (MC). When a device transitions across link layers, the device credentials is validated, and if a match is found, the MC ensures that the same IP address is assigned to the new interface.

## Features of Mobility

- Mobility Controller (MC)—The controller provides mobility management services for inter-peer group roaming events. The MC provides a central point of contact for management and policy based control protocols, such as RADIUS. This eliminates the need for the infrastructure servers to maintain a user's location as it transitions throughout the network. The MC sends the configuration to all the mobility agents under its sub-domain of their mobility configuration, peer group membership and list of members. A sub-domain is synonymous to the MC that forms it. Each sub-domain consists of an MC and zero or more access switches that have AP's associated to them.
- Mobility Agents (MA)— A mobility agent is either an access switch that has a wireless module running on it or an MC with an internal MA running on it. A mobility agent is the wireless component that maintains client mobility state machine for a mobile client that is connected via an AP to the device that the MA is running on.
- Mobility Sub Domain— It is an autonomous portion of the mobility domain network. A mobility sub-domain comprises of a single mobility controller and its associated mobility agents (MAs).

**Note** Even when more than one mobility controller is present, only one MC can be active at any given time.

A mobility sub-domain is the set of devices managed by the active mobility controller. A mobility sub-domain comprises of a set of mobility agents and associated access points.

- **Mobility Group**— A collection of mobility controllers (MCs) across which fast roaming is supported. The concept of mobility group is the same as a collection of buildings in a campus across which frequent roaming is expected.
- **Mobility Domain**— A collection of mobility sub-domains across which mobility is supported. The term mobility domain may be the same as a campus network.
- **Mobility Oracle (MO)**—The mobility oracle acts as the point of contact for mobility events that occur across mobility sub-domains. It also maintains a local database of each station in the entire mobility domain, their home and current sub-domain. A mobility domain includes one or more mobility oracle, though only one would be active at any given time.
- **Mobility Tunnel Endpoint (MTE)**— The mobility tunnel endpoint (MTE) provides data plane services for mobile devices through the use of tunneling. This minimizes the impact of roaming events on the network by keeping the user's point of presence on the network a constant.
- **Point of Attachment**— A station's point of attachment is where its data path is initially processed upon entry in the network. This could either be the access switch that is currently providing it service, or the wireless LAN controller.
- **Point of Presence**— A station's point of presence is the place in the network where the station is being advertised. For instance, if an access switch is advertising reachability to the station via a routing protocol, the interface on which the route is being advertised is considered the station's point of presence.
- **Switch Peer Group (SPG)**— A peer group is a statically created list of neighboring access switches between which fast mobility services is provided. A peer group limits the scope of interactions between switches during handoffs to only those that are geographically proximate.
- **Station**—A user's device that connects to and requests service from the network. The device may have a wired, wireless or both interfaces.
- **Switch in the same SPG**—A peer switch that is part of the peer group of the local switch.
- **Switch outside the SPG**—A peer access switch that is not part of the local switch's peer group.
- **Foreign Mobility Controller**— The mobility controller providing mobility management service for the station in a foreign mobility sub-domain. The foreign mobility controller acts as a liaison between access switches in the foreign sub-domain and the mobility controller in the home domain.
- **Foreign Mobility Sub-Domain**— The mobility sub-domain, controlled by a mobility controller, supporting a station which is anchored in another mobility sub-domain
- **Foreign Switch**— The access switch in the foreign mobility sub-domain currently providing service to the station.
- **Anchor Mobility Controller**— The mobility controller providing a single point of control and mobility management service for stations in their home mobility sub-domain.
- **Anchor Mobility Sub-Domain**— The mobility sub-domain, controlled by a mobility controller, for a station where its IP address was assigned.
- **Anchor Switch**— The switch in the home mobility sub-domain that last provided service to a station.

## Sticky Anchoring for Low Latency Roaming

Sticky Anchoring ensures low roaming latency from the client's point of presence is maintained at the switch where the client initially joins the network. It is expensive to apply client policies at a switch for a roaming client. There can be considerable delay as it involves contacting the AAA server for downloadable ACLs which is not acceptable for restoring time sensitive client traffic.

To manage this delay, when the client roams between APs connected to different switches, irrespective of whether it is an intra sub-domain roam or inter sub-domain roam, the client traffic is always tunneled to the switch where the client first associates. The client is anchored at its first point of attachment for its lifetime in the network.

This behavior is enabled by default. You can also disable this behavior to allow the client anchoring only for inter-subnet roams. This configuration is per WLAN config and is available under the WLAN config mode. The customer can configure different SSIDs for time sensitive and non time sensitive applications.

## Bridge Domain ID and L2/L3 Roaming

Bridge domain ID provides the mobility nodes with information to decide on specific roam type, either as L2 or L3 roam. It also allows the network administrators to reuse the VLAN IDs across network distribution. When the VLAN IDs do not have the associated subnet configurations, they may require additional parameter to use in conjunction with VLAN ID. The network administrator ensures that the given VLAN under the same bridge domain ID are associated with the unique subnet. The mobility nodes will first check for the bridge domain ID for the given node and the VLAN ID associated with the client to identify the roam type. The bridge domain ID and the VLAN ID must be same to treat a roam as L2 roam.

The bridge domain ID is configured for each SPG when creating a SPG and later on the MC. The bridge domain ID could be same for more than one SPG and all the MAs under the SPG will share the same bridge domain ID. This information is pushed to the MAs as part of the configuration download when MA comes up initially. If the bridge domain ID is modified when the system is up, it will be pushed to all the MAs in the modified SPG and will take immediate effect for the future roams.

**Note**

---

The MC can also have a bridge domain ID for it self, as the MC can also be part of a SPG.

---

## Link Down Behavior

This section provides information about data synchronization between MA-MC and MC-MO when MC or MO faces downtime in absence of redundancy manager. When Keepalive is configured between MA-MC or MC-MO the clients database is synchronized between the MO and the MCs and the MC and its MAs respectively.

## Platform Specific Scale Requirement for the Mobility Controller

The Mobility Controller (MC) role is supported on a number of different platforms like, the Cisco WLC 5700 Series, CUWN and Catalyst 3850 Switches. The scale requirements on these three platforms are summarized in the table below:

| <b>Scalability</b>                        | <b>Catalyst 3850 as MC</b> | <b>Catalyst 3650 as MC</b> | <b>Cisco WLC 5700 as MC</b> | <b>CUWN 5508 as MC</b> | <b>WiSM2 as MC</b> |
|-------------------------------------------|----------------------------|----------------------------|-----------------------------|------------------------|--------------------|
| Max number of MC in Mobility Domain       | 8                          | 8                          | 72                          | 72                     | 72                 |
| Max number of MC in Mobility Group        | 8                          | 8                          | 24                          | 24                     | 24                 |
| Max number of MAs in Sub-domain (per MC)  | 16                         | 16                         | 350                         | 350                    | 350                |
| Max number of SPGs in Sub-domain (per MC) | 8                          | 8                          | 24                          | 24                     | 24                 |
| Max number of MAs in a SPG                | 16                         | 16                         | 64                          | 64                     | 64                 |

## Mobility Network Elements

---

- [Mobility Agent, page 765](#)
- [Mobility Controller, page 766](#)
- [Mobility Oracle, page 767](#)
- [Guest Controller, page 767](#)

### Mobility Agent

A Mobility Controller resides on the switch. It is both, control path and data path entity and is responsible for:

- Handling the mobility events on the switch
- Configuring the datapath elements on the switch for mobility, and
- Communicating with the mobility controller

As MA, the switch performs the datapath functions by terminating the CAPWAP tunnels that encapsulate 802.11 traffic sourced by wireless stations.

This allows the switch to apply features to wired and wireless traffic in a uniform fashion. As far as switch is concerned, 802.11 is just another access medium.

The MA performs the following functions:

- Support the mobility protocol – The MA is responsible for responding in a timely manner, ensuring the switch is capable of achieving its roaming budget.
- Point of presence – If the wireless subnets are not available at the MC, the MA assumes the point of presence if the wireless client VLAN is not available at the new point of attachment and tunnel the client traffic accordingly.
- ARP Server – When the network is configured in a layer 2 mode, the MA is responsible for advertising reachability for the stations connected to it. If tunneling is employed, the ARP request is transmitted on behalf of the station through the tunnel, which the point of presence (anchor switch) would bridge onto its uplink interface.

- Proxy IGMP – The MA on the switch is responsible for subscribing to multicast groups on behalf of a station after a roaming event has occurred. This information is passed as part of the context to the new switch. This ensures the multicast flows follow the user as it roams.
- Routing – When the switch is connected to a layer 3 access network, the MA is responsible for injecting routes for the stations that are associated with it for which tunneling is not provided.
- 802.1X Authenticator – The authenticator function is included in the MA, and handles both wired and wireless stations.
- Secure PMK Sharing – When a station successfully authenticates to the network, the MA forwards the PMK to the MC. The MC is responsible for flooding the PMK to all the MAs under its sub-domain and to the peer MCs in the mobility group.

The MA also performs the following datapath functions:

- Mobility tunnel – If tunneling is used, the MA encapsulates and decapsulates packets from the mobility tunnel to the MC, and to other MA in the peer group, if the access switches are serving as points of presence. The MA supports the tunneling of client data traffic between the point of attachment and the point of attachment. The packet format used for other switches is CAPWAP with an 802.3 payload. The MA also supports reassembly and fragmentation for mobility tunnels.
- Encryption – The mobility control traffic between the mobility nodes is DTLS encrypted. The MA also encrypts the CAPWAP control and data (optional) at the point of attachment.
- CAPWAP – The switch supports the CAPWAP control and data planes. The switch forwarding logic is responsible for terminating the CAPWAP tunnels with 802.11 as well as 802.3 payloads. Since support for large frames (greater than 1500bytes) is not universally available, the switch supports CAPWAP fragmentation and reassembly.

## Mobility Controller

The main function of mobility controller is to coordinate the client roaming beyond a switch peer group. The other features of the mobility controller are:

- Station Database—The Mobility Controller maintains a database of all the clients that are connected within the local mobility sub-domain.
- Mobility Protocol—The MC supports the mobility protocol which ensures the target roaming point responds in a timely manner and achieves the 150ms roaming budget
- Interface to Mobility Oracle—The Mobility Controller acts as a gateway between the switch and the Mobility Oracle. When the Mobility Controller does not find a match in its local database, it suggests a match for a wireless client entry (in its database) and forwards the request to the Mobility Oracle, which manages the Mobility Domain.

---

**Note** Mobility Oracle function can be enabled on an MC only if it is supported by the platform.

---

- ARP Server—When tunneling is employed for a station, its point of presence on the network is the Mobility Tunnel Endpoint (MTE). The Mobility Controller responds to any ARP requests received for the stations it is responsible for.

- Routing—When the Mobility Controller is connected to a layer three network, the Mobility Controller is responsible for injecting routes for the stations it supports into the network.
- Configures MTE—The Mobility Controller is the control point for the switch for all mobility management related requests. When a change in a station's point of attachment occurs, the Mobility Controller is responsible for configuring the forwarding policy on the MTE.
- NTP Server—The Mobility Controller acts as an NTP server to the switch and supports all the nodes to have their clocks synchronized with it.

## Mobility Oracle

The Mobility Oracle coordinates the client roams beyond the subdomain on a need basis and consists of the following features:

- Station Database—The Mobility Oracle maintains a database of all stations that are serviced within the mobility domain. This database is populated during the Mobility Oracle's interactions with all the Mobility Controllers, in all of the mobility sub-domains it supports.
- Interface to Mobility Controller—When the Mobility Oracle receives a request from a Mobility Controller, it performs a station lookup, and forwards, whenever needed, the request to the proper Mobility Controller.
- NTP Server—The Mobility Oracle acts as an NTP server to the Mobility Controllers and synchronizes all the **switch** clocks within the mobility domain.

## Guest Controller

The guest access feature provides guest access to wireless clients. The guest tunnels use the same format as the mobility tunnels. Using the guest access feature, there is no need to configure guest VLANs on the access switch. Traffic from the wired and wireless clients terminates on Guest Controller. Since the guest VLAN is not present on the access switch, the traffic is tunneled to the MTE over the existing mobility tunnel, and then via a guest tunnel to the Guest Controller.

The advantage of this approach is that all guest traffic passes through the MTE before it is tunneled to the Guest Controller. The Guest Controller only needs to support tunnels between itself and all the MTEs.

The disadvantage is that the traffic from the guest client is tunneled twice - once to the MTE and then again to the Guest Controller.

## Mobility Control Protocols

---

- [About Mobility Control Protocols, page 769](#)

- [Initial Association, page 770](#)
- [Intra Switch Handoff, page 771](#)
- [Intra Switch Peer Group Handoff, page 771](#)
- [Inter Switch Peer Group Handoff, page 772](#)
- [Inter Sub Domain Handoff, page 774](#)
- [Inter Mobility Group Handoff, page 775](#)

### About Mobility Control Protocols

The mobility control protocol is used regardless of whether tunneled or routed. The mobility control protocol is used for mobility events between the MO, MC and MA.

The mobility architecture uses both,

- Distributed approach, using the direct communication with the switches in their respective SPG, as well as
- Centralized approach, using the MC and MO.

The goal is to reduce the overhead on the centralized MC, while limiting the interactions between switches to help scale the overall system.

### Initial Association and Roaming

The following scenarios are applicable to the mobility management protocol:

- Initial Association
- Intra Switch Roam
- Intra Switch Peer Group Roam

- Inter Switch Peer Group Roam
- Inter Sub-Domain Roam
- Inter Group Roam

## Initial Association

The illustration below explains the initial association process followed by the switch:

**Figure 47: Initial Association**

- 1 When a station initially associates with a mobility agent, the MA performs a lookup to determine whether keying information for key caching is locally available in the MA. If no keying information is available, which is the case when the station first appears in the network, the switch prompts the device to authenticate

itself to generate the Pairwise Master Key (PMK). The PMK is generated on the client and the RADIUS server side, and the RADIUS sever forwards the PMK to the authenticator, the MA.

- 2 The MA sends the PMK to the MC.
- 3 After receiving the PMK from the MA, the MC transmits the PMK to all the MAs in its sub-domain, and to all the other MCs in its mobility group.
- 4 The mobility group is a single key domain. This ensures that 802.11r compliant stations recognize the key domain, and attempts to utilize the fast transition procedures defined in 802.11r.

**Note**

The 802.11r protocol defines a key domain, which is a collection of access points that share keying information.

- 5 (Refer to step 2B in the illustration). Since the station is new to the mobility sub-domain, as indicated by the fact that the PMK is not in the MA local key cache, the MA transmits a mobile announce message to the MC.
- 6 The MC checks if the client exists in its database. As the client cannot be found, the MC in turn forwards it to the MO, if available.
- 7 (Refer to step 5 in the illustration). As the station is new to the network, the MO returns a negative response (NACK), which is forwarded by the MC to the switch. If the Mobility Oracle is not available then the MC is responsible for not responding to the Mobile Announce.
- 8 The MA on the switch informs the MC about the station's new point of attachment via the Handoff Complete message.
- 9 The MA then informs the other MAs in its switch peer group (SPG) about the station's new point of attachment via the Handoff Notification message. It is necessary to transmit this notification to the MAs in its SPG to allow local handoff without interacting with the MC. The Handoff Notification message sent to MAs in SPG need not carry all the information in Handoff Complete message sent to the MC.
- 10 (Refer to step 7B in the illustration). The MC updates its database and forwards the Handoff Complete message to the Mobility Oracle. This ensures that the Mobility Oracle's database is updated to record the station's current home mobility sub-domain.

To eliminate race conditions that could occur with devices moving quickly across switch, regardless of whether they are within a mobility sub-domain or not, the messages between MA and MC/MO are time synchronized. This would allow the MC and MO to properly process requests, if they are received out of order.

The Handoff Notification sent to MAs in the SPG are not acknowledged.

## Intra Switch Handoff

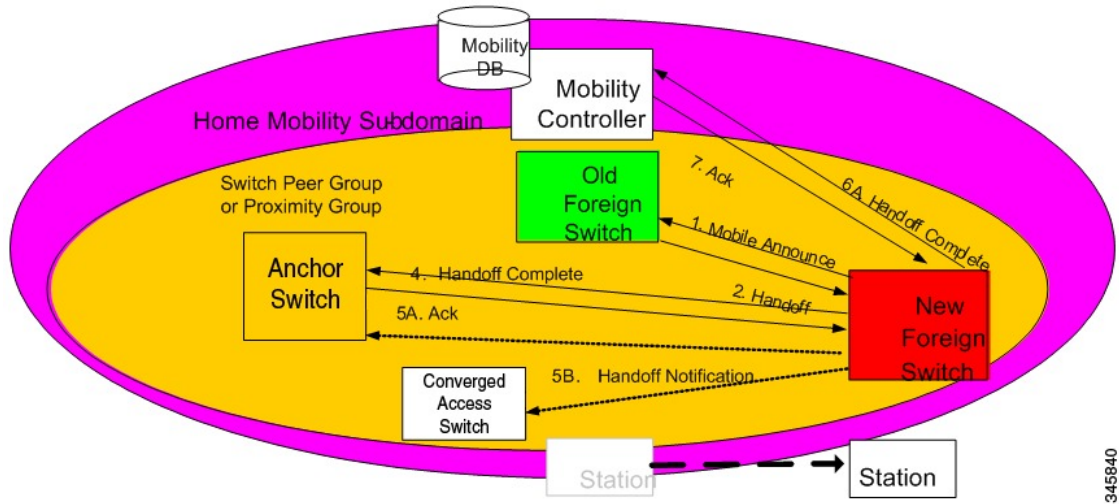

Mobility events within an MA are completely transparent to the SPG and the MC. When a station moves across APs on the same MA and attempts to perform a fast handoff, the PMK is present on the MA. The MA will complete the fast handoff without invoking any additional signal.

## Intra Switch Peer Group Handoff

The switch peer group (SPG) is a group of MAs between which users may roam, and expect fast roaming services. Allowing the MA to handoff directly within a SPG reduces the overhead on the MC as it requires fewer messages to be exchanged.

After the initial association is complete the station moves to another MA belonging to its SPG. In an intra switch peer group roam, the initial association, the stations PMK was forwarded to all MAs in the mobility sub-domain.

Figure 48: Intra Switch Peer Group Handoff

The following process explains the intra switch peer group handoff:

- 1 In the initial association example, the Handoff Notification message is sent to all MAs in its SPG to know the station's current point of attachment.
- 2 The new MA sends a unicast Mobile Announce message to the previous MA to which the client is associated.
- 3 After the handoff completion, the new MA transmits a Handoff Complete message to the MC.
- 4 The new switch sends a Handoff Notification to all MA in its own SPG to inform them about the clients new point of presence.

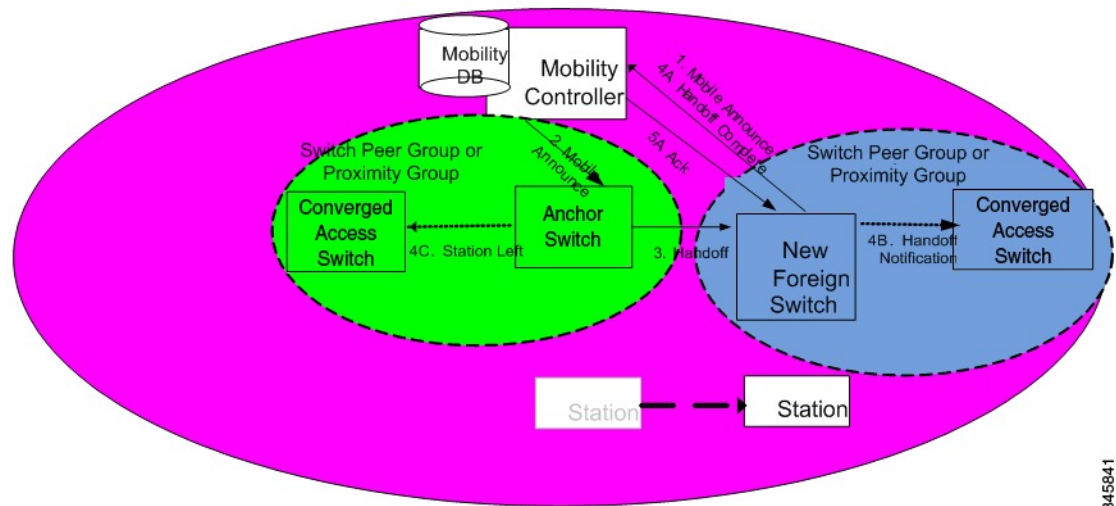

## Inter Switch Peer Group Handoff

The Intra SPG roams do not cover all possible scenarios and there can be cases where it is possible for mobility events to occur between two MAs that are not in the same SPG.

When a MA does not have any information about a station's current point of attachment, because of the Handoff Notification message getting lost in the network, or because of the the station roaming to an MA that is not in the new SPG, the MA consults the MC. The MC provides information about the clients point of

presence within the mobility sub-domain. This eliminates the need to consult all other MCs within the mobility sub-domain.

**Figure 49: Inter Switch Peer Group Handoff**

The image above illustrates an example of a mobility event that occurs across MAs that are not in the same SPG, but within the same mobility sub-domain.

**Note**

The MA color matches the circle representing its SPG.

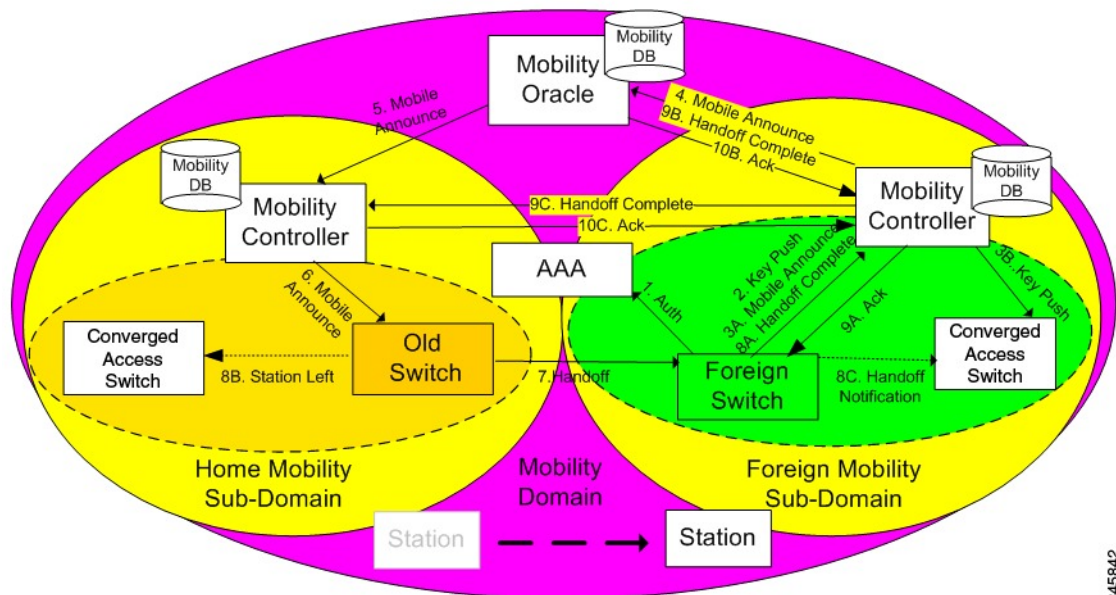

- 1 The new MA will have the PMK for the station, which was forwarded to each MA in the mobility sub-domain upon client initial authentication.
- 2 Since the MA had not been previously notified of the station's presence on a neighboring MA inside a different SPG transmits the mobile announce to the sub-domain's MC.
- 3 (Refer to step 2 in the illustration) On receiving the mobile announce message, the MC performs a lookup in its database, and forwards the request to the MA that was previously providing service to the station. This information is known to the MC through a previously received Handoff Complete message sent in a reliable fashion from the old MA.
- 4 (Refer to step 3 in the illustration) The old MA, shown in green above, transmits a Handoff message directly to the new MA.
- 5 The old MA needs to notify other MAs within its SPG of the fact that the station has left the group using a Station Left message. This ensures that if the station were to come back to one of the MA, they would be aware of the fact that the station is no longer being serviced by the old MA.
- 6 Once the handoff is complete, the new MA transmits the Handoff Complete message in a reliable fashion to the MC.
- 7 The new MA then transmits the Handoff Notification to the other MAs within its SPG.

## Inter Sub Domain Handoff

A sub-domain is an ensemble formed by a mobility controller and the mobility agents it directly manages. An inter sub-domain mobility event implies communication between two mobility controllers. These 2 mobility controllers can be configured with the same mobility group value and recognize each other. They will appear in each other's mobility list, or they can be configured with different mobility group values, and still recognize each other.

When the roaming event occurs across sub-domains between MCs in the same mobility group, the 802.11r key domain advertised by the new APs are the same. Additionally, the client PMK is also transmitted to all MCs upon the client's initial authentication. The new MC does not need to force the client to reauthenticate, and the new MC also knows which previous MC was managing the wireless client mobility.

**Figure 50: Inter Sub Domain Handoff**

345842

The following steps are involved in the inter sub domain handoff, when mobility controllers belong to the same mobility group:

- 1 When a client's PMK was sent by the initial MA to all the MCs in the mobility group, the new MA already had already received the client PMK from its MC, and re-authentication is not required.
- 2 The new MA was not notified previously of the station's presence on a neighboring MA inside a different SPG it transmits the mobile announce to the sub-domain's MC.
- 3 On receiving the mobile announce message, the MC forwards the mobile announce to the MO, which performs a lookup in its database, and forwards the request to the MC that was previously providing service to the station.
- 4 The previous MC, in turn, forwards the request to the MA that was previously providing service to the station.
- 5 The old MA, shown in yellow color above, transmits a Handoff message directly to the new MA.

- 6 The old MA must notify the other MAs within its SPG of the fact that the station has left the SPG using a Station Left message. This ensures that if the station comes back to one of the MA, the MA is aware of the fact that the station is no longer serviced by the old MA.
- 7 Once the handoff is complete, the new MA transmits the Handoff Complete message in a reliable fashion to the new Mobility Controller.
- 8 The new MA then transmits the Handoff Notification to all other MAs.
- 9 The new MC then transmits the Handoff Complete to the old MC.

## Inter Mobility Group Handoff

A mobility group is formed by MCs sharing the same mobility group name, and knowing each other.

Since the roaming event occurs across mobility groups, the 802.11r key domain advertised by the new APs differ. This forces the client to re-authenticate. They are propagated only within a mobility group, and roaming across mobility groups requires the stations to re-authenticate when they cross mobility group boundaries. When the authentication is complete, the PMK that is generated is pushed to the MAs and MCs within the same mobility group. The stations cache the PMK from the previous sub-domain because each PMK is associated to a given sub-domain (802.11y key domain). This ensures that you do not have to re-authenticate when the PMK roams back to the previous sub-domain within the pmk cache timeout interval. The remaining procedure follows the inter-sub-domain handoff steps, except that these steps relate to inter mobility group roaming.

## Configuring Mobility

- [Configuring Mobility Controller, page 777](#)
- [Configuring Mobility Agent, page 785](#)

### Configuring Mobility Controller

#### Configuring Converged Access Controllers

##### Creating Peer Groups, Peer Group Member, and Bridge Domain ID (CLI)

###### Before You Begin

- On the mobility agent, you can only configure the IP address of the mobility controller.
- On the mobility controller, you can define the peer group and the IP address of each peer group member.

###### SUMMARY STEPS

1. `wireless mobility controller`
2. `wireless mobility controller peer-group SPG1`
3. `wireless mobility controller peer-group SPG1 member ip member-ip-addr public-ip public-ip-addr`
4. `wireless mobility controller peer-group SPG1 member ip member-ip-addr public-ip public-ip-addr`
5. `wireless mobility controller peer-group SPG2`
6. `wireless mobility controller peer-group SPG2 member ip member-ip-addr public-ip public-ip-addr`
7. `wireless mobility controller peer-group SPG1 bridge-domain-id id`

## DETAILED STEPS

|               | Command or Action                                                                                                                                                                                                                               | Purpose                                                                                                                                                                                                                                                                                                                                     |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>wireless mobility controller</b><br><br><b>Example:</b><br>Switch(config)# <b>wireless mobility controller</b>                                                                                                                               | Enables the mobility controller functionality on the device. This command is applicable only to the switch. The controller is by default a mobility controller.                                                                                                                                                                             |
| <b>Step 2</b> | <b>wireless mobility controller peer-group SPG1</b><br><br><b>Example:</b><br>Switch(config)# <b>wireless mobility controller peer-group SPG1</b>                                                                                               | Creates a peer group named SPG1.                                                                                                                                                                                                                                                                                                            |
| <b>Step 3</b> | <b>wireless mobility controller peer-group SPG1 member ip member-ip-addr public-ip public-ip-addr</b><br><br><b>Example:</b><br>Switch(config)# <b>wireless mobility controller peer-group SPG1 member ip 10.10.20.2 public-ip 10.10.20.2</b>   | Adds a mobility agent to the peer group.<br><b>Note</b> The 10.10.20.2 is the mobility agent's direct IP address. When NAT is used, use the optional public IP address to enter the mobility agent's NATed address. When NAT is not used, the public IP address is not used and the device displays the mobility agent's direct IP address. |
| <b>Step 4</b> | <b>wireless mobility controller peer-group SPG1 member ip member-ip-addr public-ip public-ip-addr</b><br><br><b>Example:</b><br>Switch(config)# <b>wireless mobility controller peer-group SPG1 member ip 10.10.20.6 public-ip 10.10.20.6</b>   | Adds another member to the peer group SPG1.                                                                                                                                                                                                                                                                                                 |
| <b>Step 5</b> | <b>wireless mobility controller peer-group SPG2</b><br><br><b>Example:</b><br>Switch(config)# <b>wireless mobility controller peer-group SPG2</b>                                                                                               | Creates another peer group SPG2.                                                                                                                                                                                                                                                                                                            |
| <b>Step 6</b> | <b>wireless mobility controller peer-group SPG2 member ip member-ip-addr public-ip public-ip-addr</b><br><br><b>Example:</b><br>Switch(config)# <b>wireless mobility controller peer-group SPG2 member ip 10.10.10.20 public-ip 10.10.10.20</b> | Adds a member to peer group SPG2.                                                                                                                                                                                                                                                                                                           |
| <b>Step 7</b> | <b>wireless mobility controller peer-group SPG1 bridge-domain-id id</b><br><br><b>Example:</b><br>Switch(config)# <b>wireless mobility controller peer-group SPG1 bridge-domain-id 54</b>                                                       | (Optional) Adds a bridge domain to SPG1 used for defining the subnet-VLAN mapping with other SPGs.                                                                                                                                                                                                                                          |

This example shows how to create peer group and add members to it:

```
Switch(config)# wireless mobility controller
Switch(config)# wireless mobility controller peer-group SPG1
Switch(config)# wireless mobility controller peer-group SPG1
Switch(config)# wireless mobility controller peer-group SPG1 member ip 10.10.20.2 public-ip
10.10.20.2
Switch(config)# wireless mobility controller peer-group SPG1 member ip 10.10.20.6 public-ip
10.10.20.6
Switch(config)# wireless mobility controller peer-group SPG2
Switch(config)# wireless mobility controller peer-group SPG2 member ip 10.10.10.20 public-ip
10.10.10.20
Switch(config)# wireless mobility controller peer-group SPG1 bridge-domain-id 54
```

## Creating Peer Groups, Peer Group Member, and Bridge Domain ID (GUI)

### Before You Begin

- Ensure that the device is in mobility controller state.
- On the mobility agent, you can only configure the IP address of the mobility controller.
- On the mobility controller, you can define the peer group and the IP address of each peer group member.

- 
- Step 1** Choose **Controller > Mobility Management > Switch Peer Group**.  
The **Mobility Switch Peer Groups** page is displayed.
- Step 2** Click **New**.
- Step 3** Enter the following details:
- Switch Peer Group Name**
  - Bridge Domain ID**
  - Multicast IP Address**
- Step 4** Click **Apply**.
- Step 5** Click **Save Configuration**.
- 

## Configuring Local Mobility Group (CLI)

Configuration for wireless mobility groups and mobility group members where the mobility group is a group of MCs.

### Before You Begin

MCs can belong only to one mobility group, and can know MCs in several mobility groups.

## SUMMARY STEPS

1. **wireless mobility group name** *group-name*
2. **wireless mobility group member ip** *member-ip-addr* **public-ip** *public-ip-addr*
3. **wireless mobility group keepalive interval** *time-in-seconds*
4. **wireless mobility group keepalive count** *count*

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                                 | Purpose                                                                                                                                                                                     |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>wireless mobility group name</b> <i>group-name</i><br><br><b>Example:</b><br>Switch(config)# <b>wireless mobility group name</b> Mygroup                                                                                       | Creates a mobility group named Mygroup.                                                                                                                                                     |
| Step 2 | <b>wireless mobility group member ip</b> <i>member-ip-addr</i> <b>public-ip</b> <i>public-ip-addr</i><br><br><b>Example:</b><br>Switch(config)# <b>wireless mobility group member ip</b> 10.10.34.10 <b>public-ip</b> 10.10.34.28 | Adds a mobility controller to the Mygroup mobility group.<br><br><b>Note</b> When NAT is used, use the optional public IP address to enter the NATed IP address of the mobility controller. |
| Step 3 | <b>wireless mobility group keepalive interval</b> <i>time-in-seconds</i><br><br><b>Example:</b><br>Switch(config)# <b>wireless mobility group keepalive interval</b> 5                                                            | Configures the interval between two keepalives sent to a mobility member.                                                                                                                   |
| Step 4 | <b>wireless mobility group keepalive count</b> <i>count</i><br><br><b>Example:</b><br>Switch(config)# <b>wireless mobility group keepalive count</b> 3                                                                            | Configures the keep alive retries before a member status is termed DOWN.                                                                                                                    |

```
Switch(config)# wireless mobility group name Mygroup
Switch(config)# wireless mobility group member ip 10.10.34.10 public-ip 10.10.34.28
Switch(config)# wireless mobility group keepalive interval 5
Switch(config)# wireless mobility group keepalive count 3
```

## Configuring Local Mobility Group (GUI)

## Before You Begin

Mobility controllers can belong to only one mobility group and can know mobility controllers in several mobility groups.

---

**Step 1** Choose Controller > Mobility Management > Mobility Global Config.

The **Mobility Controller Configuration** page is displayed.

**Step 2**

Enter the following details:

- a) **Mobility Group Name**
- b) **Mobility Keepalive Interval**
- c) **Mobility Keepalive Count**
- d) **Multicast IP Address** if you want to enable multicast mode to send mobile announce messages to the mobility members.  
**Note** If you do not enable multicast IP address, the device uses unicast mode to send mobile announce messages.

**Step 3**

Click **Apply**.

**Step 4**

Click **Save Configuration**.

### Adding a Peer Mobility Group (CLI)

#### Before You Begin

MCs belong to only one group, and can know MCs in several groups.

#### SUMMARY STEPS

1. `wireless mobility group member ip member-ip-addr public-ip public-ip-addr group group-name`

#### DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                                                        | Purpose                                                             |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------|
| Step 1 | <p><code>wireless mobility group member ip member-ip-addr public-ip public-ip-addr group group-name</code></p> <p><b>Example:</b><br/> Switch(config)# <code>wireless mobility group member ip 10.10.10.24 public-ip 10.10.10.25 group Group2</code></p> | Adds the member as a peer MC in a different group than the Mygroup. |

### Adding a Peer Mobility Group (GUI)

#### Before You Begin

Mobility controllers belong to only one group, and can know several mobility groups.

**Step 1**

Choose **Controller > Mobility Management > Mobility Peer**.

The **Mobility Peer** page is displayed.

**Step 2** Click **New**.

**Step 3** Enter the following details:

- a) **Mobility Member IP**
- b) **Mobility Member Public IP**
- c) **Mobility Member Group Name**
- d) **Multicast IP Address**

**Step 4** Click **Apply**.

**Step 5** Click **Save Configuration**.

### Configuring Optional Parameters for Roaming Behavior

Use this configuration to disable the sticky anchor. This command can also be used, if required, between all MA's and MC's where roaming is expected for the target SSID.

#### SUMMARY STEPS

1. `wlan open21`
2. `no mobility anchor sticky`

#### DETAILED STEPS

|               | Command or Action                                                                                                            | Purpose                                      |
|---------------|------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------|
| <b>Step 1</b> | <code>wlan open21</code><br><br><b>Example:</b><br><code>Switch(config)# wlan open20</code>                                  | Configures a WLAN.                           |
| <b>Step 2</b> | <code>no mobility anchor sticky</code><br><br><b>Example:</b><br><code>Switch(config-wlan)# no mobility anchor sticky</code> | Disables the default sticky mobility anchor. |

```
Switch(config)# wlan open20
Switch(config-wlan)# no mobility anchor sticky
```

### Pointing the Mobility Controller to a Mobility Oracle (CLI)

#### Before You Begin

You can configure a mobility oracle on a known mobility controller.

## SUMMARY STEPS

1. `wireless mobility group member ip member-ip-addr group group-name`
2. `wireless mobility oracle ip oracle-ip-addr`

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                              | Purpose                                                |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------|
| Step 1 | <code>wireless mobility group member ip member-ip-addr group group-name</code><br><br><b>Example:</b><br><pre>Switch(config)# wireless mobility group member ip 10.10.10.10 group Group3</pre> | Creates and adds a MC to a mobility group.             |
| Step 2 | <code>wireless mobility oracle ip oracle-ip-addr</code><br><br><b>Example:</b><br><pre>Switch(config)# wireless mobility oracle ip 10.10.10.10</pre>                                           | Configures the mobility controller as mobility oracle. |

```
Switch(config)# wireless mobility group member ip 10.10.10.10 group Group3
Switch(config)# wireless mobility oracle ip 10.10.10.10
```

## Pointing the Mobility Controller to a Mobility Oracle (GUI)

### Before You Begin

You can configure a mobility oracle on a known mobility controller.

- 
- Step 1** Choose **Controller > Mobility Management > Mobility Global Config**. The **Mobility Controller Configuration** page is displayed.
  - Step 2** Enter the **Mobility Oracle IP Address**.  
**Note** To make the mobility controller itself a mobility oracle, select the **Mobility Oracle Enabled** check box.
  - Step 3** Click **Apply**.
  - Step 4** Click **Save Configuration**.
- 

## Configuring Guest Controller

A guest controller is used when the client traffic is tunneled to a guest anchor controller in the demilitarized zone (DMZ). The guest client goes through a web authentication process. The web authentication process is optional, and the guest is allowed to pass traffic without authentication too.

Enable the WLAN on the mobility agent on which the guest client connects with the mobility anchor address of the guest controller.

On the guest controller WLAN, which can be Cisco 5500 Series WLC, Cisco WiSM2, or Cisco 5700 Series WLC, configure the IP address of the mobility anchor as its own IP address. This allows the traffic to be tunneled to the guest controller from the mobility agent.

**SUMMARY STEPS**

1. **wlan** *wlan-id*
2. **mobility anchor** *guest-anchor-ip-addr*
3. **client vlan** *vlan-name*
4. **security open**

**DETAILED STEPS**

|               | Command or Action                                                                                                                   | Purpose                                                                                                                                                                                                                                                                    |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>wlan</b> <i>wlan-id</i><br><br><b>Example:</b><br>Switch(config)# <b>wlan Mywlan1</b>                                            | Creates a WLAN for the client.                                                                                                                                                                                                                                             |
| <b>Step 2</b> | <b>mobility anchor</b> <i>guest-anchor-ip-addr</i><br><br><b>Example:</b><br>Switch(config-wlan)# <b>mobility anchor 10.10.10.2</b> | Enables the guest anchors (GA) IP address on the MA.<br><b>Note</b> To enable guest anchor on the mobility controller, you need not enter the IP address. Enter the <b>mobility anchor</b> command in the WLAN configuration mode to enable GA on the mobility controller. |
| <b>Step 3</b> | <b>client vlan</b> <i>vlan-name</i><br><br><b>Example:</b><br>Switch(config-wlan)# <b>client vlan gc_ga_vlan1</b>                   | Assigns a VLAN to the client's WLAN.                                                                                                                                                                                                                                       |
| <b>Step 4</b> | <b>security open</b><br><br><b>Example:</b><br>Switch(config-wlan)# <b>security open</b>                                            | Assigns a security type to the WLAN.                                                                                                                                                                                                                                       |

```
Switch(config)# wlan Mywlan1
Switch(config-wlan)# mobility anchor 10.10.10.2
Switch(config-wlan)# client vlan gc_ga_vlan1
Switch(config-wlan)# security open
```

## Configuring Guest Anchor

### SUMMARY STEPS

1. **wlan** Mywlan1
2. **mobility anchor** <guest-anchors-own-ip-address>
3. **client vlan**<vlan-name>
4. **security open**

### DETAILED STEPS

|               | Command or Action                                                                                                               | Purpose                                                                                                  |
|---------------|---------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>wlan</b> Mywlan1<br><br><b>Example:</b><br>Switch(config)# wlan Mywlan1                                                      | Creates a wlan for the client.                                                                           |
| <b>Step 2</b> | <b>mobility anchor</b> <guest-anchors-own-ip-address><br><br><b>Example:</b><br>Switch(config-wlan)# mobility anchor 10.10.10.2 | Enables the guest anchors IP address on the guest anchor (GA). The GA assigns its own address on itself. |
| <b>Step 3</b> | <b>client vlan</b> <vlan-name><br><br><b>Example:</b><br>Switch(config-wlan)# client vlan gc_ga_vlan1                           | Assigns a vlan to the clients wlan.                                                                      |
| <b>Step 4</b> | <b>security open</b><br><br><b>Example:</b><br>Switch(config-wlan)# security open                                               | Assigns a security type to the wlan.                                                                     |

```
Switch(config)# wlan Mywlan1
Switch(config-wlan)# mobility anchor 10.10.10.2
Switch(config-wlan)# client vlan gc_ga_vlan1
Switch(config-wlan)# security open
```

## Configuring Mobility Agent

### Configuring Mobility Agent by Pointing to Mobility Controller (CLI)

#### Before You Begin

- By default, the switches are configured as mobility agents.
- Your network must have at least one mobility controller and the network connectivity with the mobility controller must be operational.

- You cannot configure mobility from the mobility agent. On the mobility agent, you can configure only the IP address of the mobility controller to download the SPG configuration.
- On the mobility agent, you can either configure the mobility controller address to point to an external mobility agent, or enable the mobility controller function.

**SUMMARY STEPS**

1. **configure terminal**
2. **wireless management interface** vlan 21

**DETAILED STEPS**

|               | <b>Command or Action</b>                                                                                                         | <b>Purpose</b>                                                                                                                                                |
|---------------|----------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                                            | Enters global configuration mode.                                                                                                                             |
| <b>Step 2</b> | <b>wireless management interface</b> vlan 21<br><br><b>Example:</b><br>Switch (config)# wireless management interface<br>vlan 21 | Enables the wireless functionality on the device and activates the mobility agent function. This ensures the APs have a place to terminate the CAPWAP tunnel. |

This example shows how to add a mobility agent into the mobility group by pointing it to a mobility controller:

```
Switch(config)# wireless management interface vlan 21
```

**Configuring Mobility Agent by Pointing to Mobility Controller (GUI)**

**Before You Begin**

- By default, the switches are configured as mobility agents.
- Your network must have at least one mobility controller and the network connectivity with the mobility controller must be operational.
- You cannot configure mobility from the mobility agent. On the mobility agent, you can configure only the IP address of the mobility controller to download the SPG configuration.
- On the mobility agent, you can either configure the mobility controller address to point to an external mobility agent, or enable the mobility controller function.

---

**Step 1** Choose **Configuration > Controller > Mobility Management > Mobility Global Config**

The **Mobility Controller Configuration** page is displayed.

- Step 2** From the **Mobility Role** drop-down list, choose **Mobility Agent**.
- Step 3** In the **Mobility Controller IP Address**, enter the IP address of the mobility controller.
- Step 4** Click **Apply**.
- Step 5** Click **Save Configuration**.
- Step 6** Reboot the device.

## Configuring the Mobility Controller for the Mobility Agent (CLI)

### SUMMARY STEPS

1. `wireless mobility controller`
2. `wireless mobility controller ip ip-addr`

### DETAILED STEPS

|               | Command or Action                                                                                                                                                                                                                          | Purpose                                                                                                                                                                                                                                                                                    |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <p><b>wireless mobility controller</b></p> <p><b>Example:</b><br/> Switch (config)# <code>wireless mobility controller</code></p> <p>Mobility role changed to Mobility Controller.<br/> Please save config and reboot the whole stack.</p> | <p>Enables the mobility function on the switch.</p> <p><b>Note</b> After you enter this command, save the configuration and reboot the switch for the mobility controller function to take effect.</p>                                                                                     |
| <b>Step 2</b> | <p><b>wireless mobility controller ip ip-addr</b></p> <p><b>Example:</b><br/> Switch (config)# <code>wireless mobility controller ip 10.10.21.3</code></p>                                                                                 | <p>Specifies the mobility controller to which the mobility agent relates.</p> <p><b>Note</b> If a mobility agent is configured and the mobility controller exists on a different device, configure the SPG on the mobility controller to ensure the mobility agent functions properly.</p> |

### What to Do Next

After you add a mobility controller role to the mobility agent, you can configure optional parameters on the mobility agent.

## Adding a Mobility Controller Role to the Mobility Agent

### SUMMARY STEPS

1. `wireless mobility controller ip 10.10.21.3`

### DETAILED STEPS

|        | Command or Action                                                                                                                      | Purpose                                               |
|--------|----------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------|
| Step 1 | <b>wireless mobility controller ip 10.10.21.3</b><br><br><b>Example:</b><br>Switch(config)# wireless mobility controller ip 10.10.21.3 | Converts the mobility agent to a mobility controller. |

This example shows how to add the mobility controller role to a mobility agent:

```
Switch(config)# wireless mobility controller ip 10.10.21.3
Mobility role changed to Mobility Controller.
Please save config and reboot the whole stack.
```

## Configuring Optional Parameters on a Mobility Agent (CLI)

This section shows how to configure load-balancing on a switch.

- By default, the load-balancing is enabled and it cannot be disabled.
- The switch supports a maximum of 2000 clients and the default threshold value is fifty percent of client max load.
- When the switch reaches its threshold, it redistributes the new clients load to other mobility agents in the same SPG, if their client load is lower.

### SUMMARY STEPS

1. `wireless mobility load-balance threshold threshold-value`

### DETAILED STEPS

|        | Command or Action                                                                                                                                             | Purpose                                                |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------|
| Step 1 | <b>wireless mobility load-balance threshold <i>threshold-value</i></b><br><br><b>Example:</b><br>Switch(config)# wireless mobility load-balance threshold 150 | Configures the threshold that triggers load-balancing. |

### Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

### Prerequisites for Configuring the Configuration Engine

- Obtain the name of the configuration engine instance to which you are connecting.
- Because the CNS uses both the event bus and the configuration server to provide configurations to devices, you must define both ConfigID and Device ID for each configured switch.
- All switches configured with the **cns config partial** global configuration command must access the event bus. The DeviceID, as originated on the switch, must match the DeviceID of the corresponding switch definition in the Cisco Configuration Engine. You must know the hostname of the event bus to which you are connecting.

**Related Topics**

[Cisco Networking Services IDs and Device Hostnames](#), on page 794  
[DeviceID](#), on page 795

## Restrictions for Configuring the Configuration Engine

- Within the scope of a single instance of the configuration server, no two configured switches can share the same value for ConfigID.
- Within the scope of a single instance of the event bus, no two configured switches can share the same value for DeviceID.

## Information About Configuring the Configuration Engine

### Cisco Configuration Engine Software

The Cisco Configuration Engine is network management utility software that acts as a configuration service for automating the deployment and management of network devices and services. Each Cisco Configuration Engine manages a group of Cisco devices (switches and routers) and the services that they deliver, storing their configurations and delivering them as needed. The Cisco Configuration Engine automates initial configurations and configuration updates by generating device-specific configuration changes, sending them to the device, executing the configuration change, and logging the results.

The Cisco Configuration Engine supports standalone and server modes and has these Cisco Networking Services (CNS) components:

- Configuration service:
  - Web server
  - File manager
  - Namespace mapping server
- Event service (event gateway)
- Data service directory (data models and schema)

In standalone mode, the Cisco Configuration Engine supports an embedded directory service. In this mode, no external directory or other data store is required. In server mode, the Cisco Configuration Engine supports the use of a user-defined external directory.

**Figure 51: Cisco Configuration Engine Architectural Overview**

## Configuration Service

The Configuration Service is the core component of the Cisco Configuration Engine. It consists of a Configuration Server that works with Cisco IOS CNS agents on the switch. The Configuration Service delivers device and service configurations to the switch for initial configuration and mass reconfiguration by logical groups. Switches receive their initial configuration from the Configuration Service when they start up on the network for the first time.

The Configuration Service uses the CNS Event Service to send and receive configuration change events and to send success and failure notifications.

The Configuration Server is a web server that uses configuration templates and the device-specific configuration information stored in the embedded (standalone mode) or remote (server mode) directory.

Configuration templates are text files containing static configuration information in the form of CLI commands. In the templates, variables are specified by using Lightweight Directory Access Protocol (LDAP) URLs that reference the device-specific configuration information stored in a directory.

The Cisco IOS agent can perform a syntax check on received configuration files and publish events to show the success or failure of the syntax check. The configuration agent can either apply configurations immediately or delay the application until receipt of a synchronization event from the configuration server.

## Event Service

The Cisco Configuration Engine uses the Event Service for receipt and generation of configuration events. The Event Service consists of an event agent and an event gateway. The event agent is on the switch and facilitates the communication between the switch and the event gateway on the Cisco Configuration Engine.

The Event Service is a highly capable publish-and-subscribe communication method. The Event Service uses subject-based addressing to send messages to their destinations. Subject-based addressing conventions define a simple, uniform namespace for messages and their destinations.

### Related Topics

[Enabling the CNS Event Agent, on page 798](#)

## NameSpace Mapper

The Cisco Configuration Engine includes the NameSpace Mapper (NSM) that provides a lookup service for managing logical groups of devices based on application, device or group ID, and event.

Cisco IOS devices recognize only event subject-names that match those configured in Cisco IOS software; for example, `cisco.cns.config.load`. You can use the namespace mapping service to designate events by using any desired naming convention. When you have populated your data store with your subject names, NSM changes your event subject-name strings to those known by Cisco IOS.

For a subscriber, when given a unique device ID and event, the namespace mapping service returns a set of events to which to subscribe. Similarly, for a publisher, when given a unique group ID, device ID, and event, the mapping service returns a set of events on which to publish.

## Cisco Networking Services IDs and Device Hostnames

The Cisco Configuration Engine assumes that a unique identifier is associated with each configured switch. This unique identifier can take on multiple synonyms, where each synonym is unique within a particular namespace. The event service uses namespace content for subject-based addressing of messages.

The Cisco Configuration Engine intersects two namespaces, one for the event bus and the other for the configuration server. Within the scope of the configuration server namespace, the term *ConfigID* is the unique identifier for a device. Within the scope of the event bus namespace, the term *DeviceID* is the CNS unique identifier for a device.

### Related Topics

[Prerequisites for Configuring the Configuration Engine, on page 791](#)

[Restrictions for Configuring the Configuration Engine, on page 792](#)

## ConfigID

Each configured switch has a unique ConfigID, which serves as the key into the Cisco Configuration Engine directory for the corresponding set of switch CLI attributes. The ConfigID defined on the switch must match the ConfigID for the corresponding switch definition on the Cisco Configuration Engine.

The ConfigID is fixed at startup time and cannot be changed until the device restarts, even if the switch hostname is reconfigured.

## DeviceID

Each configured switch participating on the event bus has a unique DeviceID, which is analogous to the switch source address so that the switch can be targeted as a specific destination on the bus.

The origin of the DeviceID is defined by the Cisco IOS hostname of the switch. However, the DeviceID variable and its usage reside within the event gateway adjacent to the switch.

The logical Cisco IOS termination point on the event bus is embedded in the event gateway, which in turn functions as a proxy on behalf of the switch. The event gateway represents the switch and its corresponding DeviceID to the event bus.

The switch declares its hostname to the event gateway immediately after the successful connection to the event gateway. The event gateway couples the DeviceID value to the Cisco IOS hostname each time this connection is established. The event gateway retains this DeviceID value for the duration of its connection to the switch.

### Related Topics

[Prerequisites for Configuring the Configuration Engine, on page 791](#)

## Hostname and DeviceID

The DeviceID is fixed at the time of the connection to the event gateway and does not change even when the switch hostname is reconfigured.

When changing the switch hostname on the switch, the only way to refresh the DeviceID is to break the connection between the switch and the event gateway. For instructions on refreshing DeviceIDs, see "Related Topics."

When the connection is reestablished, the switch sends its modified hostname to the event gateway. The event gateway redefines the DeviceID to the new value.

### Caution

---

When using the Cisco Configuration Engine user interface, you must first set the DeviceID field to the hostname value that the switch acquires *after*, not *before*, and you must reinitialize the configuration for your Cisco IOS CNS agent. Otherwise, subsequent partial configuration command operations may malfunction.

---

### Related Topics

[Refreshing DeviceIDs, on page 806](#)

## Hostname, DeviceID, and ConfigID

In standalone mode, when a hostname value is set for a switch, the configuration server uses the hostname as the DeviceID when an event is sent on hostname. If the hostname has not been set, the event is sent on the cn=<value> of the device.

In server mode, the hostname is not used. In this mode, the unique DeviceID attribute is always used for sending an event on the bus. If this attribute is not set, you cannot update the switch.

These and other associated attributes (tag value pairs) are set when you run **Setup** on the Cisco Configuration Engine.

## Cisco IOS CNS Agents

The CNS event agent feature allows the switch to publish and subscribe to events on the event bus and works with the Cisco IOS CNS agent. These agents, embedded in the switch Cisco IOS software, allow the switch to be connected and automatically configured.

### Initial Configuration

When the switch first comes up, it attempts to get an IP address by broadcasting a Dynamic Host Configuration Protocol (DHCP) request on the network. Assuming there is no DHCP server on the subnet, the distribution switch acts as a DHCP relay agent and forwards the request to the DHCP server. Upon receiving the request, the DHCP server assigns an IP address to the new switch and includes the Trivial File Transfer Protocol (TFTP) server Internet Protocol (IP) address, the path to the bootstrap configuration file, and the default gateway IP address in a unicast reply to the DHCP relay agent. The DHCP relay agent forwards the reply to the switch.

The switch automatically configures the assigned IP address on interface VLAN 1 (the default) and downloads the bootstrap configuration file from the TFTP server. Upon successful download of the bootstrap configuration file, the switch loads the file in its running configuration.

The Cisco IOS CNS agents initiate communication with the Configuration Engine by using the appropriate ConfigID and EventID. The Configuration Engine maps the Config ID to a template and downloads the full configuration file to the switch.

The following figure shows a sample network configuration for retrieving the initial bootstrap configuration file by using DHCP-based autoconfiguration.

**Figure 52: Initial Configuration**

### Related Topics

[Automated CNS Configuration, on page 797](#)

## Incremental (Partial) Configuration

After the network is running, new services can be added by using the Cisco IOS CNS agent. Incremental (partial) configurations can be sent to the switch. The actual configuration can be sent as an event payload by way of the event gateway (push operation) or as a signal event that triggers the switch to initiate a pull operation.

The switch can check the syntax of the configuration before applying it. If the syntax is correct, the switch applies the incremental configuration and publishes an event that signals success to the configuration server. If the switch does not apply the incremental configuration, it publishes an event showing an error status. When the switch has applied the incremental configuration, it can write it to nonvolatile random-access memory (NVRAM) or wait until signaled to do so.

## Synchronized Configuration

When the switch receives a configuration, it can defer application of the configuration upon receipt of a write-signal event. The write-signal event tells the switch not to save the updated configuration into its NVRAM. The switch uses the updated configuration as its running configuration. This ensures that the switch configuration is synchronized with other network activities before saving the configuration in NVRAM for use at the next reboot.

## Automated CNS Configuration

To enable automated CNS configuration of the switch, you must first complete the prerequisites listed in this topic. When you complete them, power on the switch. At the **setup** prompt, do nothing; the switch begins the initial configuration. When the full configuration file is loaded on your switch, you do not need to do anything else.

For more information on what happens during initial configuration, see "Related Topics."

**Table 66: Prerequisites for Enabling Automatic Configuration**

| Device              | Required Configuration                                                                                                                                                                                               |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access switch       | Factory default (no configuration file)                                                                                                                                                                              |
| Distribution switch | <ul style="list-style-type: none"> <li>• IP helper address</li> <li>• Enable DHCP relay agent<sup>2</sup></li> <li>• IP routing (if used as default gateway)</li> </ul>                                              |
| DHCP server         | <ul style="list-style-type: none"> <li>• IP address assignment</li> <li>• TFTP server IP address</li> <li>• Path to bootstrap configuration file on the TFTP server</li> <li>• Default gateway IP address</li> </ul> |

| Device                   | Required Configuration                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TFTP server              | <ul style="list-style-type: none"> <li>• A bootstrap configuration file that includes the CNS configuration commands that enable the switch to communicate with the Configuration Engine</li> <li>• The switch configured to use either the switch MAC address or the serial number (instead of the default hostname) to generate the ConfigID and EventID</li> <li>• The CNS event agent configured to push the configuration file to the switch</li> </ul> |
| CNS Configuration Engine | One or more templates for each type of device, with the ConfigID of the device mapped to the template.                                                                                                                                                                                                                                                                                                                                                       |

<sup>2</sup> A DHCP Relay is needed only when the DHCP Server is on a different subnet from the client.

## How to Configure the Configuration Engine

### Enabling the CNS Event Agent

#### Note

You must enable the CNS event agent on the switch before you enable the CNS configuration agent.

Beginning in privileged EXEC mode, follow these steps to enable the CNS event agent on the switch.

#### SUMMARY STEPS

1. **configure terminal**
2. **cns event** {hostname | ip-address} [port-number] [ [keepalive seconds retry-count] [failover-time seconds] [reconnect-time time] | backup]
3. **end**

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                                                                                                                                | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Step 1 | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                                                                                                                                                                                                                                            | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Step 2 | <b>cns event</b> { <i>hostname</i>   <i>ip-address</i> } [ <i>port-number</i> ] [ [ <b>keepalive</b> <i>seconds</i> <i>retry-count</i> ] [ <b>failover-time</b> <i>seconds</i> ] [ <b>reconnect-time</b> <i>time</i> ]   <b>backup</b> ]<br><br><b>Example:</b><br>Switch(config)# <b>cns event 10.180.1.27 keepalive 120 10</b> | Enables the event agent, and enters the gateway parameters. <ul style="list-style-type: none"> <li>• For {<i>hostname</i>   <i>ip-address</i>}, enter either the hostname or the IP address of the event gateway.</li> <li>• (Optional) For <i>port number</i>, enter the port number for the event gateway. The default port number is 11011.</li> <li>• (Optional) For <b>keepalive</b> <i>seconds</i>, enter how often the switch sends keepalive messages. For <i>retry-count</i>, enter the number of unanswered keepalive messages that the switch sends before the connection is terminated. The default for each is 0.</li> <li>• (Optional) For <b>failover-time</b> <i>seconds</i>, enter how long the switch waits for the primary gateway route after the route to the backup gateway is established.</li> <li>• (Optional) For <b>reconnect-time</b> <i>time</i>, enter the maximum time interval that the switch waits before trying to reconnect to the event gateway.</li> <li>• (Optional) Enter <b>backup</b> to show that this is the backup gateway. (If omitted, this is the primary gateway.)</li> </ul> <p><b>Note</b> Though visible in the command-line help string, the <b>encrypt</b> and the <b>clock-timeout</b> <i>time</i> keywords are not supported.</p> |
| Step 3 | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b>                                                                                                                                                                                                                                                                  | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

This example shows how to enable the CNS event agent, set the IP address gateway to 10.180.1.27, set 120 seconds as the keepalive interval, and set 10 as the retry count.

```
Switch(config)# cns event 10.180.1.27 keepalive 120 10
```

**What to Do Next**

To verify information about the event agent, use the **show cns event connections** command in privileged EXEC mode.

To disable the CNS event agent, use the **no cns event** { *ip-address* | *hostname* } global configuration command.

**Enabling the Cisco IOS CNS Agent**

Beginning in privileged EXEC mode, follow these steps to enable the Cisco IOS CNS agent on the switch.

**Before You Begin**

You must enable the CNS event agent on the switch before you enable this agent.

**SUMMARY STEPS**

1. **configure terminal**
2. **cns config initial** *{hostname | ip-address}* [*port-number*]
3. **cns config partial** *{hostname | ip-address}* [*port-number*]
4. **end**
5. Start the Cisco IOS CNS agent on the switch.

**DETAILED STEPS**

|               | Command or Action                                                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                                                                                 | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Step 2</b> | <b>cns config initial</b> <i>{hostname   ip-address}</i> [ <i>port-number</i> ]<br><br><b>Example:</b><br>Switch(config)# <b>cns config initial</b><br>10.180.1.27 10 | Enables the Cisco IOS CNS agent, and enters the configuration server parameters. <ul style="list-style-type: none"> <li>• For <i>{hostname   ip-address}</i>, enter either the hostname or the IP address of the configuration server.</li> <li>• (Optional) For <i>port number</i>, enter the port number for the configuration server.</li> </ul> This command enables the Cisco IOS CNS agent and initiates an initial configuration on the switch. |
| <b>Step 3</b> | <b>cns config partial</b> <i>{hostname   ip-address}</i> [ <i>port-number</i> ]<br><br><b>Example:</b><br>Switch(config)# <b>cns config partial</b><br>10.180.1.27 10 | Enables the Cisco IOS CNS agent, and enters the configuration server parameters. <ul style="list-style-type: none"> <li>• For <i>{hostname   ip-address}</i>, enter either the hostname or the IP address of the configuration server.</li> <li>• (Optional) For <i>port number</i>, enter the port number for the configuration server.</li> </ul>                                                                                                    |

|               | Command or Action                                               | Purpose                                                                              |
|---------------|-----------------------------------------------------------------|--------------------------------------------------------------------------------------|
|               |                                                                 | Enables the Cisco IOS CNS agent and initiates a partial configuration on the switch. |
| <b>Step 4</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b> | Returns to privileged EXEC mode.                                                     |
| <b>Step 5</b> | Start the Cisco IOS CNS agent on the switch.                    |                                                                                      |

### What to Do Next

You can now use the Cisco Configuration Engine to remotely send incremental configurations to the switch.

## Enabling an Initial Configuration for Cisco IOS CNS Agent

Beginning in privileged EXEC mode, follow these steps to enable the CNS configuration agent and initiate an initial configuration on the switch.

## SUMMARY STEPS

1. **configure terminal**
2. **cns template connect** *name*
3. **cli** *config-text*
4. Repeat Steps 2 to 3 to configure another CNS connect template.
5. **exit**
6. **cns connect** *name* [**retries** *number*] [**retry-interval** *seconds*] [**sleep** *seconds*] [**timeout** *seconds*]
7. **discover** {**controller** *controller-type* | **dcli** [**subinterface** *subinterface-number*] | **interface** [*interface-type*] | **line** *line-type*}
8. **template** *name* [... *name*]
9. Repeat Steps 7 to 8 to specify more interface parameters and CNS connect templates in the CNS connect profile.
10. **exit**
11. **hostname** *name*
12. **ip route** *network-number*
13. **cns id** *interface num* {**dns-reverse** | **ipaddress** | **mac-address**} [**event**] [**image**]
14. **cns id** {**hardware-serial** | **hostname** | **string** *string* | **udi**} [**event**] [**image**]
15. **cns config initial** {*hostname* | *ip-address*} [*port-number*] [**event**] [**no-persist**] [**page** *page*] [**source** *ip-address*] [**syntax-check**]
16. **end**

## DETAILED STEPS

| Step 15 | <p><b>cns config initial</b> {hostname   ip-address} [port-number] [event] [no-persist] [page page] [source ip-address] [syntax-check]</p> <p><b>Example:</b></p> <pre>RemoteSwitch(config)# <b>cns config initial 10.1.1.1 no-persist</b></pre> | <p>Enables the Cisco IOS agent, and initiates an initial configuration.</p> <ul style="list-style-type: none"> <li>For {hostname   ip-address}, enter the hostname or the IP address of the configuration server.</li> <li>(Optional) For <i>port-number</i>, enter the port number of the configuration server. The default port number is 80.</li> <li>(Optional) Enable <b>event</b> for configuration success, failure, or warning messages when the configuration is finished.</li> <li>(Optional) Enable <b>no-persist</b> to suppress the automatic writing to NVRAM of the configuration pulled as a result of entering the <b>cns config initial</b> global configuration command. If the <b>no-persist</b> keyword is not entered, using the <b>cns config initial</b> command causes the resultant configuration to be automatically written to NVRAM.</li> <li>(Optional) For <b>page page</b>, enter the web page of the initial configuration. The default is /Config/config/asp.</li> <li>(Optional) Enter <b>source ip-address</b> to use for source IP address.</li> <li>(Optional) Enable <b>syntax-check</b> to check the syntax when this parameter is entered.</li> </ul> <p><b>Note</b> Though visible in the command-line help string, the <b>encrypt</b>, <b>status url</b>, and <b>inventory</b> keywords are not supported.</p> |
| Step 16 | <p><b>end</b></p> <p><b>Example:</b></p> <pre>RemoteSwitch(config)# <b>end</b></pre>                                                                                                                                                             | <p>Returns to privileged EXEC mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

This example shows how to configure an initial configuration on a remote switch when the switch configuration is unknown (the CNS Zero Touch feature).

```
Switch(config)# cns template connect template-dhcp
Switch(config-tmpl-conn)# cli ip address dhcp
Switch(config-tmpl-conn)# exit
Switch(config)# cns template connect ip-route
Switch(config-tmpl-conn)# cli ip route 0.0.0.0 0.0.0.0 ${next-hop}
Switch(config-tmpl-conn)# exit
Switch(config)# cns connect dhcp
Switch(config-cns-conn)# discover interface gigabitethernet
Switch(config-cns-conn)# template template-dhcp
Switch(config-cns-conn)# template ip-route
Switch(config-cns-conn)# exit
Switch(config)# hostname RemoteSwitch
RemoteSwitch(config)# cns config initial 10.1.1.1 no-persist
```

This example shows how to configure an initial configuration on a remote switch when the switch IP address is known. The Configuration Engine IP address is 172.28.129.22.

```
Switch(config)# cns template connect template-dhcp
Switch(config-tmpl-conn)# cli ip address dhcp
Switch(config-tmpl-conn)# exit
Switch(config)# cns template connect ip-route
Switch(config-tmpl-conn)# cli ip route 0.0.0.0 0.0.0.0 ${next-hop}
Switch(config-tmpl-conn)# exit
Switch(config)# cns connect dhcp
Switch(config-cns-conn)# discover interface gigabitethernet
Switch(config-cns-conn)# template template-dhcp
Switch(config-cns-conn)# template ip-route
Switch(config-cns-conn)# exit
Switch(config)# hostname RemoteSwitch
RemoteSwitch(config)# ip route 172.28.129.22 255.255.255.255 11.11.11.1
RemoteSwitch(config)# cns id ethernet 0 ipaddress
RemoteSwitch(config)# cns config initial 172.28.129.22 no-persist
```

### What to Do Next

To verify information about the configuration agent, use the **show cns config connections** command in privileged EXEC mode.

To disable the CNS Cisco IOS agent, use the **no cns config initial { ip-address | hostname }** global configuration command.

## Refreshing DeviceIDs

Beginning in privileged EXEC mode, follow these steps to refresh a DeviceID when changing the hostname on the switch.

### SUMMARY STEPS

1. **show cns config connections**
2. Make sure that the CNS event agent is properly connected to the event gateway.
3. **show cns event connections**
4. Record from the output of Step 3 the information for the currently connected connection listed below. You will be using the IP address and port number in subsequent steps of these instructions.
5. **configure terminal**
6. **no cns event ip-address port-number**
7. **cns event ip-address port-number**
8. **end**
9. Make sure that you have reestablished the connection between the switch and the event connection by examining the output from **show cns event connections**.

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                 | Purpose                                                                                                                                                                                                                                                                                                                                        |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <p><b>show cns config connections</b></p> <p><b>Example:</b></p> <pre>Switch# show cns config connections</pre>                                                                                   | Displays whether the CNS event agent is connecting to the gateway, connected, or active, and the gateway used by the event agent, its IP address and port number.                                                                                                                                                                              |
| Step 2 | Make sure that the CNS event agent is properly connected to the event gateway.                                                                                                                    | <p>Examine the output of <b>show cns config connections</b> for the following:</p> <ul style="list-style-type: none"> <li>• Connection is active.</li> <li>• Connection is using the currently configured switch hostname. The DeviceID will be refreshed to correspond to the new hostname configuration using these instructions.</li> </ul> |
| Step 3 | <p><b>show cns event connections</b></p> <p><b>Example:</b></p> <pre>Switch# show cns event connections</pre>                                                                                     | Displays the event connection information for your switch.                                                                                                                                                                                                                                                                                     |
| Step 4 | Record from the output of Step 3 the information for the currently connected connection listed below. You will be using the IP address and port number in subsequent steps of these instructions. |                                                                                                                                                                                                                                                                                                                                                |
| Step 5 | <p><b>configure terminal</b></p> <p><b>Example:</b></p> <pre>Switch# configure terminal</pre>                                                                                                     | Enters global configuration mode.                                                                                                                                                                                                                                                                                                              |
| Step 6 | <p><b>no cns event ip-address port-number</b></p> <p><b>Example:</b></p> <pre>Switch(config)# no cns event 172.28.129.22 2012</pre>                                                               | <p>Specifies the IP address and port number that you recorded in Step 4 in this command.</p> <p>This command breaks the connection between the switch and the event gateway. It is necessary to first break, then reestablish, this connection to refresh the DeviceID.</p>                                                                    |
| Step 7 | <p><b>cns event ip-address port-number</b></p> <p><b>Example:</b></p> <pre>Switch(config)# cns event 172.28.129.22 2012</pre>                                                                     | <p>Specifies the IP address and port number that you recorded in Step 4 in this command.</p> <p>This command reestablishes the connection between the switch and the event gateway.</p>                                                                                                                                                        |
| Step 8 | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Switch(config)# end</pre>                                                                                                                           | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                               |

|               | Command or Action                                                                                                                                                 | Purpose |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| <b>Step 9</b> | Make sure that you have reestablished the connection between the switch and the event connection by examining the output from <b>show cns event connections</b> . |         |

## Enabling a Partial Configuration for Cisco IOS CNS Agent

Beginning in privileged EXEC mode, follow these steps to enable the Cisco IOS CNS agent and to initiate a partial configuration on the switch.

### SUMMARY STEPS

1. **configure terminal**
2. **cns config partial** *{ip-address | hostname}* [*port-number*] [**source** *ip-address*]
3. **end**

### DETAILED STEPS

| Step 3 | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b> | Returns to privileged EXEC mode. |

### What to Do Next

To verify information about the configuration agent, use either the **show cns config stats** or the **show cns config outstanding** command in privileged EXEC mode.

To disable the Cisco IOS agent, use the **no cns config partial** { *ip-address* | *hostname* } global configuration command. To cancel a partial configuration, use the **cns config cancel** global configuration command.

## Monitoring CNS Configurations

**Table 67: CNS show Commands**

| Command                                                                              | Purpose                                                                                                          |
|--------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| <b>show cns config connections</b><br><br>Switch# <b>show cns config connections</b> | Displays the status of the CNS Cisco IOS CNS agent connections.                                                  |
| <b>show cns config outstanding</b><br><br>Switch# <b>show cns config outstanding</b> | Displays information about incremental (partial) CNS configurations that have started but are not yet completed. |

# Configuring the Cisco Discovery Protocol

- [Finding Feature Information, page 813](#)
- [Information About CDP, page 813](#)
- [How to Configure CDP, page 814](#)
- [Monitoring and Maintaining CDP, page 820](#)
- [Additional References, page 821](#)
- [Feature History and Information for Cisco Discovery Protocol, page 822](#)

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Information About CDP

### CDP Overview

CDP is a device discovery protocol that runs over Layer 2 (the data-link layer) on all Cisco-manufactured devices (routers, bridges, access servers, controllers, and switches) and allows network management applications to discover Cisco devices that are neighbors of already known devices. With CDP, network management applications can learn the device type and the Simple Network Management Protocol (SNMP) agent address of neighboring devices running lower-layer, transparent protocols. This feature enables applications to send SNMP queries to neighboring devices.

CDP runs on all media that support Subnetwork Access Protocol (SNAP). Because CDP runs over the data-link layer only, two systems that support different network-layer protocols can learn about each other.

Each CDP-configured device sends periodic messages to a multicast address, advertising at least one address at which it can receive SNMP messages. The advertisements also contain time-to-live, or holdtime information,

which is the length of time a receiving device holds CDP information before discarding it. Each device also listens to the messages sent by other devices to learn about neighboring devices.

On the switch, CDP enables Network Assistant to display a graphical view of the network. The switch uses CDP to find cluster candidates and maintain information about cluster members and other devices up to three cluster-enabled devices away from the command switch by default.

## CDP and Stacks

A switch stack appears as a single switch in the network. Therefore, CDP discovers the switch stack, not the individual stack members. The switch stack sends CDP messages to neighboring network devices when there are changes to the switch stack membership, such as stack members being added or removed.

## Default CDP Configuration

This table shows the default CDP configuration.

| Feature                             | Default Setting |
|-------------------------------------|-----------------|
| CDP global state                    | Enabled         |
| CDP interface state                 | Enabled         |
| CDP timer (packet update frequency) | 60 seconds      |
| CDP holdtime (before discarding)    | 180 seconds     |
| CDP Version-2 advertisements        | Enabled         |

# How to Configure CDP

## Configuring CDP Characteristics

You can configure these CDP characteristics:

- Frequency of CDP updates
- Amount of time to hold the information before discarding it
- Whether or not to send Version-2 advertisements

### Note

Steps 2 through 4 are all optional and can be performed in any order.

Beginning in privileged EXEC mode, follow these steps to configure these characteristics.

## SUMMARY STEPS

1. **configure terminal**
2. **cdp timer *seconds***
3. **cdp holdtime *seconds***
4. **cdp advertise-v2**
5. **end**

## DETAILED STEPS

|               | Command or Action                                                                                   | Purpose                                                                                                                                                                                             |
|---------------|-----------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>               | Enters the global configuration mode.                                                                                                                                                               |
| <b>Step 2</b> | <b>cdp timer <i>seconds</i></b><br><br><b>Example:</b><br>Switch(config)# <b>cdp timer 20</b>       | (Optional) Sets the transmission frequency of CDP updates in seconds.<br><br>The range is 5 to 254; the default is 60 seconds.                                                                      |
| <b>Step 3</b> | <b>cdp holdtime <i>seconds</i></b><br><br><b>Example:</b><br>Switch(config)# <b>cdp holdtime 60</b> | (Optional) Specifies the amount of time a receiving device should hold the information sent by your device before discarding it.<br><br>The range is 10 to 255 seconds; the default is 180 seconds. |
| <b>Step 4</b> | <b>cdp advertise-v2</b><br><br><b>Example:</b><br>Switch(config)# <b>cdp advertise-v2</b>           | (Optional) Configures CDP to send Version-2 advertisements.<br><br>This is the default state.                                                                                                       |
| <b>Step 5</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b>                                     | Returns to privileged EXEC mode.                                                                                                                                                                    |

### Example

The following example shows how to configure CDP characteristics:

```
Switch# configure terminal
Switch(config)# cdp timer 50
Switch(config)# cdp holdtime 120
Switch(config)# cdp advertise-v2
Switch(config)# end
```

**What to Do Next**

Use the **no** form of the CDP commands to return to the default settings.

**Related Topics**

[Monitoring and Maintaining CDP, on page 820](#)

**Disabling CDP**

CDP is enabled by default.

**Note**

Switch clusters and other Cisco devices (such as Cisco IP Phones) regularly exchange CDP messages. Disabling CDP can interrupt cluster discovery and device connectivity.

Beginning in privileged EXEC mode, follow these steps to disable the CDP device discovery capability.

**SUMMARY STEPS**

1. **configure terminal**
2. **no cdp run**
3. **end**

**DETAILED STEPS**

|               | <b>Command or Action</b>                                                              | <b>Purpose</b>                        |
|---------------|---------------------------------------------------------------------------------------|---------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b> | Enters the global configuration mode. |
| <b>Step 2</b> | <b>no cdp run</b><br><br><b>Example:</b><br>Switch(config)# <b>no cdp run</b>         | Disables CDP.                         |
| <b>Step 3</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b>                       | Returns to privileged EXEC mode.      |

**What to Do Next**

You must reenable CDP to use it.

**Related Topics**[Enabling CDP, on page 817](#)**Enabling CDP**

CDP is enabled by default.

**Note**

Switch clusters and other Cisco devices (such as Cisco IP Phones) regularly exchange CDP messages. Disabling CDP can interrupt cluster discovery and device connectivity.

Beginning in privileged EXEC mode, follow these steps to enable CDP when it has been disabled.

**Before You Begin**

CDP must be disabled, or it cannot be enabled.

**SUMMARY STEPS**

1. **configure terminal**
2. **cdp run**
3. **end**

**DETAILED STEPS**

|               | <b>Command or Action</b>                                                              | <b>Purpose</b>                        |
|---------------|---------------------------------------------------------------------------------------|---------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b> | Enters the global configuration mode. |
| <b>Step 2</b> | <b>cdp run</b><br><br><b>Example:</b><br>Switch(config)# <b>cdp run</b>               | Enables CDP if it has been disabled.  |
| <b>Step 3</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b>                       | Returns to privileged EXEC mode.      |

**Example**

The following example shows how to enable CDP if it has been disabled:

```
Switch# configure terminal
Switch(config)# cdp run
Switch(config)# end
```

**What to Do Next**

Use the **show run all** command to show that CDP has been enabled. If you enter only **show run**, the enabling of CDP may not be displayed.

## Monitoring and Maintaining CDP

**Table 68: Commands for Displaying CDP Information**

| Command                                                      | Description                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>clear cdp counters</b>                                    | Resets the traffic counters to zero.                                                                                                                                                                                                                                                                                                                                          |
| <b>clear cdp table</b>                                       | Deletes the CDP table of information about neighbors.                                                                                                                                                                                                                                                                                                                         |
| <b>show cdp</b>                                              | Displays global information, such as frequency of transmissions and the holdtime for packets being sent.                                                                                                                                                                                                                                                                      |
| <b>show cdp entry</b> <i>entry-name</i> [version] [protocol] | Displays information about a specific neighbor.<br><br>You can enter an asterisk (*) to display all CDP neighbors, or you can enter the name of the neighbor about which you want information.<br><br>You can also limit the display to information about the protocols enabled on the specified neighbor or information about the version of software running on the device. |
| <b>show cdp interface</b> [ <i>interface-id</i> ]            | Displays information about interfaces where CDP is enabled.<br><br>You can limit the display to the interface about which you want information.                                                                                                                                                                                                                               |

| Command                                                                | Description                                                                                                                                                                                                                                                                       |
|------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>show cdp neighbors</b> [ <i>interface-id</i> ]<br>[ <i>detail</i> ] | Displays information about neighbors, including device type, interface type and number, holdtime settings, capabilities, platform, and port ID.<br><br>You can limit the display to neighbors of a specific interface or expand the display to provide more detailed information. |
| <b>show cdp traffic</b>                                                | Displays CDP counters, including the number of packets sent and received and checksum errors.                                                                                                                                                                                     |

### Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

### Prerequisites for SNMP

#### Supported SNMP Versions

This software release supports the following SNMP versions:

- SNMPv1—The Simple Network Management Protocol, a Full Internet Standard, defined in RFC 1157.
- SNMPv2C replaces the Party-based Administrative and Security Framework of SNMPv2Classic with the community-string-based Administrative Framework of SNMPv2C while retaining the bulk retrieval and improved error handling of SNMPv2Classic. It has these features:

- SNMPv2—Version 2 of the Simple Network Management Protocol, a Draft Internet Standard, defined in RFCs 1902 through 1907.
- SNMPv2C—The community-string-based Administrative Framework for SNMPv2, an Experimental Internet Protocol defined in RFC 1901.
- SNMPv3—Version 3 of the SNMP is an interoperable standards-based protocol defined in RFCs 2273 to 2275. SNMPv3 provides secure access to devices by authenticating and encrypting packets over the network and includes these security features:
  - Message integrity—Ensures that a packet was not tampered with in transit.
  - Authentication—Determines that the message is from a valid source.
  - Encryption—Mixes the contents of a package to prevent it from being read by an unauthorized source.

**Note**

---

To select encryption, enter the **priv** keyword.

---

Both SNMPv1 and SNMPv2C use a community-based form of security. The community of managers able to access the agent's MIB is defined by an IP address access control list and password.

SNMPv2C includes a bulk retrieval function and more detailed error message reporting to management stations. The bulk retrieval function retrieves tables and large quantities of information, minimizing the number of round-trips required. The SNMPv2C improved error-handling includes expanded error codes that distinguish different kinds of error conditions; these conditions are reported through a single error code in SNMPv1. Error return codes in SNMPv2C report the error type.

SNMPv3 provides for both security models and security levels. A security model is an authentication strategy set up for a user and the group within which the user resides. A security level is the permitted level of security within a security model. A combination of the security level and the security model determine which security method is used when handling an SNMP packet. Available security models are SNMPv1, SNMPv2C, and SNMPv3.

The following table identifies characteristics and compares different combinations of security models and levels:

**Table 69: SNMP Security Models and Levels**

| Model   | Level        | Authentication   | Encryption | Result                                            |
|---------|--------------|------------------|------------|---------------------------------------------------|
| SNMPv1  | noAuthNoPriv | Community string | No         | Uses a community string match for authentication. |
| SNMPv2C | noAuthNoPriv | Community string | No         | Uses a community string match for authentication. |
| SNMPv3  | noAuthNoPriv | Username         | No         | Uses a username match for authentication.         |

| Model  | Level      | Authentication                                        | Encryption                                                           | Result                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------|------------|-------------------------------------------------------|----------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SNMPv3 | authNoPriv | Message Digest 5 (MD5) or Secure Hash Algorithm (SHA) | No                                                                   | Provides authentication based on the HMAC-MD5 or HMAC-SHA algorithms.                                                                                                                                                                                                                                                                                                                                                 |
| SNMPv3 | authPriv   | MD5 or SHA                                            | Data Encryption Standard (DES) or Advanced Encryption Standard (AES) | <p>Provides authentication based on the HMAC-MD5 or HMAC-SHA algorithms.</p> <p>Allows specifying the User-based Security Model (USM) with these encryption algorithms:</p> <ul style="list-style-type: none"> <li>• DES 56-bit encryption in addition to authentication based on the CBC-DES (DES-56) standard.</li> <li>• 3DES 168-bit encryption</li> <li>• AES 128-bit, 192-bit, or 256-bit encryption</li> </ul> |

You must configure the SNMP agent to use the SNMP version supported by the management station. Because an agent can communicate with multiple managers, you can configure the software to support communications using SNMPv1, SNMPv2C, or SNMPv3.

## Restrictions for SNMP

### Version Restrictions

- SNMPv1 does not support informs.

# Information About SNMP

## SNMP Overview

SNMP is an application-layer protocol that provides a message format for communication between managers and agents. The SNMP system consists of an SNMP manager, an SNMP agent, and a management information base (MIB). The SNMP manager can be part of a network management system (NMS) such as Cisco Prime Infrastructure. The agent and MIB reside on the switch. To configure SNMP on the switch, you define the relationship between the manager and the agent.

The SNMP agent contains MIB variables whose values the SNMP manager can request or change. A manager can get a value from an agent or store a value into the agent. The agent gathers data from the MIB, the repository for information about device parameters and network data. The agent can also respond to a manager's requests to get or set data.

An agent can send unsolicited traps to the manager. Traps are messages alerting the SNMP manager to a condition on the network. Traps can mean improper user authentication, restarts, link status (up or down), MAC address tracking, closing of a TCP connection, loss of connection to a neighbor, or other significant events.

The active switch handles the SNMP requests and traps for the whole switch stack. The active switch transparently manages any requests or traps that are related to all stack members. When a new active switch is elected, the new active switch continues to handle SNMP requests and traps as configured on the previous active switch, assuming that IP connectivity to the SNMP management stations is still in place after the new active switch has taken control.

## SNMP Manager Functions

The SNMP manager uses information in the MIB to perform the operations described in the following table:

**Table 70: SNMP Operations**

| Operation                     | Description                                                                                                                                   |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| get-request                   | Retrieves a value from a specific variable.                                                                                                   |
| get-next-request              | Retrieves a value from a variable within a table. <sup>3</sup>                                                                                |
| get-bulk-request <sup>4</sup> | Retrieves large blocks of data, such as multiple rows in a table, that would otherwise require the transmission of many small blocks of data. |
| get-response                  | Replies to a get-request, get-next-request, and set-request sent by an NMS.                                                                   |
| set-request                   | Stores a value in a specific variable.                                                                                                        |
| trap                          | An unsolicited message sent by an SNMP agent to an SNMP manager when some event has occurred.                                                 |

<sup>3</sup> With this operation, an SNMP manager does not need to know the exact variable name. A sequential search is performed to find the needed variable from within a table.

<sup>4</sup> The get-bulk command only works with SNMPv2 or later.

## SNMP Agent Functions

The SNMP agent responds to SNMP manager requests as follows:

- Get a MIB variable—The SNMP agent begins this function in response to a request from the NMS. The agent retrieves the value of the requested MIB variable and responds to the NMS with that value.
- Set a MIB variable—The SNMP agent begins this function in response to a message from the NMS. The SNMP agent changes the value of the MIB variable to the value requested by the NMS.

The SNMP agent also sends unsolicited trap messages to notify an NMS that a significant event has occurred on the agent. Examples of trap conditions include, but are not limited to, when a port or module goes up or down, when spanning-tree topology changes occur, and when authentication failures occur.

## SNMP Community Strings

SNMP community strings authenticate access to MIB objects and function as embedded passwords. In order for the NMS to access the switch, the community string definitions on the NMS must match at least one of the three community string definitions on the switch.

A community string can have one of the following attributes:

- Read-only (RO)—Gives all objects in the MIB except the community strings read access to authorized management stations, but does not allow write access.
- Read-write (RW)—Gives all objects in the MIB read and write access to authorized management stations, but does not allow access to the community strings.
- When a cluster is created, the command switch manages the exchange of messages among member switches and the SNMP application. The Network Assistant software appends the member switch number (@esN, where N is the switch number) to the first configured RW and RO community strings on the command switch and propagates them to the member switches.

## SNMP MIB Variables Access

An example of an NMS is the Cisco Prime Infrastructure network management software. Cisco Prime Infrastructure 2.0 software uses the switch MIB variables to set device variables and to poll devices on the network for specific information. The results of a poll can be displayed as a graph and analyzed to troubleshoot internetworking problems, increase network performance, verify the configuration of devices, monitor traffic loads, and more.

As shown in the figure, the SNMP agent gathers data from the MIB. The agent can send traps, or notification of certain events, to the SNMP manager, which receives and processes the traps. Traps alert the SNMP manager to a condition on the network such as improper user authentication, restarts, link status (up or down), MAC

address tracking, and so forth. The SNMP agent also responds to MIB-related queries sent by the SNMP manager in get-request, get-next-request, and set-request format.

**Figure 53: SNMP Network**

## SNMP Notifications

SNMP allows the switch to send notifications to SNMP managers when particular events occur. SNMP notifications can be sent as traps or inform requests. In command syntax, unless there is an option in the command to select either traps or informs, the keyword traps refers to either traps or informs, or both. Use the **snmp-server host** command to specify whether to send SNMP notifications as traps or informs.

**Note** SNMPv1 does not support informs.

Traps are unreliable because the receiver does not send an acknowledgment when it receives a trap, and the sender cannot determine if the trap was received. When an SNMP manager receives an inform request, it acknowledges the message with an SNMP response protocol data unit (PDU). If the sender does not receive a response, the inform request can be sent again. Because they can be resent, informs are more likely than traps to reach their intended destination.

The characteristics that make informs more reliable than traps also consume more resources in the switch and in the network. Unlike a trap, which is discarded as soon as it is sent, an inform request is held in memory until a response is received or the request times out. Traps are sent only once, but an inform might be resent or retried several times. The retries increase traffic and contribute to a higher overhead on the network. Therefore, traps and informs require a trade-off between reliability and resources. If it is important that the SNMP manager receive every notification, use inform requests. If traffic on the network or memory in the switch is a concern and notification is not required, use traps.

## SNMP ifIndex MIB Object Values

In an NMS, the IF-MIB generates and assigns an interface index (ifIndex) object value that is a unique number greater than zero to identify a physical or a logical interface. When the switch reboots or the switch software is upgraded, the switch uses this same value for the interface. For example, if the switch assigns a port 2 an ifIndex value of 10003, this value is the same after the switch reboots.

The switch uses one of the values in the following table to assign an ifIndex value to an interface:

**Table 71: ifIndex Values**

| Interface Type   | ifIndex Range |
|------------------|---------------|
| SVI <sup>5</sup> | 1–4999        |
| EtherChannel     | 5000–5012     |

| Interface Type                                                             | ifIndex Range |
|----------------------------------------------------------------------------|---------------|
| Loopback                                                                   | 5013–5077     |
| Tunnel                                                                     | 5078–5142     |
| Physical (such as Gigabit Ethernet or SFP <sup>6</sup> -module interfaces) | 10000–14500   |
| Null                                                                       | 14501         |

<sup>5</sup> SVI = switch virtual interface

<sup>6</sup> SFP = small form-factor pluggable

## Default SNMP Configuration

| Feature                | Default Setting                                                                           |
|------------------------|-------------------------------------------------------------------------------------------|
| SNMP agent             | Disabled <sup>7</sup> .                                                                   |
| SNMP trap receiver     | None configured.                                                                          |
| SNMP traps             | None enabled except the trap for TCP connections (tty).                                   |
| SNMP version           | If no version keyword is present, the default is Version 1.                               |
| SNMPv3 authentication  | If no keyword is entered, the default is the <b>noauth</b> (noAuthNoPriv) security level. |
| SNMP notification type | If no type is specified, all notifications are sent.                                      |

<sup>7</sup> This is the default when the switch starts and the startup configuration does not have any **snmp-server** global configuration commands.

## SNMP Configuration Guidelines

If the switch starts and the switch startup configuration has at least one **snmp-server** global configuration command, the SNMP agent is enabled.

An SNMP *group* is a table that maps SNMP users to SNMP views. An SNMP *user* is a member of an SNMP group. An SNMP *host* is the recipient of an SNMP trap operation. An SNMP *engine ID* is a name for the local or remote SNMP engine.

When configuring SNMP, follow these guidelines:

- When configuring an SNMP group, do not specify a notify view. The **snmp-server host** global configuration command auto-generates a notify view for the user and then adds it to the group associated with that user. Modifying the group's notify view affects all users associated with that group.
- To configure a remote user, specify the IP address or port number for the remote SNMP agent of the device where the user resides.
- Before you configure remote users for a particular agent, configure the SNMP engine ID, using the **snmp-server engineID** global configuration command with the **remote** option. The remote agent's SNMP engine ID and user password are used to compute the authentication and privacy digests. If you do not configure the remote engine ID first, the configuration command fails.

- When configuring SNMP informs, you need to configure the SNMP engine ID for the remote agent in the SNMP database before you can send proxy requests or informs to it.
- If a local user is not associated with a remote host, the switch does not send informs for the **auth** (authNoPriv) and the **priv** (authPriv) authentication levels.
- Changing the value of the SNMP engine ID has significant results. A user's password (entered on the command line) is converted to an MD5 or SHA security digest based on the password and the local engine ID. The command-line password is then destroyed, as required by RFC 2274. Because of this deletion, if the value of the engine ID changes, the security digests of SNMPv3 users become invalid, and you need to reconfigure SNMP users by using the **snmp-server user *username*** global configuration command. Similar restrictions require the reconfiguration of community strings when the engine ID changes.

## How to Configure SNMP

### Disabling the SNMP Agent

The **no snmp-server** global configuration command disables all running versions (Version 1, Version 2C, and Version 3) of the SNMP agent on the device. You reenables all versions of the SNMP agent by the first **snmp-server** global configuration command that you enter. There is no Cisco IOS command specifically designated for enabling SNMP.

Beginning in privileged EXEC mode, follow these steps to disable the SNMP agent.

#### Before You Begin

The SNMP Agent must be enabled before it can be disabled. The SNMP agent is enabled by the first **snmp-server** global configuration command entered on the device.

#### SUMMARY STEPS

1. **configure terminal**
2. **no snmp-server**
3. **end**

#### DETAILED STEPS

| <b>Step 3</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b>                       | Returns to privileged EXEC mode.   |

## Configuring Community Strings

You use the SNMP community string to define the relationship between the SNMP manager and the agent. The community string acts like a password to permit access to the agent on the switch. Optionally, you can specify one or more of these characteristics associated with the string:

- An access list of IP addresses of the SNMP managers that are permitted to use the community string to gain access to the agent
- A MIB view, which defines the subset of all MIB objects accessible to the given community
- Read and write or read-only permission for the MIB objects accessible to the community

Beginning in privileged EXEC mode, follow these steps to configure a community string on the switch.

### SUMMARY STEPS

1. **configure terminal**
2. **snmp-server community** *string* [**view** *view-name*] [**ro** | **rw**] [*access-list-number*]
3. **access-list** *access-list-number* {**deny** | **permit**} *source* [*source-wildcard*]
4. **end**

|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 2</b> | <p><b>snmp-server community</b> <i>string</i><br/> [<b>view</b> <i>view-name</i>] [<b>ro</b>   <b>rw</b>]<br/> [<i>access-list-number</i>]</p> <p><b>Example:</b></p> <pre>Switch(config)# snmp-server community comaccess ro 4</pre> | <p>Configures the community string.</p> <p><b>Note</b> The @ symbol is used for delimiting the context information. Avoid using the @ symbol as part of the SNMP community string when configuring this command.</p> <ul style="list-style-type: none"> <li>For <i>string</i>, specify a string that acts like a password and permits access to the SNMP protocol. You can configure one or more community strings of any length.</li> <li>(Optional) For <i>view-name</i>, specify the view record accessible to the community.</li> <li>(Optional) Specify either read-only (<b>ro</b>) if you want authorized management stations to retrieve MIB objects, or specify read-write (<b>rw</b>) if you want authorized management stations to retrieve and modify MIB objects. By default, the community string permits read-only access to all objects.</li> <li>(Optional) For <i>access-list-number</i>, enter an IP standard access list numbered from 1 to 99 and 1300 to 1999.</li> </ul> |
| <b>Step 3</b> | <p><b>access-list</b> <i>access-list-number</i> {<b>deny</b>   <b>permit</b>} <i>source</i> [<i>source-wildcard</i>]</p> <p><b>Example:</b></p> <pre>Switch(config)# access-list 4 deny any</pre>                                     | <p>(Optional) If you specified an IP standard access list number in Step 2, then create the list, repeating the command as many times as necessary.</p> <ul style="list-style-type: none"> <li>For <i>access-list-number</i>, enter the access list number specified in Step 2.</li> <li>The <b>deny</b> keyword denies access if the conditions are matched. The <b>permit</b> keyword permits access if the conditions are matched.</li> <li>For <i>source</i>, enter the IP address of the SNMP managers that are permitted to use the community string to gain access to the agent.</li> <li>(Optional) For <i>source-wildcard</i>, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.</li> </ul> <p>Recall that the access list is always terminated by an implicit deny statement for everything.</p>                                                                                               |
| <b>Step 4</b> | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Switch(config)# end</pre>                                                                                                                                                               | <p>Returns to privileged EXEC mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

This example shows how to assign the comaccess string to SNMP, to allow read-only access, and to specify that IP access list 4 can use the community string to gain access to the switch SNMP agent:

```
Switch(config)# snmp-server community comaccess ro 4
```

### What to Do Next

To disable access for an SNMP community, set the community string for that community to the null string (do not enter a value for the community string).

To remove a specific community string, use the **no snmp-server** community string global configuration command.

You can specify an identification name (engine ID) for the local or remote SNMP server engine on the switch. You can configure an SNMP server group that maps SNMP users to SNMP views, and you can add new users to the SNMP group.

## Configuring SNMP Groups and Users

You can specify an identification name (engine ID) for the local or remote SNMP server engine on the switch. You can configure an SNMP server group that maps SNMP users to SNMP views, and you can add new users to the SNMP group.

Beginning in privileged EXEC mode, follow these steps to configure SNMP groups and users on the switch.

### SUMMARY STEPS

1. **configure terminal**
2. **snmp-server engineID** {local *engineid-string* | remote *ip-address* [**udp-port** *port-number*] *engineid-string*}
3. **snmp-server group** *group-name* {v1 | v2c | v3 {auth | noauth | priv}} [**read** *readview*] [**write** *writeview*] [**notify** *notifyview*] [**access** *access-list*]
4. **snmp-server user** *username* *group-name* {remote *host* [**udp-port** *port*]} {v1 [**access** *access-list*] | v2c [**access** *access-list*] | v3 [**encrypted**] [**access** *access-list*] [**auth** {md5 | sha} *auth-password*] } [**priv** {des | 3des | aes {128 | 192 | 256}}] *priv-password*]
5. **end**

### DETAILED STEPS

|        | Command or Action                                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                                                                | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Step 2 | <b>snmp-server engineID</b> {local <i>engineid-string</i>   remote <i>ip-address</i> [ <b>udp-port</b> <i>port-number</i> ] <i>engineid-string</i> } | Configures a name for either the local or remote copy of SNMP. <ul style="list-style-type: none"> <li>• The <i>engineid-string</i> is a 24-character ID string with the name of the copy of SNMP. You need not specify the entire 24-character engine ID if it has trailing zeros. Specify only the portion of the engine ID up to the point where only zeros remain in the value. The Step Example configures an engine ID of 123400000000000000000000.</li> <li>• If you select <b>remote</b>, specify the <i>ip-address</i> of the device that contains the remote copy of SNMP and the optional User Datagram Protocol (UDP) port on the remote device. The default is 162.</li> </ul> |

|               | Command or Action                                                                                                                                                                                                                                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 3</b> | <pre>snmp-server group group-name {v1   v2c   v3 {auth   noauth   priv}} [read readview] [write writeview] [notify notifyview] [access access-list]</pre> <p><b>Example:</b></p> <pre>Switch(config)# snmp-server group public v2c access lmnop</pre>                                                                                                  | <p>Configures a new SNMP group on the remote device.</p> <p>For <i>group-name</i>, specify the name of the group.</p> <p>Specify one of the following security models:</p> <ul style="list-style-type: none"> <li>• <b>v1</b> is the least secure of the possible security models.</li> <li>• <b>v2c</b> is the second least secure model. It allows transmission of informs and integers twice the normal width.</li> <li>• <b>v3</b>, the most secure, requires you to select one of the following authentication levels: <ul style="list-style-type: none"> <li><b>auth</b>—Enables the Message Digest 5 (MD5) and the Secure Hash Algorithm (SHA) packet authentication.</li> <li><b>noauth</b>—Enables the noAuthNoPriv security level. This is the default if no keyword is specified.</li> <li><b>priv</b>—Enables Data Encryption Standard (DES) packet encryption (also called privacy).</li> </ul> </li> </ul> <p>(Optional) Enter <b>read</b> <i>readview</i> with a string (not to exceed 64 characters) that is the name of the view in which you can only view the contents of the agent.</p> <p>(Optional) Enter <b>write</b> <i>writeview</i> with a string (not to exceed 64 characters) that is the name of the view in which you enter data and configure the contents of the agent.</p> <p>(Optional) Enter <b>notify</b> <i>notifyview</i> with a string (not to exceed 64 characters) that is the name of the view in which you specify a notify, inform, or trap.</p> <p>(Optional) Enter <b>access</b> <i>access-list</i> with a string (not to exceed 64 characters) that is the name of the access list.</p> |
| <b>Step 4</b> | <pre>snmp-server user username group-name {remote host [ udp-port port]} {v1 [access access-list]   v2c [access access-list]   v3 [encrypted] [access access-list] [auth {md5   sha} auth-password]} [priv {des   3des   aes {128   192   256}} priv-password]</pre> <p><b>Example:</b></p> <pre>Switch(config)# snmp-server user Pat public v2c</pre> | <p>Adds a new user for an SNMP group.</p> <p>The <i>username</i> is the name of the user on the host that connects to the agent.</p> <p>The <i>group-name</i> is the name of the group to which the user is associated.</p> <p>Enter <b>remote</b> to specify a remote SNMP entity to which the user belongs and the hostname or IP address of that entity with the optional UDP port number. The default is 162.</p> <p>Enter the SNMP version number (<b>v1</b>, <b>v2c</b>, or <b>v3</b>). If you enter <b>v3</b>, you have these additional options:</p> <ul style="list-style-type: none"> <li>• <b>encrypted</b> specifies that the password appears in encrypted format. This keyword is available only when the <b>v3</b> keyword is specified.</li> <li>• <b>auth</b> is an authentication level setting session that can be either the HMAC-MD5-96 (<b>md5</b>) or the HMAC-SHA-96 (<b>sha</b>) authentication level and requires a password string <i>auth-password</i> (not to exceed 64 characters).</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|               | Command or Action                                                       | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Step 5</b> | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Switch(config)# end</pre> | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Configuring SNMP Notifications

A trap manager is a management station that receives and processes traps. Traps are system alerts that the switch generates when certain events occur. By default, no trap manager is defined, and no traps are sent. Switches running this Cisco IOS release can have an unlimited number of trap managers.

**Note** Many commands use the word **traps** in the command syntax. Unless there is an option in the command to select either traps or informs, the keyword **traps** refers to traps, informs, or both. Use the **snmp-server host** global configuration command to specify whether to send SNMP notifications as traps or informs.

You can use the **snmp-server host** global configuration command for a specific host to receive the notification types listed in the following table. You can enable any or all of these traps and configure a trap manager to receive them.

**Table 72: Device Notification Types**

| Notification Type Keyword | Description                                              |
|---------------------------|----------------------------------------------------------|
| <b>bridge</b>             | Generates STP bridge MIB traps.                          |
| <b>cluster</b>            | Generates a trap when the cluster configuration changes. |
| <b>config</b>             | Generates a trap for SNMP configuration changes.         |
| <b>copy-config</b>        | Generates a trap for SNMP copy configuration changes.    |

| Notification Type Keyword | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>cpu threshold</b>      | Allow CPU-related traps.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>entity</b>             | Generates a trap for SNMP entity changes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>envmon</b>             | Generates environmental monitor traps. You can enable any or all of these environmental traps: fan, shutdown, status, supply, temperature.                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>flash</b>              | Generates SNMP FLASH notifications. In a switch stack, you can optionally enable notification for flash insertion or removal, which would cause a trap to be issued whenever a switch in the stack is removed or inserted (physical removal, power cycle, or reload).                                                                                                                                                                                                                                                                               |
| <b>fru-ctrl</b>           | Generates entity field-replaceable unit (FRU) control traps. In the switch stack, this trap refers to the insertion or removal of a switch in the stack.                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>hsrp</b>               | Generates a trap for Hot Standby Router Protocol (HSRP) changes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>ipmulticast</b>        | Generates a trap for IP multicast routing changes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>mac-notification</b>   | Generates a trap for MAC address notifications.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>ospf</b>               | Generates a trap for Open Shortest Path First (OSPF) changes. You can enable any or all of these traps: Cisco specific, errors, link-state advertisement, rate limit, retransmit, and state changes.                                                                                                                                                                                                                                                                                                                                                |
| <b>pim</b>                | Generates a trap for Protocol-Independent Multicast (PIM) changes. You can enable any or all of these traps: invalid PIM messages, neighbor changes, and rendezvous point (RP)-mapping changes.                                                                                                                                                                                                                                                                                                                                                     |
| <b>port-security</b>      | <p>Generates SNMP port security traps. You can also set a maximum trap rate per second. The range is from 0 to 1000; the default is 0, which means that there is no rate limit.</p> <p><b>Note</b> When you configure a trap by using the notification type <b>port-security</b>, configure the port security trap first, and then configure the port security trap rate:</p> <ol style="list-style-type: none"> <li><b>snmp-server enable traps port-security</b></li> <li><b>snmp-server enable traps port-security trap-rate rate</b></li> </ol> |
| <b>snmp</b>               | Generates a trap for SNMP-type notifications for authentication, cold start, warm start, link up or link down.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>storm-control</b>      | Generates a trap for SNMP storm-control. You can also set a maximum trap rate per minute. The range is from 0 to 1000; the default is 0 (no limit is imposed; a trap is sent at every occurrence).                                                                                                                                                                                                                                                                                                                                                  |
| <b>stpx</b>               | Generates SNMP STP Extended MIB traps.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>syslog</b>             | Generates SNMP syslog traps.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>tty</b>                | Generates a trap for TCP connections. This trap is enabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Notification Type Keyword | Description                                                |
|---------------------------|------------------------------------------------------------|
| <b>vlan-membership</b>    | Generates a trap for SNMP VLAN membership changes.         |
| <b>vlancreate</b>         | Generates SNMP VLAN created traps.                         |
| <b>vlandelete</b>         | Generates SNMP VLAN deleted traps.                         |
| <b>vtp</b>                | Generates a trap for VLAN Trunking Protocol (VTP) changes. |

Beginning in privileged EXEC mode, follow these steps to configure the switch to send traps or informs to a host.

## SUMMARY STEPS

1. **configure terminal**
2. **snmp-server engineID remote ip-address engineid-string**
3. **snmp-server user username group-name {remote host [ udp-port port]} {v1 [access access-list] | v2c [access access-list] | v3 [encrypted] [access access-list] [auth {md5 | sha} auth-password] }**
4. **snmp-server group group-name {v1 | v2c | v3 {auth | noauth | priv}} [read readview] [write writeview] [notify notifyview] [access access-list]**
5. **snmp-server host host-addr [informs | traps] [version {1 | 2c | 3 {auth | noauth | priv}}] community-string [notification-type]**
6. **snmp-server enable traps notification-types**
7. **snmp-server trap-source interface-id**
8. **snmp-server queue-length length**
9. **snmp-server trap-timeout seconds**
10. **end**

## DETAILED STEPS

|               | Command or Action                                                                                                                                                                | Purpose                                                                          |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                                                                                            | Enters the global configuration mode.                                            |
| <b>Step 2</b> | <b>snmp-server engineID remote ip-address engineid-string</b><br><br><b>Example:</b><br>Switch(config)# <b>snmp-server engineID remote 192.180.1.27 00000063000100a1c0b4011b</b> | Specifies the engine ID for the remote host.                                     |
| <b>Step 3</b> | <b>snmp-server user username group-name {remote host [ udp-port port]} {v1 [access access-list]  </b>                                                                            | Configures an SNMP user to be associated with the remote host created in Step 2. |

|               | Command or Action                                                                                                                                                                                                                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | <p><b>v2c</b> [<i>access access-list</i>]   <b>v3</b> [<b>encrypted</b>] [<i>access access-list</i>] [<b>auth</b> {<b>md5</b>   <b>sha</b>} <i>auth-password</i> ] }</p> <p><b>Example:</b><br/>Switch(config)# <b>snmp-server user Pat public v2c</b></p>                                                                            | <p><b>Note</b> You cannot configure a remote user for an address without first configuring the engine ID for the remote host. Otherwise, you receive an error message, and the command is not executed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Step 4</b> | <p><b>snmp-server group</b> <i>group-name</i> {<b>v1</b>   <b>v2c</b>   <b>v3</b> {<b>auth</b>   <b>noauth</b>   <b>priv</b>}} [<b>read readview</b>] [<b>write writeview</b>] [<b>notify notifyview</b>] [<i>access access-list</i>]</p> <p><b>Example:</b><br/>Switch(config)# <b>snmp-server group public v2c access lmnop</b></p> | Configures an SNMP group.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Step 5</b> | <p><b>snmp-server host</b> <i>host-addr</i> [<b>informs</b>   <b>traps</b>] [<b>version</b> {<b>1</b>   <b>2c</b>   <b>3</b> {<b>auth</b>   <b>noauth</b>   <b>priv</b>}}] [<i>community-string</i>] [<i>notification-type</i>]</p> <p><b>Example:</b><br/>Switch(config)# <b>snmp-server host 203.0.113.1 comaccess snmp</b></p>     | <p>Specifies the recipient of an SNMP trap operation.</p> <p>For <i>host-addr</i>, specify the name or Internet address of the host (the targeted recipient).</p> <p>(Optional) Specify <b>traps</b> (the default) to send SNMP traps to the host.</p> <p>(Optional) Specify <b>informs</b> to send SNMP informs to the host.</p> <p>(Optional) Specify the SNMP <b>version</b> (<b>1</b>, <b>2c</b>, or <b>3</b>). SNMPv1 does not support informs.</p> <p>(Optional) For Version 3, select authentication level <b>auth</b>, <b>noauth</b>, or <b>priv</b>.</p> <p>For <i>community-string</i>, when <b>version 1</b> or <b>version 2c</b> is specified, enter the password-like community string sent with the notification operation. When <b>version 3</b> is specified, enter the SNMPv3 username.</p> <p>The @ symbol is used for delimiting the context information. Avoid using the @ symbol as part of the SNMP community string when configuring this command.</p> <p>(Optional) For <i>notification-type</i>, use the keywords listed in the table above. If no type is specified, all notifications are sent.</p> |
| <b>Step 6</b> | <p><b>snmp-server enable traps</b> <i>notification-types</i></p> <p><b>Example:</b><br/>Switch(config)# <b>snmp-server enable traps snmp</b></p>                                                                                                                                                                                      | <p>Enables the switch to send traps or informs and specifies the type of notifications to be sent. For a list of notification types, see the table above, or enter <b>snmp-server enable traps ?</b></p> <p>To enable multiple types of traps, you must enter a separate <b>snmp-server enable traps</b> command for each trap type.</p> <p><b>Note</b> When you configure a trap by using the notification type <b>port-security</b>, configure the port security trap first, and then configure the port security trap rate:</p> <ol style="list-style-type: none"> <li><b>snmp-server enable traps port-security</b></li> <li><b>snmp-server enable traps port-security trap-rate rate</b></li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                       |

|         | Command or Action                                                                                                                                   | Purpose                                                                                                                                                  |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 7  | <b>snmp-server trap-source</b> <i>interface-id</i><br><br><b>Example:</b><br>Switch(config)# <b>snmp-server trap-source</b><br>GigabitEthernet1/0/1 | (Optional) Specifies the source interface, which provides the IP address for the trap message. This command also sets the source IP address for informs. |
| Step 8  | <b>snmp-server queue-length</b> <i>length</i><br><br><b>Example:</b><br>Switch(config)# <b>snmp-server queue-length</b><br>20                       | (Optional) Establishes the message queue length for each trap host. The range is 1 to 1000; the default is 10.                                           |
| Step 9  | <b>snmp-server trap-timeout</b> <i>seconds</i><br><br><b>Example:</b><br>Switch(config)# <b>snmp-server trap-timeout</b><br>60                      | (Optional) Defines how often to resend trap messages. The range is 1 to 1000; the default is 30 seconds.                                                 |
| Step 10 | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b>                                                                                     | Returns to privileged EXEC mode.                                                                                                                         |

### What to Do Next

The **snmp-server host** command specifies which hosts receive the notifications. The **snmp-server enable trap** command globally enables the method for the specified notification (for traps and informs). To enable a host to receive an inform, you must configure an **snmp-server host informs** command for the host and globally enable informs by using the **snmp-server enable traps** command.

To remove the specified host from receiving traps, use the **no snmp-server host** *host* global configuration command. The **no snmp-server host** command with no keywords disables traps, but not informs, to the host. To disable informs, use the **no snmp-server host informs** global configuration command. To disable a specific trap type, use the **no snmp-server enable traps** *notification-types* global configuration command.

## Setting the Agent Contact and Location Information

Beginning in privileged EXEC mode, follow these steps to set the system contact and location of the SNMP agent so that these descriptions can be accessed through the configuration file.

### SUMMARY STEPS

1. **configure terminal**
2. **snmp-server contact** *text*
3. **snmp-server location** *text*
4. **end**

## DETAILED STEPS

|        | Command or Action                                                                                                                                    | Purpose                               |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------|
| Step 1 | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                                                                | Enters the global configuration mode. |
| Step 2 | <b>snmp-server contact <i>text</i></b><br><br><b>Example:</b><br>Switch(config)# <b>snmp-server contact Dial System Operator<br/>at beeper 21555</b> | Sets the system contact string.       |
| Step 3 | <b>snmp-server location <i>text</i></b><br><br><b>Example:</b><br>Switch(config)# <b>snmp-server location Building 3/Room<br/>222</b>                | Sets the system location string.      |
| Step 4 | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b>                                                                                      | Returns to privileged EXEC mode.      |

## Limiting TFTP Servers Used Through SNMP

Beginning in privileged EXEC mode, follow these steps to limit the TFTP servers used for saving and loading configuration files through SNMP to the servers specified in an access list.

## SUMMARY STEPS

1. **configure terminal**
2. **snmp-server tftp-server-list *access-list-number***
3. **access-list *access-list-number* {deny | permit} *source* [*source-wildcard*]**
4. **end**

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <p><b>configure terminal</b></p> <p><b>Example:</b><br/>Switch# <b>configure terminal</b></p>                                                                                                                        | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Step 2 | <p><b>snmp-server tftp-server-list</b><br/><i>access-list-number</i></p> <p><b>Example:</b><br/>Switch(config)# <b>snmp-server</b><br/><b>tftp-server-list 44</b></p>                                                | <p>Limits the TFTP servers used for configuration file copies through SNMP to the servers in the access list.</p> <p>For <i>access-list-number</i>, enter an IP standard access list numbered from 1 to 99 and 1300 to 1999.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Step 3 | <p><b>access-list</b> <i>access-list-number</i> {<b>deny</b>   <b>permit</b>} <i>source</i> [<i>source-wildcard</i>]</p> <p><b>Example:</b><br/>Switch(config)# <b>access-list 44 permit</b><br/><b>10.1.1.2</b></p> | <p>Creates a standard access list, repeating the command as many times as necessary.</p> <p>For <i>access-list-number</i>, enter the access list number specified in Step 2.</p> <p>The <b>deny</b> keyword denies access if the conditions are matched. The <b>permit</b> keyword permits access if the conditions are matched.</p> <p>For <i>source</i>, enter the IP address of the TFTP servers that can access the switch.</p> <p>(Optional) For <i>source-wildcard</i>, enter the wildcard bits, in dotted decimal notation, to be applied to the source. Place ones in the bit positions that you want to ignore.</p> <p>The access list is always terminated by an implicit deny statement for everything.</p> |
| Step 4 | <p><b>end</b></p> <p><b>Example:</b><br/>Switch(config)# <b>end</b></p>                                                                                                                                              | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Configuring Trap Flags for SNMP

### SUMMARY STEPS

1. `configure terminal`
2. `trapflags ap { interfaceup | register }`
3. `trapflags client { dot11 | excluded }`
4. `trapflags dot11-security { ids-sig-attack | wep-decrypt-error }`
5. `trapflags mesh`
6. `trapflags rogueap`
7. `trapflags rrm-params { channels | tx-power }`
8. `trapflags rrm-profile { coverage | interference | load | noise }`
9. `end`

### DETAILED STEPS

|               | Command or Action                                                                                                                                                              | Purpose                                                                                                                                                                                                                                                                                                                      |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <code>configure terminal</code><br><br><b>Example:</b><br><code>Switch# configure terminal</code>                                                                              | Enters the global configuration mode.                                                                                                                                                                                                                                                                                        |
| <b>Step 2</b> | <code>trapflags ap { interfaceup   register }</code><br><br><b>Example:</b><br><code>Switch(config)# trapflags ap interfaceup</code>                                           | Enables sending AP-related traps. Use the <b>no</b> form of the command to disable the trap flags. <ul style="list-style-type: none"> <li>• <b>interfaceup</b>– Enables trap when a Cisco AP interface (A or B) comes up.</li> <li>• <b>register</b>– Enables trap when a Cisco AP registers with a Cisco switch.</li> </ul> |
| <b>Step 3</b> | <code>trapflags client { dot11   excluded }</code><br><br><b>Example:</b><br><code>Switch(config)# trapflags client excluded</code>                                            | Enables sending client-related dot11 traps. Use the <b>no</b> form of the command to disable the trap flags. <ul style="list-style-type: none"> <li>• <b>dot11</b>– Enables Dot11 traps for clients.</li> <li>• <b>excluded</b>– Enables excluded traps for clients.</li> </ul>                                              |
| <b>Step 4</b> | <code>trapflags dot11-security { ids-sig-attack   wep-decrypt-error }</code><br><br><b>Example:</b><br><code>Switch(config)# trapflags dot11-security wep-decrypt-error</code> | Enables sending 802.11 security-related traps. Use the <b>no</b> form of the command to disable the trap flags. <ul style="list-style-type: none"> <li>• <b>ids-sig-attack</b>– Enables IDS signature attack traps.</li> <li>• <b>wep-decrypt-error</b>– Enables traps for WEP decrypt error for clients.</li> </ul>         |

|               | Command or Action                                                                                                                                         | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 5</b> | <b>trapflags mesh</b><br><br><b>Example:</b><br>Switch(config)# <b>trapflags mesh</b>                                                                     | Enables trap for the mesh. Use the <b>no</b> form of the command to disable the trap flags.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Step 6</b> | <b>trapflags rogueap</b><br><br><b>Example:</b><br>Switch(config)# <b>trapflags rogueap</b>                                                               | Enables trap for rogue AP detection. Use the <b>no</b> form of the command to disable the trap flags.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Step 7</b> | <b>trapflags rrm-params {channels   tx-power}</b><br><br><b>Example:</b><br>Switch(config)# <b>trapflags rrm-params tx-power</b>                          | Enables sending RRM-parameter update-related traps. Use the <b>no</b> form of the command to disable the trap flags. <ul style="list-style-type: none"> <li>• <b>channels</b>– Enables trap when RF Manager automatically changes a channel number for the Cisco AP interface.</li> <li>• <b>tx-power</b>– Enables the trap when RF Manager automatically changes Tx-Power level for the Cisco AP interface.</li> </ul>                                                                                                                                            |
| <b>Step 8</b> | <b>trapflags rrm-profile {coverage   interference   load   noise}</b><br><br><b>Example:</b><br>Switch(config)# <b>trapflags rrm-profile interference</b> | Enables sending RRM-profile-related traps. Use the <b>no</b> form of the command to disable the trap flags. <ul style="list-style-type: none"> <li>• <b>coverage</b>– Enables the trap when the coverage profile maintained by RF Manager fails.</li> <li>• <b>interference</b>– Enables the trap when the interference profile maintained by RF Manager fails.</li> <li>• <b>load</b>– Enables trap when the load profile maintained by RF Manager fails.</li> <li>• <b>noise</b>– Enables trap when the noise profile maintained by RF Manager fails.</li> </ul> |
| <b>Step 9</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b>                                                                                           | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Enabling SNMP Wireless Trap Notification

### SUMMARY STEPS

1. `configure terminal`
2. `snmp-server enable traps wireless [AP | RRM | bsn80211SecurityTrap | bsnAPPParamUpdate | bsnAPPProfile | bsnAccessPoint | bsnMobileStation | bsnRogue | client | mfp | rogue]`
3. `end`

### DETAILED STEPS

|               | Command or Action                                                                                                                                                                                                                                                                        | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <p><code>configure terminal</code></p> <p><b>Example:</b></p> <pre>Switch# configure terminal</pre>                                                                                                                                                                                      | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Step 2</b> | <p><code>snmp-server enable traps wireless [AP   RRM   bsn80211SecurityTrap   bsnAPPParamUpdate   bsnAPPProfile   bsnAccessPoint   bsnMobileStation   bsnRogue   client   mfp   rogue]</code></p> <p><b>Example:</b></p> <pre>Switch(config)# snmp-server enable traps wireless AP</pre> | <p>Enables SNMP wireless trap notification.</p> <ul style="list-style-type: none"> <li>• <b>AP</b>– Enables access point traps.</li> <li>• <b>RRM</b>– Enables RRM traps.</li> <li>• <b>bsn80211SecurityTrap</b>– Enables the security-related trap.</li> <li>• <b>bsnAPPParamUpdate</b>– Enables the trap for AP parameters that get updated.</li> <li>• <b>bsnAPPProfile</b>– Enables BSN AP profile traps.</li> <li>• <b>bsnAccessPoint</b>– Enables BSN access point traps.</li> <li>• <b>bsnMobileStation</b>– Controls wireless client traps.</li> <li>• <b>bsnRogue</b>– Enables BSN rogue-related traps.</li> <li>• <b>client</b>– Enables client traps.</li> <li>• <b>mfp</b>– Enables MFP traps.</li> <li>• <b>rogue</b>– Enables rogue-related traps.</li> </ul> |
| <b>Step 3</b> | <p><code>end</code></p> <p><b>Example:</b></p> <pre>Switch(config)# end</pre>                                                                                                                                                                                                            | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Monitoring SNMP Status

To display SNMP input and output statistics, including the number of illegal community string entries, errors, and requested variables, use the **show snmp** privileged EXEC command. You also can use the other privileged EXEC commands listed in the table to display SNMP information.

**Table 73: Commands for Displaying SNMP Information**

| Command                   | Purpose                                                                                                                                                                                                                                                                                       |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>show snmp</b>          | Displays SNMP statistics.                                                                                                                                                                                                                                                                     |
|                           | Displays information on the local SNMP engine and all remote engines that have been configured on the device.                                                                                                                                                                                 |
| <b>show snmp group</b>    | Displays information on each SNMP group on the network.                                                                                                                                                                                                                                       |
| <b>show snmp pending</b>  | Displays information on pending SNMP requests.                                                                                                                                                                                                                                                |
| <b>show snmp sessions</b> | Displays information on the current SNMP sessions.                                                                                                                                                                                                                                            |
| <b>show snmp user</b>     | Displays information on each SNMP user name in the SNMP users table.<br><br><b>Note</b> You must use this command to display SNMPv3 configuration information for <b>auth</b>   <b>noauth</b>   <b>priv</b> mode. This information is not displayed in the <b>show running-config</b> output. |

## SNMP Examples

This example shows how to enable all versions of SNMP. The configuration permits any SNMP manager to access all objects with read-only permissions using the community string *public*. This configuration does not cause the switch to send any traps.

```
Switch(config)# snmp-server community public
```

This example shows how to permit any SNMP manager to access all objects with read-only permission using the community string *public*. The switch also sends VTP traps to the hosts 192.180.1.111 and 192.180.1.33 using SNMPv1 and to the host 192.180.1.27 using SNMPv2C. The community string *public* is sent with the traps.

```
Switch(config)# snmp-server community public
Switch(config)# snmp-server enable traps vtp
Switch(config)# snmp-server host 192.180.1.27 version 2c public
Switch(config)# snmp-server host 192.180.1.111 version 1 public
Switch(config)# snmp-server host 192.180.1.33 public
```

This example shows how to allow read-only access for all objects to members of access list 4 that use the *comaccess* community string. No other SNMP managers have access to any objects. SNMP Authentication Failure traps are sent by SNMPv2C to the host *cisco.com* using the community string *public*.

```
Switch(config)# snmp-server community comaccess ro 4
Switch(config)# snmp-server enable traps snmp authentication
Switch(config)# snmp-server host cisco.com version 2c public
```

This example shows how to send Entity MIB traps to the host *cisco.com*. The community string is restricted. The first line enables the switch to send Entity MIB traps in addition to any traps previously enabled. The second line specifies the destination of these traps and overwrites any previous **snmp-server** host commands for the host *cisco.com*.

```
Switch(config)# snmp-server enable traps entity
Switch(config)# snmp-server host cisco.com restricted entity
```

This example shows how to enable the switch to send all traps to the host *myhost.cisco.com* using the community string *public*:

```
Switch(config)# snmp-server enable traps
Switch(config)# snmp-server host myhost.cisco.com public
```

This example shows how to associate a user with a remote host and to send **auth** (authNoPriv) authentication-level informs when the user enters global configuration mode:

```
Switch(config)# snmp-server engineID remote 192.180.1.27 00000063000100a1c0b4011b
Switch(config)# snmp-server group authgroup v3 auth
Switch(config)# snmp-server user authuser authgroup remote 192.180.1.27 v3 auth md5 mypassword
Switch(config)# snmp-server user authuser authgroup v3 auth md5 mypassword
Switch(config)# snmp-server host 192.180.1.27 informs version 3 auth authuser config
Switch(config)# snmp-server enable traps
Switch(config)# snmp-server inform retries 0
```

# Configuring Service Level Agreements

This chapter describes how to use Cisco IOS IP Service Level Agreements (SLAs) on the switch.

Unless otherwise noted, the term *switch* refers to a standalone switch or a switch stack.

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Restrictions on SLAs

This section lists the restrictions on SLAs.

The following are restrictions on IP SLAs network performance measurement:

- The switch does not support VoIP service levels using the gatekeeper registration delay operations measurements.
- Only a Cisco IOS device can be a source for a destination IP SLAs responder.

- You cannot configure the IP SLAs responder on non-Cisco devices and Cisco IOS IP SLAs can send operational packets only to services native to those devices.

## Information About SLAs

### Cisco IOS IP Service Level Agreements (SLAs)

Cisco IOS IP SLAs send data across the network to measure performance between multiple network locations or across multiple network paths. They simulate network data and IP services and collect network performance information in real time. Cisco IOS IP SLAs generate and analyze traffic either between Cisco IOS devices or from a Cisco IOS device to a remote IP device such as a network application server. Measurements provided by the various Cisco IOS IP SLA operations can be used for troubleshooting, for problem analysis, and for designing network topologies.

Depending on the specific Cisco IOS IP SLA operations, various network performance statistics are monitored within the Cisco device and stored in both command-line interface (CLI) and Simple Network Management Protocol (SNMP) MIBs. IP SLA packets have configurable IP and application layer options such as source and destination IP address, User Datagram Protocol (UDP)/TCP port numbers, a type of service (ToS) byte (including Differentiated Services Code Point [DSCP] and IP Prefix bits), Virtual Private Network (VPN) routing/forwarding instance (VRF), and URL web address.

Because Cisco IP SLAs are Layer 2 transport independent, you can configure end-to-end operations over disparate networks to best reflect the metrics that an end user is likely to experience. IP SLAs collect a unique subset of the following performance metrics:

- Delay (both round-trip and one-way)
- Jitter (directional)
- Packet loss (directional)
- Packet sequencing (packet ordering)
- Path (per hop)
- Connectivity (directional)
- Server or website download time

Because Cisco IOS IP SLAs is SNMP-accessible, it can also be used by performance-monitoring applications like Cisco Prime Internetwork Performance Monitor (IPM) and other third-party Cisco partner performance management products.

Using IP SLAs can provide the following benefits:

- Service-level agreement monitoring, measurement, and verification.
- Network performance monitoring

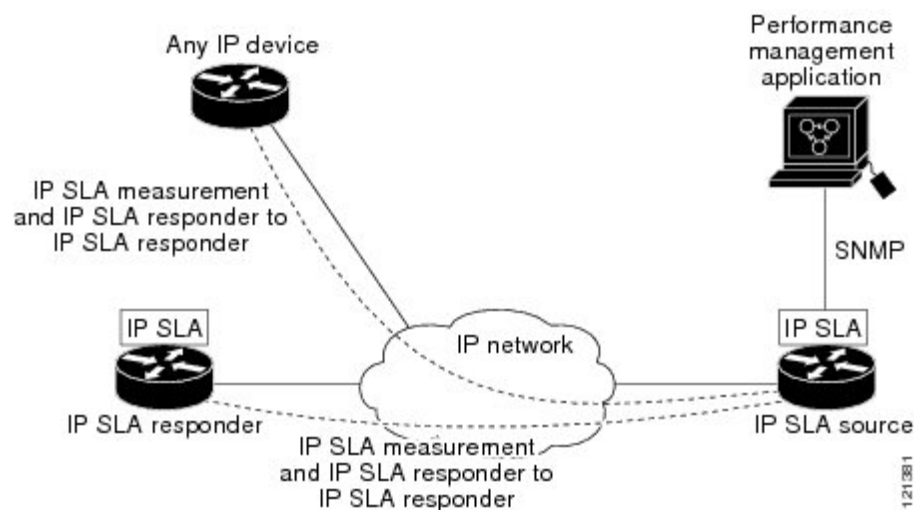

- Measurement of jitter, latency, or packet loss in the network.
- Continuous, reliable, and predictable measurements.
- IP service network health assessment to verify that the existing QoS is sufficient for new IP services.
- Edge-to-edge network availability monitoring for proactive verification and connectivity testing of network resources (for example, shows the network availability of an NFS server used to store business critical data from a remote site).
- Network operation troubleshooting by providing consistent, reliable measurement that immediately identifies problems and saves troubleshooting time.
- Multiprotocol Label Switching (MPLS) performance monitoring and network verification (if the switch supports MPLS).

## Network Performance Measurement with Cisco IOS IP SLAs

You can use IP SLAs to monitor the performance between any area in the network—core, distribution, and edge—without deploying a physical probe. It uses generated traffic to measure network performance between two networking devices.

The following figure shows how IP SLAs begin when the source device sends a generated packet to the destination device. After the destination device receives the packet, depending on the type of IP SLAs operation, it responds with time-stamp information for the source to make the calculation on performance metrics. An IP SLAs operation performs a network measurement from the source device to a destination in the network using a specific protocol such as UDP.

## IP SLA Responder and IP SLA Control Protocol

The IP SLA responder is a component embedded in the destination Cisco device that allows the system to anticipate and respond to IP SLA request packets. The responder provides accurate measurements without the need for dedicated probes. The responder uses the Cisco IOS IP SLA Control Protocol to provide a mechanism through which it can be notified on which port it should listen and respond.

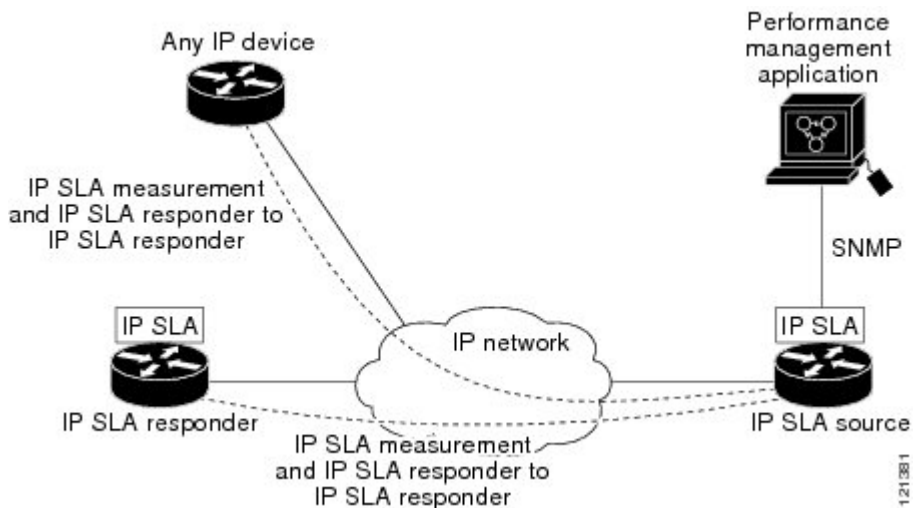

### Note

The IP SLA responder can be a Cisco IOS Layer 2, responder-configurable switch. The responder does not need to support full IP SLA functionality.

The following figure shows where the Cisco IOS IP SLA responder fits in the IP network. The responder listens on a specific port for control protocol messages sent by an IP SLA operation. Upon receipt of the control message, it enables the specified UDP or TCP port for the specified duration. During this time, the responder accepts the requests and responds to them. It disables the port after it responds to the IP SLA packet, or when the specified time expires. MD5 authentication for control messages is available for added security.

**Figure 55: Cisco IOS IP SLAs Operation**

You do not need to enable the responder on the destination device for all IP SLA operations. For example, a responder is not required for services that are already provided by the destination router (such as Telnet or HTTP).

## Response Time Computation for IP SLAs

Switches, controllers, and routers can take tens of milliseconds to process incoming packets due to other high priority processes. This delay affects the response times because the test-packet reply might be in a queue while waiting to be processed. In this situation, the response times would not accurately represent true network delays. IP SLAs minimize these processing delays on the source device as well as on the target device (if the

responder is being used) to determine true round-trip times. IP SLA test packets use time stamping to minimize the processing delays.

When the IP SLA responder is enabled, it allows the target device to take time stamps when the packet arrives on the interface at interrupt level and again just as it is leaving, eliminating the processing time. This time stamping is made with a granularity of sub-milliseconds (ms).

The following figure demonstrates how the responder works. Four time stamps are taken to make the calculation for round-trip time. At the target router, with the responder functionality enabled, time stamp 2 (TS2) is subtracted from time stamp 3 (TS3) to produce the time spent processing the test packet as represented by delta. This delta value is then subtracted from the overall round-trip time. Notice that the same principle is applied by IP SLAs on the source router where the incoming time stamp 4 (TS4) is also taken at the interrupt level to allow for greater accuracy.

**Figure 56: Cisco IOS IP SLA Responder Time Stamping**

An additional benefit of the two time stamps at the target device is the ability to track one-way delay, jitter, and directional packet loss. Because much network behavior is asynchronous, it is critical to have these statistics. However, to capture one-way delay measurements, you must configure both the source router and target router with Network Time Protocol (NTP) so that the source and target are synchronized to the same clock source. One-way jitter measurements do not require clock synchronization.

## IP SLAs Operation Scheduling

When you configure an IP SLAs operation, you must schedule the operation to begin capturing statistics and collecting error information. You can schedule an operation to start immediately or to start at a certain month, day, and hour. You can use the *pending* option to set the operation to start at a later time. The pending option is an internal state of the operation that is visible through SNMP. The pending state is also used when an operation is a reaction (threshold) operation waiting to be triggered. You can schedule a single IP SLAs operation or a group of operations at one time.

You can schedule several IP SLAs operations by using a single command through the Cisco IOS CLI or the CISCO RTTMON-MIB. Scheduling the operations to run at evenly distributed times allows you to control the amount of IP SLAs monitoring traffic. This distribution of IP SLA operations helps minimize the CPU utilization and thus improves network scalability.

For more details about the IP SLA multi-operations scheduling functionality, see the “IP SLAs—Multiple Operation Scheduling” chapter of the *Cisco IOS IP SLAs Configuration Guide*.

## IP SLA Operation Threshold Monitoring

To support successful service level agreement monitoring, you must have mechanisms that notify you immediately of any possible violation. IP SLAs can send SNMP traps that are triggered by events such as the following:

- Connection loss
- Timeout
- Round-trip time threshold
- Average jitter threshold
- One-way packet loss
- One-way jitter
- One-way mean opinion score (MOS)
- One-way latency

An IP SLA threshold violation can also trigger another IP SLA operation for further analysis. For example, the frequency could be increased or an Internet Control Message Protocol (ICMP) path echo or ICMP path jitter operation could be initiated for troubleshooting.

### ICMP Echo

The ICMP echo operation measures the end-to-end response time between a Cisco device and any other device that uses IP. The response time is computed by measuring the time it takes to send an ICMP echo request message to a destination and receive an ICMP echo reply. Many customers use IP SLA ICMP-based operations, in-house ping testing, or ping-based dedicated probes to measure this response time. The IP SLA ICMP echo operation conforms to the same specifications as ICMP ping testing, and both methods result in the same response times.

## UDP Jitter

Jitter is a simple term that describes interpacket delay variance. When multiple packets are sent consecutively at an interval of 10 ms from source to destination, the destination should receive them 10 ms apart (if the network is behaving correctly). However, if there are delays in the network (such as queuing, arriving through alternate routes, and so on), the time interval between packet arrivals might be more or less than 10 ms. A positive jitter value indicates that the packets arrived more than 10 ms apart. A negative jitter value indicates that the packets arrived less than 10 ms apart. If the packets arrive 12 ms apart, the positive jitter is 2 ms; if the packets arrive 8 ms apart, the negative jitter is 2 ms. For delay-sensitive networks, positive jitter values are undesirable, and a jitter value of 0 is ideal.

In addition to monitoring jitter, the IP SLA UDP jitter operation can be used as a multipurpose data gathering operation. The packets generated by IP SLAs carry sequence information and time stamps from the source and operational target that include packet sending and receiving data. Based on this data, UDP jitter operations measure the following:

- Per-direction jitter (source to destination and destination to source)
- Per-direction packet-loss
- Per-direction delay (one-way delay)
- Round-trip delay (average round-trip time)

Because the paths for the sending and receiving of data can be different (asymmetric), you can use the per-direction data to more readily identify where congestion or other problems are occurring in the network.

The UDP jitter operation generates synthetic (simulated) UDP traffic and sends a number of UDP packets, each of a specified size, sent a specified number of milliseconds apart, from a source router to a target router, at a given frequency. By default, ten packet-frames, each with a payload size of 10 bytes are generated every 10 ms, and the operation is repeated every 60 seconds. You can configure each of these parameters to best simulate the IP service you want to provide.

To provide accurate one-way delay (latency) measurements, time synchronization (as provided by NTP) is required between the source and the target device. Time synchronization is not required for the one-way jitter and packet loss measurements. If the time is not synchronized between the source and target devices, one-way jitter and packet loss data is returned, but values of 0 are returned for the one-way delay measurements provided by the UDP jitter operation.

## Configuration Guidelines

For information on the IP SLA commands, see the *Cisco IOS IP SLAs Command Reference, Release 12.4T* command reference.

For detailed descriptions and configuration procedures, see the *Cisco IOS IP SLAs Configuration Guide, Release 12.4TL*.

Not all of the IP SLA commands or operations described in the referenced guide are supported on the switch. The switch supports IP service level analysis by using UDP jitter, UDP echo, HTTP, TCP connect, ICMP echo, ICMP path echo, ICMP path jitter, FTP, DNS, and DHCP, as well as multiple operation scheduling and proactive threshold monitoring. It does not support VoIP service levels using the gatekeeper registration delay operations measurements.

Before configuring any IP SLAs application, you can use the **show ip sla application** privileged EXEC command to verify that the operation type is supported on your software image. This is an example of the output from the command:

```
Switch# show ip sla application

      IP Service Level Agreements
Version: Round Trip Time MIB 2.2.0, Infrastructure Engine-III

Supported Operation Types:
  icmpEcho, path-echo, path-jitter, udpEcho, tcpConnect, http
  dns, udpJitter, dhcp, ftp, udpApp, wspApp

Supported Features:
  IPSLAs Event Publisher

IP SLAs low memory water mark: 33299323
Estimated system max number of entries: 24389

Estimated number of configurable operations: 24389
Number of Entries configured      : 0
Number of active Entries          : 0
Number of pending Entries         : 0
Number of inactive Entries        : 0
Time of last change in whole IP SLAs: *13:04:37.668 UTC Wed Dec 19 2012
```

## How to Configure IP SLAs Operations

This section does not include configuration information for all available operations as the configuration information details are included in the *Cisco IOS IP SLAs Configuration Guide*. It does include several operations as examples, including configuring the responder, configuring a UDP jitter operation, which requires a responder, and configuring an ICMP echo operation, which does not require a responder. For details about configuring other operations, see the *Cisco IOS IP SLAs Configuration Guide*.

### Configuring the IP SLA Responder

The IP SLA responder is available only on Cisco IOS software-based devices, including some Layer 2 switches that do not support full IP SLA functionality.

Beginning in privileged EXEC mode, follow these steps to configure the IP SLA responder on the target device (the operational target):

#### SUMMARY STEPS

1. **configure terminal**
2. **ip sla responder {tcp-connect | udp-echo} ipaddress ip-address port port-number**
3. **end**

#### DETAILED STEPS

|               | Command or Action                                                                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                                                                                                 | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Step 2</b> | <b>ip sla responder {tcp-connect   udp-echo} ipaddress ip-address port port-number</b><br><br><b>Example:</b><br>Switch(config)# <b>ip sla responder udp-echo 172.29.139.134 5000</b> | Configures the switch as an IP SLA responder.<br>The keywords have these meanings: <ul style="list-style-type: none"> <li>• <b>tcp-connect</b>—Enables the responder for TCP connect operations.</li> <li>• <b>udp-echo</b>—Enables the responder for User Datagram Protocol (UDP) echo or jitter operations.</li> <li>• <b>ipaddress ip-address</b>—Enter the destination IP address.</li> <li>• <b>port port-number</b>—Enter the destination port number.</li> </ul> <p><b>Note</b> The IP address and port number must match those configured on the source device for the IP SLA operation.</p> |

|        | Command or Action                                               | Purpose                          |
|--------|-----------------------------------------------------------------|----------------------------------|
| Step 3 | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b> | Returns to privileged EXEC mode. |

### UDP Jitter Example

This example shows how to configure the device as a responder for the UDP jitter IP SLA operation in the next procedure:

```
Switch(config)# ip sla responder udp-echo 172.29.139.134 5000
```

## Implementing IP SLA Network Performance Measurement

Beginning in privileged EXEC mode, follow these steps to implement IP SLA network performance measurement on your switch:

### Before You Begin

Use the **show ip sla application** privileged EXEC command to verify that the desired operation type is supported on your software image.

### SUMMARY STEPS

1. **configure terminal**
2. **ip sla operation-number**
3. **udp-jitter** {*destination-ip-address* | *destination-hostname*} *destination-port* [**source-ip** {*ip-address* | *hostname*}] [**source-port** *port-number*] [**control** {**enable** | **disable**}] [**num-packets** *number-of-packets*] [**interval** *interpacket-interval*]
4. **frequency** *seconds*
5. **threshold** *milliseconds*
6. **exit**
7. **ip sla schedule** *operation-number* [**life** {**forever** | *seconds*}] [**start-time** {*hh:mm* [:*ss*] [*month day* | *day month*] | **pending** | **now** | **after** *hh:mm:ss*] [**ageout** *seconds*] [**recurring**]
8. **end**

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                                                                                                                                                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Step 3 | <p><b>udp-jitter</b> {<i>destination-ip-address</i>   <i>destination-hostname</i>} <i>destination-port</i> [<b>source-ip</b> {<i>ip-address</i>   <i>hostname</i>}] [<b>source-port</b> <i>port-number</i>] [<b>control</b> {<b>enable</b>   <b>disable</b>}] [<b>num-packets</b> <i>number-of-packets</i>] [<b>interval</b> <i>interpacket-interval</i>]</p> <p><b>Example:</b></p> <pre>Switch(config-ip-sla)# udp-jitter 172.29.139.134 5000</pre> | <p>Configures the IP SLA operation as the operation type of your choice (a UDP jitter operation is used in the example), and enters its configuration mode (UDP jitter configuration mode is used in the example).</p> <ul style="list-style-type: none"> <li>• <i>destination-ip-address</i>   <i>destination-hostname</i>—Specifies the destination IP address or hostname.</li> <li>• <i>destination-port</i>—Specifies the destination port number in the range from 1 to 65535.</li> <li>• (Optional) <b>source-ip</b> {<i>ip-address</i>   <i>hostname</i>}—Specifies the source IP address or hostname. When a source IP address or hostname is not specified, IP SLA chooses the IP address nearest to the destination</li> <li>• (Optional) <b>source-port</b> <i>port-number</i>—Specifies the source port number in the range from 1 to 65535. When a port number is not specified, IP SLA chooses an available port.</li> <li>• (Optional) <b>control</b>—Enables or disables sending of IP SLA control messages to the IP SLA responder. By default, IP SLA control messages are sent to the destination device to establish a connection with the IP SLA responder</li> <li>• (Optional) <b>num-packets</b> <i>number-of-packets</i>—Enters the number of packets to be generated. The range is 1 to 6000; the default is 10.</li> <li>• (Optional) <b>interval</b> <i>inter-packet-interval</i>—Enters the interval between sending packets in milliseconds. The range is 1 to 6000; the default value is 20 ms.</li> </ul> |
| Step 4 | <p><b>frequency</b> <i>seconds</i></p> <p><b>Example:</b></p> <pre>Switch(config-ip-sla-jitter)# frequency 45</pre>                                                                                                                                                                                                                                                                                                                                   | (Optional) Configures options for the SLA operation. This example sets the rate at which a specified IP SLA operation repeats. The range is from 1 to 604800 seconds; the default is 60 seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|        | Command or Action                                                                                                                                                                                                                                                                                                                                                                                               | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Step 5 | <b>threshold</b> <i>milliseconds</i><br><br><b>Example:</b><br><pre>Switch(config-ip-sla-jitter)# <b>threshold 200</b></pre>                                                                                                                                                                                                                                                                                    | (Optional) Configures threshold conditions. This example sets the threshold of the specified IP SLA operation to 200. The range is from 0 to 60000 milliseconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Step 6 | <b>exit</b><br><br><b>Example:</b><br><pre>Switch(config-ip-sla-jitter)# <b>exit</b></pre>                                                                                                                                                                                                                                                                                                                      | Exits the SLA operation configuration mode (UDP jitter configuration mode in this example), and returns to global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Step 7 | <b>ip sla schedule</b> <i>operation-number</i> [ <b>life</b> { <b>forever</b>   <i>seconds</i> }] [ <b>start-time</b> { <i>hh:mm:ss</i>   <i>month day   day month</i> }   <b>pending</b>   <b>now</b>   <b>after</b> <i>hh:mm:ss</i> ] [ <b>ageout</b> <i>seconds</i> ] [ <b>recurring</b> ]<br><br><b>Example:</b><br><pre>Switch(config)# <b>ip sla schedule 10</b> <b>start-time now life forever</b></pre> | <p>Configures the scheduling parameters for an individual IP SLA operation.</p> <ul style="list-style-type: none"> <li>• <i>operation-number</i>—Enter the RTR entry number.</li> <li>• (Optional) <b>life</b>—Sets the operation to run indefinitely (<b>forever</b>) or for a specific number of <i>seconds</i>. The range is from 0 to 2147483647. The default is 3600 seconds (1 hour).</li> <li>• (Optional) <b>start-time</b>—Enters the time for the operation to begin collecting information:<br/> <p>To start at a specific time, enter the hour, minute, second (in 24-hour notation), and day of the month. If no month is entered, the default is the current month.</p> <p>Enter <b>pending</b> to select no information collection until a start time is selected.</p> <p>Enter <b>now</b> to start the operation immediately.</p> <p>Enter <b>after</b> <i>hh:mm:ss</i> to show that the operation should start after the entered time has elapsed.</p> </li> <li>• (Optional) <b>ageout</b> <i>seconds</i>—Enter the number of seconds to keep the operation in memory when it is not actively collecting information. The range is 0 to 2073600 seconds, the default is 0 seconds (never ages out).</li> <li>• (Optional) <b>recurring</b>—Set the operation to automatically run every day.</li> </ul> |
| Step 8 | <b>end</b><br><br><b>Example:</b><br><pre>Switch(config)# <b>end</b></pre>                                                                                                                                                                                                                                                                                                                                      | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## UDP Jitter Configuration

This example shows how to configure a UDP jitter IP SLA operation:

```
Switch(config)# ip sla 10
Switch(config-ip-sla)# udp-jitter 172.29.139.134 5000
Switch(config-ip-sla-jitter)# frequency 30
Switch(config-ip-sla-jitter)# exit
Switch(config)# ip sla schedule 5 start-time now life forever
Switch(config)# end
Switch# show ip sla configuration 10
IP SLAs, Infrastructure Engine-II.

Entry number: 10
Owner:
Tag:
Type of operation to perform: udp-jitter
Target address/Source address: 1.1.1.1/0.0.0.0
Target port/Source port: 2/0
Request size (ARR data portion): 32
Operation timeout (milliseconds): 5000
Packet Interval (milliseconds)/Number of packets: 20/10
Type Of Service parameters: 0x0
Verify data: No
Vrf Name:
Control Packets: enabled
Schedule:
  Operation frequency (seconds): 30
  Next Scheduled Start Time: Pending trigger
  Group Scheduled : FALSE
  Randomly Scheduled : FALSE
  Life (seconds): 3600
  Entry Ageout (seconds): never
  Recurring (Starting Everyday): FALSE
  Status of entry (SNMP RowStatus): notInService
Threshold (milliseconds): 5000
Distribution Statistics:
  Number of statistic hours kept: 2
  Number of statistic distribution buckets kept: 1
  Statistic distribution interval (milliseconds): 20
Enhanced History:

## Analyzing IP Service Levels by Using the UDP Jitter Operation

Beginning in privileged EXEC mode, follow these steps to configure a UDP jitter operation on the source device:

### Before You Begin

You must enable the IP SLA responder on the target device (the operational target) to configure a UDP jitter operation on the source device.

## SUMMARY STEPS

1. **configure terminal**
2. **ip sla operation-number**
3. **udp-jitter** {*destination-ip-address* | *destination-hostname*} *destination-port* [**source-ip** {*ip-address* | *hostname*}] [**source-port** *port-number*] [**control** {**enable** | **disable**}] [**num-packets** *number-of-packets*] [**interval** *interpacket-interval*]
4. **frequency** *seconds*
5. **exit**
6. **ip sla schedule** *operation-number* [**life** {**forever** | *seconds*}] [**start-time** {*hh:mm* [:*ss*] [*month day* | *day month*] | **pending** | **now** | **after** *hh:mm:ss*] [**ageout** *seconds*] [**recurring**]
7. **end**

### Configuring a UDP Jitter IP SLA Operation

This example shows how to configure a UDP jitter IP SLA operation:

```
Switch(config)# ip sla 10
Switch(config-ip-sla)# udp-jitter 172.29.139.134 5000
Switch(config-ip-sla-jitter)# frequency 30
Switch(config-ip-sla-jitter)# exit
Switch(config)# ip sla schedule 5 start-time now life forever
Switch(config)# end
Switch# show ip sla configuration 10
IP SLAs, Infrastructure Engine-II.

Entry number: 10
Owner:
Tag:
Type of operation to perform: udp-jitter
Target address/Source address: 1.1.1.1/0.0.0.0
Target port/Source port: 2/0
Request size (ARR data portion): 32
Operation timeout (milliseconds): 5000
Packet Interval (milliseconds)/Number of packets: 20/10
Type Of Service parameters: 0x0
Verify data: No
Vrf Name:
Control Packets: enabled
Schedule:
  Operation frequency (seconds): 30
  Next Scheduled Start Time: Pending trigger
  Group Scheduled : FALSE
  Randomly Scheduled : FALSE
  Life (seconds): 3600
  Entry Ageout (seconds): never
  Recurring (Starting Everyday): FALSE
  Status of entry (SNMP RowStatus): notInService
Threshold (milliseconds): 5000
Distribution Statistics:
  Number of statistic hours kept: 2
  Number of statistic distribution buckets kept: 1
  Statistic distribution interval (milliseconds): 20

## Analyzing IP Service Levels by Using the ICMP Echo Operation

Beginning in privileged EXEC mode, follow these steps to configure an ICMP echo operation on the source device:

## Before You Begin

This operation does not require the IP SLA responder to be enabled.

## SUMMARY STEPS

1. **configure terminal**
2. **ip sla operation-number**
3. **icmp-echo** {*destination-ip-address* | *destination-hostname*} [**source-ip** {*ip-address* | *hostname*} | **source-interface** *interface-id*]
4. **frequency** *seconds*
5. **exit**
6. **ip sla schedule** *operation-number* [**life** {**forever** | *seconds*}] [**start-time** {*hh:mm* [:*ss*] [*month day* | *day month*]} | **pending** | **now** | **after** *hh:mm:ss*] [**ageout** *seconds*] [**recurring**]
7. **end**

| <b>Step 6</b> | <b>ip sla schedule</b> <i>operation-number</i> [ <b>life</b> { <b>forever</b>   <i>seconds</i> }] [ <b>start-time</b> { <i>hh:mm[:ss]</i> [ <i>month day</i>   <i>day month</i> ]   <b>pending</b>   <b>now</b>   <b>after</b> <i>hh:mm:ss</i> }] [ <b>ageout</b> <i>seconds</i> ] [ <b>recurring</b> ]<br><br><b>Example:</b><br>Switch(config)# <b>ip sla schedule</b> 5 <b>start-time</b> <b>now</b> <b>life</b> <b>forever</b> | Configures the scheduling parameters for an individual IP SLA operation. <ul style="list-style-type: none"> <li>• <i>operation-number</i>—Enter the RTR entry number.</li> <li>• (Optional) <b>life</b>—Sets the operation to run indefinitely (<b>forever</b>) or for a specific number of <i>seconds</i>. The range is from 0 to 2147483647. The default is 3600 seconds (1 hour)</li> <li>• (Optional) <b>start-time</b>—Enter the time for the operation to begin collecting information:<br/><br/> To start at a specific time, enter the hour, minute, second (in 24-hour notation), and day of the month. If no month is entered, the default is the current month.<br/><br/> Enter <b>pending</b> to select no information collection until a start time is selected.<br/><br/> Enter <b>now</b> to start the operation immediately.<br/><br/> Enter <b>after</b> <i>hh:mm:ss</i> to indicate that the operation should start after the entered time has elapsed.</li> <li>• (Optional) <b>ageout</b> <i>seconds</i>—Enter the number of seconds to keep the operation in memory when it is not actively collecting information. The range is 0 to 2073600 seconds; the default is 0 seconds (never ages out).</li> <li>• (Optional) <b>recurring</b>—Sets the operation to automatically run every day.</li> </ul> |
| <b>Step 7</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b>                                                                                                                                                                                                                                                                                                                                                                    | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

### Configuring an ICMP Echo IP SLA Operation

This example shows how to configure an ICMP echo IP SLA operation:

```
Switch(config)# ip sla 12
Switch(config-ip-sla)# icmp-echo 172.29.139.134
```

```

Switch(config-ip-sla-echo)# frequency 30
Switch(config-ip-sla-echo)# exit
Switch(config)# ip sla schedule 5 start-time now life forever
Switch(config)# end
Switch# show ip sla configuration 22
IP SLAs, Infrastructure Engine-II.

Entry number: 12

## Monitoring IP SLA Operations

The following table describes the commands used to display IP SLA operation configurations and results:

**Table 74: Monitoring IP SLA Operations**

|                                                 |                                                                                                         |
|-------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| <b>show ip sla application</b>                  | Displays global information about Cisco IOS IP SLAs.                                                    |
| <b>show ip sla authentication</b>               | Displays IP SLA authentication information.                                                             |
| <b>show ip sla configuration</b> [entry-number] | Displays configuration values including all defaults for all IP SLA operations or a specific operation. |

|                                                                                                                                                       |                                                                                                                                                  |
|-------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>show ip sla enhanced-history</b> {collection-statistics   distribution statistics} [entry-number]                                                  | Displays enhanced history statistics for collected history buckets or distribution statistics for all IP SLA operations or a specific operation. |
| <b>show ip sla ethernet-monitor configuration</b> [entry-number]                                                                                      | Displays IP SLA automatic Ethernet configuration.                                                                                                |
| <b>show ip sla group schedule</b> [schedule-entry-number]                                                                                             | Displays IP SLA group scheduling configuration and details.                                                                                      |
| <b>show ip sla history</b> [entry-number   full   tabular]                                                                                            | Displays history collected for all IP SLA operations.                                                                                            |
| <b>show ip sla mpls-lsp-monitor</b> {collection-statistics   configuration   ldp operational-state   scan-queue   summary [entry-number]   neighbors} | Displays MPLS label switched path (LSP) Health Monitor operations.                                                                               |
| <b>show ip sla reaction-configuration</b> [entry-number]                                                                                              | Displays the configured proactive threshold monitoring settings for all IP SLA operations or a specific operation.                               |
| <b>show ip sla reaction-trigger</b> [entry-number]                                                                                                    | Displays the reaction trigger information for all IP SLA operations or a specific operation.                                                     |
| <b>show ip sla responder</b>                                                                                                                          | Displays information about the IP SLA responder.                                                                                                 |
| <b>show ip sla statistics</b> [entry-number   aggregated   details]                                                                                   | Displays current or aggregated operational status and statistics.                                                                                |

## Monitoring IP SLA Operation Examples

The following example shows all IP SLAs by application:

```
Switch# show ip sla application
      IP Service Level Agreements
Version: Round Trip Time MIB 2.2.0, Infrastructure Engine-III
Supported Operation Types:
      icmpEcho, path-echo, path-jitter, udpEcho, tcpConnect, http
      dns, udpJitter, dhcp, ftp, udpApp, wspApp
Supported Features:
      IPSLAs Event Publisher
IP SLAs low memory water mark: 33299323
Estimated system max number of entries: 24389
Estimated number of configurable operations: 24389
Number of Entries configured   : 0
Number of active Entries      : 0
```

```
Number of pending Entries      : 0
Number of inactive Entries    : 0
Time of last change in whole IP SLAs: *13:04:37.668 UTC Wed Dec 19 2012
```

The following example shows all IP SLA distribution statistics:

```
Switch# show ip sla enhanced-history distribution-statistics

Point by point Enhanced History
Entry = Entry Number
Int   = Aggregation Interval
BucI  = Bucket Index
StartT = Aggregation Start Time
Pth   = Path index
Hop   = Hop in path index
Comps = Operations completed
OvrTh = Operations completed over thresholds
SumCmp = Sum of RTT (milliseconds)
SumCmp2L = Sum of RTT squared low 32 bits (milliseconds)
SumCmp2H = Sum of RTT squared high 32 bits (milliseconds)
TMax   = RTT maximum (milliseconds)
TMin   = RTT minimum (milliseconds)

Entry Int BucI StartT      Pth Hop Comps OvrTh SumCmp      SumCmp2L  SumCmp2H  T
Max   TMin
```

### Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

### Prerequisites for SPAN and RSPAN

#### SPAN

- You can limit SPAN traffic to specific VLANs by using the **filter vlan** keyword. If a trunk port is being monitored, only traffic on the VLANs specified with this keyword is monitored. By default, all VLANs are monitored on a trunk port.

#### RSPAN

- We recommend that you configure an RSPAN VLAN before you configure an RSPAN source or a destination session.

## Restrictions for SPAN and RSPAN

### SPAN

- On each switch, you can configure a maximum of 8 source sessions and 58 RSPAN destination sessions. A source session is either a local SPAN session or an RSPAN source session.
- For SPAN sources, you can monitor traffic for a single port or VLAN or a series or range of ports or VLANs for each session. You cannot mix source ports and source VLANs within a single SPAN session.
- The destination port cannot be a source port; a source port cannot be a destination port.
- You cannot have two SPAN sessions using the same destination port.
- When you configure a switch port as a SPAN destination port, it is no longer a normal switch port; only monitored traffic passes through the SPAN destination port.
- Entering SPAN configuration commands does not remove previously configured SPAN parameters. You must enter the **no monitor session** {*session\_number* | **all** | **local** | **remote**} global configuration command to delete configured SPAN parameters.
- For local SPAN, outgoing packets through the SPAN destination port carry the original encapsulation headers—untagged or IEEE 802.1Q—if the **encapsulation replicate** keywords are specified. If the keywords are not specified, the packets are sent in native form.
- You can configure a disabled port to be a source or destination port, but the SPAN function does not start until the destination port and at least one source port or source VLAN are enabled.
- You cannot mix source VLANs and filter VLANs within a single SPAN session.
- Stacking is supported only on switches running the LAN Base image.

Traffic monitoring in a SPAN session has the following restrictions:

- Sources can be ports or VLANs, but you cannot mix source ports and source VLANs in the same session.
  - You can run both a local SPAN and an RSPAN source session in the same switch or switch stack. The switch or switch stack supports a total of 66 source and RSPAN destination sessions.
  - You can configure two separate SPAN or RSPAN source sessions with separate or overlapping sets of SPAN source ports and VLANs. Both switched and routed ports can be configured as SPAN sources and destinations.
- You can have multiple destination ports in a SPAN session, but no more than 66 destination ports per switch stack.
- SPAN sessions do not interfere with the normal operation of the switch. However, an oversubscribed SPAN destination, for example, a 10-Mb/s port monitoring a 100-Mb/s port, can result in dropped or lost packets.
- When SPAN or RSPAN is enabled, each packet being monitored is sent twice, once as normal traffic and once as a monitored packet. Monitoring a large number of ports or VLANs could potentially generate large amounts of network traffic.
- You can configure SPAN sessions on disabled ports; however, a SPAN session does not become active unless you enable the destination port and at least one source port or VLAN for that session.

- The switch does not support a combination of local SPAN and RSPAN in a single session.
  - An RSPAN source session cannot have a local destination port.
  - An RSPAN destination session cannot have a local source port.
  - An RSPAN destination session and an RSPAN source session that are using the same RSPAN VLAN cannot run on the same switch or switch stack.

## RSPAN

- RSPAN does not support BPDU packet monitoring or other Layer 2 switch protocols.
- The RSPAN VLAN is configured only on trunk ports and not on access ports. To avoid unwanted traffic in RSPAN VLANs, make sure that the VLAN remote-span feature is supported in all the participating switches.
- RSPAN VLANs are included as sources for port-based RSPAN sessions when source trunk ports have active RSPAN VLANs. RSPAN VLANs can also be sources in SPAN sessions. However, since the switch does not monitor spanned traffic, it does not support egress spanning of packets on any RSPAN VLAN identified as the destination of an RSPAN source session on the switch.
- If you enable VTP and VTP pruning, RSPAN traffic is pruned in the trunks to prevent the unwanted flooding of RSPAN traffic across the network for VLAN IDs that are lower than 1005.

## Flow-Based SPAN (FSPAN) and Flow-Based RSPAN (FRSPAN)

- More than one SPAN or RSPAN session can have ACLs attached. However, the size of the ACL should not exceed the size of the TCAM memory allocated to FSPAN.
- When no FSPAN ACLs are attached, FSPAN is disabled, and all traffic is copied to the SPAN destination ports.
- When you attach an empty FSPAN ACL to a SPAN session, it does not filter packets, and all traffic is monitored.
- FSPAN ACLs cannot be applied to per-port-per-VLAN sessions. You can configure per-port-per-VLAN sessions by first configuring a port-based session and then configuring specific VLANs to the session. For example:

```
Switch(config)# monitor session session_number source interface interface-id
Switch(config)# monitor session session_number filter vlan vlan-id
Switch(config)# monitor session session_number filter ip access-group {access-list-number |
name}
```

---

**Note** Both the **filter vlan** and **filter ip access-group** commands cannot be configured at the same time. Configuring one results in rejection of the other.

---

- EtherChannels are not supported in an FSPAN session.
- FSPAN ACLs with TCP flags or the **log** keyword are not supported.

- If you configure an IPv6 FSPAN ACL when the switch is running the advanced IP Services feature set but later run a different feature set, after rebooting the switch, the switch might lose the IPv6 FSPAN ACL configuration.
- IPv6 FSPAN ACLs are supported only on IPv6-enabled SDM templates. If you configure an IPv6 FSPAN ACL when running an IPv6 enabled SDM template, but later configure a non-IPv6 SDM template and reboot the switch, you lose the IPv6 FSPAN ACL configuration.

## Information About SPAN and RSPAN

### SPAN and RSPAN

You can analyze network traffic passing through ports or VLANs by using SPAN or RSPAN to send a copy of the traffic to another port on the switch or on another switch that has been connected to a network analyzer or other monitoring or security device. SPAN copies (or mirrors) traffic received or sent (or both) on source ports or source VLANs to a destination port for analysis. SPAN does not affect the switching of network traffic on the source ports or VLANs. You must dedicate the destination port for SPAN use. Except for traffic that is required for the SPAN or RSPAN session, destination ports do not receive or forward traffic.

Only traffic that enters or leaves source ports or traffic that enters or leaves source VLANs can be monitored by using SPAN; traffic routed to a source VLAN cannot be monitored. For example, if incoming traffic is being monitored, traffic that gets routed from another VLAN to the source VLAN cannot be monitored; however, traffic that is received on the source VLAN and routed to another VLAN can be monitored.

You can use the SPAN or RSPAN destination port to inject traffic from a network security device. For example, if you connect a Cisco Intrusion Detection System (IDS) sensor appliance to a destination port, the IDS device can send TCP reset packets to close down the TCP session of a suspected attacker.

### Local SPAN

Local SPAN supports a SPAN session entirely within one switch; all source ports or source VLANs and destination ports are in the same switch or switch stack. Local SPAN copies traffic from one or more source ports in any VLAN or from one or more VLANs to a destination port for analysis.

All traffic on port 5 (the source port) is mirrored to port 10 (the destination port). A network analyzer on port 10 receives all network traffic from port 5 without being physically attached to port 5.

**Figure 57: Example of Local SPAN Configuration on a Single Device**

This is an example of a local SPAN in a switch stack, where the source and destination ports reside on different stack members.

**Figure 58: Example of Local SPAN Configuration on a Device Stack**

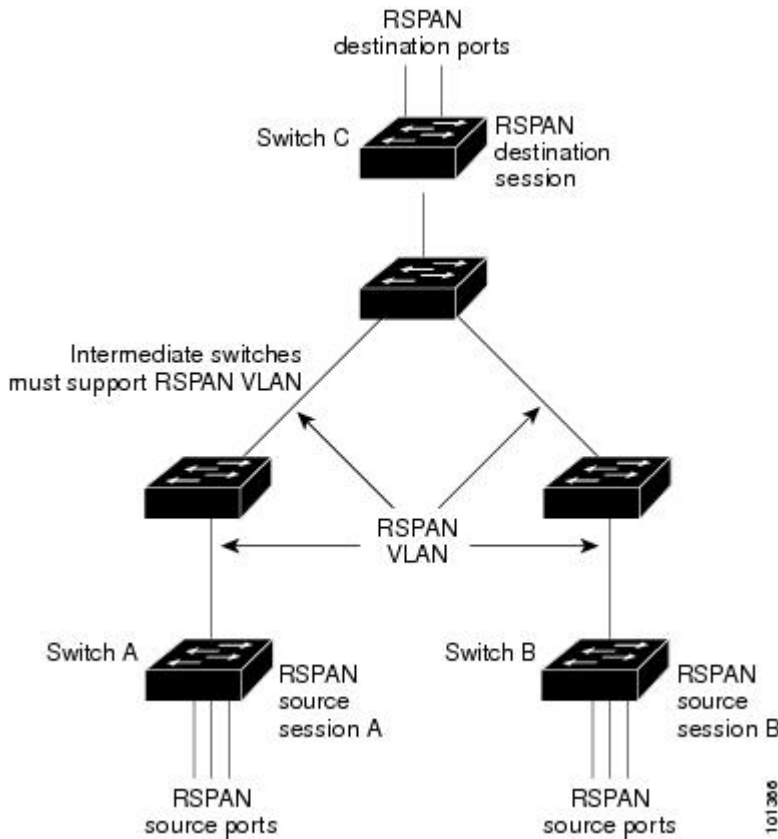

**Remote SPAN**

RSPAN supports source ports, source VLANs, and destination ports on different switches (or different switch stacks), enabling remote monitoring of multiple switches across your network.

The figure below shows source ports on Switch A and Switch B. The traffic for each RSPAN session is carried over a user-specified RSPAN VLAN that is dedicated for that RSPAN session in all participating switches. The RSPAN traffic from the source ports or VLANs is copied into the RSPAN VLAN and forwarded over trunk ports carrying the RSPAN VLAN to a destination session monitoring the RSPAN VLAN. Each RSPAN source switch must have either ports or VLANs as RSPAN sources. The destination is always a physical port, as shown on Switch C in the figure.

**Figure 59: Example of RSPAN Configuration**

## SPAN Sessions

SPAN sessions (local or remote) allow you to monitor traffic on one or more ports, or one or more VLANs, and send the monitored traffic to one or more destination ports.

A local SPAN session is an association of a destination port with source ports or source VLANs, all on a single network device. Local SPAN does not have separate source and destination sessions. Local SPAN sessions gather a set of ingress and egress packets specified by the user and form them into a stream of SPAN data, which is directed to the destination port.

RSPAN consists of at least one RSPAN source session, an RSPAN VLAN, and at least one RSPAN destination session. You separately configure RSPAN source sessions and RSPAN destination sessions on different network devices. To configure an RSPAN source session on a device, you associate a set of source ports or source VLANs with an RSPAN VLAN. The output of this session is the stream of SPAN packets that are sent to the RSPAN VLAN. To configure an RSPAN destination session on another device, you associate the destination port with the RSPAN VLAN. The destination session collects all RSPAN VLAN traffic and sends it out the RSPAN destination port.

An RSPAN source session is very similar to a local SPAN session, except for where the packet stream is directed. In an RSPAN source session, SPAN packets are relabeled with the RSPAN VLAN ID and directed over normal trunk ports to the destination switch.

An RSPAN destination session takes all packets received on the RSPAN VLAN, strips off the VLAN tagging, and presents them on the destination port. The session presents a copy of all RSPAN VLAN packets (except Layer 2 control packets) to the user for analysis.

A single RSPAN session with multiple source and destination ports can be in the same session but more than one source session with the source being the same remote vlan is not allowed.

Traffic monitoring in a SPAN session has these restrictions:

- Sources can be ports or VLANs, but you cannot mix source ports and source VLANs in the same session.
- The switch supports up to two local SPAN or RSPAN source sessions.
  - You can run both a local SPAN and an RSPAN source session in the same switch or switch stack. The switch or switch stack supports a total of 64 source and RSPAN destination sessions.
  - You can configure two separate SPAN or RSPAN source sessions with separate or overlapping sets of SPAN source ports and VLANs. Both switched and routed ports can be configured as SPAN sources and destinations.
- You can have multiple destination ports in a SPAN session, but no more than 64 destination ports per switch stack.
- SPAN sessions do not interfere with the normal operation of the switch. However, an oversubscribed SPAN destination, for example, a 10-Mb/s port monitoring a 100-Mb/s port, can result in dropped or lost packets.
- When SPAN or RSPAN is enabled, each packet being monitored is sent twice, once as normal traffic and once as a monitored packet. Therefore monitoring a large number of ports or VLANs could potentially generate large amounts of network traffic.
- You can configure SPAN sessions on disabled ports; however, a SPAN session does not become active unless you enable the destination port and at least one source port or VLAN for that session.
- The switch does not support a combination of local SPAN and RSPAN in a single session.
  - An RSPAN source session cannot have a local destination port.

- An RSPAN destination session cannot have a local source port.
- An RSPAN destination session and an RSPAN source session that are using the same RSPAN VLAN cannot run on the same switch or switch stack.

### Monitored Traffic

SPAN sessions can monitor these traffic types:

- Receive (Rx) SPAN—Receive (or ingress) SPAN monitors as much as possible all of the packets received by the source interface or VLAN before any modification or processing is performed by the switch. A copy of each packet received by the source is sent to the destination port for that SPAN session.

Packets that are modified because of routing or Quality of Service (QoS)—for example, modified Differentiated Services Code Point (DSCP)—are copied before modification.

Features that can cause a packet to be dropped during receive processing have no effect on ingress SPAN; the destination port receives a copy of the packet even if the actual incoming packet is dropped. These features include IP standard and extended input Access Control Lists (ACLs), ingress QoS policing, VLAN ACLs, and egress QoS policing.

- Transmit (Tx) SPAN—Transmit (or egress) SPAN monitors as much as possible all of the packets sent by the source interface after all modification and processing is performed by the switch. A copy of each packet sent by the source is sent to the destination port for that SPAN session. The copy is provided after the packet is modified.

Packets that are modified because of routing (for example, with modified time-to-live (TTL), MAC address, or QoS values) are duplicated (with the modifications) at the destination port.

Features that can cause a packet to be dropped during transmit processing also affect the duplicated copy for SPAN. These features include IP standard and extended output ACLs and egress QoS policing.

- Both—In a SPAN session, you can also monitor a port or VLAN for both received and sent packets. This is the default.

The default configuration for local SPAN session ports is to send all packets untagged. SPAN also does not normally monitor bridge protocol data unit (BPDU) packets and Layer 2 protocols, such as Cisco Discovery Protocol (CDP), VLAN Trunk Protocol (VTP), Dynamic Trunking Protocol (DTP), Spanning Tree Protocol (STP), and Port Aggregation Protocol (PAgP). However, when you enter the **encapsulation replicate** keywords when configuring a destination port, these changes occur:

- Packets are sent on the destination port with the same encapsulation (untagged or IEEE 802.1Q) that they had on the source port.
- Packets of all types, including BPDU and Layer 2 protocol packets, are monitored.

Therefore, a local SPAN session with encapsulation replicate enabled can have a mixture of untagged and IEEE 802.1Q tagged packets appear on the destination port.

Switch congestion can cause packets to be dropped at ingress source ports, egress source ports, or SPAN destination ports. In general, these characteristics are independent of one another. For example:

- A packet might be forwarded normally but dropped from monitoring due to an oversubscribed SPAN destination port.
- An ingress packet might be dropped from normal forwarding, but still appear on the SPAN destination port.

- An egress packet dropped because of switch congestion is also dropped from egress SPAN.

In some SPAN configurations, multiple copies of the same source packet are sent to the SPAN destination port. For example, a bidirectional (both Rx and Tx) SPAN session is configured for the Rx monitor on port A and Tx monitor on port B. If a packet enters the switch through port A and is switched to port B, both incoming and outgoing packets are sent to the destination port. Both packets are the same unless a Layer 3 rewrite occurs, in which case the packets are different because of the packet modification.

### Source Ports

A source port (also called a monitored port) is a switched or routed port that you monitor for network traffic analysis. In a local SPAN session or RSPAN source session, you can monitor source ports or VLANs for traffic in one or both directions. The switch supports any number of source ports (up to the maximum number of available ports on the switch) and any number of source VLANs (up to the maximum number of VLANs supported). However, the switch supports a maximum of (local or RSPAN) with source ports or VLANs. You cannot mix ports and VLANs in a single session.

A source port has these characteristics:

- It can be monitored in multiple SPAN sessions.
- Each source port can be configured with a direction (ingress, egress, or both) to monitor.
- It can be any port type (for example, EtherChannel, Gigabit Ethernet, and so forth).
- For EtherChannel sources, you can monitor traffic for the entire EtherChannel or individually on a physical port as it participates in the port channel.
- It can be an access port, trunk port, routed port, or voice VLAN port.
- It cannot be a destination port.
- Source ports can be in the same or different VLANs.
- You can monitor multiple source ports in a single session.

### Source VLANs

VLAN-based SPAN (VSPAN) is the monitoring of the network traffic in one or more VLANs. The SPAN or RSPAN source interface in VSPAN is a VLAN ID, and traffic is monitored on all the ports for that VLAN.

VSPAN has these characteristics:

- All active ports in the source VLAN are included as source ports and can be monitored in either or both directions.
- On a given port, only traffic on the monitored VLAN is sent to the destination port.
- If a destination port belongs to a source VLAN, it is excluded from the source list and is not monitored.
- If ports are added to or removed from the source VLANs, the traffic on the source VLAN received by those ports is added to or removed from the sources being monitored.
- You cannot use filter VLANs in the same session with VLAN sources.
- You can monitor only Ethernet VLANs.

### VLAN Filtering

When you monitor a trunk port as a source port, by default, all VLANs active on the trunk are monitored. You can limit SPAN traffic monitoring on trunk source ports to specific VLANs by using VLAN filtering.

- VLAN filtering applies only to trunk ports or to voice VLAN ports.
- VLAN filtering applies only to port-based sessions and is not allowed in sessions with VLAN sources.
- When a VLAN filter list is specified, only those VLANs in the list are monitored on trunk ports or on voice VLAN access ports.
- SPAN traffic coming from other port types is not affected by VLAN filtering; that is, all VLANs are allowed on other ports.
- VLAN filtering affects only traffic forwarded to the destination SPAN port and does not affect the switching of normal traffic.

### Destination Port

Each local SPAN session or RSPAN destination session must have a destination port (also called a monitoring port) that receives a copy of traffic from the source ports or VLANs and sends the SPAN packets to the user, usually a network analyzer.

A destination port has these characteristics:

- For a local SPAN session, the destination port must reside on the same switch or switch stack as the source port. For an RSPAN session, it is located on the switch containing the RSPAN destination session. There is no destination port on a switch or switch stack running only an RSPAN source session.
- When a port is configured as a SPAN destination port, the configuration overwrites the original port configuration. When the SPAN destination configuration is removed, the port reverts to its previous configuration. If a configuration change is made to the port while it is acting as a SPAN destination port, the change does not take effect until the SPAN destination configuration had been removed.

---

**Note** When QoS is configured on the SPAN destination port, QoS takes effect immediately.

---

- If the port was in an EtherChannel group, it is removed from the group while it is a destination port. If it was a routed port, it is no longer a routed port.
- It can be any Ethernet physical port.
- It cannot be a secure port.
- It cannot be a source port.
- It can be an EtherChannel group.
- It cannot be a VLAN.
- It can participate in only one SPAN session at a time (a destination port in one SPAN session cannot be a destination port for a second SPAN session).
- When it is active, incoming traffic is disabled. The port does not transmit any traffic except that required for the SPAN session. Incoming traffic is never learned or forwarded on a destination port.
- If ingress traffic forwarding is enabled for a network security device, the destination port forwards traffic at Layer 2.
- It does not participate in any of the Layer 2 protocols (STP, VTP, CDP, DTP, PagP).
- A destination port that belongs to a source VLAN of any SPAN session is excluded from the source list and is not monitored.

- The maximum number of destination ports in a switch or switch stack is 64.

Local SPAN and RSPAN destination ports function differently with VLAN tagging and encapsulation:

- For local SPAN, if the **encapsulation replicate** keywords are specified for the destination port, these packets appear with the original encapsulation (untagged, ISL, or IEEE 802.1Q). If these keywords are not specified, packets appear in the untagged format. Therefore, the output of a local SPAN session with **encapsulation replicate** enabled can contain a mixture of untagged, ISL, or IEEE 802.1Q-tagged packets.
- For RSPAN, the original VLAN ID is lost because it is overwritten by the RSPAN VLAN identification. Therefore, all packets appear on the destination port as untagged.

### RSPAN VLAN

The RSPAN VLAN carries SPAN traffic between RSPAN source and destination sessions. RSPAN VLAN has these special characteristics:

- All traffic in the RSPAN VLAN is always flooded.
- No MAC address learning occurs on the RSPAN VLAN.
- RSPAN VLAN traffic only flows on trunk ports.
- RSPAN VLANs must be configured in VLAN configuration mode by using the **remote-span** VLAN configuration mode command.
- STP can run on RSPAN VLAN trunks but not on SPAN destination ports.
- An RSPAN VLAN cannot be a private-VLAN primary or secondary VLAN.

For VLANs 1 to 1005 that are visible to VLAN Trunking Protocol (VTP), the VLAN ID and its associated RSPAN characteristic are propagated by VTP. If you assign an RSPAN VLAN ID in the extended VLAN range (1006 to 4094), you must manually configure all intermediate switches.

It is normal to have multiple RSPAN VLANs in a network at the same time with each RSPAN VLAN defining a network-wide RSPAN session. That is, multiple RSPAN source sessions anywhere in the network can contribute packets to the RSPAN session. It is also possible to have multiple RSPAN destination sessions throughout the network, monitoring the same RSPAN VLAN and presenting traffic to the user. The RSPAN VLAN ID separates the sessions.

### SPAN and RSPAN Interaction with Other Features

SPAN interacts with these features:

- Routing—SPAN does not monitor routed traffic. VSPAN only monitors traffic that enters or exits the switch, not traffic that is routed between VLANs. For example, if a VLAN is being Rx-monitored and the switch routes traffic from another VLAN to the monitored VLAN, that traffic is not monitored and not received on the SPAN destination port.
- STP—A destination port does not participate in STP while its SPAN or RSPAN session is active. The destination port can participate in STP after the SPAN or RSPAN session is disabled. On a source port, SPAN does not affect the STP status. STP can be active on trunk ports carrying an RSPAN VLAN.
- CDP—A SPAN destination port does not participate in CDP while the SPAN session is active. After the SPAN session is disabled, the port again participates in CDP.
- VTP—You can use VTP to prune an RSPAN VLAN between switches.

- **VLAN and trunking**—You can modify VLAN membership or trunk settings for source or destination ports at any time. However, changes in VLAN membership or trunk settings for a destination port do not take effect until you remove the SPAN destination configuration. Changes in VLAN membership or trunk settings for a source port immediately take effect, and the respective SPAN sessions automatically adjust accordingly.
- **EtherChannel**—You can configure an EtherChannel group as a source port or a SPAN destination port. When a group is configured as a SPAN source, the entire group is monitored.

If a physical port is added to a monitored EtherChannel group, the new port is added to the SPAN source port list. If a port is removed from a monitored EtherChannel group, it is automatically removed from the source port list.

A physical port that belongs to an EtherChannel group can be configured as a SPAN source port and still be a part of the EtherChannel. In this case, data from the physical port is monitored as it participates in the EtherChannel. However, if a physical port that belongs to an EtherChannel group is configured as a SPAN destination, it is removed from the group. After the port is removed from the SPAN session, it rejoins the EtherChannel group. Ports removed from an EtherChannel group remain members of the group, but they are in the inactive or suspended state.

If a physical port that belongs to an EtherChannel group is a destination port and the EtherChannel group is a source, the port is removed from the EtherChannel group and from the list of monitored ports.

- **Multicast traffic** can be monitored. For egress and ingress port monitoring, only a single unedited packet is sent to the SPAN destination port. It does not reflect the number of times the multicast packet is sent.
- A private-VLAN port cannot be a SPAN destination port.
- A secure port cannot be a SPAN destination port.

For SPAN sessions, do not enable port security on ports with monitored egress when ingress forwarding is enabled on the destination port. For RSPAN source sessions, do not enable port security on any ports with monitored egress.

- An IEEE 802.1x port can be a SPAN source port. You can enable IEEE 802.1x on a port that is a SPAN destination port; however, IEEE 802.1x is disabled until the port is removed as a SPAN destination.

For SPAN sessions, do not enable IEEE 802.1x on ports with monitored egress when ingress forwarding is enabled on the destination port. For RSPAN source sessions, do not enable IEEE 802.1x on any ports that are egress monitored.

## SPAN and RSPAN and Device Stacks

Because the stack of switches represents one logical switch, local SPAN source ports and destination ports can be in different switches in the stack. Therefore, the addition or deletion of switches in the stack can affect a local SPAN session, as well as an RSPAN source or destination session. An active session can become inactive when a switch is removed from the stack or an inactive session can become active when a switch is added to the stack.

## Flow-Based SPAN

You can control the type of network traffic to be monitored in SPAN or RSPAN sessions by using flow-based SPAN (FSPAN) or flow-based RSPAN (FRSPAN), which apply access control lists (ACLs) to the monitored traffic on the source ports. The FSPAN ACLs can be configured to filter IPv4, IPv6, and non-IP monitored traffic.

You apply an ACL to a SPAN session through the interface. It is applied to all the traffic that is monitored on all interfaces in the SPAN session. The packets that are permitted by this ACL are copied to the SPAN destination port. No other packets are copied to the SPAN destination port.

The original traffic continues to be forwarded, and any port, VLAN, and router ACLs attached are applied. The FSPAN ACL does not have any effect on the forwarding decisions. Similarly, the port, VLAN, and router ACLs do not have any effect on the traffic monitoring. If a security input ACL denies a packet and it is not forwarded, the packet is still copied to the SPAN destination ports if the FSPAN ACL permits it. But if the security output ACL denies a packet and it is not sent, it is not copied to the SPAN destination ports. However, if the security output ACL permits the packet to go out, it is only copied to the SPAN destination ports if the FSPAN ACL permits it. This is also true for an RSPAN session.

You can attach three types of FSPAN ACLs to the SPAN session:

- IPv4 FSPAN ACL— Filters only IPv4 packets.
- IPv6 FSPAN ACL— Filters only IPv6 packets.
- MAC FSPAN ACL— Filters only non-IP packets.

The security ACLs have higher priority than the FSPAN ACLs on a switch. If FSPAN ACLs are applied, and you later add more security ACLs that cannot fit in the hardware memory, the FSPAN ACLs that you applied are removed from memory to allow space for the security ACLs. A system message notifies you of this action, which is called unloading. When there is again space for the FSPAN ACLs to reside in memory, they are added to the hardware memory on the switch. A system message notifies you of this action, which is called reloading. The IPv4, IPv6 and MAC FSPAN ACLs can be unloaded or reloaded independently.

If a VLAN-based FSPAN session configured on a stack cannot fit in the hardware memory on one or more switches, it is treated as unloaded on those switches, and traffic meant for the FSPAN ACL and sourcing on that switch is not copied to the SPAN destination ports. The FSPAN ACL continues to be correctly applied, and traffic is copied to the SPAN destination ports on the switches where the FSPAN ACL fits in the hardware memory.

When an empty FSPAN ACL is attached, some hardware functions copy all traffic to the SPAN destination ports for that ACL. If sufficient hardware resources are not available, even an empty FSPAN ACL can be unloaded.

IPv4 and MAC FSPAN ACLs are supported on all feature sets. IPv6 FSPAN ACLs are supported only in the advanced IP Services feature set.

## Default SPAN and RSPAN Configuration

**Table 75: Default SPAN and RSPAN Configuration**

| Feature                               | Default Setting                                 |
|---------------------------------------|-------------------------------------------------|
| SPAN state (SPAN and RSPAN)           | Disabled.                                       |
| Source port traffic to monitor        | Both received and sent traffic ( <b>both</b> ). |
| Encapsulation type (destination port) | Native form (untagged packets).                 |
| Ingress forwarding (destination port) | Disabled.                                       |

| Feature        | Default Setting                                                      |
|----------------|----------------------------------------------------------------------|
| VLAN filtering | On a trunk interface used as a source port, all VLANs are monitored. |
| RSPAN VLANs    | None configured.                                                     |

## Configuration Guidelines

### SPAN Configuration Guidelines

- To remove a source or destination port or VLAN from the SPAN session, use the **no monitor session session\_number source {interface interface-id | vlan vlan-id}** global configuration command or the **no monitor session session\_number destination interface interface-id** global configuration command. For destination interfaces, the **encapsulation** options are ignored with the **no** form of the command.
- To monitor all VLANs on the trunk port, use the **no monitor session session\_number filter** global configuration command.

### RSPAN Configuration Guidelines

- All the SPAN configuration guidelines apply to RSPAN.
- As RSPAN VLANs have special properties, you should reserve a few VLANs across your network for use as RSPAN VLANs; do not assign access ports to these VLANs.
- You can apply an output ACL to RSPAN traffic to selectively filter or monitor specific packets. Specify these ACLs on the RSPAN VLAN in the RSPAN source switches.
- For RSPAN configuration, you can distribute the source ports and the destination ports across multiple switches in your network.
- Access ports (including voice VLAN ports) on the RSPAN VLAN are put in the inactive state.
- You can configure any VLAN as an RSPAN VLAN as long as these conditions are met:
  - The same RSPAN VLAN is used for an RSPAN session in all the switches.
  - All participating switches support RSPAN.

### FSPAN and FRSPAN Configuration Guidelines

- When at least one FSPAN ACL is attached, FSPAN is enabled.
- When you attach at least one FSPAN ACL that is not empty to a SPAN session, and you have not attached one or more of the other FSPAN ACLs (for instance, you have attached an IPv4 ACL that is not empty, and have not attached IPv6 and MAC ACLs), FSPAN blocks the traffic that would have been filtered by the unattached ACLs. Therefore, this traffic is not monitored.

# How to Configure SPAN and RSPAN

## Creating a Local SPAN Session

Beginning in privileged EXEC mode, follow these steps to create a SPAN session and specify the source (monitored) ports or VLANs and the destination (monitoring) ports.

### SUMMARY STEPS

1. **configure terminal**
2. **no monitor session** *{session\_number | all | local | remote}*
3. **monitor session** *session\_number* **source** *{interface interface-id | vlan vlan-id}* [, | -] [**both** | **rx** | **tx**]
4. **monitor session** *session\_number* **destination** *{interface interface-id* [, | -] [**encapsulation replicate**]
5. **end**

### DETAILED STEPS

|               | Command or Action                                                                                                                                                                                                                                                  | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                                                                                                                                                                              | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Step 2</b> | <b>no monitor session</b> <i>{session_number   all   local   remote}</i><br><br><b>Example:</b><br>Switch(config)# <b>no monitor session all</b>                                                                                                                   | Removes any existing SPAN configuration for the session. <ul style="list-style-type: none"> <li>• For <i>session_number</i>, the range is 1 to 66.</li> <li>• <b>all</b>—Removes all SPAN sessions.</li> <li>• <b>local</b>—Removes all local sessions.</li> <li>• <b>remote</b>—Removes all remote SPAN sessions.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Step 3</b> | <b>monitor session</b> <i>session_number</i> <b>source</b> <i>{interface interface-id   vlan vlan-id}</i> [,   -] [ <b>both</b>   <b>rx</b>   <b>tx</b> ]<br><br><b>Example:</b><br>Switch(config)# <b>monitor session 1 source interface gigabitethernet1/0/1</b> | Specifies the SPAN session and the source port (monitored port). <ul style="list-style-type: none"> <li>• For <i>session_number</i>, the range is 1 to 66.</li> <li>• For <i>interface-id</i>, specify the source port to monitor. Valid interfaces include physical interfaces and port-channel logical interfaces (<b>port-channel port-channel-number</b>). Valid port-channel numbers are 1 to 48.</li> <li>• For <i>vlan-id</i>, specify the source VLAN to monitor. The range is 1 to 4094 (excluding the RSPAN VLAN).</li> </ul> <p><b>Note</b> A single session can include multiple sources (ports or VLANs) defined in a series of commands, but you cannot combine source ports and source VLANs in one session.</p> |

|               | Command or Action                                                                                                                                                                                                                                        | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               |                                                                                                                                                                                                                                                          | <ul style="list-style-type: none"> <li>• (Optional) [, -] Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen.</li> <li>• (Optional) <b>both</b>   <b>rx</b>   <b>tx</b>—Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the source interface sends both sent and received traffic. <ul style="list-style-type: none"> <li>◦ <b>both</b>—Monitors both received and sent traffic.</li> <li>◦ <b>rx</b>—Monitors received traffic.</li> <li>◦ <b>tx</b>—Monitors sent traffic.</li> </ul> </li> </ul> <p><b>Note</b> You can use the <b>monitor session session_number source</b> command multiple times to configure multiple source ports.</p>                                                                                                                                                                                                                                                                              |
| <b>Step 4</b> | <p><b>monitor session session_number destination {interface interface-id [, -] [encapsulation replicate]}</b></p> <p><b>Example:</b></p> <pre>Switch(config)# monitor session 1 destination interface gigabitethernet1/0/2 encapsulation replicate</pre> | <p>Specifies the SPAN session and the destination port (monitoring port).</p> <p><b>Note</b> For local SPAN, you must use the same session number for the source and destination interfaces.</p> <ul style="list-style-type: none"> <li>• For <i>session_number</i>, specify the session number entered in step 3.</li> <li>• For <i>interface-id</i>, specify the destination port. The destination interface must be a physical port; it cannot be an EtherChannel, and it cannot be a VLAN.</li> <li>• (Optional) [, -] Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen.</li> </ul> <p>(Optional) <b>encapsulation replicate</b> specifies that the destination interface replicates the source interface encapsulation method. If not selected, the default is to send packets in native form (untagged).</p> <p><b>Note</b> You can use <b>monitor session session_number destination</b> command multiple times to configure multiple destination ports.</p> |
| <b>Step 5</b> | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Switch(config)# end</pre>                                                                                                                                                                                  | <p>Returns to privileged EXEC mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Creating a Local SPAN Session and Configuring Incoming Traffic

Beginning in privileged EXEC mode, follow these steps to create a SPAN session, to specify the source ports or VLANs and the destination ports, and to enable incoming traffic on the destination port for a network security device (such as a Cisco IDS Sensor Appliance).

## SUMMARY STEPS

1. **configure terminal**
2. **no monitor session** *{session\_number | all | local | remote}*
3. **monitor session** *session\_number* **source** *{interface interface-id | vlan vlan-id}* [, | -] [**both** | **rx** | **tx**]

## Specifying VLANs to Filter

Beginning in privileged EXEC mode, follow these steps to limit SPAN source traffic to specific VLANs.

### SUMMARY STEPS

1. **configure terminal**
2. **no monitor session** {*session\_number* | **all** | **local** | **remote**}
3. **monitor session** *session\_number* **source interface** *interface-id*
4. **monitor session** *session\_number* **filter vlan** *vlan-id* [, | -]
5. **monitor session** *session\_number* **destination** {**interface** *interface-id* [, | -] [**encapsulation replicate**]}
6. **end**

### DETAILED STEPS

|               | Command or Action                                                                               | Purpose                                                  |
|---------------|-------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>           | Enters the global configuration mode.                    |
| <b>Step 2</b> | <b>no monitor session</b> { <i>session_number</i>   <b>all</b>   <b>local</b>   <b>remote</b> } | Removes any existing SPAN configuration for the session. |

|               | Command or Action                                                                                                                                                                                                                                                   | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

Enter a space before and after the comma; enter a space before and after the hyphen.</li> </ul>                                                                                                                                                                                                                                                                                                                            |
| <b>Step 5</b> | <p><b>monitor session</b> <i>session_number</i> <b>destination</b> {<b>interface</b> <i>interface-id</i> [, -] [<b>encapsulation replicate</b>]}</p> <p><b>Example:</b></p> <pre>Switch(config)# monitor session 2 destination interface gigabitethernet1/0/1</pre> | <p>Specifies the SPAN session and the destination port (monitoring port).</p> <ul style="list-style-type: none"> <li>• For <i>session_number</i>, specify the session number entered in Step 3.</li> <li>• For <i>interface-id</i>, specify the destination port. The destination interface must be a physical port; it cannot be an EtherChannel, and it cannot be a VLAN.</li> <li>• (Optional) [, -] Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen.</li> <li>• (Optional) <b>encapsulation replicate</b> specifies that the destination interface replicates the source interface encapsulation method. If not selected, the default is to send packets in native form (untagged).</li> </ul> |
| <b>Step 6</b> | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Switch(config)# end</pre>                                                                                                                                                                                             | <p>Returns to privileged EXEC mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Configuring a VLAN as an RSPAN VLAN

Beginning in privileged EXEC mode, follow these steps to create a new VLAN, then configure it to be the RSPAN VLAN for the RSPAN session.

### SUMMARY STEPS

1. **configure terminal**
2. **vlan *vlan-id***
3. **remote-span**
4. **end**

### DETAILED STEPS

|               | Command or Action                                                                     | Purpose                                                                                                                                                                                                                                                                                      |
|---------------|---------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b> | Enters the global configuration mode.                                                                                                                                                                                                                                                        |
| <b>Step 2</b> | <b>vlan <i>vlan-id</i></b><br><br><b>Example:</b><br>Switch(config)# <b>vlan 100</b>  | Enters a VLAN ID to create a VLAN, or enters the VLAN ID of an existing VLAN, and enters VLAN configuration mode. The range is 2 to 1001 and 1006 to 4094.<br><br>The RSPAN VLAN cannot be VLAN 1 (the default VLAN) or VLAN IDs 1002 through 1005 (reserved for Token Ring and FDDI VLANs). |
| <b>Step 3</b> | <b>remote-span</b><br><br><b>Example:</b><br>Switch(config-vlan)# <b>remote-span</b>  | Configures the VLAN as an RSPAN VLAN.                                                                                                                                                                                                                                                        |
| <b>Step 4</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config-vlan)# <b>end</b>                  | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                             |

### What to Do Next

You must create the RSPAN VLAN in all switches that will participate in RSPAN. If the RSPAN VLAN-ID is in the normal range (lower than 1005) and VTP is enabled in the network, you can create the RSPAN VLAN in one switch, and VTP propagates it to the other switches in the VTP domain. For extended-range VLANs (greater than 1005), you must configure RSPAN VLAN on both source and destination switches and any intermediate switches.

Use VTP pruning to get an efficient flow of RSPAN traffic, or manually delete the RSPAN VLAN from all trunks that do not need to carry the RSPAN traffic.

To remove the remote SPAN characteristic from a VLAN and convert it back to a normal VLAN, use the **no remote-span** VLAN configuration command.

To remove a source port or VLAN from the SPAN session, use the **no monitor session** *session\_number* **source** {**interface** *interface-id* | **vlan** *vlan-id*} global configuration command. To remove the RSPAN VLAN from the session, use the **no monitor session** *session\_number* **destination remote vlan** *vlan-id*.

## Creating an RSPAN Source Session

Beginning in privileged EXEC mode, follow these steps to create and start an RSPAN source session and to specify the monitored source and the destination RSPAN VLAN.

### SUMMARY STEPS

1. **configure terminal**
2. **no monitor session** {*session\_number* | **all** | **local** | **remote**}
3. **monitor session** *session\_number* **source** {**interface** *interface-id* | **vlan** *vlan-id*} [, | -] [**both** | **rx** | **tx**]
4. **monitor session** *session\_number* **destination remote vlan** *vlan-id*
5. **end**

## Specifying VLANs to Filter

Beginning in privileged EXEC mode, follow these steps to configure the RSPAN source session to limit RSPAN source traffic to specific VLANs.

## SUMMARY STEPS

1. **configure terminal**
2. **no monitor session** {*session\_number* | **all** | **local** | **remote**}
3. **monitor session** *session\_number* **source interface** *interface-id*
4. **monitor session** *session\_number* **filter vlan** *vlan-id* [, | -]
5. **monitor session** *session\_number* **destination remote vlan** *vlan-id*
6. **end**

## DETAILED STEPS

|               | Command or Action                                                                                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|               | <p><b>Example:</b></p> <pre>Switch(config)# monitor session 2 destination remote vlan 902</pre> | <ul style="list-style-type: none"> <li>For <i>session_number</i>, enter the session number specified in Step 3.</li> <li>For <i>vlan-id</i>, specify the RSPAN VLAN to carry the monitored traffic to the destination port.</li> </ul> |
| <b>Step 6</b> | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Switch(config)# end</pre>                         | Returns to privileged EXEC mode.                                                                                                                                                                                                       |

## Creating an RSPAN Destination Session

You configure an RSPAN destination session on a different switch or switch stack; that is, not the switch or switch stack on which the source session was configured.

Beginning in privileged EXEC mode, follow these steps to define the RSPAN VLAN on that switch, to create an RSPAN destination session, and to specify the source RSPAN VLAN and the destination port.

### SUMMARY STEPS

1. **configure terminal**
2. **vlan** *vlan-id*
3. **remote-span**
4. **exit**
5. **no monitor session** {*session\_number* | **all** | **local** | **remote**}
6. **monitor session** *session\_number* **source remote vlan** *vlan-id*
7. **monitor session** *session\_number* **destination interface** *interface-id*
8. **end**

### DETAILED STEPS

|               | Command or Action                                                                             | Purpose                               |
|---------------|-----------------------------------------------------------------------------------------------|---------------------------------------|
| <b>Step 1</b> | <p><b>configure terminal</b></p> <p><b>Example:</b></p> <pre>Switch# configure terminal</pre> | Enters the global configuration mode. |

|               | Command or Action                                                                                                                                                                                           | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 2</b> | <b>vlan</b> <i>vlan-id</i><br><br><b>Example:</b><br>Switch(config)# <b>vlan 901</b>                                                                                                                        | Specifies the VLAN ID of the RSPAN VLAN created from the source switch, and enters VLAN configuration mode.<br><br>If both switches are participating in VTP and the RSPAN VLAN ID is from 2 to 1005, Steps 2 through 4 are not required because the RSPAN VLAN ID is propagated through the VTP network.                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Step 3</b> | <b>remote-span</b><br><br><b>Example:</b><br>Switch(config-vlan)# <b>remote-span</b>                                                                                                                        | Identifies the VLAN as the RSPAN VLAN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Step 4</b> | <b>exit</b><br><br><b>Example:</b><br>Switch(config-vlan)# <b>exit</b>                                                                                                                                      | Returns to global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Step 8 | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b> | Returns to privileged EXEC mode. |

## Creating an RSPAN Destination Session and Configuring Incoming Traffic

Beginning in privileged EXEC mode, follow these steps to create an RSPAN destination session, to specify the source RSPAN VLAN and the destination port, and to enable incoming traffic on the destination port for a network security device (such as a Cisco IDS Sensor Appliance).

### SUMMARY STEPS

1. **configure terminal**
2. **no monitor session** *{session\_number | all | local | remote}*
3. **monitor session** *session\_number* **source remote vlan** *vlan-id*
4. **monitor session** *session\_number* **destination** *{interface interface-id [, | -] [ingress {dot1q vlan vlan-id | isl | untagged vlan vlan-id | vlan vlan-id}]}*
5. **end**

### DETAILED STEPS

|        | Command or Action                                                                                                                              | Purpose                                                                                                                                                                                                                                                                                                                       |

| <b>Step 4</b> | <p><b>monitor session</b> <i>session_number</i><br/> <b>destination</b> {<b>interface</b> <i>interface-id</i> [,   -]<br/> [<b>ingress</b> {<b>dot1q vlan</b> <i>vlan-id</i>   <b>isl</b>  <br/> <b>untagged vlan</b> <i>vlan-id</i>   <b>vlan</b> <i>vlan-id</i>}]}</p> <p><b>Example:</b></p> <pre>Switch(config)# monitor session 2 destination interface gigabitethernet1/0/2 ingress vlan 6</pre> | <p>Specifies the SPAN session, the destination port, the packet encapsulation, and the incoming VLAN and encapsulation.</p> <ul style="list-style-type: none"> <li>For <i>session_number</i>, enter the number defined in Step 4.<br/> In an RSPAN destination session, you must use the same session number for the source RSPAN VLAN and the destination port.</li> <li>For <i>interface-id</i>, specify the destination interface. The destination interface must be a physical interface.</li> <li>Though visible in the command-line help string, <b>encapsulation replicate</b> is not supported for RSPAN. The original VLAN ID is overwritten by the RSPAN VLAN ID, and all packets appear on the destination port as untagged.</li> <li>(Optional) [,   -] Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen.</li> <li>Enter <b>ingress</b> with additional keywords to enable forwarding of incoming traffic on the destination port and to specify the encapsulation type: <ul style="list-style-type: none"> <li><b>dot1q vlan</b> <i>vlan-id</i>—Forwards incoming packets with IEEE 802.1Q encapsulation with the specified VLAN as the default VLAN.</li> <li><b>isl</b>—Forwards ingress packets with ISL encapsulation.</li> <li><b>untagged vlan</b> <i>vlan-id</i> or <b>vlan</b> <i>vlan-id</i>—Forwards incoming packets with untagged encapsulation type with the specified VLAN as the default VLAN.</li> </ul> </li> </ul> |
| <b>Step 5</b> | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Switch(config)# end</pre>                                                                                                                                                                                                                                                                                                                                | <p>Returns to privileged EXEC mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Configuring an FSPAN Session

Beginning in privileged EXEC mode, follow these steps to create a SPAN session, specify the source (monitored) ports or VLANs and the destination (monitoring) ports, and configure FSPAN for the session.

## SUMMARY STEPS

1. **configure terminal**
2. **no monitor session** {*session\_number* | **all** | **local** | **remote**}
3. **monitor session** *session\_number* **source** {**interface** *interface-id* | **vlan** *vlan-id*} [, | -] [**both** | **rx** | **tx**]
4. **monitor session** *session\_number* **destination** {**interface** *interface-id* [, | -] [**encapsulation replicate**]}
5. **monitor session** *session\_number* **filter** {**ip** | **ipv6** | **mac**} **access-group** {*access-list-number* | *name*}
6. **end**

## DETAILED STEPS

|               | Command or Action                                                                                                                                                                                                                                                                         | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Configuring an FRSPAN Session

Beginning in privileged EXEC mode, follow these steps to start an RSPAN source session, specify the monitored source and the destination RSPAN VLAN, and configure FRSPAN for the session.

## SUMMARY STEPS

1. **configure terminal**
2. **no monitor session** {*session\_number* | **all** | **local** | **remote**}
3. **monitor session** *session\_number* **source** {**interface** *interface-id* | **vlan** *vlan-id*} [, | -] [**both** | **rx** | **tx**]
4. **monitor session** *session\_number* **destination remote vlan** *vlan-id*
5. **vlan** *vlan-id*
6. **remote-span**
7. **exit**
8. **monitor session** *session\_number* **filter** {**ip** | **ipv6** | **mac**} **access-group** {*access-list-number* | *name*}
9. **end**

## DETAILED STEPS

|               | Command or Action                                                                                                                                                                                                                                                                         | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Step 4</b> | <p><b>monitor session session_number destination remote vlan vlan-id</b></p> <p><b>Example:</b></p> <pre>Switch(config)# monitor session 2 destination remote vlan 5</pre>                                  | <p>Specifies the RSPAN session and the destination RSPAN VLAN.</p> <ul style="list-style-type: none"> <li>• For <i>session_number</i>, enter the number defined in Step 3.</li> <li>• For <i>vlan-id</i>, specify the destination RSPAN VLAN to monitor.</li> </ul>                                                                                                                                                                                                                                                                                                          |
| <b>Step 5</b> | <p><b>vlan vlan-id</b></p> <p><b>Example:</b></p> <pre>Switch(config)# vlan 10</pre>                                                                                                                        | <p>Enters the VLAN configuration mode. For <i>vlan-id</i>, specify the source RSPAN VLAN to monitor.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Step 6</b> | <p><b>remote-span</b></p> <p><b>Example:</b></p> <pre>Switch(config-vlan)# remote-span</pre>                                                                                                                | <p>Specifies that the VLAN you specified in Step 5 is part of the RSPAN VLAN.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Step 7</b> | <p><b>exit</b></p> <p><b>Example:</b></p> <pre>Switch(config-vlan)# exit</pre>                                                                                                                              | <p>Returns to global configuration mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Step 8</b> | <p><b>monitor session session_number filter {ip   ipv6   mac} access-group {access-list-number   name}</b></p> <p><b>Example:</b></p> <pre>Switch(config)# monitor session 2 filter ip access-group 7</pre> | <p>Specifies the RSPAN session, the types of packets to filter, and the ACLs to use in an FRSPAN session.</p> <ul style="list-style-type: none"> <li>• For <i>session_number</i>, specify the session number entered in Step 3.</li> <li>• For <i>access-list-number</i>, specify the ACL number that you want to use to filter traffic.</li> <li>• For <i>name</i>, specify the ACL name that you want to use to filter traffic.</li> </ul>                                                                                                                                 |
| <b>Step 9</b> | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Switch(config)# end</pre>                                                                                                                                     | <p>Returns to privileged EXEC mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Monitoring SPAN and RSPAN Operations

The following table describes the command used to display SPAN and RSPAN operations configuration and results to monitor operations:

**Table 76: Monitoring SPAN and RSPAN Operations**

| Command                   | Purpose                                                           |
|---------------------------|-------------------------------------------------------------------|
| <code>show monitor</code> | Displays the current SPAN, RSPAN, FSPAN, or FRSPAN configuration. |

## SPAN and RSPAN Configuration Examples

### Example: Configuring Local SPAN

This example shows how to set up SPAN session 1 for monitoring source port traffic to a destination port. First, any existing SPAN configuration for session 1 is deleted, and then bidirectional traffic is mirrored from source Gigabit Ethernet port 1 to destination Gigabit Ethernet port 2, retaining the encapsulation method.

```
Switch(config)# no monitor session 1
Switch(config)# monitor session 1 source interface gigabitethernet1/0/1
Switch(config)# monitor session 1 destination interface gigabitethernet1/0/2
encapsulation replicate
Switch(config)# end
```

This example shows how to remove port 1 as a SPAN source for SPAN session 1:

```
Switch(config)# no monitor session 1 source interface gigabitethernet1/0/1
Switch(config)# end
```

This example shows how to disable received traffic monitoring on port 1, which was configured for bidirectional monitoring:

```
Switch(config)# no monitor session 1 source interface gigabitethernet1/0/1 rx
```

The monitoring of traffic received on port 1 is disabled, but traffic sent from this port continues to be monitored.

This example shows how to remove any existing configuration on SPAN session 2, configure SPAN session 2 to monitor received traffic on all ports belonging to VLANs 1 through 3, and send it to destination Gigabit Ethernet port 2. The configuration is then modified to also monitor all traffic on all ports belonging to VLAN 10.

```
Switch(config)# no monitor session 2
Switch(config)# monitor session 2 source vlan 1 - 3 rx
Switch(config)# monitor session 2 destination interface gigabitethernet1/0/2
Switch(config)# monitor session 2 source vlan 10
Switch(config)# end
```

This example shows how to remove any existing configuration on SPAN session 2, configure SPAN session 2 to monitor received traffic on Gigabit Ethernet source port 1, and send it to destination Gigabit Ethernet port 2 with the same egress encapsulation type as the source port, and to enable ingress forwarding with IEEE 802.1Q encapsulation and VLAN 6 as the default ingress VLAN:

```
Switch(config)# no monitor session 2
Switch(config)# monitor session 2 source gigabitethernet1/0/1 rx
Switch(config)# monitor session 2 destination interface gigabitethernet1/0/2 encapsulation
  replicate ingress dot1q vlan 6
Switch(config)# end
```

This example shows how to remove any existing configuration on SPAN session 2, configure SPAN session 2 to monitor traffic received on Gigabit Ethernet trunk port 2, and send traffic for only VLANs 1 through 5 and VLAN 9 to destination Gigabit Ethernet port 1:

```
Switch(config)# no monitor session 2
Switch(config)# monitor session 2 source interface gigabitethernet1/0/2 rx
Switch(config)# monitor session 2 filter vlan 1 - 5 , 9
Switch(config)# monitor session 2 destination interface gigabitethernet1/0/1
Switch(config)# end
```

## Examples: Creating an RSPAN VLAN

This example shows how to create the RSPAN VLAN 901:

```
Switch(config)# vlan 901
Switch(config-vlan)# remote span
Switch(config-vlan)# end
```

This example shows how to remove any existing RSPAN configuration for session 1, configure RSPAN session 1 to monitor multiple source interfaces, and configure the destination as RSPAN VLAN 901:

```
Switch(config)# no monitor session 1
Switch(config)# monitor session 1 source interface gigabitethernet1/0/1 tx
Switch(config)# monitor session 1 source interface gigabitethernet1/0/2 rx
Switch(config)# monitor session 1 source interface port-channel 2
Switch(config)# monitor session 1 destination remote vlan 901
Switch(config)# end
```

This example shows how to remove any existing configuration on RSPAN session 2, configure RSPAN session 2 to monitor traffic received on trunk port 2, and send traffic for only VLANs 1 through 5 and 9 to destination RSPAN VLAN 902:

```
Switch(config)# no monitor session 2
Switch(config)# monitor session 2 source interface gigabitethernet1/0/2 rx
Switch(config)# monitor session 2 filter vlan 1 - 5 , 9
Switch(config)# monitor session 2 destination remote vlan 902
Switch(config)# end
```

This example shows how to configure VLAN 901 as the source remote VLAN and port 1 as the destination interface:

```
Switch(config)# monitor session 1 source remote vlan 901
Switch(config)# monitor session 1 destination interface gigabitethernet2/0/1
Switch(config)# end
```

This example shows how to configure VLAN 901 as the source remote VLAN in RSPAN session 2, to configure Gigabit Ethernet source port 2 as the destination interface, and to enable forwarding of incoming traffic on the interface with VLAN 6 as the default receiving VLAN:

```
Switch(config)# monitor session 2 source remote vlan 901
Switch(config)# monitor session 2 destination interface gigabitethernet1/0/2 ingress vlan 6
Switch(config)# end
```

## Feature History and Information for SPAN and RSPAN

| Release            | Modification                                                                                                                                                                                                                                                                                                                                 |

### Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

### Prerequisites for Wireshark

- Wireshark is supported on Supervisor Engine 7-E, Supervisor Engine 7L-E, Catalyst 3850, Catalyst 3650, Wireless LAN Controller 5700 Series, Catalyst 4500X-16, and Catalyst 4500X-32.

### Restrictions for Wireshark

- Starting in Cisco IOS Release XE 3.3.0(SE), global packet capture on Wireshark is not supported.

- Capture filters are not supported.
- The CLI for configuring Wireshark requires that the feature be executed only from EXEC mode. Actions that usually occur in configuration submode (such as defining capture points), are handled at the EXEC mode instead. All key commands are not NVGEN'd and are not synchronized to the standby supervisor in NSF and SSO scenarios.
- Packets captured in the output direction of an interface might not reflect the changes made by switch rewrite (includes TTL, VLAN tag, CoS, checksum, MAC addresses, DSCP, precedent, UP, etc.).
- Limiting circular file storage by file size is not supported.

### Wireless Packet Capture

- The only form of wireless capture is a CAPWAP tunnel capture.
- When capturing CAPWAP tunnels, no other interface types can be used as attachment points on the same capture point.
- Capturing multiple CAPWAP tunnels is supported.
- Core filters are not applied and should be omitted when capturing a CAPWAP tunnel.
- To capture a CAPWAP data tunnel, each CAPWAP tunnel is mapped to a physical port and an appropriate ACL will be applied to filter the traffic.
- To capture a CAPWAP non-data tunnel, the switch is set to capture traffic on all ports and apply an appropriate ACL to filter the traffic.

### Configuration Limitations

- Multiple capture points can be defined, but only one can be active at a time. You need to stop one before you can start the other.
- Neither VRFs, management ports, nor private VLANs can be used as attachment points.
- Only one ACL of each type (IPv4, IPv6, MAC) is allowed in a Wireshark class map. There can be a maximum of three ACLs in a class map: one for IPv4, one for IPv6, and the other for MAC.
- Wireshark cannot capture packets on a destination SPAN port.
- Wireshark will stop capturing when one of the attachment points (interfaces) attached to a capture point stops working. For example, if the device that is associated with an attachment point is unplugged from the switch. To resume capturing, the capture must be restarted manually.
- CPU-injected packets are considered control plane packets. Therefore, these types of packets will not be captured on an interface egress capture.
- MAC ACL is only used for non-IP packets such as ARP. It will not be supported on a Layer 3 port or SVI.
- IPv6-based ACLs are not supported in VACL.
- Layer 2 and Layer 3 EtherChannels are not supported.
- ACL logging and Wireshark are incompatible. Once Wireshark is activated, it takes priority. All traffic, including that being captured by ACL logging on any ports, will be redirected to Wireshark. We

recommended that you deactivate ACL logging before starting Wireshark. Otherwise, Wireshark traffic will be contaminated by ACL logging traffic.

- Wireshark does not capture packets dropped by floodblock.
- If you capture both PACL and RACL on the same port, only one copy is sent to the CPU. If you capture a DTLS-encrypted CAPWAP interface, two copies are sent to Wireshark, one encrypted and the other decrypted. The same behavior will occur if we capture a Layer 2 interface carrying DTLS-encrypted CAPWAP traffic. The core filter is based on the outer CAPWAP header.

## Information About Wireshark

### Wireshark Overview

Wireshark is a packet analyzer program, formerly known as Ethereal, that supports multiple protocols and presents information in a text-based user interface.

The ability to capture and analyze traffic provides data on network activity. Prior to Cisco IOS Release XE 3.3.0(SE), only two features addressed this need: SPAN and debug platform packet. Both have limitations. SPAN is ideal for capturing packets, but can only deliver them by forwarding them to some specified local or remote destination; it provides no local display or analysis support. The **debug platform packet** command is specific to the Catalyst 4500 series and only works on packets that come from the software process-forwarding path. Also, the **debug platform packet** command has limited local display capabilities and no analysis support.

So the need exists for a traffic capture and analysis mechanism that is applicable to both hardware and software forwarded traffic and that provides strong packet capture, display, and analysis support, preferably using a well known interface.

Wireshark dumps packets to a file using a well known format called .pcap, and is applied or enabled on individual interfaces. You specify an interface in EXEC mode along with the filter and other parameters. The Wireshark application is applied only when you enter a **start** command, and is removed only when Wireshark stops capturing packets either automatically or manually.

### Capture Points

A capture point is the central policy definition of the Wireshark feature. The capture point describes all of the characteristics associated with a given instance of Wireshark: which packets to capture, where to capture them from, what to do with the captured packets, and when to stop. Capture points can be modified after creation, and do not become active until explicitly activated with a **start** command. This process is termed activating the capture point or starting the capture point. Capture points are identified by name and can also be manually or automatically deactivated or stopped.

Multiple capture points can be defined, but only one can be active at a time. You need to stop one before you can start the other.

### Attachment Points

An attachment point is a point in the logical packet process path associated with a capture point. An attachment point is an attribute of the capture point. Packets that impact an attachment point are tested against capture point filters; packets that match are copied and sent to the associated Wireshark instance of the capture point. A specific capture point can be associated with multiple attachment points, with limits on mixing attachment

points of different types. Some restrictions apply when you specify attachment points of different types. Attachment points are directional (input or output or both) with the exception of the Layer 2 VLAN attachment point, which is always bidirectional.

## Filters

Filters are attributes of a capture point that identify and limit the subset of traffic traveling through the attachment point of a capture point, which is copied and passed to Wireshark. To be displayed by Wireshark, a packet must pass through an attachment point, as well as all of the filters associated with the capture point.

A capture point has the following types of filters:

- Core system filter—The core system filter is applied by hardware, and its match criteria is limited by hardware. This filter determines whether hardware-forwarded traffic is copied to software for Wireshark purposes.
- Display filter—The display filter is applied by Wireshark. Packets that fail the display filter are not displayed.

### Core System Filter

You can specify core system filter match criteria by using the class map or ACL, or explicitly by using the CLI.

#### Note

When specifying CAPWAP as an attachment point, the core system filter is not used.

In some installations, you need to obtain authorization to modify the switch configuration, which can lead to extended delays if the approval process is lengthy. This can limit the ability of network administrators to monitor and analyze traffic. To address this situation, Wireshark supports explicit specification of core system filter match criteria from the EXEC mode CLI. The disadvantage is that the match criteria that you can specify is a limited subset of what class map supports, such as MAC, IP source and destination addresses, ether-type, IP protocol, and TCP/UDP source and destination ports.

If you prefer to use configuration mode, you can define ACLs or have class maps refer capture points to them. Explicit and ACL-based match criteria are used internally to construct class maps and policy maps.

Note The ACL and class map configuration are part of the system and not aspects of the Wireshark feature.

### Display Filter

With the display filter, you can direct Wireshark to further narrow the set of packets to display when decoding and displaying from a .pcap file.

### Related Topics

## Actions

Wireshark can be invoked on live traffic or on a previously existing .pcap file. When invoked on live traffic, it can perform four types of actions on packets that pass its display filters:

- Captures to buffer in memory to decode and analyze and store

- Stores to a .pcap file
- Decodes and displays
- Stores and displays

When invoked on a .pcap file only, only the decode and display action is applicable.

## Storage of Captured Packets to Buffer in Memory

Packets can be stored in the capture buffer in memory for subsequent decode, analysis, or storage to a .pcap file.

The capture buffer can be in linear or circular mode. In linear mode, new packets are discarded when the buffer is full. In circular mode, if the buffer is full, the oldest packets are discarded to accommodate the new packets. Although the buffer can also be cleared when needed, this mode is mainly used for debugging network traffic.

---

**Note** If you have more than one capture that is storing packets in a buffer, clear the buffer before starting a new capture to avoid memory loss.

---

## Storage of Captured Packets to a .pcap File

---

**Note** When WireShark is used on switches in a stack, packet captures can be stored only on flash or USB flash devices connected to the active switch.

For example, if flash1 is connected to the active switch, and flash2 is connected to the secondary switch, only flash1 can be used to store packet captures.

Attempts to store packet captures on devices other than flash or USB flash devices connected to the active switch will probably result in errors.

---

Wireshark can store captured packets to a .pcap file. The capture file can be located on the following storage devices:

- Switch on-board flash storage (flash:)
- USB drive (usbflash0:)

---

**Note** Attempts to store packet captures on unsupported devices or devices not connected to the active switch will probably result in errors.

---

When configuring a Wireshark capture point, you can associate a filename. When the capture point is activated, Wireshark creates a file with the specified name and writes packets to it. If the file already exists when the file is associated or the capture point is activated, Wireshark queries you as to whether the file can be overwritten. Only one capture point may be associated with a given filename.

If the destination of the Wireshark writing process is full, Wireshark fails with partial data in the file. You must ensure that there is sufficient space in the file system before you start the capture session. With Cisco IOS Release IOS XE 3.3.0(SE), the file system full status is not detected for some storage devices.

You can reduce the required storage space by retaining only a segment, instead of the entire packet. Typically, you do not require details beyond the first 64 or 128 bytes. The default behavior is to store the entire packet.

To avoid possible packet drops when processing and writing to the file system, Wireshark can optionally use a memory buffer to temporarily hold packets as they arrive. Memory buffer size can be specified when the capture point is associated with a .pcap file.

## Packet Decoding and Display

Wireshark can decode and display packets to the console. This functionality is possible for capture points applied to live traffic and for capture points applied to a previously existing .pcap file.

### Note

---

Decoding and displaying packets may be CPU intensive.

---

Wireshark can decode and display packet details for a wide variety of packet formats. The details are displayed by entering the **monitor capture name start** command with one of the following keyword options, which place you into a display and decode mode:

- **brief**—Displays one line per packet (the default).
- **detailed**—Decodes and displays all the fields of all the packets whose protocols are supported. Detailed modes require more CPU than the other two modes.
- **(hexadecimal) dump**—Displays one line per packet as a hexadecimal dump of the packet data and the printable characters of each packet.

When you enter the **capture** command with the decode and display option, the Wireshark output is returned to Cisco IOS and displayed on the console unchanged.

### Live Traffic Display

Wireshark receives copies of packets from the core system. Wireshark applies its display filters to discard uninteresting packets, and then decodes and displays the remaining packets.

### .pcap File Display

Wireshark can decode and display packets from a previously stored .pcap file and direct the display filter to selectively displayed packets.

## Packet Storage and Display

Functionally, this mode is a combination of the previous two modes. Wireshark stores packets in the specified .pcap file and decodes and displays them to the console. Only the core filters are applicable here.

## Wireshark Capture Point Activation and Deactivation

After a Wireshark capture point has been defined with its attachment points, filters, actions, and other options, it must be activated. Until the capture point is activated, it does not actually capture packets.

Before a capture point is activated, some functional checks are performed. A capture point cannot be activated if it has neither a core system filter nor attachment points defined. Attempting to activate a capture point that does not meet these requirements generates an error.\*

### Note

---

\*When performing a wireless capture with a CAPWAP tunneling interface, the core system filter is not required and cannot be used.

---

The display filters are specified as needed.

After Wireshark capture points are activated, they can be deactivated in multiple ways. A capture point that is storing only packets to a .pcap file can be halted manually or configured with time or packet limits, after which the capture point halts automatically.

When a Wireshark capture point is activated, a fixed rate policer is applied automatically in the hardware so that the CPU is not flooded with Wireshark-directed packets. The disadvantage of the rate policer is that you cannot capture contiguous packets beyond the established rate even if more resources are available.

## Wireshark Features

This section describes how Wireshark features function in the switch environment:

- If port security and Wireshark are applied on an ingress capture, a packet that is dropped by port security will still be captured by Wireshark. If port security is applied on an ingress capture, and Wireshark is applied on an egress capture, a packet that is dropped by port security will not be captured by Wireshark.
- Packets dropped by Dynamic ARP Inspection (DAI) are not captured by Wireshark.
- If a port that is in STP blocked state is used as an attachment point and the core filter is matched, Wireshark will capture the packets that come into the port, even though the packets will be dropped by the switch.
- Classification-based security features—Packets that are dropped by input classification-based security features (such as ACLs and IPSG) are not caught by Wireshark capture points that are connected to attachment points at the same layer. In contrast, packets that are dropped by output classification-based security features are caught by Wireshark capture points that are connected to attachment points at the same layer. The logical model is that the Wireshark attachment point occurs after the security feature lookup on the input side, and symmetrically before the security feature lookup on the output side.

On ingress, a packet goes through a Layer 2 port, a VLAN, and a Layer 3 port/SVI. On egress, the packet goes through a Layer 3 port/SVI, a VLAN, and a Layer 2 port. If the attachment point is before the point where the packet is dropped, Wireshark will capture the packet. Otherwise, Wireshark will not capture the packet. For example, Wireshark capture policies connected to Layer 2 attachment points in the input direction capture packets dropped by Layer 3 classification-based security features. Symmetrically, Wireshark capture policies attached to Layer 3 attachment points in the output direction capture packets dropped by Layer 2 classification-based security features.

- Routed ports and switch virtual interfaces (SVIs)—Wireshark cannot capture the output of an SVI because the packets that go out of an SVI's output are generated by CPU. To capture these packets, include the control plane as an attachment point.
- VLANs—When a VLAN is used as a Wireshark attachment point, packets are captured in the input direction only.
- Redirection features—In the input direction, features traffic redirected by Layer 3 (such as PBR and WCCP) are logically later than Layer 3 Wireshark attachment points. Wireshark captures these packets even though they might later be redirected out another Layer 3 interface. Symmetrically, output features redirected by Layer 3 (such as egress WCCP) are logically prior to Layer 3 Wireshark attachment points, and Wireshark will not capture them.
- SPAN—Wireshark and SPAN sources are compatible. You can configure an interface as a SPAN source and as a Wireshark attachment point simultaneously. Configuring a SPAN destination port as a Wireshark attachment point is not supported.
- You can capture packets from a maximum of 1000 VLANs at a time, if no ACLs are applied. If ACLs are applied, the hardware will have less space for Wireshark to use. As a result, the maximum number of VLANs than can be used for packet capture at a time will be lower. Using more than 1000 VLANs tunnels at a time or extensive ACLs might have unpredictable results. For example, mobility may go down.

---

**Note** Capturing an excessive number of attachment points at the same time is strongly discouraged because it may cause excessive CPU utilization and unpredictable hardware behavior.

---

### Wireless Packet Capture in Wireshark

- Wireless traffic is encapsulated inside CAPWAP packets. However, capturing only a particular wireless client's traffic inside a CAPWAP tunnel is not supported when using the CAPWAP tunnel as an attachment point. To capture only a particular wireless client's traffic, use the client VLAN as an attachment point and formulate the core filter accordingly.
- Limited decoding of inner wireless traffic is supported. Decoding of inner wireless packets inside encrypted CAPWAP tunnels is not supported.
- No other interface type can be used with the CAPWAP tunneling interface on the same capture point. A CAPWAP tunneling interface and a Level 2 port cannot be attachment points on the same capture point.
- You cannot specify a core filter when capturing packets for Wireshark via the CAPWAP tunnel. However, you can use the Wireshark display filters for filtering wireless client traffic against a specific wireless client.
- You can capture packets from a maximum of 135 CAPWAP tunnels at a time if no ACLs are applied. If ACLs are applied, the hardware memory will have less space for Wireshark to use. As a result, the maximum number of CAPWAP tunnels than can be used for packet capture at a time will be lower. Using more than 135 CAPWAP tunnels at a time or using extensive ACLs might have unpredictable results. For example, mobility may go down.

**Note**

Capturing an excessive number of attachment points at the same time is strongly discouraged because it may cause excessive CPU utilization and unpredictable hardware behavior.

## Guidelines for Wireshark

- During Wireshark packet capture, hardware forwarding happens concurrently.
- Before starting a Wireshark capture process, ensure that CPU usage is moderate and that sufficient memory (at least 200 MB) is available.
- If you plan to store packets to a storage file, ensure that sufficient space is available before beginning a Wireshark capture process.
- The CPU usage during Wireshark capture depends on how many packets match the specified conditions and on the intended actions for the matched packets (store, decode and display, or both).
- Where possible, keep the capture to the minimum (limit by packets, duration) to avoid high CPU usage and other undesirable conditions.
- Because packet forwarding typically occurs in hardware, packets are not copied to the CPU for software processing. For Wireshark packet capture, packets are copied and delivered to the CPU, which causes an increase in CPU usage.

To avoid high CPU usage, do the following:

- Attach only relevant ports.
  - Use a class map, and secondarily, an access list to express match conditions. If neither is viable, use an explicit, in-line filter.
  - Adhere closely to the filter rules. Restrict the traffic type (such as, IPv4 only) with a restrictive, rather than relaxed ACL, which elicits unwanted traffic.
- Always limit packet capture to either a shorter duration or a smaller packet number. The parameters of the capture command enable you to specify the following:
    - Capture duration
    - Number of packets captured
    - File size
    - Packet segment size
  - Run a capture session without limits if you know that very little traffic matches the core filter.
  - You might experience high CPU (or memory) usage if:
    - You leave a capture session enabled and unattended for a long period of time, resulting in unanticipated bursts of traffic.
    - You launch a capture session with ring files or capture buffer and leave it unattended for a long time, resulting in performance or system health issues.

- During a capture session, watch for high CPU usage and memory consumption due to Wireshark that may impact switch performance or health. If these situations arise, stop the Wireshark session immediately.
- Avoid decoding and displaying packets from a .pcap file for a large file. Instead, transfer the .pcap file to a PC and run Wireshark on the PC.
- You can define up to eight Wireshark instances. An active **show** command that decodes and displays packets from a .pcap file or capture buffer counts as one instance. However, only one of the instances can be active.
- Whenever an ACL that is associated with a running capture is modified, you must restart the capture for the ACL modifications to take effect. If you do not restart the capture, it will continue to use the original ACL as if it had not been modified.
- To avoid packet loss, consider the following:
  - Use store-only (when you do not specify the display option) while capturing live packets rather than decode and display, which is an CPU-intensive operation (especially in detailed mode).
  - If you have more than one capture that is storing packets in a buffer, clear the buffer before starting a new capture to avoid memory loss.
  - If you use the default buffer size and see that you are losing packets, you can increase the buffer size to avoid losing packets.
  - Writing to flash disk is a CPU-intensive operation, so if the capture rate is insufficient, you may want to use a buffer capture.
  - The Wireshark capture session operates normally in streaming mode where packets are both captured and processed. However, when you specify a buffer size of at least 32 MB, the session automatically turns on lock-step mode in which a Wireshark capture session is split into two phases: capture and process. In the capture phase, the packets are stored in the temporary buffer. The duration parameter in lock-step mode serves as capture duration rather than session duration. When the buffer is full or the capture duration or packet limit has been attained, a session transitions to the process phase, wherein it stops accepting packets and starts processing packets in the buffer. You can also stop the capture manually. You will see a message in the output when the capture stops. With this second approach (lock-step mode), a higher capture throughput can be achieved.

---

**Note** If you are capturing packets to a buffer, there is no file storage defined. Hence, you must export your capture from the buffer to a static storage file. Use the **monitor capture capture-name export file-location : file-name** command.

---

- The streaming capture mode supports approximately 1000 pps; lock-step mode supports approximately 2 Mbps (measured with 256-byte packets). When the matching traffic rate exceeds this number, you may experience packet loss.
- If you want to decode and display live packets in the console window, ensure that the Wireshark session is bounded by a short capture duration.

---

**Note** **Warning:** A Wireshark session with either a longer duration limit or no capture duration (using a terminal with no auto-more support using the **term len 0** command) may make the console or terminal unusable.

---

- When using Wireshark to capture live traffic that leads to high CPU, usage, consider applying a QoS policy temporarily to limit the actual traffic until the capture process concludes.
- All Wireshark-related commands are in EXEC mode; no configuration commands exist for Wireshark. If you need to use access list or class-map in the Wireshark CLI, you must define an access list and class map with configuration commands.
- No specific order applies when defining a capture point; you can define capture point parameters in any order, provided that CLI allows this. The Wireshark CLI allows as many parameters as possible on a single line. This limits the number of commands required to define a capture point.
- All parameters except attachment points take a single value. Generally, you can replace the value with a new one by reentering the command. After user confirmation, the system accepts the new value and overrides the older one. A **no** form of the command is unnecessary to provide a new value, but it is necessary to remove a parameter.
- Wireshark allows you to specify one or more attachment points. To add more than one attachment point, reenter the command with the new attachment point. To remove an attachment point, use the **no** form of the command. You can specify an interface range as an attachment point. For example, enter **monitor capture mycap interface GigabitEthernet1/0/1 in** where interface GigabitEthernet1/0/1 is an attachment point.

If you also need to attach interface GigabitEthernet1/0/2, specify it in another line as follows:

**monitor capture mycap interface GigabitEthernet1/0/2 in**

- You can modify any of the parameters of a capture point while a session is active, but you must restart the session for the modifications to take effect.
- The action you want to perform determines which parameters are mandatory. The Wireshark CLI allows you to specify or modify any parameter prior to entering the **start** command. When you enter the **start** command, Wireshark will start only after determining that all mandatory parameters have been provided.
- If the capture file already exists, it provides a warning and receives confirmation before proceeding. This prevents you from mistakenly overwriting a file.
- The core filter can be an explicit filter, access list, or class map. Specifying a newer filter of these types replaces the existing one.

**Note** A core filter is required except when using a CAPWAP tunnel interface as a capture point attachment point.

- You can terminate a Wireshark session with an explicit **stop** command or by entering **q** in automore mode. The session could terminate itself automatically when a stop condition such as duration or packet capture limit is met.

## Default Wireshark Configuration

The table below shows the default Wireshark configuration.

| Feature  | Default Setting |
|----------|-----------------|
| Duration | No limit        |

| Feature             | Default Setting        |
|---------------------|------------------------|
| Packets             | No limit               |
| Packet-length       | No limit (full packet) |
| File size           | No limit               |
| Ring file storage   | No                     |
| Buffer storage mode | Linear                 |

## How to Configure Wireshark

To configure Wireshark, perform these basic steps.

- 1 Define a capture point.
- 2 (Optional) Add or modify the capture point's parameters.
- 3 Activate or deactivate a capture point.
- 4 Delete the capture point when you are no longer using it.

## Defining a Capture Point

The example in this procedure defines a very simple capture point. If you choose, you can define a capture point and all of its parameters with one instance of the **monitor capture** command.

### Note

You must define an attachment point, direction of capture, and core filter to have a functional capture point.

An exception to needing to define a core filter is when you are defining a wireless capture point using a CAPWAP tunneling interface. In this case, you do not define your core filter. It cannot be used.

In privileged EXEC mode, follow these steps to define a capture point.

## SUMMARY STEPS

1. `show capwap summary`
2. `monitor capture {capture-name} {interface interface-type interface-id | control-plane} {in | out | both}`
3. `monitor capture {capture-name}[match {any | ipv4 any any | ipv6} any any]`
4. `show monitor capture {capture-name}[ parameter]`

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <p><code>show capwap summary</code></p> <p><b>Example:</b><br/>Switch# <code>show capwap summary</code></p>                                                                                                                          | <p>Displays the CAPWAP tunnels available as attachment points for a wireless capture.</p> <p><b>Note</b> Use this command only if you are using a CAPWAP tunnel as an attachment point to perform a wireless capture. See the CAPWAP example in the examples section.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Step 2 | <p><code>monitor capture {capture-name} {interface interface-type interface-id   control-plane} {in   out   both}</code></p> <p><b>Example:</b><br/>Switch# <code>monitor capture mycap interface GigabitEthernet1/0/1 in</code></p> | <p>Defines the capture point, specifies the attachment point with which the capture point is associated, and specifies the direction of the capture.</p> <p>The keywords have these meanings:</p> <ul style="list-style-type: none"> <li>• <i>capture-name</i>—Specifies the name of the capture point to be defined (mycap is used in the example).</li> <li>• (Optional) <b>interface interface-type interface-id</b>—Specifies the attachment point with which the capture point is associated (GigabitEthernet1/0/1 is used in the example).</li> </ul> <p><b>Note</b> Optionally, you can define multiple attachment points and all of the parameters for this capture point with this one command instance. These parameters are discussed in the instructions for modifying capture point parameters. Range support is also available both for adding and removing attachment points.</p> <p>Use one of the following for <i>interface-type</i>:</p> <ul style="list-style-type: none"> <li>◦ <b>GigabitEthernet</b>—Specifies the attachment point as GigabitEthernet.</li> <li>◦ <b>vlan</b>—Specifies the attachment point as a VLAN.</li> </ul> <p><b>Note</b> Only ingress capture (in) is allowed when using this interface as an attachment point.</p> <ul style="list-style-type: none"> <li>◦ <b>capwap</b>—Specifies the attachment point as a CAPWAP tunnel.</li> </ul> <p><b>Note</b> When using this interface as an attachment point, a core filter cannot be used.</p> <ul style="list-style-type: none"> <li>• (Optional) <b>control-plane</b>—Specifies the control plane as an attachment point.</li> <li>• <b>in   out   both</b>—Specifies the direction of capture.</li> </ul> |

|        | Command or Action                                                                                                                                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 3 | <p><b>monitor capture</b><br/> <code>{capture-name}[match {any   ipv4 any any   ipv6} any any]</code></p> <p><b>Example:</b><br/> <pre>Switch# monitor capture mycap interface GigabitEthernet1/0/1 in match any</pre></p>                            | <p>Defines the core system filter.</p> <p><b>Note</b> When using the CAPWAP tunneling interface as an attachment point, do not perform this step because a core filter cannot be used.</p> <p>The keywords have these meanings:</p> <ul style="list-style-type: none"> <li>• <i>capture-name</i>—Specifies the name of the capture point to be defined (mycap is used in the example).</li> <li>• <b>match</b>—Specifies a filter. The first filter defined is the core filter.</li> </ul> <p><b>Note</b> A capture point cannot be activated if it has neither a core system filter nor attachment points defined. Attempting to activate a capture point that does not meet these requirements generates an error.</p> <ul style="list-style-type: none"> <li>• <b>ipv4</b>—Specifies an IP version 4 filter.</li> <li>• <b>ipv6</b>—Specifies an IP version 6 filter.</li> </ul> |
| Step 4 | <p><b>show monitor capture</b> <code>{capture-name}[parameter]</code></p> <p><b>Example:</b><br/> <pre>Switch# show monitor capture mycap parameter monitor capture mycap interface GigabitEthernet1/0/1 in monitor capture mycap match any</pre></p> | <p>Displays the capture point parameters that you defined in Step 1 and confirms that you defined a capture point.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

To define a capture point with a CAPWAP attachment point:

```
Switch# show capwap summary
```

```
CAPWAP Tunnels General Statistics:
Number of Capwap Data Tunnels      = 1
Number of Capwap Mobility Tunnels   = 0
Number of Capwap Multicast Tunnels = 0
```

| Name | APName           | Type | PhyPortIf | Mode    | McastIf |

| Ca0  | 10.10.14.32 | 5247    | 10.10.14.2 | 38514   | No     | 1449 | 0    |

```
Switch# monitor capture mycap interface capwap 0 both
Switch# monitor capture mycap file location flash:mycap.pcap
Switch# monitor capture mycap file buffer-size 1
Switch# monitor capture mycap start
```

```
*Aug 20 11:02:21.983: %BUFCAP-6-ENABLE: Capture Point mycap enabled.on
```

```
Switch# show monitor capture mycap parameter
monitor capture mycap interface capwap 0 in
monitor capture mycap interface capwap 0 out
```

```

monitor capture mycap file location flash:mycap.pcap buffer-size 1
Switch#
Switch# show monitor capture mycap

Status Information for Capture mycap
  Target Type:
  Interface: CAPWAP,
  Ingress:
0
  Egress:
0
  Status : Active
  Filter Details:
    Capture all packets
  Buffer Details:
    Buffer Type: LINEAR (default)
  File Details:
    Associated file name: flash:mycap.pcap
    Size of buffer(in MB): 1
  Limit Details:
    Number of Packets to capture: 0 (no limit)
    Packet Capture duration: 0 (no limit)
    Packet Size to capture: 0 (no limit)
    Packets per second: 0 (no limit)
    Packet sampling rate: 0 (no sampling)
Switch#
Switch# show monitor capture file flash:mycap.pcap

```

### What to Do Next

You can add additional attachment points, modify the parameters of your capture point, then activate it, or if you want to use your capture point just as it is, you can now activate it.

#### Note

You cannot change a capture point's parameters using the methods presented in this topic.

## Adding or Modifying Capture Point Parameters

Although listed in sequence, the steps to specify values for the parameters can be executed in any order. You can also specify them in one, two, or several lines. Except for attachment points, which can be multiple, you can replace any value with a more recent value by redefining the same option.

In privileged EXEC mode, follow these steps to modify a capture point's parameters.

### Before You Begin

A capture point must be defined before you can use these instructions.

### SUMMARY STEPS

1. **monitor capture** *{capture-name}* **match** {**any** | **mac** *mac-match-string* | **ipv4** {**any** | **host** | **protocol**} {**any** | **host**} | **ipv6** {**any** | **host** | **protocol**} {**any** | **host**}}
2. **monitor capture** *{capture-name}* **limit** {[**duration** *seconds*][**packet-length** *size*][**packets** *num*]}
3. **monitor capture** *{capture-name}* **file** {**location** *filename*}
4. **monitor capture** *{capture-name}* **file** {**buffer-size** *size*}
5. **show monitor capture** *{capture-name}* [**parameter**]

### DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                                                                                                | Purpose                                                                                                                                                                                                                                                                                |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>monitor capture</b> <i>{capture-name}</i> <b>match</b> { <b>any</b>   <b>mac</b> <i>mac-match-string</i>   <b>ipv4</b> { <b>any</b>   <b>host</b>   <b>protocol</b> } { <b>any</b>   <b>host</b> }   <b>ipv6</b> { <b>any</b>   <b>host</b>   <b>protocol</b> } { <b>any</b>   <b>host</b> }} | Defines the core system filter ( <b>ipv4 any any</b> ), defined either explicitly, through ACL or through a class map.<br><br><b>Note</b> If you are defining a wireless capture point using a CAPWAP tunneling interface, this command will have no effect, so it should not be used. |

|               | Command or Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Purpose                                                                                                                        |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
|               | <p><b>Example:</b><br/>Switch# <code>monitor capture mycap match ipv4 any any</code></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                                                                                                                |
| <b>Step 2</b> | <p><code>monitor capture {capture-name} limit {{duration seconds}}[[packet-length size]][[packets num]]</code></p> <p><b>Example:</b><br/>Switch# <code>monitor capture mycap limit duration 60 packet-len 400</code></p>                                                                                                                                                                                                                                                                                                                                                  | Specifies the session limit in seconds (60), packets captured, or the packet segment length to be retained by Wireshark (400). |
| <b>Step 3</b> | <p><code>monitor capture {capture-name} file {location filename}</code></p> <p><b>Example:</b><br/>Switch# <code>monitor capture mycap file location flash:mycap.pcap</code></p>                                                                                                                                                                                                                                                                                                                                                                                           | Specifies the file association, if the capture point intends to capture packets rather than only display them.                 |
| <b>Step 4</b> | <p><code>monitor capture {capture-name} file {buffer-size size}</code></p> <p><b>Example:</b><br/>Switch# <code>monitor capture mycap file buffer-size 100</code></p>                                                                                                                                                                                                                                                                                                                                                                                                      | Specifies the size of the memory buffer used by Wireshark to handle traffic bursts.                                            |
| <b>Step 5</b> | <p><code>show monitor capture {capture-name} [ parameter]</code></p> <p><b>Example:</b><br/>Switch# <code>show monitor capture mycap parameter</code><br/> <code>monitor capture mycap interface GigabitEthernet1/0/1</code><br/> <code>in</code><br/> <code>monitor capture mycap match ipv4 any any</code><br/> <code>monitor capture mycap limit duration 60 packet-len</code><br/> <code>400</code><br/> <code>monitor capture point mycap file location</code><br/> <code>bootdisk:mycap.pcap</code><br/> <code>monitor capture mycap file buffer-size 100</code></p> | Displays the capture point parameters that you defined previously.                                                             |

## Examples

### Modifying Parameters

#### Associating or Disassociating a Capture File

```
Switch# monitor capture point mycap file location flash:mycap.pcap
Switch# no monitor capture mycap file
```

#### Specifying a Memory Buffer Size for Packet Burst Handling

```
Switch# monitor capture mycap buffer size 100
```

#### Defining an Explicit Core System Filter to Match Both IPv4 and IPv6

```
Switch# monitor capture mycap match any
```

### What to Do Next

if your capture point contains all of the parameters you want, activate it.

**Deleting Capture Point Parameters**

Although listed in sequence, the steps to delete parameters can be executed in any order. You can also delete them in one, two, or several lines. Except for attachment points, which can be multiple, you can delete any parameter.

In privileged EXEC mode, follow these steps to delete a capture point's parameters.

**Before You Begin**

A capture point parameter must be defined before you can use these instructions to delete it.

**SUMMARY STEPS**

1. **no monitor capture** *{capture-name}* **match**
2. **no monitor capture** *{capture-name}* **limit** [**duration**][**packet-length**][**packets**]
3. **no monitor capture** *{capture-name}* **file** [**location**] [**buffer-size**]
4. **show monitor capture** *{capture-name}* [**parameter**]

**DETAILED STEPS**

|               | Command or Action                                                                                                                                                                                                                                                       | Purpose                                                                                                                                                                                                                                                                                                    |

## Deleting a Capture Point

In privileged EXEC mode, follow these steps to delete a capture point.

### Before You Begin

A capture point must be defined before you can use these instructions to delete it.

### SUMMARY STEPS

1. **no monitor capture** *{capture-name}*
2. **show monitor capture** *{capture-name}* [**parameter**]

### DETAILED STEPS

|               | Command or Action                                                                                                                                                                    | Purpose                                                                                                    |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>no monitor capture</b> <i>{capture-name}</i><br><br><b>Example:</b><br>Switch# <b>no monitor capture mycap</b>                                                                    | Deletes the specified capture point (mycap).                                                               |
| <b>Step 2</b> | <b>show monitor capture</b> <i>{capture-name}</i> [ <b>parameter</b> ]<br><br><b>Example:</b><br>Switch# <b>show monitor capture mycap parameter</b><br>Capture mycap does not exist | Displays a message indicating that the specified capture point does not exist because it has been deleted. |

### What to Do Next

You can define a new capture point with the same name as the one you deleted. These instructions are usually performed when one wants to start over with defining a capture point.

## Activating and Deactivating a Capture Point

In privileged EXEC mode, follow these steps to activate or deactivate a capture point.

### Before You Begin

A capture point cannot be activated unless an attachment point and a core system filter have been defined and the associated filename (if any) does not already exist. A capture point with no associated filename can only be activated to display. If no capture or display filters are specified, all of the packets captured by the core system filter are displayed. The default display mode is brief.

#### Note

When using a CAPWAP tunneling interface as an attachment point, core filters are not used, so there is no requirement to define them in this case.

### SUMMARY STEPS

1. `monitor capture {capture-name} start[display [display-filter filter-string]][brief | detailed | dump]`
2. `monitor capture {capture-name} stop`

### DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                                  | Purpose                                                                                            |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------|
| Step 1 | <p><code>monitor capture {capture-name} start[display [display-filter filter-string]][brief   detailed   dump]</code></p> <p><b>Example:</b><br/>Switch# <code>monitor capture mycap start display display-filter "stp"</code></p> | Activates a capture point and filters the display, so only packets containing "stp" are displayed. |
| Step 2 | <p><code>monitor capture {capture-name} stop</code></p> <p><b>Example:</b><br/>Switch# <code>monitor capture name stop</code></p>                                                                                                  | Deactivates a capture point.                                                                       |

**Clearing the Capture Point Buffer**

In privileged EXEC mode, follow these steps to clear the buffer contents or save them to an external file for storage.

**Note**

If you have more than one capture that is storing packets in a buffer, clear the buffer before starting a new capture to avoid memory loss.

**SUMMARY STEPS**

1. **monitor capture** *{capture-name}* [**clear** | **export filename**]

**DETAILED STEPS**

|               | Command or Action                                                                                                                                           | Purpose                                                         |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------|
| <b>Step 1</b> | <b>monitor capture</b> <i>{capture-name}</i> [ <b>clear</b>   <b>export filename</b> ]<br><br><b>Example:</b><br>Switch# <b>monitor capture mycap clear</b> | Clears capture buffer contents or stores the packets to a file. |

**Examples: Capture Point Buffer Handling****Exporting Capture to a File**

```
Switch# monitor capture mycap export flash:mycap.pcap
```

Storage configured as File for this capture

**Clearing Capture Point Buffer**

```
Switch# monitor capture mycap clear
```

Capture configured with file options

**Monitoring Wireshark**

The commands in this table are used to monitor Wireshark.

| Command                                                       | Purpose                                                                                                                                                                                                                           |
|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>show monitor capture</b> [ <i>capture-name</i> ]           | Displays the capture point state so that you can see what capture points are defined, what their attributes are, and whether they are active. When capture point name is specified, it displays specific capture point's details. |
| <b>show monitor capture</b> [ <i>capture-name parameter</i> ] | Displays the capture point parameters.                                                                                                                                                                                            |
| <b>show capwap summary</b>                                    | Displays all the CAPWAP tunnels on the switch. Use this command to determine which CAPWAP tunnels are available to use for a wireless capture.                                                                                    |

## Configuration Examples for Wireshark

### Example: Displaying a Brief Output from a .pcap File

You can display the output from a .pcap file by entering:

```
Switch# show monitor capture file flash:mycap.pcap
 1  0.000000  10.1.1.140 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
 2  1.000000  10.1.1.141 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
 3  2.000000  10.1.1.142 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
 4  3.000000  10.1.1.143 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
 5  4.000000  10.1.1.144 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
 6  5.000000  10.1.1.145 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
 7  6.000000  10.1.1.146 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
 8  7.000000  10.1.1.147 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
 9  8.000000  10.1.1.148 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
10  9.000000  10.1.1.149 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
11 10.000000  10.1.1.150 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
12 11.000000  10.1.1.151 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
13 12.000000  10.1.1.152 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
14 13.000000  10.1.1.153 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
15 14.000000  10.1.1.154 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
16 15.000000  10.1.1.155 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
17 16.000000  10.1.1.156 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
18 17.000000  10.1.1.157 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
19 18.000000  10.1.1.158 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
```

|    |           |                        |                        |                         |

| 37 | 36.000000 | 10.1.1.176 -> 20.1.1.2 | UDP Source port: 20001 | Destination port: 20002 |
| 38 | 37.000000 | 10.1.1.177 -> 20.1.1.2 | UDP Source port: 20001 | Destination port: 20002 |
| 39 | 38.000000 | 10.1.1.178 -> 20.1.1.2 | UDP Source port: 20001 | Destination port: 20002 |
| 40 | 39.000000 | 10.1.1.179 -> 20.1.1.2 | UDP Source port: 20001 | Destination port: 20002 |
| 41 | 40.000000 | 10.1.1.180 -> 20.1.1.2 | UDP Source port: 20001 | Destination port: 20002 |
| 42 | 41.000000 | 10.1.1.181 -> 20.1.1.2 | UDP Source port: 20001 | Destination port: 20002 |
| 43 | 42.000000 | 10.1.1.182 -> 20.1.1.2 | UDP Source port: 20001 | Destination port: 20002 |
| 44 | 43.000000 | 10.1.1.183 -> 20.1.1.2 | UDP Source port: 20001 | Destination port: 20002 |
| 45 | 44.000000 | 10.1.1.184 -> 20.1.1.2 | UDP Source port: 20001 | Destination port: 20002 |
| 46 | 45.000000 | 10.1.1.185 -> 20.1.1.2 | UDP Source port: 20001 | Destination port: 20002 |
| 47 | 46.000000 | 10.1.1.186 -> 20.1.1.2 | UDP Source port: 20001 | Destination port: 20002 |
| 48 | 47.000000 | 10.1.1.187 -> 20.1.1.2 | UDP Source port: 20001 | Destination port: 20002 |
| 49 | 48.000000 | 10.1.1.188 -> 20.1.1.2 | UDP Source port: 20001 | Destination port: 20002 |
| 50 | 49.000000 | 10.1.1.189 -> 20.1.1.2 | UDP Source port: 20001 | Destination port: 20002 |
| 51 | 50.000000 | 10.1.1.190 -> 20.1.1.2 | UDP Source port: 20001 | Destination port: 20002 |
| 52 | 51.000000 | 10.1.1.191 -> 20.1.1.2 | UDP Source port: 20001 | Destination port: 20002 |
| 53 | 52.000000 | 10.1.1.192 -> 20.1.1.2 | UDP Source port: 20001 | Destination port: 20002 |
| 54 | 53.000000 | 10.1.1.193 -> 20.1.1.2 | UDP Source port: 20001 | Destination port: 20002 |
| 55 | 54.000000 | 10.1.1.194 -> 20.1.1.2 | UDP Source port: 20001 | Destination port: 20002 |

```

56 55.000000 10.1.1.195 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
57 56.000000 10.1.1.196 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
58 57.000000 10.1.1.197 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
59 58.000000 10.1.1.198 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002

```

## Example: Displaying Detailed Output from a .pcap File

You can display the detailed .pcap file output by entering:

```
Switch# show monitor capture file flash:mycap.pcap detailed
```

```

```

## Example: Simple Capture and Display

This example shows how to monitor traffic in the Layer 3 interface Gigabit Ethernet 1/0/1:

**Step 1:** Define a capture point to match on the relevant traffic by entering:

```

Switch# monitor capture mycap interface GigabitEthernet1/0/1 in
Switch# monitor capture mycap match ipv4 any any
Switch# monitor capture mycap limit duration 60 packets 100
Switch# monitor capture mycap buffer size 100

```

To avoid high CPU utilization, a low packet count and duration as limits has been set.

**Step 2:** Confirm that the capture point has been correctly defined by entering:

```

Switch# show monitor capture mycap parameter
  monitor capture mycap interface GigabitEthernet1/0/1 in
  monitor capture mycap match ipv4 any any
  monitor capture mycap buffer size 100
  monitor capture mycap limit packets 100 duration 60

```

```

Switch# show monitor capture mycap

```

```

Status Information for Capture mycap
Target Type:
  Interface: GigabitEthernet1/0/1, Direction: in
  Status : Inactive
Filter Details:
  IPv4
  Source IP: any
  Destination IP: any
  Protocol: any
Buffer Details:
  Buffer Type: LINEAR (default)
  Buffer Size (in MB): 100
File Details:
  File not associated

```

```

Limit Details:
Number of Packets to capture: 100
Packet Capture duration: 60
Packet Size to capture: 0 (no limit)
Packets per second: 0 (no limit)
Packet sampling rate: 0 (no sampling)

```

**Step 3:** Start the capture process and display the results.

```

Switch# monitor capture mycap start display
0.000000 10.1.1.30 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
1.000000 10.1.1.31 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
2.000000 10.1.1.32 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
3.000000 10.1.1.33 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
4.000000 10.1.1.34 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
5.000000 10.1.1.35 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
6.000000 10.1.1.36 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
7.000000 10.1.1.37 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
8.000000 10.1.1.38 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
9.000000 10.1.1.39 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002

```

**Step 4:** Delete the capture point by entering:

```
Switch# no monitor capture mycap
```

## Example: Simple Capture and Store

This example shows how to capture packets to a filter:

**Step 1:** Define a capture point to match on the relevant traffic and associate it to a file by entering:

```

Switch# monitor capture mycap interface GigabitEthernet1/0/1 in
Switch# monitor capture mycap match ipv4 any any
Switch# monitor capture mycap limit duration 60 packets 100
Switch# monitor capture mycap file location flash:mycap.pcap

```

**Step 2:** Confirm that the capture point has been correctly defined by entering:

```

Switch# show monitor capture mycap parameter
monitor capture mycap interface GigabitEthernet1/0/1 in
monitor capture mycap match ipv4 any any
monitor capture mycap file location flash:mycap.pcap
monitor capture mycap limit packets 100 duration 60

```

```
Switch# show monitor capture mycap
```

```

Status Information for Capture mycap
Target Type:
Interface: GigabitEthernet1/0/1, Direction: in
Status : Inactive
Filter Details:
IPv4
Source IP: any
Destination IP: any
Protocol: any
Buffer Details:
Buffer Type: LINEAR (default)
File Details:
Associated file name: flash:mycap.pcap
Limit Details:
Number of Packets to capture: 100
Packet Capture duration: 60
Packet Size to capture: 0 (no limit)
Packets per second: 0 (no limit)
Packet sampling rate: 0 (no sampling)

```

**Step 3:** Launch packet capture by entering:

```
Switch# monitor capture mycap start
```

**Step 4:** After sufficient time has passed, stop the capture by entering:

```
Switch# monitor capture mycap stop
```

**Note**

Alternatively, you could allow the capture operation stop automatically after the time has elapsed or the packet count has been met.

The mycap.pcap file now contains the captured packets.

**Step 5:** Display the packets by entering:

```
Switch# show monitor capture file flash:mycap.pcap
```

```
0.000000 10.1.1.30 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
1.000000 10.1.1.31 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
2.000000 10.1.1.32 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
3.000000 10.1.1.33 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
4.000000 10.1.1.34 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
5.000000 10.1.1.35 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
6.000000 10.1.1.36 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
7.000000 10.1.1.37 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
8.000000 10.1.1.38 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
9.000000 10.1.1.39 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
```

**Step 6:** Delete the capture point by entering:

```
Switch# no monitor capture mycap
```

## Example: Using Buffer Capture

This example shows how to use buffer capture:

**Step 1:** Launch a capture session with the buffer capture option by entering:

```
Switch# monitor capture mycap interface GigabitEthernet1/0/1 in
Switch# monitor capture mycap match ipv4 any any
Switch# monitor capture mycap buffer circular size 1
Switch# monitor capture mycap start
```

**Step 2:** Determine whether the capture is active by entering:

```
Switch# show monitor capture mycap
```

```
Status Information for Capture mycap
Target Type:
  Interface: GigabitEthernet1/0/1, Direction: in
  Status : Active
Filter Details:
  IPv4
  Source IP: any
  Destination IP: any
  Protocol: any
Buffer Details:
  Buffer Type: CIRCULAR
  Buffer Size (in MB): 1
File Details:
  File not associated
Limit Details:
  Number of Packets to capture: 0 (no limit)
  Packet Capture duration: 0 (no limit)
  Packet Size to capture: 0 (no limit)
  Packets per second: 0 (no limit)
  Packet sampling rate: 0 (no sampling)
```

**Step 3: Display the packets in the buffer by entering:**

```
Switch# show monitor capture mycap buffer brief
```

```

0.000000 10.1.1.215 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
1.000000 10.1.1.216 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
2.000000 10.1.1.217 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
3.000000 10.1.1.218 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
4.000000 10.1.1.219 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
5.000000 10.1.1.220 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
6.000000 10.1.1.221 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
7.000000 10.1.1.222 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
8.000000 10.1.1.223 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
9.000000 10.1.1.224 -> 20.1.1.2      UDP Source port: 20001 Destination port: 20002
10.000000 10.1.1.225 -> 20.1.1.2     UDP Source port: 20001 Destination port: 20002
11.000000 10.1.1.226 -> 20.1.1.2     UDP Source port: 20001 Destination port: 20002
12.000000 10.1.1.227 -> 20.1.1.2     UDP Source port: 20001 Destination port: 20002
13.000000 10.1.1.228 -> 20.1.1.2     UDP Source port: 20001 Destination port: 20002
14.000000 10.1.1.229 -> 20.1.1.2     UDP Source port: 20001 Destination port: 20002
15.000000 10.1.1.230 -> 20.1.1.2     UDP Source port: 20001 Destination port: 20002
16.000000 10.1.1.231 -> 20.1.1.2     UDP Source port: 20001 Destination port: 20002
17.000000 10.1.1.232 -> 20.1.1.2     UDP Source port: 20001 Destination port: 20002
18.000000 10.1.1.233 -> 20.1.1.2     UDP Source port: 20001 Destination port: 20002
19.000000 10.1.1.234 -> 20.1.1.2     UDP Source port: 20001 Destination port: 20002
20.000000 10.1.1.235 -> 20.1.1.2     UDP Source port: 20001 Destination port: 20002
21.000000 10.1.1.236 -> 20.1.1.2     UDP Source port: 20001 Destination port: 20002

```

Notice that the packets have been buffered.

**Step 4: Display the packets in other display modes.**

```
Switch# show monitor capture mycap buffer detailed
```

```

```

**Step 5a:** Clear the buffer by entering:

```
Switch# monitor capture mycap clear
```

**Step 5b:** Wait for 10 seconds.

**Step 5c:** Stop the traffic by entering:

```
Switch# monitor capture mycap stop
```

**Step 6:** Confirm that the same set of packets are displayed after this time gap by entering:

```
Switch# show monitor capture mycap buffer brief
```

```
0.000000 10.1.1.2 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
1.000000 10.1.1.3 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
2.000000 10.1.1.4 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
3.000000 10.1.1.5 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
4.000000 10.1.1.6 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
5.000000 10.1.1.7 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
6.000000 10.1.1.8 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
7.000000 10.1.1.9 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
8.000000 10.1.1.10 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
9.000000 10.1.1.11 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
```

**Step 7:** Wait for 10 seconds, then confirm that the same set of packets are displayed after this time gap by entering:

```
Switch# show monitor capture mycap buffer brief
```

```
0.000000 10.1.1.2 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
1.000000 10.1.1.3 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
2.000000 10.1.1.4 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
3.000000 10.1.1.5 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
4.000000 10.1.1.6 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
5.000000 10.1.1.7 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
6.000000 10.1.1.8 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
7.000000 10.1.1.9 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
8.000000 10.1.1.10 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
9.000000 10.1.1.11 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
```

**Step 8:** Repeat Step 7.

**Step 9:** Clear the buffer by entering:

```
Switch# monitor capture mycap clear
```

**Step 10:** Confirm that the buffer is now empty by entering:

```
Switch# show monitor capture mycap buffer brief
```

**Step 11:** Wait about 10 seconds, then display the buffer contents by entering:

```
Switch# show monitor capture mycap buffer brief
```

**Step 12:** Restart the traffic, wait for 10 seconds, then display the buffer contents by entering:

```
Switch# monitor capture mycap start
```

```
wait for 10 seconds...
```

```
Switch# show monitor capture mycap buffer brief
```

```
0.000000 10.1.1.2 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
1.000000 10.1.1.3 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
2.000000 10.1.1.4 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
3.000000 10.1.1.5 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
4.000000 10.1.1.6 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
```

```

5.000000    10.1.1.7 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
6.000000    10.1.1.8 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
7.000000    10.1.1.9 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
8.000000    10.1.1.10 -> 20.1.1.2   UDP Source port: 20001 Destination port: 20002
9.000000    10.1.1.11 -> 20.1.1.2  UDP Source port: 20001 Destination port: 20002

```

**Step 13:** Store the buffer contents to the mycap1.pcap file in the internal flash: storage device by entering:

```

Switch# monitor capture mycap export flash:mycap1.pcap
Exported Successfully

```

**Step 14:** Check that the file has been created and that it contains the packets by entering:

```

Switch# dir flash:mycap1.pcap
Directory of flash:/mycap1.pcap

14758  -rw-          20152  Apr 15 2012 16:00:28 -07:00  mycap1.pcap

10  9.000000    10.1.1.11 -> 20.1.1.2   UDP Source port: 20001 Destination port: 20002
11 10.000000    10.1.1.12 -> 20.1.1.2   UDP Source port: 20001 Destination port: 20002
12 11.000000    10.1.1.13 -> 20.1.1.2   UDP Source port: 20001 Destination port: 20002
13 12.000000    10.1.1.14 -> 20.1.1.2   UDP Source port: 20001 Destination port: 20002
14 13.000000    10.1.1.15 -> 20.1.1.2   UDP Source port: 20001 Destination port: 20002
15 14.000000    10.1.1.16 -> 20.1.1.2   UDP Source port: 20001 Destination port: 20002
16 15.000000    10.1.1.17 -> 20.1.1.2   UDP Source port: 20001 Destination port: 20002

```

**Step 15:** Stop the packet capture and display the buffer contents by entering:

```

Switch# monitor capture mycap stop
Switch# show monitor capture mycap buffer brief

0.000000    10.1.1.2 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
1.000000    10.1.1.3 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
2.000000    10.1.1.4 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
3.000000    10.1.1.5 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
4.000000    10.1.1.6 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
5.000000    10.1.1.7 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
6.000000    10.1.1.8 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
7.000000    10.1.1.9 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
8.000000    10.1.1.10 -> 20.1.1.2   UDP Source port: 20001 Destination port: 20002
9.000000    10.1.1.11 -> 20.1.1.2   UDP Source port: 20001 Destination port: 20002
10.000000   10.1.1.12 -> 20.1.1.2   UDP Source port: 20001 Destination port: 20002
11.000000   10.1.1.13 -> 20.1.1.2   UDP Source port: 20001 Destination port: 20002

```

**Step 16:** Clear the buffer and then try to display packets from the buffer by entering:

```
Switch# monitor capture mycap clear
Switch# show monitor capture mycap buffer brief
```

**Step 17:** Delete the capture point by entering:

```
Switch# no monitor capture mycap
```

## Example: Capture Sessions

```
Switch# monitor capture mycap start display display-filter "stp"

## Example: Capture and Store in Lock-step Mode

This example captures live traffic and stores the packets in lock-step mode.

**Note**

The capture rate might be slow for the first 15 seconds. If possible and necessary, start the traffic 15 seconds after the capture session starts.

**Step 1:** Define a capture point to match on the relevant traffic and associate it to a file by entering:

```
Switch# monitor capture mycap interface GigabitEthernet1/0/1 in
Switch# monitor capture mycap match ipv4 any any
Switch# monitor capture mycap limit duration 60 packets 100
Switch# monitor capture mycap file location flash:mycap.pcap buffer-size 64
```

**Step 2:** Confirm that the capture point has been correctly defined by entering:

```
Switch# show monitor capture mycap parameter
monitor capture mycap interface GigabitEthernet1/0/1 in
monitor capture mycap file location flash:mycap.pcap buffer-size 64
monitor capture mycap limit packets 100 duration 60
```

```
Switch# show monitor capture mycap
```

```
Status Information for Capture mycap
Target Type:
Interface: GigabitEthernet1/0/1, Direction: in
Status : Inactive
Filter Details:
Filter not attached
Buffer Details:
Buffer Type: LINEAR (default)
File Details:
Associated file name: flash:mycap.pcap
Size of buffer(in MB): 64
Limit Details:
Number of Packets to capture: 100
Packet Capture duration: 60
Packet Size to capture: 0 (no limit)
Packets per second: 0 (no limit)
Packet sampling rate: 0 (no sampling)
```

**Step 3:** Launch packet capture by entering:

```
Switch# monitor capture mycap start
A file by the same capture file name already exists, overwrite?[confirm]
Turning on lock-step mode
```

```
Switch#
*Oct 14 09:35:32.661: %BUFCAP-6-ENABLE: Capture Point mycap enabled.
```

**Step 4:** Display the packets by entering:

```
Switch# show monitor capture file flash:mycap.pcap
0.000000 10.1.1.30 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
1.000000 10.1.1.31 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
2.000000 10.1.1.32 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
3.000000 10.1.1.33 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
4.000000 10.1.1.34 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
5.000000 10.1.1.35 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
6.000000 10.1.1.36 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
7.000000 10.1.1.37 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
8.000000 10.1.1.38 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
9.000000 10.1.1.39 -> 20.1.1.2 UDP Source port: 20001 Destination port: 20002
```

**Step 5:** Delete the capture point by entering:

```
Switch# no monitor capture mycap
```

## Example: Simple Capture and Store of Packets in Egress Direction

This example shows how to capture packets to a filter:

**Step 1:** Define a capture point to match on the relevant traffic and associate it to a file by entering:

```
Switch# monitor capture mycap interface Gigabit 1/0/1 out match ipv4 any any
Switch# monitor capture mycap limit duration 60 packets 100
Switch# monitor capture mycap file location flash:mycap.pcap buffer-size 90
```

**Step 2:** Confirm that the capture point has been correctly defined by entering:

```
Switch# show monitor capture mycap parameter
    monitor capture mycap interface GigabitEthernet1/0/1 out
    monitor capture mycap match ipv4 any any
    monitor capture mycap file location flash:mycap.pcap buffer-size 90
    monitor capture mycap limit packets 100 duration 60

Switch# show monitor capture mycap

Status Information for Capture mycap
Target Type:
  Interface: GigabitEthernet1/0/1, Direction: out
  Status : Inactive
Filter Details:
  IPv4
  Source IP: any
  Destination IP: any
  Protocol: any
Buffer Details:
  Buffer Type: LINEAR (default)
File Details:
  Associated file name: flash:mycap.pcap
  Size of buffer(in MB): 90
Limit Details:
  Number of Packets to capture: 100
  Packet Capture duration: 60
  Packet Size to capture: 0 (no limit)
  Packets per second: 0 (no limit)
  Packet sampling rate: 0 (no sampling)
```

**Step 3:** Launch packet capture by entering:

```
Switch# monitor capture mycap start
A file by the same capture file name already exists, overwrite?[confirm]
Turning on lock-step mode

Switch#
*Oct 14 09:35:32.661: %BUFCAP-6-ENABLE: Capture Point mycap enabled.
```

**Note**

Allow the capture operation stop automatically after the time has elapsed or the packet count has been met. When you see the following message in the output, will know that the capture operation has stopped:

```
*Oct 14 09:36:34.632: %BUFCAP-6-DISABLE_ASYNC: Capture Point mycap disabled. Reason : Wireshark Session Ended
The mycap.pcap file now contains the captured packets.
```

**Step 4:** Display the packets by entering:

```
Switch# show monitor capture file flash:mycap.pcap
0.000000 10.1.1.30 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
1.000000 10.1.1.31 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
2.000000 10.1.1.32 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
3.000000 10.1.1.33 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
4.000000 10.1.1.34 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
5.000000 10.1.1.35 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
6.000000 10.1.1.36 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
7.000000 10.1.1.37 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
8.000000 10.1.1.38 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
9.000000 10.1.1.39 -> 20.1.1.2    UDP Source port: 20001 Destination port: 20002
```

**Step 5:** Delete the capture point by entering:

```
Switch# no monitor capture mycap
```

### Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

### Prerequisites for QoS

Before configuring standard QoS, you must have a thorough understanding of these items:

- Standard QoS concepts.

- Wireless concepts and network topologies.
- Classic Cisco IOS QoS.
- Modular QoS CLI (MQC).
- Understanding of QoS implementation.
- The types of applications used and the traffic patterns on your network.
- Traffic characteristics and needs of your network. For example, is the traffic on your network bursty? Do you need to reserve bandwidth for voice and video streams?
- Bandwidth requirements and speed of the network.
- Location of congestion points in the network.

## QoS Components

QoS consists of the following key components:

- **Classification**— Classification is the process of distinguishing one type of traffic from another based upon ACLs, Differentiated Services Code Point (DSCP), Class of Service (CoS), and other factors.
- **Marking and mutation**— Marking is used on traffic to convey specific information to a downstream device in the network, or to carry information from one interface in a switch to another. When traffic is marked, QoS operations on that traffic can be applied. This can be accomplished directly using the `set` command or through a table map, which takes input values and translates them directly to values on output.
- **Shaping and policing**— Shaping is the process of imposing a maximum rate of traffic, while regulating the traffic rate in such a way that downstream devices are not subjected to congestion. Shaping in the most common form is used to limit the traffic sent from a physical or logical interface. Policing is used to impose a maximum rate on a traffic class. If the rate is exceeded, then a specific action is taken as soon as the event occurs.
- **Queuing** — Queueing is used to prevent traffic congestion. Traffic is sent to specific queues for servicing and scheduling based upon bandwidth allocation. Traffic is then scheduled or sent out through the port.
- **Bandwidth**—Bandwidth allocation determines the available capacity for traffic that is subject to QoS policies.
- **Trust**— Trust enables traffic to pass through the switch, and the DSCP, precedence, or CoS values coming in from the end points are retained in the absence of any explicit policy configuration.

## QoS Terminology

The following terms are used interchangeably in this QoS configuration guide:

- Upstream (direction towards the switch) is the same as ingress.

- Downstream (direction from the switch) is the same as egress.

**Note**

---

Upstream is wireless to wired. Downstream is wired to wireless. Wireless to wireless has no specific term.

---

## Information About QoS

### QoS Overview

By configuring the quality of service (QoS), you can provide preferential treatment to specific types of traffic at the expense of other traffic types. Without QoS, the switch offers best-effort service to each packet, regardless of the packet contents or size. The switch sends the packets without any assurance of reliability, delay bounds, or throughput.

The following are specific features provided by QoS:

- Low latency
- Bandwidth guarantee
- Buffering capabilities and dropping disciplines
- Traffic policing
- Enables the changing of the attribute of the frame or packet header
- Relative services

### Modular QoS Command-Line Interface

With the switch, QoS features are enabled through the Modular QoS command-line interface (MQC). The MQC is a command-line interface (CLI) structure that allows you to create traffic policies and attach these policies to interfaces. A traffic policy contains a traffic class and one or more QoS features. A traffic class is used to classify traffic, while the QoS features in the traffic policy determine how to treat the classified traffic. One of the main goals of MQC is to provide a platform-independent interface for configuring QoS across Cisco platforms.

### Wireless QoS Overview

Wireless QoS can be configured on the following wireless targets:

- Wireless ports, including all physical ports to which an access point can be associated.
- Radio
- SSID (applicable on a per-radio, per-AP, and per-SSID)

- Client

The following table displays how policies are supported for the wireless targets.

**Table 77: Wireless Targets Policies Support**

| Wireless Target | Policies on Wireless Targets Supported | Policies Supported Downstream Direction | Policies Supported Upstream Direction |
|-----------------|----------------------------------------|-----------------------------------------|---------------------------------------|
| Wireless port   | Yes                                    | Yes - user configurable                 | No                                    |
| Radio           | Yes                                    | Yes - but not configurable by user      | No                                    |
| SSID            | Yes                                    | Yes - user configurable                 | Yes - user configurable               |
| Client          | Yes                                    | Yes - user configurable                 | Yes - user configurable               |

**Note**

Additional polices that are user configured include multi-destination policers and VLANs.

Wireless QoS supports the following additional features:

- Queuing support
- Policing of wireless traffic
- Shaping of wireless traffic
- Rate limiting in both downstream and upstream direction
- Approximate Fair Drop (AFD)
- Mobility support for QoS
- Compatibility with precious metal QoS policies available on Cisco Unified Wireless Controllers.

### QoS and IPv6 for Wireless

From this release onwards, the switch supports QoS for both IPv4 and IPv6 traffic, and client policies can now have IPv4 and IPv6 filters.

### Wired and Wireless Access Supported Features

The following table describes the supported features for both wired and wireless access.

**Table 78: Supported QoS Features for Wired and Wireless Access**

| Feature                                  | Wired                                                                                                               | Wireless                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

### Port Policies

The switch supports port-based policies. The port policies includes port shaper and a child policy (port\_child\_policy).

#### Note

Port child policies only apply to wireless ports and not to wired ports on the switch. A wireless port is defined as a port to which APs join. A default port child policy is applied on the switch to the wireless ports at start up. The port shaper rate is limited to 1G

Port shaper specifies the traffic policy applicable between the device and the AP. This is the sum of the radio rates supported on the access point.

The child policy determines the mapping between packets and queues defined by the port-child policy. The child policy can be configured to include voice, video, class-default, and non-client-nrt classes where voice

and video are based on DSCP value (which is the outer CAPWAP header DSCP value). The definition of class-default is known to the system as any value other than voice and video DSCP.

The DSCP value is assigned when the packet reaches the port. Before the packet arrives at the port, the SSID policies are applied on the packet. Port child policy also includes multicast percentage for a given port traffic. By default, the port child policy allocates up to 10 percent of the available rate.

### Port Policy Format

This section describes the behavior of the port policies on a switch. The ports on the switch do not distinguish between wired or wireless physical ports. Depending on the kind of device associated to the switch, the policies are applied. For example, when an access point is connected to a switch port, the switch detects it as a wireless device and applies the default hierarchical policy which is in the format of a parent-child policy. This policy is an hierarchical policy. The parent policy cannot be modified but the child policy (port-child policy) can be modified to suit the QoS configuration. The switch is pre configured with a default class map and a policy map.

Default class map:

```
Class Map match-any non-client-nrt-class
  Match non-client-nrt
```

The above port policy processes all network traffic to the Q3 queue. You can view the class map by executing the **show class-map** command.

Default policy map:

```
Policy Map port_child_policy
  Class non-client-nrt-class
    bandwidth remaining ratio 10
```

#### Note

The class map and policy map listed are system-defined policies and cannot be changed.

The following is the system-defined policy map available on the ports on which wireless devices are associated. The format consists of a parent policy and a service child policy (**port\_child\_policy**). To customize the policies to suite your network needs, you must configure the port child policy.

```
Policy-map policy_map_name
  Class class-default
    Shape average average_rate
  Service-policy port_child_policy
```

#### Note

The parent policy is system generated and cannot be changed. You must configure the *port\_child\_policy* policy to suit the QoS requirements on your network.

Depending on the type of traffic in your network, you can configure the port child policy. For example, in a typical wireless network deployment, you can assign specific priorities to voice and video traffic. Here is an example:

```
Policy-map port_child_policy
  Class voice-policy-name (match dscp ef)
    Priority level 1
    Police (multicast-policer-name-voice) Multicast Policer
  Class video-policy-name (match dscp af41)
    Priority level 2
    Police (multicast-policer-name-video) Multicast Policer
  Class non-client-nrt-class traffic (match non-client-nrt)
    Bandwidth remaining ratio (brr-value-nrt-q2)
  Class class-default (NRT Data)
    Bandwidth remaining ratio (brr-value-q3)
```

In the above port child policy:

- *voice-policy-name*— Refers to the name of the class that specifies rules for the traffic for voice packets. Here the DSCP value is mapped to a value of 46 (represented by the keyword **ef**). The voice traffic is assigned the highest priority of 1.
- *video-policy-name*— Refers to the name of the class that specifies rules for the traffic for video packets. The DSCP value is mapped to a value of 34 (represented by the keyword **af41**).
- *multicast-policer-name-voice*— If you need to configure multicast voice traffic, you can configure policing for the voice class map.
- *multicast-policer-name-video*— If you need to configure multicast video traffic, you can configure policing for the video class map.

In the above sample configuration, all voice and video traffic is directed to the Q0 and Q1 queues, respectively. These queues maintain a strict priority. The packets in Q0 and Q1 are processed in that order. The bandwidth remaining ratios *brr-value-nrt-q2* and *brr-value-q3* are directed to the Q2 and Q3 respectively specified by the class maps and *class-default* and *non-client-nrt*. The processing of packets on Q2 and Q3 are based on a weighted round-robin approach. For example, if the *brr-value-nrtq2* has a value of 90 and *brr-value-nrtq3* is 10, the packets in queue 2 and queue 3 are processed in the ratio of 9:1.

## Radio Policies

The radio policies are system defined and are not user configurable. Radio wireless targets are only applicable in the downstream direction.

Radio policies are applicable on a per-radio, per-access point basis. The rate limit on the radios is the practical limit of the AP radio rate. This value is equivalent to the sum of the radios supported by the access point.

The following radios are supported:

- 802.11 a/n
- 802.11 b/n
- 802.11 a/c

### Related Topics

[Restrictions for QoS on Wireless Targets, on page 978](#)

[Supported QoS Features on Wireless Targets, on page 944](#)

## SSID Policies

You can create QoS policies on SSID BSSID (Basic Service Set Identification) in both the upstream and downstream directions. By default, there is no SSID policy. You can configure an SSID policy based on the SSID name. The policy is applicable on a per BSSID.

The types of policies you can create on SSID include marking by using table maps (table-maps), shape rate, and RT1 (Real Time 1) and RT2 (Real Time 2) policers. If traffic is upstream, you usually configure a marking policy on the SSID. If traffic is downstream, you can configure marking and queuing.

There should be a one-to-one mapping between the policies configured on a port and an SSID. For example, if you configure class voice and class video on the port, you can have a similar policy on the SSID.

SSID priorities can be specified by configuring bandwidth remaining ratio. Queuing SSID policies are applied in the downstream direction.

[Supported QoS Features on Wireless Targets, on page 944](#)

[Examples: SSID Policy](#)

[Examples: Configuring Downstream SSID Policy, on page 1041](#)

## Client Policies

Client policies are applicable in the upstream and downstream direction. The wireless control module of the switch applies the default client policies when admission control is enabled for WMM clients. When admission control is disabled, there is no default client policy. You can configure policing and marking policies on clients.

### Note

A client policy can have both IPv4 and IPv6 filters.

You can configure client policies in the following ways:

- Using AAA—You can use a combination of AAA and TCLAS, and AAA and SIP snooping when configuring with AAA.
- Using the Cisco IOS MQC CLI—You can use a combination of CLI and TCLAS and CLI and SIP snooping.

- Using the default configuration

---

**Note** When applying client policies on a WLAN, you must disable the WLAN before modifying the client policy. SSID policies can be modified even if the WLAN is enabled.

---

---

**Note** If you configured AAA by configuring the unified wireless controller procedure, and using the MQC QoS commands, the policy configuration performed through the MQC QoS commands takes precedence.

---

For client policies, the following filters are supported:

- ACL
- DSCP
- COS
- WLAN UP

## Hierarchical QoS

The switch supports hierarchical QoS (HQoS). HQoS allows you to perform:

- Hierarchical classification— Traffic classification is based upon other classes.
- Hierarchical policing—The process of having the policing configuration at multiple levels in a hierarchical policy.
- Hierarchical shaping—Shaping can also be configured at multiple levels in the hierarchy.

---

**Note** Hierarchical shaping is only supported for the port shaper, where for the parent you only have a configuration for the class default, and the only action for the class default is shaping.

---

### Related Topics

[Examples: Hierarchical Classification, on page 1038](#)

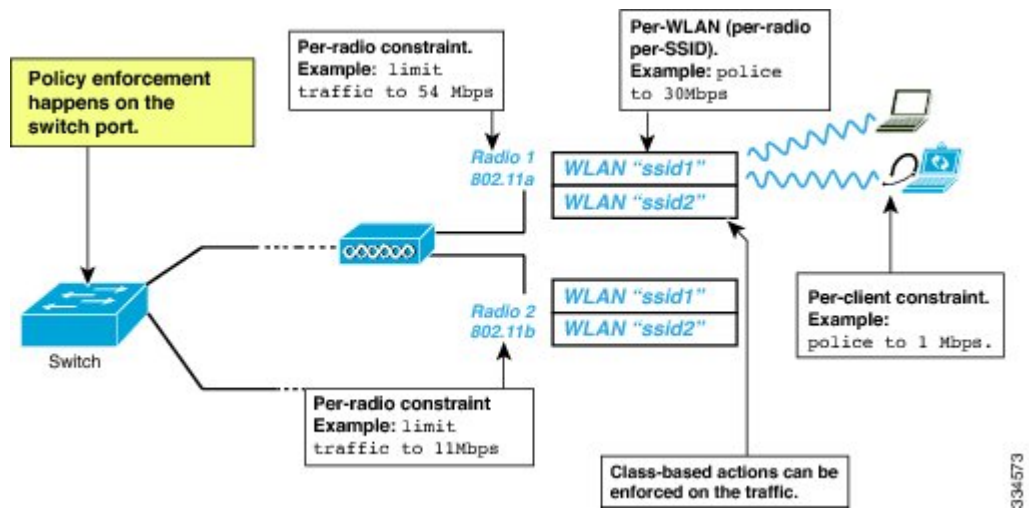

[Examples: Hierarchical Policy Configuration, on page 1039](#)

### Hierarchical Wireless QoS

The switch supports hierarchical QoS for wireless targets. Hierarchical QoS policies are applicable on port, radio, SSID, and client. QoS policies configured on the device (including marking, shaping, policing) can be applied across the targets. If the network contains non-realtime traffic, the non-realtime traffic is subject to approximate fair drop. Hierarchy refers to the process of application of the various QoS policies on the packets arriving to the device.

This figure shows the various targets available on a wireless network, as well as a hierarchal wireless configuration. Wireless QoS is applied per-radio constraint, per-WLAN, and per-client constraint.

**Figure 60: Hierarchical QoS**

### Wireless Packet Format

This figure displays the wireless packet flow and encapsulation used in hierarchical wireless QoS. The incoming packet enters the switch. The switch encapsulates this incoming packet and adds the 802.11e and CAPWAP headers.

**Figure 61: Wireless Packet Path in the Egress Direction during First Pass**

### *Hierarchical AFD*

Approximate Fair Dropping (AFD) is a feature provided by the QoS infrastructure in Cisco IOS. For wireless targets, AFD can be configured on SSID (via shaping) and clients (via policing). AFD shaping rate is only applicable for downstream direction. Unicast real-time traffic is not subjected to AFD drops.

## **QoS Implementation**

Typically, networks operate on a best-effort delivery basis, which means that all traffic has equal priority and an equal chance of being delivered in a timely manner. When congestion occurs, all traffic has an equal chance of being dropped.

When you configure the QoS feature, you can select specific network traffic, prioritize it according to its relative importance, and use congestion-management and congestion-avoidance techniques to provide preferential treatment. Implementing QoS in your network makes network performance more predictable and bandwidth utilization more effective.

The QoS implementation is based on the Differentiated Services (Diff-Serv) architecture, a standard from the Internet Engineering Task Force (IETF). This architecture specifies that each packet is classified upon entry into the network.

The classification is carried in the IP packet header, using 6 bits from the deprecated IP type of service (ToS) field to carry the classification (*class*) information. Classification can also be carried in the Layer 2 frame.

The special bits in the Layer 2 frame or a Layer 3 packet are shown in the following figure:

**Figure 62: QoS Classification Layers in Frames and Packets**

Encapsulated Packet

Layer 2 ISL Frame

Layer 2 802.1Q and 802.1p Frame

Layer 3 IPv4 Packet

Layer 3 IPv6 Packet

**Related Topics**

[Restrictions for QoS on Wired Targets, on page 976](#)

[Restrictions for QoS on Wireless Targets, on page 978](#)

**Layer 2 Frame Prioritization Bits**

Layer 2 Inter-Switch Link (ISL) frame headers have a 1-byte User field that carries an IEEE 802.1p class of service (CoS) value in the three least-significant bits. On ports configured as Layer 2 ISL trunks, all traffic is in ISL frames.

Layer 2 802.1Q frame headers have a 2-byte Tag Control Information field that carries the CoS value in the three most-significant bits, which are called the User Priority bits. On ports configured as Layer 2 802.1Q trunks, all traffic is in 802.1Q frames except for traffic in the native VLAN.

Other frame types cannot carry Layer 2 CoS values.

Layer 2 CoS values range from 0 for low priority to 7 for high priority.

### Layer 3 Packet Prioritization Bits

Layer 3 IP packets can carry either an IP precedence value or a Differentiated Services Code Point (DSCP) value. QoS supports the use of either value because DSCP values are backward-compatible with IP precedence values.

IP precedence values range from 0 to 7. DSCP values range from 0 to 63.

### End-to-End QoS Solution Using Classification

All switches and routers that access the Internet rely on the class information to provide the same forwarding treatment to packets with the same class information and different treatment to packets with different class information. The class information in the packet can be assigned by end hosts or by switches or routers along the way, based on a configured policy, detailed examination of the packet, or both. Detailed examination of the packet is expected to occur closer to the edge of the network, so that the core switches and routers are not overloaded with this task.

Switches and routers along the path can use the class information to limit the amount of resources allocated per traffic class. The behavior of an individual device when handling traffic in the Diff-Serv architecture is called per-hop behavior. If all devices along a path provide a consistent per-hop behavior, you can construct an end-to-end QoS solution.

Implementing QoS in your network can be a simple task or complex task and depends on the QoS features offered by your internetworking devices, the traffic types and patterns in your network, and the granularity of control that you need over incoming and outgoing traffic.

### Packet Classification

Packet classification is the process of identifying a packet as belonging to one of several classes in a defined policy, based on certain criteria. The Modular QoS CLI (MQC) is a policy-class based language. The policy class language is used to define the following:

- Class-map template with one or several match criteria
- Policy-map template with one or several classes associated to the policy map

The policy map template is then associated to one or several interfaces on the switch.

Packet classification is the process of identifying a packet as belonging to one of the classes defined in the policy map. The process of classification will exit when the packet being processed matches a specific filter in a class. This is referred to as first-match exit. If a packet matches multiple classes in a policy, irrespective of the order of classes in the policy map, it would still exit the classification process after matching the first class.

If a packet does not match any of the classes in the policy, it would be classified into the default class in the policy. Every policy map has a default class, which is a system-defined class to match packets that do not match any of the user-defined classes.

Packet classification can be categorized into the following types:

- Classification based on information that is propagated with the packet
- Classification based on information that is switch specific
- Hierarchical classification

*Classification Based on Information That is Propagated with the Packet*

Classification that is based on information that is part of the packet and propagated either end-to-end or between hops, typically includes the following:

- Classification based on Layer 3 or 4 headers
- Classification based on Layer 2 information

*Classification Based on Layer 3 or Layer 4 Header*

This is the most common deployment scenario. Numerous fields in the Layer 3 and Layer 4 headers can be used for packet classification.

At the most granular level, this classification methodology can be used to match an entire flow. For this deployment type, an access control list (ACLs) can be used. ACLs can also be used to match based on various subsets of the flow (for example, source IP address only, or destination IP address only, or a combination of both).

Classification can also be done based on the precedence or DSCP values in the IP header. The IP precedence field is used to indicate the relative priority with which a particular packet needs to be handled. It is made up of three bits in the IP header's type of service (ToS) byte.

The following table shows the different IP precedence bit values and their names.

**Note** IP precedence is not supported for wireless QoS.

**Table 80: IP Precedence Values and Names**

| IP Precedence Value | IP Precedence Bits | IP Precedence Names  |
|---------------------|--------------------|----------------------|
| 0                   | 000                | Routine              |
| 1                   | 001                | Priority             |
| 2                   | 010                | Immediate            |
| 3                   | 011                | Flash                |
| 4                   | 100                | Flash Override       |
| 5                   | 101                | Critical             |
| 6                   | 110                | Internetwork control |
| 7                   | 111                | Network control      |

**Note**

All routing control traffic in the network uses IP precedence value 6 by default. IP precedence value 7 also is reserved for network control traffic. Therefore, the use of IP precedence values 6 and 7 is not recommended for user traffic.

The DSCP field is made up of 6 bits in the IP header and is being standardized by the Internet Engineering Task Force (IETF) Differentiated Services Working Group. The original ToS byte contained the DSCP bits

has been renamed the DSCP byte. The DSCP field is part of the IP header, similar to IP precedence. The DSCP field is a super set of the IP precedence field. Therefore, the DSCP field is used and is set in ways similar to what was described with respect to IP precedence.

---

**Note** The DSCP field definition is backward-compatible with the IP precedence values.

---

#### Classification Based on Layer 2 Header

A variety of methods can be used to perform classification based on the Layer 2 header information. The most common methods include the following:

- MAC address-based classification (only for access groups)—Classification is based upon the source MAC address (for policies in the input direction) and destination MAC address (for policies in the output direction).
- Class-of-Service—Classification is based on the 3 bits in the Layer 2 header based on the IEEE 802.1p standard. This usually maps to the ToS byte in the IP header.
- VLAN ID—Classification is based on the VLAN ID of the packet.

---

**Note** Some of these fields in the Layer 2 header can also be set using a policy.

---

#### *Classification Based on Information that is Device Specific (QoS Groups)*

The switch also provides classification mechanisms that are available where classification is not based on information in the packet header or payload.

At times you might be required to aggregate traffic coming from multiple input interfaces into a specific class in the output interface. For example, multiple customer edge routers might be going into the same access switch on different interfaces. The service provider might want to police all the aggregate voice traffic going into the core to a specific rate. However, the voice traffic coming in from the different customers could have a different ToS settings. QoS group-based classification is a feature that is useful in these scenarios.

Policies configured on the input interfaces set the QoS group to a specific value, which can then be used to classify packets in the policy enabled on output interface.

The QoS group is a field in the packet data structure internal to the switch. It is important to note that a QoS group is an internal label to the switch and is not part of the packet header.

#### *Hierarchical Classification*

The switch permits you to perform a classification based on other classes. Typically, this action may be required when there is a need to combine the classification mechanisms (that is, filters) from two or more classes into a single class map.

## QoS Wired Model

To implement QoS, the switch must perform the following tasks:

- Traffic classification—Distinguishes packets or flows from one another.
- Traffic marking and policing—Assigns a label to indicate the given quality of service as the packets move through the switch, and then make the packets comply with the configured resource usage limits.

- Queuing and scheduling—Provides different treatment in all situations where resource contention exists.
- Shaping—Ensures that traffic sent from the switch meets a specific traffic profile.

### Ingress Port Activity

The following activities occur at the ingress port of the switch:

- Classification—Classifying a distinct path for a packet by associating it with a QoS label. For example, the switch maps the CoS or DSCP in the packet to a QoS label to distinguish one type of traffic from another. The QoS label that is generated identifies all future QoS actions to be performed on this packet.
- Policing—Policing determines whether a packet is in or out of profile by comparing the rate of the incoming traffic to the configured policer. The policer limits the bandwidth consumed by a flow of traffic. The result is passed to the marker.
- Marking—Marking evaluates the policer and configuration information for the action to be taken when a packet is out of profile and determines what to do with the packet (pass through a packet without modification, mark down the QoS label in the packet, or drop the packet).

#### Note

---

Applying polices on the wireless ingress port is not supported on the switch.

---

### Egress Port Activity

The following activities occur at the egress port of the switch:

- Policing—Policing determines whether a packet is in or out of profile by comparing the rate of the incoming traffic to the configured policer. The policer limits the bandwidth consumed by a flow of traffic. The result is passed to the marker.
- Marking—Marking evaluates the policer and configuration information for the action to be taken when a packet is out of profile and determines what to do with the packet (pass through a packet without modification, mark down the QoS label in the packet, or drop the packet).
- Queueing—Queueing evaluates the QoS packet label and the corresponding DSCP or CoS value before selecting which of the egress queues to use. Because congestion can occur when multiple ingress ports simultaneously send data to an egress port, Weighted Tail Drop (WTD) differentiates traffic classes and subjects the packets to different thresholds based on the QoS label. If the threshold is exceeded, the packet is dropped.

## Classification

Classification is the process of distinguishing one kind of traffic from another by examining the fields in the packet. Classification is enabled only if QoS is enabled on the switch. By default, QoS is enabled on the switch.

During classification, the switch performs a lookup and assigns a QoS label to the packet. The QoS label identifies all QoS actions to be performed on the packet and from which queue the packet is sent.

## Access Control Lists

You can use IP standard, IP extended, or Layer 2 MAC ACLs to define a group of packets with the same characteristics (class). You can also classify IP traffic based on IPv6 ACLs.

In the QoS context, the permit and deny actions in the access control entries (ACEs) have different meanings from security ACLs:

- If a match with a permit action is encountered (first-match principle), the specified QoS-related action is taken.
- If a match with a deny action is encountered, the ACL being processed is skipped, and the next ACL is processed.
- If no match with a permit action is encountered and all the ACEs have been examined, no QoS processing occurs on the packet, and the switch offers best-effort service to the packet.
- If multiple ACLs are configured on a port, the lookup stops after the packet matches the first ACL with a permit action, and QoS processing begins.

### Note

When creating an access list, note that by default the end of the access list contains an implicit deny statement for everything if it did not find a match before reaching the end.

After a traffic class has been defined with the ACL, you can attach a policy to it. A policy might contain multiple classes with actions specified for each one of them. A policy might include commands to classify the class as a particular aggregate (for example, assign a DSCP) or rate-limit the class. This policy is then attached to a particular port on which it becomes effective.

You implement IP ACLs to classify IP traffic by using the **access-list** global configuration command; you implement Layer 2 MAC ACLs to classify non-IP traffic by using the **mac access-list extended** global configuration command.

## Class Maps

A class map is a mechanism that you use to name a specific traffic flow (or class) and isolate it from all other traffic. The class map defines the criteria used to match against a specific traffic flow to further classify it. The criteria can include matching the access group defined by the ACL or matching a specific list of DSCP or IP precedence values. If you have more than one type of traffic that you want to classify, you can create another class map and use a different name. After a packet is matched against the class-map criteria, you further classify it through the use of a policy map.

You create a class map by using the **class-map** global configuration command or the **class** policy-map configuration command. You should use the **class-map** command when the map is shared among many ports. When you enter the **class-map** command, the switch enters the class-map configuration mode. In this mode, you define the match criterion for the traffic by using the **match** class-map configuration command.

You can create a default class by using the **class class-default** policy-map configuration command. The default class is system-defined and cannot be configured. Unclassified traffic (traffic that does not meet the match criteria specified in the traffic classes) is treated as default traffic.

### Related Topics

[Creating a Traffic Class \(CLI\), on page 981](#)

[Examples: Classification by Access Control Lists, on page 1037](#)

## Policy Maps

A policy map specifies which traffic class to act on. Actions can include the following:

- Setting a specific DSCP or IP precedence value in the traffic class
- Setting a CoS value in the traffic class
- Setting a QoS group
- Setting a wireless LAN (WLAN) value in the traffic class
- Specifying the traffic bandwidth limitations and the action to take when the traffic is out of profile

Before a policy map can be effective, you must attach it to a port.

You create and name a policy map using the **policy-map** global configuration command. When you enter this command, the switch enters the policy-map configuration mode. In this mode, you specify the actions to take on a specific traffic class by using the **class** or **set** policy-map configuration and policy-map class configuration commands.

The policy map can also be configured using the **police** and **bandwidth** policy-map class configuration commands, which define the policer, the bandwidth limitations of the traffic, and the action to take if the limits are exceeded. In addition, the policy-map can further be configured using the **priority** policy-map class configuration command, to schedule priority for the class or the queueing policy-map class configuration commands, **queue-buffers** and **queue-limit**.

To enable the policy map, you attach it to a port by using the **service-policy** interface configuration command.

[Port Policy Format, on page 946](#)

### *Policy Map on Physical Port*

You can configure a nonhierarchical policy map on a physical port that specifies which traffic class to act on. Actions can include setting a specific DSCP or IP precedence value in the traffic class, specifying the traffic bandwidth limitations for each matched traffic class (policer), and taking action when the traffic is out of profile (marking).

A policy map also has these characteristics:

- A policy map can contain multiple class statements, each with different match criteria and policers.
- A policy map can contain a predefined default traffic class explicitly placed at the end of the map.

When you configure a default traffic class by using the **class class-default** policy-map configuration command, unclassified traffic (traffic that does not meet the match criteria specified in the traffic classes) is treated as the default traffic class (**class-default**).

- A separate policy-map class can exist for each type of traffic received through a port.

### Related Topics

[Attaching a Traffic Policy to an Interface \(CLI\), on page 995](#)

### Policy Map on VLANs

The switch supports a VLAN QoS feature that allows the user to perform QoS treatment at the VLAN level (classification and QoS actions) using the incoming frame's VLAN information. In VLAN-based QoS, a service policy is applied to an SVI interface. All physical interfaces belonging to a VLAN policy map then need to be programmed to refer to the VLAN-based policy maps instead of the port-based policy map.

Although the policy map is applied to the VLAN SVI, any policing (rate-limiting) action can only be performed on a per-port basis. You cannot configure the policer to take account of the sum of traffic from a number of physical ports. Each port needs to have a separate policer governing the traffic coming into that port.

[Examples: Policer VLAN Configuration, on page 1047](#)

### Wireless QoS Rate Limiting

#### QoS per Client Rate Limit—Wireless

QoS policies can be configured to rate-limit client traffic using policers. This includes both real-time and non real time traffic. The non real-time traffic is policed using AFD policers. These policers can only be one rate two color.

#### Note

---

For client policy, the voice and video rate limits are applied at the same time.

---

#### QoS Downstream Rate Limit—Wireless

Downstream rate limiting is done using policing at the SSID level. AFD cannot drop real-time traffic, it can only be policed in the traffic queues. Real-time policing and AFD shaping is performed at the SSID level.

The radio has a default shaping policy. This shaping limit is the physical limit of the radio itself. You can check the policy maps on the radio by using the **show policy-map interface wireless radio** command.

### Wireless QoS Multicast

You can configure multicast policing rate at the port level.

#### Related Topics

[Configuring QoS Policies for Multicast Traffic \(CLI\), on page 1032](#)

[Examples: Wireless QoS Policy Classified by Voice, Video, and Multicast Traffic, on page 1041](#)

## Policing

After a packet is classified and has a DSCP-based, CoS-based, or QoS-group label assigned to it, the policing and marking process can begin.

Policing involves creating a policer that specifies the bandwidth limits for the traffic. Packets that exceed the limits are *out of profile* or *nonconforming*. Each policer decides on a packet-by-packet basis whether the packet is in or out of profile and specifies the actions on the packet. These actions, carried out by the marker, include passing through the packet without modification, dropping the packet, or modifying (marking down) the assigned DSCP or CoS value of the packet and allowing the packet to pass through.

To avoid out-of-order packets, both conform and nonconforming traffic typically exit the same queue.

**Note**

All traffic, regardless of whether it is bridged or routed, is subjected to a policer, if one is configured. As a result, bridged packets might be dropped or might have their DSCP or CoS fields modified when they are policed and marked.

You can only configure policing on a physical port.

After you configure the policy map and policing actions, attach the policy to an ingress port or SVI by using the **service-policy** interface configuration command.

**Related Topics**

[Configuring Police \(CLI\), on page 1019](#)

[Examples: Policing Action Configuration, on page 1046](#)

**Token-Bucket Algorithm**

Policing uses a token-bucket algorithm. As each frame is received by the switch, a token is added to the bucket. The bucket has a hole in it and leaks at a rate that you specify as the average traffic rate in bits per second. Each time a token is added to the bucket, the switch verifies that there is enough room in the bucket. If there is not enough room, the packet is marked as nonconforming, and the specified policer action is taken (dropped or marked down).

How quickly the bucket fills is a function of the bucket depth (burst-byte), the rate at which the tokens are removed (rate-bps), and the duration of the burst above the average rate. The size of the bucket imposes an upper limit on the burst length and limits the number of frames that can be transmitted back-to-back. If the burst is short, the bucket does not overflow, and no action is taken against the traffic flow. However, if a burst is long and at a higher rate, the bucket overflows, and the policing actions are taken against the frames in that burst.

You configure the bucket depth (the maximum burst that is tolerated before the bucket overflows) by using the burst-byte option of the **police** policy-map class configuration command. You configure how fast (the average rate) that the tokens are removed from the bucket by using the rate option of the **police** policy-map class configuration command.

**Related Topics**

[Configuring Police \(CLI\), on page 1019](#)

[Examples: Policing Units, on page 1047](#)

**Marking**

Marking is used to convey specific information to a downstream device in the network, or to carry information from one interface in a switch to another.

Marking can be used to set certain field/bits in the packet headers, or marking can also be used to set certain fields in the packet structure that is internal to the switch. Additionally, the marking feature can be used to define mapping between fields. The following marking methods are available for QoS:

- Packet header
- Device (switch) specific information
- Table maps

## Packet Header Marking

Marking on fields in the packet header can be classified into two general categories:

- IPv4/v6 header bit marking
- Layer 2 header bit marking

The marking feature at the IP level is used to set the precedence or the DSCP in the IP header to a specific value to get a specific per-hop behavior at the downstream device (switch or router), or it can also be used to aggregate traffic from different input interfaces into a single class in the output interface. The functionality is currently supported on both the IPv4 and IPv6 headers.

Marking in the Layer 2 headers is typically used to influence dropping behavior in the downstream devices (switch or router). It works in tandem with the match on the Layer 2 headers. The bits in the Layer 2 header that can be set using a policy map are class of service.

## Switch Specific Information Marking

This form of marking includes marking of fields in the packet data structure that are not part of the packets header, so that the marking can be used later in the data path. This is not propagated between the switches. Marking of QoS-group falls into this category. This form of marking is only supported in policies that are enabled on the input interfaces. The corresponding matching mechanism can be enabled on the output interfaces on the same switch and an appropriate QoS action can be applied.

## Table Map Marking

Table map marking enables the mapping and conversion from one field to another using a conversion table. This conversion table is called a table map.

Depending upon the table map attached to an interface, CoS, DSCP, and UP values (UP specific to wireless packets) of the packet are rewritten. The switch allows configuring both ingress table map policies and egress table map policies.

### Note

The switch stack supports a total of 14 table maps. Only one table map is supported per wired port, per direction.

As an example, a table map can be used to map the Layer 2 CoS setting to a precedence value in Layer 3. This feature enables combining multiple **set** commands into a single table, which indicates the method to perform the mapping. This table can be referenced in multiple policies, or multiple times in the same policy.

The following table shows the currently supported forms of mapping:

**Table 81: Packet-Marking Types Used for Establishing a To-From Relationship**

| The To Packet-Marking Type | The From Packet-Marking Type |
|----------------------------|------------------------------|
| Precedence                 | CoS                          |
| Precedence                 | QoS Group                    |
| DSCP                       | CoS                          |

| The To Packet-Marking Type | The From Packet-Marking Type |
|----------------------------|------------------------------|
| DSCP                       | QoS Group                    |
| CoS                        | Precedence                   |
| CoS                        | DSCP                         |
| QoS Group                  | Precedence                   |
| QoS Group                  | DSCP                         |

A table map-based policy supports the following capabilities:

- Mutation—You can have a table map that maps from one DSCP value set to another DSCP value set, and this can be attached to an egress port.
- Rewrite—Packets coming in are rewritten depending upon the configured table map.
- Mapping—Table map based policies can be used instead of set policies.

The following steps are required for table map marking:

- 1 Define the table map—Use the **table-map** global configuration command to map the values. The table does not know of the policies or classes within which it will be used. The default command in the table map is used to indicate the value to be copied into the to field when there is no matching from field.
- 2 Define the policy map—You must define the policy map where the table map will be used.
- 3 Associate the policy to an interface.

**Note**

A table map policy on an input port changes the trust setting of that port to the from type of qos-marking.

[Examples: Table Map Marking Configuration, on page 1048](#)

## Traffic Conditioning

To support QoS in a network, traffic entering the service provider network needs to be policed on the network boundary routers to ensure that the traffic rate stays within the service limit. Even if a few routers at the network boundary start sending more traffic than what the network core is provisioned to handle, the increased traffic load leads to network congestion. The degraded performance in the network makes it difficult to deliver QoS for all the network traffic.

Traffic policing functions (using the police feature) and shaping functions (using the traffic shaping feature) manage the traffic rate, but differ in how they treat traffic when tokens are exhausted. The concept of tokens comes from the token bucket scheme, a traffic metering function.

**Note**

When running QoS tests on network traffic, you may see different results for the shaper and policing data. Network traffic data from shaping provides more accurate results.

This table compares the policing and shaping functions.

**Table 82: Comparison Between Policing and Shaping Functions**

| <b>Policing Function</b>                                                                                                                                    | <b>Shaping Function</b>                                                                                                                                                                          |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Sends conforming traffic up to the line rate and allows bursts.                                                                                             | Smooths traffic and sends it out at a constant rate.                                                                                                                                             |
| When tokens are exhausted, action is taken immediately.                                                                                                     | When tokens are exhausted, it buffers packets and sends them out later, when tokens are available. A class with shaping has a queue associated with it which will be used to buffer the packets. |
| Policing has multiple units of configuration – in bits per second, packets per second and cells per second.                                                 | Shaping has only one unit of configuration - in bits per second.                                                                                                                                 |
| Policing has multiple possible actions associated with an event, marking and dropping being example of such actions.                                        | Shaping does not have the provision to mark packets that do not meet the profile.                                                                                                                |
| Works for both input and output traffic.                                                                                                                    | Implemented for output traffic only.                                                                                                                                                             |
| Transmission Control Protocol (TCP) detects the line at line speed but adapts to the configured rate when a packet drop occurs by lowering its window size. | TCP can detect that it has a lower speed line and adapt its retransmission timer accordingly. This results in less scope of retransmissions and is TCP-friendly.                                 |

## Policing

The QoS policing feature is used to impose a maximum rate on a traffic class. The QoS policing feature can also be used with the priority feature to restrict priority traffic. If the rate is exceeded, then a specific action is taken as soon as the event occurs. The rate (committed information rate [CIR] and peak information rate [PIR] ) and the burst parameters (conformed burst size [  $B_c$  ] and extended burst size [  $B_e$  ] ) are all configured in bytes per second.

The following policing forms or policers are supported for QoS:

- Single-rate two-color policing
- Dual-rate three-color policing

**Note**

Single-rate three-color policing is not supported.

### Single-Rate Two-Color Policing

Single-rate two-color policer is the mode in which you configure only a CIR and a  $B_c$ .

The  $B_c$  is an optional parameter, and if it is not specified it is computed by default. In this mode, when an incoming packet has enough tokens available, the packet is considered to be conforming. If at the time of packet arrival, enough tokens are not available within the bounds of  $B_c$ , the packet is considered to have exceeded the configured rate.

---

**Note** For information about the token-bucket algorithm, see [Token-Bucket Algorithm, on page 960](#).

---

#### Related Topics

[Configuring Police \(CLI\), on page 1019](#)

[Examples: Single-Rate Two-Color Policing Configuration, on page 1048](#)

### Dual-Rate Three-Color Policing

With the dual rate policer, the switch supports only color-blind mode. In this mode, you configure a committed information rate (CIR) and a peak information rate (PIR). As the name suggests, there are two token buckets in this case, one for the peak rate, and one for the conformed rate.

---

**Note** For information about the token-bucket algorithm, see [Token-Bucket Algorithm, on page 960](#).

---

In the color-blind mode, the incoming packet is first checked against the peak rate bucket. If there are not enough tokens available, the packet is said to violate the rate. If there are enough tokens available, then the tokens in the conformed rate buckets are checked to determine if there are enough tokens available. The tokens in the peak rate bucket are decremented by the size of the packet. If it does not have enough tokens available, the packet is said to have exceeded the configured rate. If there are enough tokens available, then the packet is said to conform, and the tokens in both the buckets are decremented by the size of the packet.

The rate at which tokens are replenished depends on the packet arrival. Assume that a packet comes in at time T1 and the next one comes in at time T2. The time interval between T1 and T2 determines the number of tokens that need to be added to the token bucket. This is calculated as:

Time interval between packets  $(T2-T1) * CIR/8$  bytes

[Configuring Police \(CLI\), on page 1019](#)

[Examples: Dual-Rate Three-Color Policing Configuration, on page 1048](#)

## Shaping

Shaping is the process of imposing a maximum rate of traffic, while regulating the traffic rate in such a way that the downstream switches and routers are not subjected to congestion. Shaping in the most common form is used to limit the traffic sent from a physical or logical interface.

Shaping has a buffer associated with it that ensures that packets which do not have enough tokens are buffered as opposed to being immediately dropped. The number of buffers available to the subset of traffic being shaped is limited and is computed based on a variety of factors. The number of buffers available can also be tuned using specific QoS commands. Packets are buffered as buffers are available, beyond which they are dropped.

### Class-Based Traffic Shaping

The switch uses class-based traffic shaping. This shaping feature is enabled on a class in a policy that is associated to an interface. A class that has shaping configured is allocated a number of buffers to hold the packets that do not have tokens. The buffered packets are sent out from the class using FIFO. In the most common form of usage, class-based shaping is used to impose a maximum rate for an physical interface or logical interface as a whole. The following shaping forms are supported in a class:

- Average rate shaping
- Hierarchical shaping

Shaping is implemented using a token bucket. The values of CIR,  $B_c$  and  $B_e$  determine the rate at which the packets are sent out and the rate at which the tokens are replenished.

#### Note

For information about the token-bucket algorithm, see [Token-Bucket Algorithm](#), on page 960.

### Average Rate Shaping

You use the **shape average** policy-map class command to configure average rate shaping.

This command configures a maximum bandwidth for a particular class. The queue bandwidth is restricted to this value even though the port has more bandwidth available. The switch supports configuring shape average by either a percentage or by a target bit rate value.

#### Related Topics

[Configuring Shaping \(CLI\)](#), on page 1029

[Examples: Average Rate Shaping Configuration](#), on page 1044

### Hierarchical Shaping

Shaping can also be configured at multiple levels in a hierarchy. This is accomplished by creating a parent policy with shaping configured, and then attaching child policies with additional shaping configurations to the parent policy.

There are two supported types of hierarchical shaping:

- Port shaper
- User-configured shaping

The port shaper uses the class default and the only action permitted in the parent is shaping. The queueing action is in the child with the port shaper. With the user configured shaping, you cannot have queueing action in the child.

#### Related Topics

[Configuring Shaping \(CLI\)](#), on page 1029

## Queueing and Scheduling

The switch uses both queueing and scheduling to help prevent traffic congestion. The switch supports the following queueing and scheduling features:

- Bandwidth

- Weighted Tail Drop
- Priority queues
- Queue buffers

## Bandwidth

The switch supports the following bandwidth configurations:

- Bandwidth percent
- Bandwidth remaining ratio

### Related Topics

[Configuring Bandwidth \(CLI\)](#), on page 1017

#### *Bandwidth Percent*

You can use the **bandwidth percent** policy-map class command to allocate a minimum bandwidth to a particular class. The total sum cannot exceed 100 percent and in case the total sum is less than 100 percent, then the rest of the bandwidth is divided equally among all bandwidth queues.

#### **Note**

A queue can oversubscribe bandwidth in case the other queues do not utilize the entire port bandwidth.

You cannot mix bandwidth types on a policy map. For example, you cannot configure bandwidth in a single policy map using both a bandwidth percent and in kilobits per second.

#### *Bandwidth Remaining Ratio*

You use the **bandwidth remaining ratio** policy-map class command to create a ratio for sharing unused bandwidth in specified queues. Any unused bandwidth will be used by these specific queues in the ratio that is specified by the configuration. Use this command when the **priority** command is also used for certain queues in the policy.

When you assign ratios, the queues will be assigned certain weights which are inline with these ratios.

You can specify ratios using a range from 0 to 100. For example, you can configure a bandwidth remaining ratio of 2 on one class, and another queue with a bandwidth remaining ratio of 4 on another class. The bandwidth remaining ratio of 4 will be scheduled twice as often as the bandwidth remaining ratio of 2.

The total bandwidth ratio allocation for the policy can exceed 100. For example, you can configure a queue with a bandwidth remaining ratio of 50, and another queue with a bandwidth remaining ratio of 100.

## Weighted Tail Drop

The switch egress queues use an enhanced version of the tail-drop congestion-avoidance mechanism called weighted tail drop (WTD). WTD is implemented on queues to manage the queue lengths and to provide drop precedences for different traffic classifications.

As a frame is enqueued to a particular queue, WTD uses the frame's assigned QoS label to subject it to different thresholds. If the threshold is exceeded for that QoS label (the space available in the destination queue is less than the size of the frame), the switch drops the frame.

Each queue has three configurable threshold values. The QoS label determines which of the three threshold values is subjected to the frame.

The following figure shows an example of WTD operating on a queue whose size is 1000 frames. Three drop percentages are configured: 40 percent (400 frames), 60 percent (600 frames), and 100 percent (1000 frames). These percentages indicate that up to 400 frames can be queued at the 40-percent threshold, up to 600 frames at the 60-percent threshold, and up to 1000 frames at the 100-percent threshold.

**Figure 63: WTD and Queue Operation**

In the example, CoS value 6 has a greater importance than the other CoS values, and is assigned to the 100-percent drop threshold (queue-full state). CoS values 4 is assigned to the 60-percent threshold, and CoS values 3 is assigned to the 40-percent threshold. All of these threshold values are assigned using the **queue-limit cos** command.

Assuming the queue is already filled with 600 frames, and a new frame arrives. It contains CoS value 4 and is subjected to the 60-percent threshold. If this frame is added to the queue, the threshold will be exceeded, so the switch drops it.

### Related Topics

[Configuring Queue Limits \(CLI\), on page 1026](#)

[Examples: Queue-limit Configuration, on page 1045](#)

### Weighted Tail Drop Default Values

The following are the Weighted Tail Drop (WTD) default values and the rules for configuring WTD threshold values.

- If you configure less than three queue-limit percentages for WTD, then WTD default values are assigned to these thresholds.

The following are the WTD threshold default values:

**Table 83: WTD Threshold Default Values**

| Threshold | Default Value Percentage |
|-----------|--------------------------|
| 0         | 80                       |
| 1         | 90                       |
| 2         | 400                      |

- If 3 different WTD thresholds are configured, then the queues are programmed as configured.

- If 2 WTD thresholds are configured, then the maximum value percentage will be 400.
- If a WTD single threshold is configured as x, then the maximum value percentage will be 400.
  - If the value of x is less than 90, then threshold1=90 and threshold 0= x.
  - If the value of x equals 90, then threshold1=90, threshold 0=80.
  - If the value x is greater than 90, then threshold1=x, threshold 0=80.

## Priority Queues

Each port supports eight egress queues, of which two can be given a priority.

You use the **priority level** policy class-map command to configure the priority for two classes. One of the classes has to be configured with a priority queue level 1, and the other class has to be configured with a priority queue level 2. Packets on these two queues are subjected to less latency with respect to other queues.

### Related Topics

[Configuring Priority \(CLI\), on page 1022](#)

## Queue Buffer

Each 1-gigabit port on the switch is allocated 168 buffers for a wireless port and 300 buffers for a wired port. Each 10-gigabit port is allocated 1800 buffers. At boot time, when there is no policy map enabled on the wired port, there are two queues created by default. Wired ports can have a maximum of 8 queues configured using MQC-based policies. The following table shows which packets go into which one of the queues:

**Table 84: DSCP, Precedence, and CoS - Queue Threshold Mapping Table**

| DSCP, Precedence or CoS | Queue | Threshold |
|-------------------------|-------|-----------|
| Control Packets         | 0     | 2         |
| Rest of Packets         | 1     | 2         |

### Note

You can guarantee the availability of buffers, set drop thresholds, and configure the maximum memory allocation for a queue. You use the **queue-buffers** policy-map class command to configure the queue buffers. You use the **queue-limit** policy-map class command to configure the maximum thresholds.

There are two types of buffer allocations: hard buffers, which are explicitly reserved for the queue, and soft buffers, which are available for other ports when unused by a given port.

For the wireless port default, Queue 0 will be given 40 percent of the buffers that are available for the interface as hard buffers, that is 67 buffers are allocated for Queue 0 in the context of 1-gigabit ports. The soft maximum for this queue is set to 268 (calculated as  $67 * 400/100$ ) for 1-gigabit ports, where 400 is the default maximum threshold that is configured for any queue.

For the wired port default, Queue 0 will be given 40 percent of the buffers that are available for the interface as hard buffers, that is 120 buffers are allocated for Queue 0 in the context of 1-gigabit ports, and 720 buffers

in the context of 10-gigabit ports. The soft maximum for this queue is set to 480 (calculated as  $120 * 400/100$ ) for 1-gigabit ports and 2880 for 10-gigabit ports, where 400 is the default maximum threshold that is configured for any queue.

Queue 1 does not have any hard buffers allocated. The default soft buffer limit is set to 400 (which is the maximum threshold). The threshold would determine the maximum number of soft buffers that can be borrowed from the common pool.

### *Queue Buffer Allocation*

The buffer allocation to any queue can be tuned using the **queue-buffers ratio** policy-map class configuration command.

### **Related Topics**

[Configuring Queue Buffers \(CLI\), on page 1024](#)

[Examples: Queue Buffers Configuration, on page 1045](#)

### *Dynamic Threshold and Scaling*

Traditionally, reserved buffers are statically allocated for each queue. No matter whether the queue is active or not, its buffers are held up by the queue. In addition, as the number of queues increases, the portion of the reserved buffers allocated for each queue can become smaller and smaller. Eventually, a situation may occur where there are not enough reserved buffers to support a jumbo frame for all queues.

The switch supports Dynamic Thresholding and Scaling (DTS), which is a feature that provides a fair and efficient allocation of buffer resources. When congestion occurs, this DTS mechanism provides an elastic buffer allocation for the incoming data based on the occupancy of the global/port resources. Conceptually, DTS scales down the queue buffer allocation gradually as the resources are used up to leave room for other queues, and vice versa. This flexible method allows the buffers to be more efficiently and fairly utilized.

As mentioned in the previous sections, there are two limits configured on a queue—a hard limit and a soft limit.

Hard limits are not part of DTS. These buffers are available only for that queue. The sum of the hard limits should be less than the globally set up hard maximum limit. The global hard limit configured for egress queuing is currently set to 5705. In the default scenario when there are no MQC policies configured, the 24 1-gigabit ports would take up  $24 * 67 = 1608$ , and the 4 10-gigabit ports would take up  $4 * 720 = 2880$ , for a total of 4488 buffers, allowing room for more hard buffers to be allocated based upon the configuration.

Soft limit buffers participate in the DTS process. Additionally, some of the soft buffer allocations can exceed the global soft limit allocation. The global soft limit allocation for egress queuing is currently set to 7607. The sum of the hard and soft limits add up to 13312, which in turn translates to 3.4 MB. Because the sum of the soft buffer allocations can exceed the global limit, it allows a specific queue to use a large number of buffers when the system is lightly loaded. The DTS process dynamically adjusts the per-queue allocation as the system becomes more heavily loaded.

## **Queuing in Wireless**

Queuing in the wireless component is performed based on the port policy and is applicable only in the downstream direction. The wireless module supports the following four queues:

- **Voice**—This is a strict priority queue. Represented by Q0, this queue processes control traffic and multicast or unicast voice traffic. All control traffic (such as CAPWAP packets) is processed through the voice queue. The QoS module uses a different threshold within the voice queue to process control and voice packets to ensure that control packets get higher priority over other non-control packets.

- Video—This is a strict priority queue. Represented by Q1, this queue processes multicast or unicast video traffic.
- Data NRT—Represented by Q2, this queue processes all non-real-time unicast traffic.
- Multicast NRT—Represented by Q3, this queue processes Multicast NRT traffic. Any traffic that does not match the traffic in Q0, Q1, or Q2 is processed through Q3.

---

**Note** By default, the queues Q0 and Q1 are not enabled.

---

---

**Note** A weighted round-robin policy is applied for traffic in the queues Q2 and Q3.

---

For upstream direction only one queue is available. Port and radio policies are applicable only in the downstream direction.

---

**Note** The wired ports support eight queues.

---

## Trust Behavior

### Trust Behavior for Wired and Wireless Ports

For wired or wireless ports that are connected to the switch (end points such as IP phones, laptops, cameras, telepresence units, or other devices), their DSCP, precedence, or CoS values coming in from these end points are trusted by the switch and therefore are retained in the absence of any explicit policy configuration.

This trust behavior is applicable to both upstream and downstream QoS.

The packets are enqueued to the appropriate queue per the default initial configuration. No priority queuing at the switch is done by default. This is true for unicast and multicast packets.

In scenarios where the incoming packet type differs from the outgoing packet type, the trust behavior and the queuing behavior are explained in the following table. Note that the default trust mode for a port is DSCP based. The trust mode 'falls back' to CoS if the incoming packet is a pure Layer 2 packet. You can also change the trust setting from DSCP to CoS. This setting change is accomplished by using an MQC policy that has a class default with a 'set cos cos table default default-cos' action, where default-cos is the name of the table map created (which only performs a default copy).

**Table 85: Trust and Queuing Behavior**

| Incoming Packet | Outgoing Packet | Trust Behavior           | Queuing Behavior                            |
|-----------------|-----------------|--------------------------|---------------------------------------------|
| Layer 3         | Layer 3         | Preserve DSCP/Precedence | Based on DSCP                               |
| Layer 2         | Layer 2         | Not applicable           | Based on CoS                                |
| Tagged          | Tagged          | Preserve DSCP and CoS    | Based on DSCP (trust DSCP takes precedence) |

| Incoming Packet | Outgoing Packet | Trust Behavior                 | Queuing Behavior |
|-----------------|-----------------|--------------------------------|------------------|
| Layer 3         | Tagged          | Preserve DSCP, CoS is set to 0 | Based on DSCP    |

The Cisco IOS XE 3.2 Release supported different trust defaults for wired and wireless ports. The trust default for wired ports was the same as for this software release. For wireless ports, the default system behavior was non-trust, which meant that when the switch came up, all markings for the wireless ports were defaulted to zero and no traffic received priority treatment. For compatibility with an existing wired switch, all traffic went to the best-effort queue by default. The access point performed priority queuing by default. In the downstream direction, the access point maintained voice, video, best-effort, and background queues for queuing. The access selected the queuing strategy based on the 11e tag information. By default, the access point treated all wireless packets as best effort.

The default trust behavior in the case of wireless ports could be changed by using the **qos wireless default untrust** command.

**Note**

If you upgrade from Cisco IOS XE 3.2 SE Release to a later release, the default behavior of the wireless traffic is still untrusted. In this situation, you can use the **no qos wireless-default untrust** command to enable trust behavior for wireless traffic. However, if you install Cisco IOS XE 3.3 SE or a later release on the switch, the default QoS behavior for wireless traffic is trust. Starting with Cisco IOS XE 3.3 SE Release and later, the packet markings are preserved in both egress and ingress directions for new installations (not upgrades) for wireless traffic.

**Related Topics**

[Configuring Trust Behavior for Wireless Traffic \(CLI\), on page 1009](#)

[Example: Table Map Configuration to Retain CoS Markings, on page 1049](#)

**Port Security on a Trusted Boundary for Cisco IP Phones**

In a typical network, you connect a Cisco IP Phone to a switch port and cascade devices that generate data packets from the back of the telephone. The Cisco IP Phone guarantees the voice quality through a shared data link by marking the CoS level of the voice packets as high priority (CoS = 5) and by marking the data packets as low priority (CoS = 0). Traffic sent from the telephone to the switch is typically marked with a tag that uses the 802.1Q header. The header contains the VLAN information and the class of service (CoS) 3-bit field, which is the priority of the packet.

For most Cisco IP Phone configurations, the traffic sent from the telephone to the switch should be trusted to ensure that voice traffic is properly prioritized over other types of traffic in the network. By using the **trust device** interface configuration command, you configure the switch port to which the telephone is connected to trust the traffic received on that port.

**Note**

The **trust device** *device\_type* interface configuration command is only supported in an auto-QoS configuration, and not as a stand-alone command on the switch. When using the **trust device** *device\_type* interface configuration command in an auto-QoS configuration, if the connected peer device is not a corresponding device (defined as a device matching your trust policy), both CoS and DSCP values are set to "0" and any input policy will not take effect.

With the trusted setting, you also can use the trusted boundary feature to prevent misuse of a high-priority queue if a user bypasses the telephone and connects the PC directly to the switch. Without trusted boundary, the CoS labels generated by the PC are trusted by the switch (because of the trusted CoS setting). By contrast, trusted boundary uses CDP to detect the presence of a Cisco IP Phone (such as the Cisco IP Phone 7910, 7935, 7940, and 7960) on a switch port. If the telephone is not detected, the trusted boundary feature disables the trusted setting on the switch port and prevents misuse of a high-priority queue. Note that the trusted boundary feature is not effective if the PC and Cisco IP Phone are connected to a hub that is connected to the switch.

**Related Topics**

[Configuring Trust Behavior for the Device Type](#)

## Wireless QoS Mobility

Wireless QoS mobility enables you to configure QoS policies so that the network provides the same service anywhere in the network. A wireless client can roam from one location to another and as a result the client can get associated to different access points associated with a different switch. Wireless client roaming can be classified into two types:

- Intra-switch roaming
- Inter-switch roaming

**Note**

The client policies must be available on all of the switches in the mobility group. The same SSID and port policy must be applied to all switches in the mobility group so that the clients get consistent treatment.

### Inter-Switch Roaming

When a client roams from one location to another, the client can get associated to access points either associated to the same switch (anchor switch) or a different switch (foreign switch). Inter-switch roaming refers to the scenario where the client gets associated to an access point that is not associated to the same device before the client roamed. The host device is now foreign to the device to which the client was initially anchored.

In the case of inter-switch roaming, the client QoS policy is always executed on the foreign controller. When a client roams from anchor switch to foreign switch, the QoS policy is uninstalled on the anchor switch and installed on the foreign switch. In the mobility handoff message, the anchor device passes the name of the policy to the foreign switch. The foreign switch should have a policy with the same name configured for the QoS policy to be applied correctly.

In the case of inter-switch roaming, all of the QoS policies are moved from the anchor device to the foreign device. While the QoS policies are in transition from the anchor device to the foreign device, the traffic on

the foreign device is provided the default treatment. This is comparable to a new policy installation on the client target.

**Note**

If the foreign device is not configured with the user-defined physical port policy, the default port policy is applicable to all traffic is routed through the NRT queue, except the control traffic which goes through RT1 queue. The network administrator must configure the same physical port policy on both the anchor and foreign devices symmetrically.

### Intra-Switch Roaming

With intra-switch roaming, the client gets associated to an access point that is associated to the same switch before the client roamed, but this association to the device occurs through a different access point.

**Note**

QoS policies remain intact in the case of intra-switch roaming.

## Precious Metal Policies for Wireless QoS

Wireless QoS is backward compatible with the precious metal policies offered by the unified wireless controller platforms. The precious metal policies are system-defined policies that are available on the controller.

The following policies are available:

- Platinum—Used for VoIP clients.
- Gold—Used for video clients.
- Silver— Used for traffic that can be considered best-effort.
- Bronze—Used for NRT traffic.

These policies (also known as profiles) can be applied to a WLAN based on the traffic. We recommend the configuration using the Cisco IOS MQC configuration. The policies are available in the system based on the precious metal policy required.

Based on the policies applied, the 802.1p, 802.11e (WMM), and DSCP fields in the packets are affected. These values are preconfigured and installed when the switch is booted.

**Note**

Unlike the precious metal policies that were applicable in the Cisco Unified Wireless controllers, the attributes `rt-average-rate`, `nrt-average-rate`, and `peak rates` are not applicable for the precious metal policies configured on this switch platform.

### Related Topics

[Configuring Precious Metal Policies \(CLI\)](#), on page 1031

## Standard QoS Default Settings

### Default Wired QoS Configuration

There are two queues configured by default on each wired interface on the switch. All control traffic traverses and is processed through queue 0. All other traffic traverses and is processed through queue 1.

### DSCP Maps

#### Default CoS-to-DSCP Map

You use the CoS-to-DSCP map to map CoS values in incoming packets to a DSCP value that QoS uses internally to represent the priority of the traffic. The following table shows the default CoS-to-DSCP map. If these values are not appropriate for your network, you need to modify them.

**Table 86: Default CoS-to-DSCP Map**

| CoS Value | DSCP Value |
|-----------|------------|
| 0         | 0          |
| 1         | 8          |
| 2         | 16         |
| 3         | 24         |
| 4         | 32         |
| 5         | 40         |
| 6         | 48         |
| 7         | 56         |

#### Default IP-Precedence-to-DSCP Map

You use the IP-precedence-to-DSCP map to map IP precedence values in incoming packets to a DSCP value that QoS uses internally to represent the priority of the traffic. The following table shows the default IP-precedence-to-DSCP map. If these values are not appropriate for your network, you need to modify them.

**Table 87: Default IP-Precedence-to-DSCP Map**

| IP Precedence Value | DSCP Value |
|---------------------|------------|
| 0                   | 0          |
| 1                   | 8          |
| 2                   | 16         |

| IP Precedence Value | DSCP Value |
|---------------------|------------|
| 3                   | 24         |
| 4                   | 32         |
| 5                   | 40         |
| 6                   | 48         |
| 7                   | 56         |

### Default DSCP-to-CoS Map

You use the DSCP-to-CoS map to generate a CoS value, which is used to select one of the four egress queues. The following table shows the default DSCP-to-CoS map. If these values are not appropriate for your network, you need to modify them.

**Table 88: Default DSCP-to-CoS Map**

| DSCP Value | CoS Value |
|------------|-----------|
| 0–7        | 0         |
| 8–15       | 1         |
| 16–23      | 2         |
| 24–31      | 3         |
| 32–39      | 4         |
| 40–47      | 5         |
| 48–55      | 6         |
| 56–63      | 7         |

### Default Wireless QoS Configuration

The ports on the switch do not distinguish between wired or wireless physical ports. Depending on the kind of device associated to the switch, the policies are applied. For example, when an access point is connected to a switch port, the switch detects it as a wireless device and applies the default hierarchical policy which is in the format of a parent-child policy. This policy is an hierarchical policy. The parent policy cannot be modified but the child policy (port-child policy) can be modified to suite the QoS configuration. The switch is preconfigured with a default class map and a policy map.

## Restrictions for QoS on Wired Targets

A target is an entity where a policy is applied. You can apply a policy to either a wired or wireless target. A wired target can be either a port or VLAN. A wireless target can be either a port, radio, SSID, or client. Only port, SSID, and client policies are user configurable. Radio policies are not user configurable. Wireless QoS policies for port, radio, SSID, and client are applied in the downstream direction, and for upstream only SSID and client targets are supported. Downstream indicates that traffic is flowing from the switch to the wireless client. Upstream indicates that traffic is flowing from wireless client to the switch.

The following are restrictions for applying QoS features on the switch for the wired target:

- A maximum of 8 queuing classes are supported on the switch port for the wired target.
- A maximum of 63 policers are supported per policy on the wired port for the wired target.
- No more than two levels are supported in a QoS hierarchy.
- In a hierarchical policy, overlapping actions between parent and child are not allowed, except when a policy has the port shaper in the parent and queueing features in the child policy.
- A QoS policy cannot be attached to any EtherChannel interface.
- Policing in both the parent and child is not supported in a QoS hierarchy.
- Marking in both the parent and child is not supported in a QoS hierarchy.
- A mixture of queue limit and queue buffer in the same policy is not supported.

---

**Note** The queue-limit percent is not supported on the switch because the **queue-buffer** command handles this functionality. Queue limit is only supported with the DSCP and CoS extensions.

---

- The classification sequence for all wired queuing-based policies should be the same across all wired upstream ports (10-Gigabit Ethernet), and the same for all downstream wired ports (1-Gigabit Ethernet).
- Empty classes are not supported.
- Class-maps with empty actions are not supported.
- A maximum of 256 classes are supported per policy on the wired port for the wired target.
- The actions under a policer within a policy map have the following restrictions:
  - The conform action must be transmit.
  - The exceed/violate action for markdown type can only be cos2cos, prec2prec, dscp2dscp.
  - The markdown types must be the same within a policy.
- Classification counters have the following specific restrictions:
  - Classification counters count packets instead of bytes.
  - Only QoS configurations with marking or policing trigger the classification counter.
  - The classification counter is not port based. This means that the classification counter aggregates all packets belonging to the same class of the same policy which attach to different interfaces.

- As long as there is policing or marking action in the policy, the class-default will have classification counters.
- When there are multiple match statements in a class, then the classification counter only shows the traffic counter for one of the match statements.
- Table maps have the following specific restrictions:
  - Only one table map for policing exceeding the markdown and one table map for policing violating the markdown per direction per target is supported.
  - Table maps must be configured under the class-default; table maps are unsupported for a user-defined class.
- Hierarchical policies are required for the following:
  - Port-shapers
  - Aggregate policers
  - PV policy
  - Parent shaping and child marking/policing
- For ports with wired targets, these are the only supported hierarchical policies:
  - Police chaining in the same policy is unsupported, except for wireless client.
  - Hierarchical queueing is unsupported in the same policy (port shaper is the exception).
  - In a parent class, all filters must have the same type. The child filter type must match the parent filter type with the following exceptions:
    - If the parent class is configured to match IP, then the child class can be configured to match the ACL.
    - If the parent class is configured to match CoS, then the child class can be configured to match the ACL.
- The **trust device** *device\_type* interface configuration command is only supported in an auto-QoS configuration, and not as a stand-alone command on the switch. When using the **trust device** *device\_type* interface configuration command in an auto-QoS configuration, if the connected peer device is not a corresponding device (defined as a device matching your trust policy), both CoS and DSCP values are set to "0" and any input policy will not take effect.

The following are restrictions for applying QoS features on the VLAN to the wired target:

- For a flat or nonhierarchical policy, only marking or a table map is supported.

The following are restrictions and considerations for applying QoS features on EtherChannel and channel member interfaces:

- QoS is not supported on an EtherChannel interface.
- QoS is supported on EtherChannel member interfaces in both ingress and egression directions. All EtherChannel members must have the same QoS policy applied. If the QoS policy is not the same, each individual policy on the different link acts independently.

- On attaching a service policy to channel members, the following warning message appears to remind the user to make sure the same policy is attached to all ports in the EtherChannel: ' Warning: add service policy will cause inconsistency with port xxx in ether channel xxx. '.
- Auto QoS is not supported on EtherChannel members.

**Note**

On attaching a service policy to an EtherChannel, the following message appears on the console: ' Warning: add service policy will cause inconsistency with port xxx in ether channel xxx. '. This warning message should be expected. This warning message is a reminder to attach the same policy to other ports in the same EtherChannel. The same message will be seen during boot up. This message does not mean there is a discrepancy between the EtherChannel member ports.

**Related Topics**

- [Restrictions for QoS on Wireless Targets, on page 978](#)

## Restrictions for QoS on Wireless Targets

**General Restrictions**

A target is an entity where a policy is applied. You can apply a policy to either a wired or wireless target. A wired target can be either a port or VLAN. A wireless target can be either a port, radio, SSID, or client. Only port, SSID, and client policies are user configurable. Radio policies are not user configurable. Wireless QoS policies for port, radio, SSID, and client are applied in the downstream direction, and for upstream only SSID and client targets are supported. Downstream indicates that traffic is flowing from the switch to the wireless client. Upstream indicates that traffic is flowing from wireless client to the switch.

- Only port, SSID, and client (using AAA and Cisco IOS command-line interface) policies are user-configurable. Radio policies are set by the wireless control module and are not user-configurable.
- Port and radio policies are applicable only in the downstream direction.
- SSID and client support non-queuing policies in the upstream direction.  
SSID and client targets can be configured with marking and policing policies.
- One policy per target per direction is supported.

**Wireless QoS Restrictions on Ports**

The following are restrictions for applying QoS features on a wireless port target:

- All wireless ports have similar parent policy with one class-default and one action shape under class-default. Shape rates are dependent on the 802.11a/b/g/ac bands.
- You can create a maximum of four classes in a child policy by modifying the `port_chlid_policy`.

- If there are four classes in the `port_child_policy` at the port level, one must be a non-client-nrt class and one must be class-default.
- No two classes can have the same priority level. Only priority level 1 (for voice traffic and control traffic) and 2 (for video) are supported.
- Priority is not supported in the multicast NRT class (non-client-nrt class) and `class-default`.
- If four classes are configured, two of them have to be priority classes. If only three classes are configured, at least one of them should be a priority class. If three classes are configured and there is no non-client-nrt class, both priority levels must be present.
- Only match DSCP is supported.
- The port policy applied by the wireless control module cannot be removed using the CLI.
- Both priority rate and police CIR (using MQC) in the same class is unsupported.
- Queue limit (which is used to configure Weighted Tail Drop) is unsupported.

### Wireless QoS Restrictions on SSID

The following are restrictions for applying QoS features on SSID:

- One table map is supported at the ingress policy.
- Table maps are supported for the parent class-default only. Up to two table maps are supported in the egress direction and three table-maps can be configured when a QoS group is involved.

---

**Note** Table-maps are not supported at the client targets.

---

- If a wireless port has a default policy with only two queues (one for multicast-NRT, one for class-default), the policy at SSID level cannot have voice and video class in the egress direction.
- Policing without priority is not supported in the egress direction.
- Priority configuration at the SSID level is used only to configure the RT1 and RT2 policers (AFD for policer). Priority configuration does not include the shape rate. Therefore, priority is restricted for SSID policies without police.
- The mapping in the DSCP2DSCP and COS2COS table should be based on the classification function for the voice and video classes in the port level policy.
- No action is allowed under the class-default of a child policy.
- For a flat policy (non hierarchical), in the ingress direction, the policy configuration must be a set (table map) or policing or both.

### Wireless QoS Restrictions on Clients

The following are restrictions for applying QoS policies on client targets:

- Queuing is not supported.
- Attaching, removing, or modifying client policies on a WLAN in the enabled state is not supported. You must shut down the WLAN to apply, remove, or modify a policy.

- Table-map configuration is not supported for client targets.
- Policing and set configured together in class-default is blocked in both the upstream and downstream direction:
 

```
policy-map foo
class class-default
police X
set dscp Y
```
- Child policy is not supported under class-default if the parent policy contains other user-defined class maps in it.
- Hierarchical client polices are only supported in the egress direction.
- For flat egress client policy, policing in class-default and marking action in other classes are not supported.
- Restrictions for ACLs:
  - All the filters in classes in a policy map for client policy must have the same attributes. Filters matching on protocol-specific attributes such as IPv4 or IPv6 addresses are considered as different attribute sets.
  - For filters matching on ACLs, all ACEs (Access Control Entry) in the access list should have the same type and number of attributes. For example, the following is an invalid access list as they match on different attributes:
 

```
policy map foo
class acl-101 (match on 3 tuple)
police X
class acl-102 (match on 5 tuple)
police Y
```
  - For filters matching on marking attributes, all filters in the policy-map must match on the same marking attribute. For example, If filter matches on DSCP, then all filters in the policy must match on DSCP.
  - ACL matching on port ranges and subnet are only supported in ingress direction.
- If an ingress SSID policy is configured along with an ingress client policy matching ACLs with port ranges, the SSID policy takes precedence over the client policy. As a result, the client policy will not take effect.

# How to Configure QoS

## Configuring Class, Policy, and Table Maps

### Creating a Traffic Class (CLI)

To create a traffic class containing match criteria, use the **class-map** command to specify the traffic class name, and then use the following **match** commands in class-map configuration mode, as needed.

#### Before You Begin

All match commands specified in this configuration task are considered optional, but you must configure at least one match criterion for a class.

### SUMMARY STEPS

1. **configure terminal**
2. **class-map** {*class-map name* | **match-any**}
3. **match access-group** {*index number* | *name*}
4. **match class-map** *class-map name*
5. **match cos** *cos value*
6. **match dscp** *dscp value*
7. **match ip** {*dscp dscp value* | **precedence** *precedence value* }
8. **match non-client-nrt**
9. **match qos-group** *qos group value*
10. **match vlan** *vlan value*
11. **match wlan user-priority** *wlan value*
12. **end**

### DETAILED STEPS

|        | Command or Action                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                   |
|--------|---------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b> | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                     |
| Step 2 | <b>class-map</b> { <i>class-map name</i>   <b>match-any</b> }                         | Enters class map configuration mode.                                                                                                                                                                                                                                                                                                      |
|        | <b>Example:</b><br>Switch(config)# <b>class-map test_1000</b><br>Switch(config-cmap)# | <ul style="list-style-type: none"> <li>• Creates a class map to be used for matching packets to the class whose name you specify.</li> <li>• If you specify <b>match-any</b>, one of the match criteria must be met for traffic entering the traffic class to be classified as part of the traffic class. This is the default.</li> </ul> |

|               | Command or Action                                                                                                                                                  | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 3</b> | <p><b>match access-group</b> <i>{index number   name}</i></p> <p><b>Example:</b></p> <pre>Switch(config-cmap) # match access-group 100 Switch(config-cmap) #</pre> | <p>The following parameters are available for this command:</p> <ul style="list-style-type: none"> <li>• access-group</li> <li>• class-map</li> <li>• cos</li> <li>• dscp</li> <li>• ip</li> <li>• non-client-nrt</li> <li>• precedence</li> <li>• qos-group</li> <li>• vlan</li> <li>• wlan user priority</li> </ul> <p>(Optional) For this example, enter the access-group ID:</p> <ul style="list-style-type: none"> <li>• Access list index (value from 1 to 2799)</li> <li>• Named access list</li> </ul> |
| <b>Step 4</b> | <p><b>match class-map</b> <i>class-map name</i></p> <p><b>Example:</b></p> <pre>Switch(config-cmap) # match class-map test_2000 Switch(config-cmap) #</pre>        | <p>(Optional) Matches to another class-map name.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Step 5</b> | <p><b>match cos</b> <i>cos value</i></p> <p><b>Example:</b></p> <pre>Switch(config-cmap) # match cos 2 3 4 5 Switch(config-cmap) #</pre>                           | <p>(Optional) Matches IEEE 802.1Q or ISL class of service (user) priority values.</p> <ul style="list-style-type: none"> <li>• Enters up to 4 CoS values separated by spaces (0 to 7).</li> </ul>                                                                                                                                                                                                                                                                                                              |
| <b>Step 6</b> | <p><b>match dscp</b> <i>dscp value</i></p> <p><b>Example:</b></p> <pre>Switch(config-cmap) # match dscp af11 af12 Switch(config-cmap) #</pre>                      | <p>(Optional) Matches the DSCP values in IPv4 and IPv6 packets.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Step 7</b> | <p><b>match ip</b> <i>{dscp dscp value   precedence precedence value }</i></p>                                                                                     | <p>(Optional) Matches IP values including the following:</p> <ul style="list-style-type: none"> <li>• <b>dscp</b>—Matches IP DSCP (DiffServ codepoints).</li> </ul>                                                                                                                                                                                                                                                                                                                                            |

|                | Command or Action                                                                                                                                          | Purpose                                                                                                                                                                                                             |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | <p><b>Example:</b></p> <pre>Switch(config-cmap) # match ip dscp af11 af12 Switch(config-cmap) #</pre>                                                      | <ul style="list-style-type: none"> <li>• <b>precedence</b>—Matches IP precedence (0 to 7).</li> </ul>                                                                                                               |
| <b>Step 8</b>  | <p><b>match non-client-nrt</b></p> <p><b>Example:</b></p> <pre>Switch(config-cmap) # match non-client-nrt Switch(config-cmap) #</pre>                      | <p>(Optional) Matches non-client NRT (Non-Real-Time).</p> <p><b>Note</b> This match is applicable only for policies on a wireless port. It carries all the multi-destination and AP (non-client) bound traffic.</p> |
| <b>Step 9</b>  | <p><b>match qos-group qos group value</b></p> <p><b>Example:</b></p> <pre>Switch(config-cmap) # match qos-group 10 Switch(config-cmap) #</pre>             | <p>(Optional) Matches QoS group value (from 0 to 31).</p>                                                                                                                                                           |
| <b>Step 10</b> | <p><b>match vlan vlan value</b></p> <p><b>Example:</b></p> <pre>Switch(config-cmap) # match vlan 210 Switch(config-cmap) #</pre>                           | <p>(Optional) Matches a VLAN ID (from 1 to 4095).</p>                                                                                                                                                               |
| <b>Step 11</b> | <p><b>match wlan user-priority wlan value</b></p> <p><b>Example:</b></p> <pre>Switch(config-cmap) # match wlan user priority 7 Switch(config-cmap) #</pre> | <p>(Optional) Matches 802.11e specific values. Enter the user priority 802.11e user priority (0 to 7).</p>                                                                                                          |
| <b>Step 12</b> | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Switch(config-cmap) # end</pre>                                                                              | <p>Saves the configuration changes.</p>                                                                                                                                                                             |

### What to Do Next

Configure the policy map.

## Creating a Traffic Policy (CLI)

To create a traffic policy, use the **policy-map** global configuration command to specify the traffic policy name.

The traffic class is associated with the traffic policy when the **class** command is used. The **class** command must be entered after you enter the policy map configuration mode. After entering the **class** command, the switch is automatically in policy map class configuration mode, which is where the QoS policies for the traffic policy are defined.

The following policy map class-actions are supported:

- **admit**—Admits the request for Call Admission Control (CAC).
- **bandwidth**—Bandwidth configuration options.
- **exit**—Exits from the QoS class action configuration mode.
- **no**—Negates or sets default values for the command.
- **police**—Policer configuration options.
- **priority**—Strict scheduling priority configuration options for this class.
- **queue-buffers**—Queue buffer configuration options.
- **queue-limit**—Queue maximum threshold for Weighted Tail Drop (WTD) configuration options.
- **service-policy**—Configures the QoS service policy.
- **set**—Sets QoS values using the following options:
  - CoS values
  - DSCP values
  - Precedence values
  - QoS group values
  - WLAN values
- **shape**—Traffic-shaping configuration options.

### Before You Begin

You should have first created a class map.

## SUMMARY STEPS

1. **configure terminal**
2. **policy-map** *policy-map name*
3. **class** {*class-name* | **class-default**}
4. **admit**
5. **bandwidth** {*kb/s kb/s value* | **percent percentage** | **remaining** {*percent* | *ratio*}}
6. **exit**
7. **no**
8. **police** {*target\_bit\_rate* | **cir** | **rate**}
9. **priority** {*kb/s* | **level level value** | **percent percentage value**}
10. **queue-buffers ratio** *ratio limit*
11. **queue-limit** {*packets* | **cos** | **dscp** | **percent**}
12. **service-policy** *policy-map name*
13. **set** {**cos** | **dscp** | **ip** | **precedence** | **qos-group** | **wlan**}
14. **shape average** {*target\_bit\_rate* | **percent**}
15. **end**

## Configuring Client Policies (GUI)

- 
- Step 1** Choose **Configuration > Wireless**.
- Step 2** Expand the **QoS** node by clicking on the left pane and choose **QOS-Policy**. The **QOS-Policy** page is displayed.
- Step 3** Click **Add New** to create a new QoS Policy. The **Create QoS Policy** page is displayed.
- Step 4** Select **Client** from the **Policy Type** drop-down menu.
- Step 5** Select the direction into which the policy needs to be applied from the **Policy Direction** drop-down menu. The available options are:
- **Ingress**
  - **Egress**
- Step 6** Specify a policy name in the **Policy Name** text box.
- Step 7** Provide a description to the policy in the **Description** text box.
- Step 8** (Optional) Configure the default voice or video configuration parameters by checking the **Enable Voice** or **Enable Video** checkbox. The following options are available:
- **Trust**—Specify the classification type behavior on this policy. The options available are:
    - **DSCP**—Assigns a label to indicate the given quality of service. The range is from 0 to 63.

- **User Priority**—This option is available when the **Policy Direction** is ingress. Enter the 802.11e user priority. The range is from 0 to 7.
- **COS**—This option is available when the **Policy Direction** is egress. Matches IEEE 802.1Q class of service. The range is from 0 to 7.
- **Mark**—Specify the marking label for each packet. The following options are available:
  - **DSCP**—Assigns a label to indicate the given quality of service. The range is from 0 to 63.
  - **CoS**—Matches IEEE 802.1Q class of service. The range is from 0 to 7.
  - **User Priority**—Enter the 802.11e user priority. The range is from 0 to 7.
- **Police(kbps)**—Specify the policing rate in kbps.

**Note** The marking and policing options are optional.

**Step 9** Specify the **Class-default** parameters. The following options are available:

- **Mark**—Specify the marking label for each packet. The following options are available:
  - **DSCP**—Assigns a label to indicate the given quality of service. The range is from 0 to 63.
  - **CoS**—Matches IEEE 802.1Q class of service. The range is from 0 to 7.
  - **User Priority**—Enter the 802.11e user priority. The range is from 0 to 7.
- **Police (kbps)**—This option is available when the **Policy Direction** is egress. This option Specify the policing rate in kbps.

**Step 10** (Optional) To configure user defined classes, check the **User Defined Classes** checkbox. The following options are available:

- **Trust**—Specify the classification type behavior on this policy.
  - **DSCP**—Assigns a label to indicate the given quality of service. The range is from 0 to 63.
  - **User Priority**—This option is available when the **Policy Direction** is ingress. Enter the 802.11e user priority. The range is from 0 to 7.
  - **COS**—This option is available when the **Policy Direction** is egress. Matches IEEE 802.1Q class of service. The range is from 0 to 7.
- **Mark**—Specify the marking label for each packet. The following options are available:
  - **DSCP**—Assigns a label to indicate the given quality of service. The range is from 0 to 63.
  - **CoS**—Matches IEEE 802.1Q class of service. The range is from 0 to 7.
  - **User Priority**—Enter the 802.11e user priority. The range is from 0 to 7.

- **Police (kbps)**—This option is available when the **Policy Direction** is egress. This option Specify the policing rate in kbps.

**Step 11** Click **Add** to add the policy.

## Configuring Class-Based Packet Marking (CLI)

This procedure explains how to configure the following class-based packet marking features on your switch:

- CoS value
- DSCP value
- IP value
- Precedence value
- QoS group value
- WLAN value

### Before You Begin

You should have created a class map and a policy map before beginning this procedure.

## SUMMARY STEPS

1. **configure terminal**
2. **policy-map** *policy name*
3. **class** *class name*
4. **set cos** {*cos value* | **cos table** *table-map name* | **dscp table** *table-map name* | **precedence table** *table-map name* | **qos-group table** *table-map name* | **wlan user-priority table** *table-map name*}
5. **set dscp** {*dscp value* | **default** | **dscp table** *table-map name* | **ef** | **precedence table** *table-map name* | **qos-group table** *table-map name* | **wlan user-priority table** *table-map name*}
6. **set ip** {**dscp** | **precedence**}
7. **set precedence** {*precedence value* | **cos table** *table-map name* | **dscp table** *table-map name* | **precedence table** *table-map name* | **qos-group table** *table-map name*}
8. **set qos-group** {*qos-group value* | **dscp table** *table-map name* | **precedence table** *table-map name*}
9. **set wlan user-priority** {*wlan user-priority value* | **cos table** *table-map name* | **dscp table** *table-map name* | **qos-group table** *table-map name* | **wlan table** *table-map name*}
10. **end**
11. **show policy-map**

| <b>Step 11</b> | <p><b>show policy-map</b></p> <p><b>Example:</b></p> <pre>Switch# show policy-map</pre>                                                                                                                                                     | (Optional) Displays policy configuration information for all classes configured for all service policies.                                                                                                                                                                                                                                                                                                                                                                                                                         |

### What to Do Next

Attach the traffic policy to an interface using the **service-policy** command.

### Configuring Class Maps for Voice and Video (CLI)

To configure class maps for voice and video traffic, follow these steps:

#### SUMMARY STEPS

1. **configure terminal**
2. **class-map** *class-map-name*
3. **match dscp** *dscp-value-for-voice*
4. **end**
5. **configure terminal**
6. **class-map** *class-map-name*
7. **match dscp** *dscp-value-for-video*
8. **end**

## DETAILED STEPS

|        | Command or Action                                                                                          | Purpose                                                                                                             |
|--------|------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                      | Enters global configuration mode.                                                                                   |
| Step 2 | <b>class-map class-map-name</b><br><br><b>Example:</b><br>Switch(config)# <b>class-map voice</b>           | Creates a class map.                                                                                                |
| Step 3 | <b>match dscp dscp-value-for-voice</b><br><br><b>Example:</b><br>Switch(config-cmap)# <b>match dscp 46</b> | Matches the DSCP value in the IPv4 and IPv6 packets. Set this value to 46.                                          |
| Step 4 | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b>                                            | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode. |
| Step 5 | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                      | Enters global configuration mode.                                                                                   |
| Step 6 | <b>class-map class-map-name</b><br><br><b>Example:</b><br>Switch(config)# <b>class-map video</b>           | Configures a class map.                                                                                             |
| Step 7 | <b>match dscp dscp-value-for-video</b><br><br><b>Example:</b><br>Switch(config-cmap)# <b>match dscp 34</b> | Matches the DSCP value in the IPv4 and IPv6 packets. Set this value to 34.                                          |
| Step 8 | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b>                                            | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode. |

### Attaching a Traffic Policy to an Interface (CLI)

After the traffic class and traffic policy are created, you must use the **service-policy** interface configuration command to attach a traffic policy to an interface, and to specify the direction in which the policy should be applied (either on packets coming into the interface or packets leaving the interface).

#### Before You Begin

A traffic class and traffic policy must be created before attaching a traffic policy to an interface.

## SUMMARY STEPS

1. **configure terminal**
2. **interface** *type*
3. **service-policy** {**input** *policy-map* | **output** *policy-map* }
4. **end**
5. **show policy map**

| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                                                                                                                              | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Step 2</b> | <b>interface</b> <i>type</i><br><br><b>Example:</b><br>Switch(config)# <b>interface</b><br><b>GigabitEthernet1/0/1</b><br>Switch(config-if)#                                                                       | Enters interface configuration mode and configures an interface.<br><br>Command parameters for the interface configuration include: <ul style="list-style-type: none"> <li>• <b>Auto Template</b>— Auto-template interface</li> <li>• <b>Capwap</b>—CAPWAP tunnel interface</li> <li>• <b>GigabitEthernet</b>—Gigabit Ethernet IEEE 802</li> <li>• <b>GroupVI</b>—Group virtual interface</li> <li>• <b>Internal Interface</b>— Internal interface</li> <li>• <b>Loopback</b>—Loopback interface</li> <li>• <b>Null</b>—Null interface</li> <li>• <b>Port-channel</b>—Ethernet Channel of interface</li> <li>• <b>TenGigabitEthernet</b>—10-Gigabit Ethernet</li> <li>• <b>Tunnel</b>—Tunnel interface</li> <li>• <b>Vlan</b>—Catalyst VLANs</li> <li>• <b>Range</b>—Interface range</li> </ul> |
| <b>Step 3</b> | <b>service-policy</b> { <b>input</b> <i>policy-map</i>   <b>output</b> <i>policy-map</i> }<br><br><b>Example:</b><br>Switch(config-if)# <b>service-policy</b><br><b>output policy_map_01</b><br>Switch(config-if)# | Attaches a policy map to an input or output interface. This policy map is then used as the service policy for that interface.<br><br>In this example, the traffic policy evaluates all traffic leaving that interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|        | Command or Action                                                                       | Purpose                                                                   |
|--------|-----------------------------------------------------------------------------------------|---------------------------------------------------------------------------|
| Step 4 | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Switch(config-if)# end Switch#</pre>      | Saves configuration changes.                                              |
| Step 5 | <p><b>show policy map</b></p> <p><b>Example:</b></p> <pre>Switch# show policy map</pre> | (Optional) Displays statistics for the policy on the specified interface. |

### What to Do Next

Proceed to attach any other traffic policy to an interface, and to specify the direction in which the policy should be applied.

## Configuring SSID Policies (GUI)

- 
- Step 1** Choose **Configuration > Wireless**.
- Step 2** Expand the **QoS** node by clicking on the left pane and choose **QOS-Policy**. The **Create QoS Policy** page is displayed.
- Step 3** Click **Add New** to create a new QoS Policy. The **QoS Policy** page is displayed.
- Step 4** Select **SSID** from the **Policy Type** drop-down menu.
- Step 5** Select the direction into which the policy needs to be applied from the **Policy Direction** drop-down list. The available options are:
- **Ingress**
  - **Egress**

**Note** Voice and video configurations are available only in the egress direction.

**Note** When creating an egress SSID policy for voice and video classes, if the **port\_child\_policy** is already configured with voice and video classes having priority level, the existing **port\_child\_policy** is used. If a **port\_child\_policy** does not exist with voice and video classes, the switch will create voice and video classes with priority levels 1 and 2 under **port\_child\_policy** for voice and video traffic.

**Step 6** Specify a policy name in the **Policy Name** text box.

**Step 7** Provide a description to the policy in the **Description** text box.

**Step 8** Select the trust parameter from the **Trust** drop-down list.  
The following options are available:

- **DSCP**— Assigns a label to indicate the given quality of service as DSCP.
- **COS**—Matches IEEE 802.1Q class of service. This option is not available when the **Policy Direction** is egress.
- **User Priority**—Enter the 802.11e user priority. This option is not available when the **Policy Direction** is egress.
- **None**—This option is available when the **Policy Direction** is egress. This option is available only for egress policies.

**Step 9** If you chose **Egress** policy above, the following options are available:

- **Bandwidth**—Specifies the bandwidth rate. The following options are available:
  - **Rate**—Specifies the bandwidth in kbps. Enter a value in kbps in the **Value** field.
  - **Remaining Ratio**—Specifies the bandwidth in BRR (bandwidth remaining ratio). Enter the percentage in the **Percent** field.

**Note** If you choose the **Rate** option for the **Bandwidth** parameter, this value must be greater than the sum of the policing values for voice and video traffic.

- **Enable Voice**—Click on the **Enable Voice** checkbox to enable voice traffic on this policy. Specify the following properties:
  - **Priority**—Sets the priority for this policy for strict scheduling. The priority level is set to 1.
  - **Police (kbps)**—Specifies the police rate in Kilobits per second.
  - **CAC**—Enables or disables CAC. If CAC is enabled, you must specify the following options:
    - **User priority**—This option is available when the **Policy Direction** is ingress. Enter the 802.11e user priority. The range is from 0 to 7. By default, a value of 6 is assigned.
    - **Rate(kbps)**
      - Note** The CAC rate must be less than the police rate.
- **Enable Video**—Check the **Enable Video** checkbox to enable video traffic on this policy. Specify the following properties:
  - **Priority**—Sets the priority for this policy for strict scheduling.
  - **Police (kbps)**—Specifies the police rate in kilobits per second.

**Step 10** Click **Apply**.

## Classifying, Policing, and Marking Traffic on Physical Ports by Using Policy Maps (CLI)

You can configure a nonhierarchical policy map on a physical port that specifies which traffic class to act on. Actions supported are remarking and policing.

### Before You Begin

You should have already decided upon the classification, policing, and marking of your network traffic by policy maps prior to beginning this procedure.

## SUMMARY STEPS

1. **configure terminal**
2. **class-map** {*class-map name* | **match-any** }
3. **match access-group** { *access list index* | *access list name* }
4. **policy-map** *policy-map-name*
5. **class** {*class-map-name* | **class-default**}
6. **set** {**cos** | **dscp** | **ip** | **precedence** | **qos-group** | **wlan user-priority**}
7. **police** {*target\_bit\_rate* | **cir** | **rate** }
8. **exit**
9. **exit**
10. **interface** *interface-id*
11. **service-policy input** *policy-map-name*
12. **end**
13. **show policy-map** [*policy-map-name* [**class** *class-map-name*]]
14. **copy running-config startup-config**

## DETAILED STEPS

|               | Command or Action                                                                                                                                                                                                | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <p><b>configure terminal</b></p> <p><b>Example:</b></p> <pre>Switch# configure terminal</pre>                                                                                                                    | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Step 2</b> | <p><b>class-map</b> {<i>class-map name</i>   <b>match-any</b> }</p> <p><b>Example:</b></p> <pre>Switch(config)# class-map ipclass1 Switch(config-cmap)# exit Switch(config)#</pre>                               | <p>Enters class map configuration mode.</p> <ul style="list-style-type: none"> <li>• Creates a class map to be used for matching packets to the class whose name you specify.</li> <li>• If you specify <b>match-any</b>, one of the match criteria must be met for traffic entering the traffic class to be classified as part of the traffic class. This is the default.</li> </ul>                                                                                                                                                                                                                                                                                                                             |
| <b>Step 3</b> | <p><b>match access-group</b> { <i>access list index</i>   <i>access list name</i> }</p> <p><b>Example:</b></p> <pre>Switch(config-cmap)# match access-group 1000 Switch(config-cmap)# exit Switch(config)#</pre> | <p>Specifies the classification criteria to match to the class map. You can match on the following criteria:</p> <ul style="list-style-type: none"> <li>• <b>access-group</b>—Matches to access group.</li> <li>• <b>class-map</b>—Matches to another class map.</li> <li>• <b>cos</b>—Matches to a CoS value.</li> <li>• <b>dscp</b>—Matches to a DSCP value.</li> <li>• <b>ip</b>—Matches to a specific IP value.</li> <li>• <b>non-client-nrt</b>—Matches non-client NRT.</li> <li>• <b>precedence</b>—Matches precedence in IPv4 and IPv6 packets.</li> <li>• <b>qos-group</b>—Matches to a QoS group.</li> <li>• <b>vlan</b>—Matches to a VLAN.</li> <li>• <b>wlan</b>—Matches to a wireless LAN.</li> </ul> |
| <b>Step 4</b> | <p><b>policy-map</b> <i>policy-map-name</i></p> <p><b>Example:</b></p> <pre>Switch(config)# policy-map flowit Switch(config-pmap)#</pre>                                                                         | <p>Creates a policy map by entering the policy map name, and enters policy-map configuration mode.</p> <p>By default, no policy maps are defined.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Step 5</b> | <p><b>class</b> {<i>class-map-name</i>   <b>class-default</b>}</p> <p><b>Example:</b></p> <pre>Switch(config-pmap)# class ipclass1 Switch(config-pmap-c)#</pre>                                                  | <p>Defines a traffic classification, and enter policy-map class configuration mode.</p> <p>By default, no policy map class-maps are defined.</p> <p>If a traffic class has already been defined by using the <b>class-map</b> global configuration command, specify its name for <i>class-map-name</i> in this command.</p>                                                                                                                                                                                                                                                                                                                                                                                       |

|                | Command or Action                                                                                                                                                                                                       | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                |                                                                                                                                                                                                                         | A <b>class-default</b> traffic class is predefined and can be added to any policy. It is always placed at the end of a policy map. With an implied <b>match any</b> included in the <b>class-default</b> class, all packets that have not already matched the other traffic classes will match <b>class-default</b> .                                                                                                                                                                                                                                                                                                           |
| <b>Step 6</b>  | <p><b>set</b> {<b>cos</b>   <b>dscp</b>   <b>ip</b>   <b>precedence</b>   <b>qos-group</b>   <b>wlan user-priority</b>}</p> <p><b>Example:</b></p> <pre>Switch(config-pmap-c)# set dscp 45 Switch(config-pmap-c)#</pre> | <p>(Optional) Sets the QoS values. Possible QoS configuration values include:</p> <ul style="list-style-type: none"> <li>• <b>cos</b>—Sets the IEEE 802.1Q/ISL class of service/user priority.</li> <li>• <b>dscp</b>—Sets DSCP in IP(v4) and IPv6 packets.</li> <li>• <b>ip</b>—Sets IP specific values.</li> <li>• <b>precedence</b>—Sets precedence in IP(v4) and IPv6 packet.</li> <li>• <b>qos-group</b>—Sets QoS group.</li> <li>• <b>wlan user-priority</b>—Sets WLAN user priority.</li> </ul> <p>In this example, the <b>set dscp</b> command classifies the IP traffic by setting a new DSCP value in the packet.</p> |
| <b>Step 7</b>  | <p><b>police</b> {<i>target_bit_rate</i>   <b>cir</b>   <b>rate</b> }</p> <p><b>Example:</b></p> <pre>Switch(config-pmap-c)# police 100000 conform-action transmit exceed-action drop Switch(config-pmap-c)#</pre>      | <p>(Optional) Configures the policer:</p> <ul style="list-style-type: none"> <li>• <i>target_bit_rate</i>—Specifies the bit rate per second, enter a value between 8000 and 10000000000.</li> <li>• <b>cir</b>—Committed Information Rate.</li> <li>• <b>rate</b>—Specifies the police rate, PCR for hierarchical policies, or SCR for single-level ATM 4.0 policer policies.</li> </ul> <p>In this example, the <b>police</b> command adds a policer to the class where any traffic beyond the 100000 set target bit rate is dropped.</p>                                                                                      |
| <b>Step 8</b>  | <p><b>exit</b></p> <p><b>Example:</b></p> <pre>Switch(config-pmap-c)# exit</pre>                                                                                                                                        | Returns to policy map configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Step 9</b>  | <p><b>exit</b></p> <p><b>Example:</b></p> <pre>Switch(config-pmap)# exit</pre>                                                                                                                                          | Returns to global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Step 10</b> | <p><b>interface</b> <i>interface-id</i></p> <p><b>Example:</b></p> <pre>Switch(config)# interface</pre>                                                                                                                 | <p>Specifies the port to attach to the policy map, and enters interface configuration mode.</p> <p>Valid interfaces include physical ports.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|                | Command or Action                                                                                                                                     | Purpose                                                                                                              |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|
|                | <code>gigabitethernet 2/0/1</code>                                                                                                                    |                                                                                                                      |
| <b>Step 11</b> | <p><b>service-policy input</b> <i>policy-map-name</i></p> <p><b>Example:</b></p> <pre>Switch(config-if)# service-policy input flowit</pre>            | Specifies the policy-map name, and applies it to an ingress port. Only one policy map per ingress port is supported. |
| <b>Step 12</b> | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Switch(config-if)# end</pre>                                                                            | Returns to privileged EXEC mode.                                                                                     |
| <b>Step 13</b> | <p><b>show policy-map</b> [<i>policy-map-name</i> [<b>class</b> <i>class-map-name</i>]]</p> <p><b>Example:</b></p> <pre>Switch# show policy-map</pre> | (Optional) Verifies your entries.                                                                                    |
| <b>Step 14</b> | <p><b>copy running-config startup-config</b></p> <p><b>Example:</b></p> <pre>Switch# copy-running-config startup-config</pre>                         | (Optional) Saves your entries in the configuration file.                                                             |

### What to Do Next

If applicable to your QoS configuration, configure classification, policing, and marking of traffic on SVIs by using policy maps.

## Classifying, Policing, and Marking Traffic on SVIs by Using Policy Maps (CLI)

### Before You Begin

You should have already decided upon the classification, policing, and marking of your network traffic by using policy maps prior to beginning this procedure.

## SUMMARY STEPS

1. **configure terminal**
2. **class-map** {*class-map name* | **match-any** }
3. **match vlan** *vlan number*
4. **policy-map** *policy-map-name*
5. **description** *description*
6. **class** {*class-map-name* | **class-default**}
7. **set** {**cos** | **dscp** | **ip** | **precedence** | **qos-group** | **wlan user-priority**}
8. **police** {*target\_bit\_rate* | **cir** | **rate**}
9. **exit**
10. **exit**
11. **interface** *interface-id*
12. **service-policy input** *policy-map-name*
13. **end**
14. **show policy-map** [*policy-map-name* [**class** *class-map-name*]]
15. **copy running-config startup-config**

## DETAILED STEPS

|               | Command or Action                                                                                                                                                | Purpose                                                                                                                                                                                                                                                                                                                                                                        |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                                                                            | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                          |
| <b>Step 2</b> | <b>class-map</b> { <i>class-map name</i>   <b>match-any</b> }<br><br><b>Example:</b><br>Switch(config)# <b>class-map class_vlan100</b>                           | Enters class map configuration mode. <ul style="list-style-type: none"> <li>• Creates a class map to be used for matching packets to the class whose name you specify.</li> <li>• If you specify <b>match-any</b>, one of the match criteria must be met for traffic entering the traffic class to be classified as part of the traffic class. This is the default.</li> </ul> |
| <b>Step 3</b> | <b>match vlan</b> <i>vlan number</i><br><br><b>Example:</b><br>Switch(config-cmap)# <b>match vlan 100</b><br>Switch(config-cmap)# <b>exit</b><br>Switch(config)# | Specifies the VLAN to match to the class map.                                                                                                                                                                                                                                                                                                                                  |

|               | Command or Action                                                                                                                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 4</b> | <p><b>policy-map</b> <i>policy-map-name</i></p> <p><b>Example:</b></p> <pre>Switch(config)# <b>policy-map</b> policy_vlan100 Switch(config-pmap)#</pre>                                                                                | <p>Creates a policy map by entering the policy map name, and enters policy-map configuration mode.</p> <p>By default, no policy maps are defined.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Step 5</b> | <p><b>description</b> <i>description</i></p> <p><b>Example:</b></p> <pre>Switch(config-pmap)# <b>description</b> vlan 100</pre>                                                                                                        | <p>(Optional) Enters a description of the policy map.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Step 6</b> | <p><b>class</b> {<i>class-map-name</i>   <b>class-default</b>}</p> <p><b>Example:</b></p> <pre>Switch(config-pmap)# <b>class</b> class_vlan100 Switch(config-pmap-c)#</pre>                                                            | <p>Defines a traffic classification, and enters the policy-map class configuration mode.</p> <p>By default, no policy map class-maps are defined.</p> <p>If a traffic class has already been defined by using the <b>class-map</b> global configuration command, specify its name for <i>class-map-name</i> in this command.</p> <p>A <b>class-default</b> traffic class is predefined and can be added to any policy. It is always placed at the end of a policy map. With an implied <b>match any</b> included in the <b>class-default</b> class, all packets that have not already matched the other traffic classes will match <b>class-default</b>.</p> |
| <b>Step 7</b> | <p><b>set</b> {<b>cos</b>   <b>dscp</b>   <b>ip</b>   <b>precedence</b>   <b>qos-group</b>   <b>wlan user-priority</b>}</p> <p><b>Example:</b></p> <pre>Switch(config-pmap-c)# <b>set dscp</b> af23 Switch(config-pmap-c)#</pre>       | <p>(Optional) Sets the QoS values. Possible QoS configuration values include:</p> <ul style="list-style-type: none"> <li>• <b>cos</b>—Sets the IEEE 802.1Q/ISL class of service/user priority.</li> <li>• <b>dscp</b>—Sets DSCP in IP(v4) and IPv6 packets.</li> <li>• <b>ip</b>—Sets IP specific values.</li> <li>• <b>precedence</b>—Sets precedence in IP(v4) and IPv6 packet.</li> <li>• <b>qos-group</b>—Sets QoS group.</li> <li>• <b>wlan user-priority</b>—Sets WLAN user-priority.</li> </ul> <p>In this example, the <b>set dscp</b> command classifies the IP traffic by matching the packets with a DSCP value of AF23 (010010).</p>             |
| <b>Step 8</b> | <p><b>police</b> {<i>target_bit_rate</i>   <b>cir</b>   <b>rate</b>}</p> <p><b>Example:</b></p> <pre>Switch(config-pmap-c)# <b>police</b> 200000 <b>conform-action</b> transmit <b>exceed-action</b> drop Switch(config-pmap-c)#</pre> | <p>(Optional) Configures the policer:</p> <ul style="list-style-type: none"> <li>• <i>target_bit_rate</i>—Specifies the bit rate per second. Enter a value between 8000 and 10000000000.</li> <li>• <b>cir</b>—Committed Information Rate.</li> <li>• <b>rate</b>—Specifies the police rate, PCR for hierarchical policies, or SCR for single-level ATM 4.0 policer policies.</li> </ul>                                                                                                                                                                                                                                                                     |

|                | Command or Action                                                                                                                              | Purpose                                                                                                                                    |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
|                |                                                                                                                                                | In this example, the <b>police</b> command adds a policer to the class where any traffic beyond the 200000 set target bit rate is dropped. |
| <b>Step 9</b>  | <b>exit</b><br><br><b>Example:</b><br>Switch(config-pmap-c) # <b>exit</b>                                                                      | Returns to policy map configuration mode.                                                                                                  |
| <b>Step 10</b> | <b>exit</b><br><br><b>Example:</b><br>Switch(config-pmap) # <b>exit</b>                                                                        | Returns to global configuration mode.                                                                                                      |
| <b>Step 11</b> | <b>interface interface-id</b><br><br><b>Example:</b><br>Switch(config) # <b>interface</b><br><b>gigabitethernet 1/0/3</b>                      | Specifies the port to attach to the policy map, and enters interface configuration mode.<br><br>Valid interfaces include physical ports.   |
| <b>Step 12</b> | <b>service-policy input policy-map-name</b><br><br><b>Example:</b><br>Switch(config-if) # <b>service-policy</b><br><b>input policy_vlan100</b> | Specifies the policy-map name, and applies it to an ingress port. Only one policy map per ingress port is supported.                       |
| <b>Step 13</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config-if) # <b>end</b>                                                                            | Returns to privileged EXEC mode.                                                                                                           |
| <b>Step 14</b> | <b>show policy-map [policy-map-name [class class-map-name]]</b><br><br><b>Example:</b><br>Switch# <b>show policy-map</b>                       | (Optional) Verifies your entries.                                                                                                          |
| <b>Step 15</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# <b>copy-running-config</b><br><b>startup-config</b>                | (Optional) Saves your entries in the configuration file.                                                                                   |

## Configuring Table Maps (CLI)

Table maps are a form of marking, and also enable the mapping and conversion of one field to another using a table. For example, a table map can be used to map and convert a Layer 2 CoS setting to a precedence value in Layer 3.

### Note

A table map can be referenced in multiple policies or multiple times in the same policy.

## SUMMARY STEPS

1. **configure terminal**
2. **table-map** *name* {**default** {*default value* | **copy** | **ignore**} | **exit** | **map** {**from** *from value* **to** *to value* } | **no**}
3. **map from** *value* **to** *value*
4. **exit**
5. **exit**
6. **show table-map**
7. **configure terminal**
8. **policy-map**
9. **class class-default**
10. **set cos dscp table** *table map name*
11. **end**

| Step 1 | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                                                                                                                                                                                        | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                    |
| Step 2 | <b>table-map</b> <i>name</i> { <b>default</b> { <i>default value</i>   <b>copy</b>   <b>ignore</b> }   <b>exit</b>   <b>map</b> { <b>from</b> <i>from value</i> <b>to</b> <i>to value</i> }   <b>no</b> }<br><br><b>Example:</b><br>Switch(config)# <b>table-map table01</b> | Creates a table map and enters the table map configuration mode. In table map configuration mode, you can perform the following tasks: <ul style="list-style-type: none"> <li>• <b>default</b>—Configures the table map default value, or sets the default behavior for a value not found in the table map to copy or ignore.</li> </ul> |

|               | Command or Action                                                                                                                                                                                                                                                                                               | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | Switch(config-tablemap) #                                                                                                                                                                                                                                                                                       | <ul style="list-style-type: none"> <li>• <b>exit</b>—Exits from the table map configuration mode.</li> <li>• <b>map</b>—Maps a <i>from</i> to a <i>to</i> value in the table map.</li> <li>• <b>no</b>—Negates or sets the default values of the command.</li> </ul>                                                                                                                                                             |
| <b>Step 3</b> | <p><b>map from value to value</b></p> <p><b>Example:</b></p> <pre>Switch(config-tablemap) # map from 0 to 2 Switch(config-tablemap) # map from 1 to 4 Switch(config-tablemap) # map from 24 to 3 Switch(config-tablemap) # map from 40 to 6 Switch(config-tablemap) # default 0 Switch(config-tablemap) #</pre> | <p>In this step, packets with DSCP values 0 are marked to the CoS value 2, DSCP value 1 to the CoS value 4, DSCP value 24 to the CoS value 3, DSCP value 40 to the CoS value 6 and all others to the CoS value 0.</p> <p><b>Note</b> The mapping from CoS values to DSCP values in this example is configured by using the <b>set</b> policy map class configuration command as described in a later step in this procedure.</p> |
| <b>Step 4</b> | <p><b>exit</b></p> <p><b>Example:</b></p> <pre>Switch(config-tablemap) # exit Switch(config) #</pre>                                                                                                                                                                                                            | Returns to global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Step 5</b> | <p><b>exit</b></p> <p><b>Example:</b></p> <pre>Switch(config) exit Switch#</pre>                                                                                                                                                                                                                                | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Step 6</b> | <p><b>show table-map</b></p> <p><b>Example:</b></p> <pre>Switch# show table-map Table Map table01   from 0 to 2   from 1 to 4   from 24 to 3   from 40 to 6   default 0</pre>                                                                                                                                   | Displays the table map configuration.                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Step 7</b> | <p><b>configure terminal</b></p> <p><b>Example:</b></p> <pre>Switch# configure terminal Switch(config) #</pre>                                                                                                                                                                                                  | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Step 8</b> | <b>policy-map</b>                                                                                                                                                                                                                                                                                               | Configures the policy map for the table map.                                                                                                                                                                                                                                                                                                                                                                                     |

|                | Command or Action                                                                                                                                                 | Purpose                                                                                                                                                          |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | <p><b>Example:</b></p> <pre>Switch(config)# policy-map table-policy Switch(config-pmap)#</pre>                                                                    |                                                                                                                                                                  |
| <b>Step 9</b>  | <p><b>class class-default</b></p> <p><b>Example:</b></p> <pre>Switch(config-pmap)# class class-default Switch(config-pmap-c)#</pre>                               | Matches the class to the system default.                                                                                                                         |
| <b>Step 10</b> | <p><b>set cos dscp table <i>table map name</i></b></p> <p><b>Example:</b></p> <pre>Switch(config-pmap-c)# set cos dscp table table01 Switch(config-pmap-c)#</pre> | If this policy is applied on input port, that port will have trust DSCP enabled on that port and marking will take place depending upon the specified table map. |
| <b>Step 11</b> | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Switch(config-pmap-c)# end Switch#</pre>                                                                            | Returns to privileged EXEC mode.                                                                                                                                 |

### What to Do Next

Configure any additional policy maps for QoS for your network. After creating your policy maps, attach the traffic policy or policies to an interface using the **service-policy** command.

## Configuring Trust

### Configuring Trust Behavior for Wireless Traffic (CLI)

The Cisco IOS XE 3.2 Release supported different trust defaults for wired and wireless ports. The trust default for wired ports was the same as for this software release. For wireless ports, the default system behavior was non-trust, which meant that when the switch came up, all markings for the wireless ports were defaulted to zero and no traffic received priority treatment. For compatibility with an existing wired switch, all traffic went to the best-effort queue by default. The access point performed priority queuing by default. In the downstream

direction, the access point maintained voice, video, best-effort, and background queues for queuing. The access selected the queuing strategy based on the 11e tag information. By default, the access point treated all wireless packets as best effort.

## SUMMARY STEPS

1. **configure terminal**
2. **qos wireless-default-untrust**
3. **end**

## Configuring QoS Features and Functionality

### Configuring Call Admission Control (CLI)

This task explains how to configure class-based, unconditional packet marking features on your switch for Call Admission Control (CAC).

**SUMMARY STEPS**

1. **configure terminal**
2. **class-map** *class name*
3. **match dscp** *dscp value*
4. **exit**
5. **class-map** *class name*
6. **match dscp** *dscp value*
7. **exit**
8. **table-map** *name*
9. **default copy**
10. **exit**
11. **table-map** *name*
12. **default copy**
13. **exit**
14. **policy-map** *policy name*
15. **class** *class-map-name*
16. **priority level** *level\_value*
17. **police** [*target\_bit\_rate* | **cir** | **rate** ]
18. **admit cac wmm-tspec**
19. **rate** *value*
20. **wlan-up** *value*
21. **exit**
22. **exit**
23. **class** *class name*
24. **priority level** *level\_value*
25. **police** [*target\_bit\_rate* | **cir** | **rate** ]
26. **admit cac wmm-tspec**
27. **rate** *value*
28. **wlan-up** *value*
29. **exit**
30. **exit**
31. **policy-map** *policy name*
32. **class** *class-map-name*
33. **set dscp dscp table** *table\_map\_name*
34. **set wlan user-priority dscp table** *table\_map\_name*
35. **shape average** {*target bit rate* | **percent** *percentage*}
36. **queue-buffers** {**ratio** *ratio value*}
37. **service-policy** *policy\_map\_name*
38. **end**
39. **show policy-map**

## DETAILED STEPS

|               | Command or Action                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------|----------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                                | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                   |
| <b>Step 2</b> | <b>class-map class name</b><br><br><b>Example:</b><br>Switch(config)# <b>class-map voice</b><br>Switch(config-cmap)# | Enters policy class map configuration mode. Specifies the name of the class whose policy you want to create or change. Command options for policy class map configuration mode include the following: <ul style="list-style-type: none"> <li>• <i>word</i>—Class map name.</li> <li>• <b>class-default</b>—System default class matching any otherwise unclassified packets.</li> </ul> |
| <b>Step 3</b> | <b>match dscp dscp value</b><br><br><b>Example:</b><br>Switch(config-cmap)# <b>match dscp 46</b>                     | (Optional) Matches the DSCP values in IPv4 and IPv6 packets.                                                                                                                                                                                                                                                                                                                            |
| <b>Step 4</b> | <b>exit</b><br><br><b>Example:</b><br>Switch(config-cmap)# <b>exit</b><br>Switch(config)#                            | Returns to global configuration mode.                                                                                                                                                                                                                                                                                                                                                   |
| <b>Step 5</b> | <b>class-map class name</b><br><br><b>Example:</b><br>Switch(config)# <b>class-map video</b><br>Switch(config-cmap)# | Enters policy class map configuration mode. Specifies the name of the class whose policy you want to create or change. Command options for policy class map configuration mode include the following: <ul style="list-style-type: none"> <li>• <i>word</i>—Class map name.</li> <li>• <b>class-default</b>—System default class matching any otherwise unclassified packets.</li> </ul> |
| <b>Step 6</b> | <b>match dscp dscp value</b><br><br><b>Example:</b><br>Switch(config-cmap)# <b>match dscp 34</b>                     | (Optional) Matches the DSCP values in IPv4 and IPv6 packets.                                                                                                                                                                                                                                                                                                                            |
| <b>Step 7</b> | <b>exit</b>                                                                                                          | Returns to global configuration mode.                                                                                                                                                                                                                                                                                                                                                   |

|                | Command or Action                                                                                                                  | Purpose                                                                                                                                                                             |
|----------------|------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | <p><b>Example:</b></p> <pre>Switch(config-cmap)# exit Switch(config)#</pre>                                                        |                                                                                                                                                                                     |
| <b>Step 8</b>  | <p><b>table-map</b> <i>name</i></p> <p><b>Example:</b></p> <pre>Switch(config)# table-map dscp2dscp Switch(config-tablemap)#</pre> | Creates a table map and enters the table map configuration mode.                                                                                                                    |
| <b>Step 9</b>  | <p><b>default copy</b></p> <p><b>Example:</b></p> <pre>Switch(config-tablemap)# default copy</pre>                                 | <p>Sets the default behavior for value not found in the table map to copy.</p> <p><b>Note</b> This is the default option. You can also do a mapping of values for DSCP to DSCP.</p> |
| <b>Step 10</b> | <p><b>exit</b></p> <p><b>Example:</b></p> <pre>Switch(config-tablemap)# exit Switch(config)#</pre>                                 | Returns to global configuration mode.                                                                                                                                               |
| <b>Step 11</b> | <p><b>table-map</b> <i>name</i></p> <p><b>Example:</b></p> <pre>Switch(config)# table-map dscp2up Switch(config-tablemap)#</pre>   | Creates a new table map and enters the table map configuration mode.                                                                                                                |
| <b>Step 12</b> | <p><b>default copy</b></p> <p><b>Example:</b></p> <pre>Switch(config-tablemap)# default copy</pre>                                 | <p>Sets the default behavior for value not found in the table map to copy.</p> <p><b>Note</b> This is the default option. You can also do a mapping of values for DSCP to UP.</p>   |
| <b>Step 13</b> | <p><b>exit</b></p> <p><b>Example:</b></p> <pre>Switch(config-tablemap)# exit Switch(config)#</pre>                                 | Returns to global configuration mode.                                                                                                                                               |
| <b>Step 14</b> | <p><b>policy-map</b> <i>policy name</i></p> <p><b>Example:</b></p> <pre>Switch(config)# policy-map ssid_child_cac</pre>            | <p>Enters policy map configuration mode.</p> <p>Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy.</p>                    |

|                | Command or Action                                                                                                                                  | Purpose                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | Switch(config-pmap) #                                                                                                                              |                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Step 15</b> | <p><b>class</b> <i>class-map-name</i></p> <p><b>Example:</b></p> <pre>Switch(config-pmap) # class voice</pre>                                      | Defines an interface-level traffic classification, and enters policy-map configuration mode.                                                                                                                                                                                                                                                                                            |
| <b>Step 16</b> | <p><b>priority level</b> <i>level_value</i></p> <p><b>Example:</b></p> <pre>Switch(config-pmap-c) # priority level 1</pre>                         | <p>The <b>priority</b> command assigns a strict scheduling priority for the class.</p> <p><b>Note</b> Priority level 1 is more important than priority level 2. Priority level 1 reserves bandwidth that is processed first for QoS, so its latency is very low. Both priority level 1 and 2 reserve bandwidth.</p>                                                                     |
| <b>Step 17</b> | <p><b>police</b> [<i>target_bit_rate</i>   <b>cir</b>   <b>rate</b> ]</p> <p><b>Example:</b></p> <pre>Switch(config-pmap-c) # police cir 10m</pre> | <p>(Optional) Configures the policer:</p> <ul style="list-style-type: none"> <li>• <i>target_bit_rate</i>—Specifies the bit rate per second. Enter a value between 8000 and 1000000000.</li> <li>• <b>cir</b>—Committed Information Rate.</li> <li>• <b>rate</b>—Specifies the police rate, PCR for hierarchical policies, or SCR for single-level ATM 4.0 policer policies.</li> </ul> |
| <b>Step 18</b> | <p><b>admit cac wmm-tspec</b></p> <p><b>Example:</b></p> <pre>Switch(config-pmap-c) # admit cac wmm-tspec Switch(config-pmap-cac-wmm) #</pre>      | <p>Configures call admission control for the policy map.</p> <p><b>Note</b> This command only configures CAC for wireless QoS.</p>                                                                                                                                                                                                                                                      |
| <b>Step 19</b> | <p><b>rate</b> <i>value</i></p> <p><b>Example:</b></p> <pre>Switch(config-pmap-admit-cac-wmm) # rate 5000</pre>                                    | Configures the target bit rate (Kilo Bits per second). Enter a value from 8 to 10000000.                                                                                                                                                                                                                                                                                                |
| <b>Step 20</b> | <p><b>wlan-up</b> <i>value</i></p> <p><b>Example:</b></p> <pre>Switch(config-pmap-admit-cac-wmm) # wlan-up 6 7</pre>                               | Configures the WLAN UP value. Enter a value from 0 to 7.                                                                                                                                                                                                                                                                                                                                |
| <b>Step 21</b> | <p><b>exit</b></p> <p><b>Example:</b></p> <pre>Switch(config-pmap-admit-cac-wmm) # exit</pre>                                                      | Returns to policy map class configuration mode.                                                                                                                                                                                                                                                                                                                                         |

|                | Command or Action                                                                                                                              | Purpose                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | Switch(config-pmap-c) #                                                                                                                        |                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Step 22</b> | <b>exit</b><br><br><b>Example:</b><br>Switch(config-pmap-c) # <b>exit</b><br>Switch(config-pmap) #                                             | Returns to policy map configuration mode.                                                                                                                                                                                                                                                                                                                                               |
| <b>Step 23</b> | <b>class class name</b><br><br><b>Example:</b><br>Switch(config-pmap) # <b>class video</b><br>Switch(config-pmap-c) #                          | Enters policy class map configuration mode. Specifies the name of the class whose policy you want to create or change. Command options for policy class map configuration mode include the following: <ul style="list-style-type: none"> <li>• <i>word</i>—Class map name.</li> <li>• <b>class-default</b>—System default class matching any otherwise unclassified packets.</li> </ul> |
| <b>Step 24</b> | <b>priority level level_value</b><br><br><b>Example:</b><br>Switch(config-pmap-c) # <b>priority level 2</b>                                    | The <b>priority</b> command assigns a strict scheduling priority for the class.<br><br><b>Note</b> Priority level 1 is more important than priority level 2. Priority level 1 reserves bandwidth that is processed first for QoS, so its latency is very low. Both priority level 1 and 2 reserve bandwidth.                                                                            |
| <b>Step 25</b> | <b>police [target_bit_rate   cir   rate ]</b><br><br><b>Example:</b><br>Switch(config-pmap-c) # <b>police cir 20m</b>                          | (Optional) Configures the policer: <ul style="list-style-type: none"> <li>• <i>target_bit_rate</i>—Specifies the bit rate per second. Enter a value between 8000 and 1000000000.</li> <li>• <b>cir</b>—Committed Information Rate.</li> <li>• <b>rate</b>—Specifies the police rate, PCR for hierarchical policies, or SCR for single-level ATM 4.0 policer policies.</li> </ul>        |
| <b>Step 26</b> | <b>admit cac wmm-tspec</b><br><br><b>Example:</b><br>Switch(config-pmap-c) # <b>admit cac wmm-tspec</b><br>Switch(config-pmap-admit-cac-wmm) # | Configures call admission control for the policy map.<br><br><b>Note</b> This command only configures CAC for wireless QoS.                                                                                                                                                                                                                                                             |
| <b>Step 27</b> | <b>rate value</b><br><br><b>Example:</b><br>Switch(config-pmap-admit-cac-wmm) # <b>rate 5000</b>                                               | Configures the target bit rate (Kilo Bits per second). Enter a value from 8 to 10000000.                                                                                                                                                                                                                                                                                                |
| <b>Step 28</b> | <b>wlan-up value</b>                                                                                                                           | Configures the WLAN UP value. Enter a value from 0 to 7.                                                                                                                                                                                                                                                                                                                                |

|                | Command or Action                                                                                                                                                         | Purpose                                                                                                                                                          |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | <p><b>Example:</b></p> <pre>Switch(config-pmap-admit-cac-wmm) # wlan-up 4 5</pre>                                                                                         |                                                                                                                                                                  |
| <b>Step 29</b> | <p><b>exit</b></p> <p><b>Example:</b></p> <pre>Switch(config-pmap-cac-wmm) # exit Switch(config-pmap) #</pre>                                                             | Returns to policy map configuration mode.                                                                                                                        |
| <b>Step 30</b> | <p><b>exit</b></p> <p><b>Example:</b></p> <pre>Switch(config-pmap) # exit Switch(config) #</pre>                                                                          | Returns to global configuration mode.                                                                                                                            |
| <b>Step 31</b> | <p><b>policy-map <i>policy name</i></b></p> <p><b>Example:</b></p> <pre>Switch(config) # policy-map ssid_cac Switch(config-pmap) #</pre>                                  | <p>Enters policy map configuration mode.</p> <p>Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy.</p> |
| <b>Step 32</b> | <p><b>class <i>class-map-name</i></b></p> <p><b>Example:</b></p> <pre>Switch(config-pmap) # class default</pre>                                                           | <p>Defines an interface-level traffic classification, and enters policy-map configuration mode.</p> <p>In this example, the class map is set to default.</p>     |
| <b>Step 33</b> | <p><b>set dscp dscp table <i>table_map_name</i></b></p> <p><b>Example:</b></p> <pre>Switch(config-pmap-c) # set dscp dscp table dscp2dscp</pre>                           | (Optional) Sets the QoS values. In this example, the <b>set dscp dscp table</b> command creates a table map and sets its values.                                 |
| <b>Step 34</b> | <p><b>set wlan user-priority dscp table <i>table_map_name</i></b></p> <p><b>Example:</b></p> <pre>Switch(config-pmap-c) # set wlan user-priority dscp table dscp2up</pre> | (Optional) Sets the QoS values. In this example, the <b>set wlan user-priority dscp table</b> command sets the WLAN user priority.                               |

|                | Command or Action                                                                                                                                                                 | Purpose                                                                                                                                                                                                                                |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 35</b> | <b>shape average</b> { <i>target bit rate</i>   <b>percent</b> <i>percentage</i> }<br><br><b>Example:</b><br><br>Switch(config-pmap-c) # <b>shape average</b><br><b>100000000</b> | Configures the average shape rate. You can configure the average shape rate by target bit rates (bits per second) or by percentage of interface bandwidth for the Committed Information Rate (CIR).                                    |
| <b>Step 36</b> | <b>queue-buffers</b> { <i>ratio ratio value</i> }<br><br><b>Example:</b><br><br>Switch(config-pmap-c) # <b>queue-buffers ratio</b><br><b>0</b>                                    | Configures the relative buffer size for the queue.<br><br><b>Note</b> The sum of all configured buffers in a policy must be less than or equal to 100 percent. Unallocated buffers are evenly distributed to all the remaining queues. |
| <b>Step 37</b> | <b>service-policy</b> <i>policy_map_name</i><br><br><b>Example:</b><br><br>Switch(config-pmap-c) # <b>service-policy</b><br><b>ssid_child_cac</b>                                 | Specifies the policy map for the service policy.                                                                                                                                                                                       |
| <b>Step 38</b> | <b>end</b><br><br><b>Example:</b><br><br>Switch(config-pmap) # <b>end</b><br>Switch#                                                                                              | Saves configuration changes.                                                                                                                                                                                                           |
| <b>Step 39</b> | <b>show policy-map</b><br><br><b>Example:</b><br><br>Switch# <b>show policy-map</b>                                                                                               | (Optional) Displays policy configuration information for all classes configured for all service policies.                                                                                                                              |

### What to Do Next

Configure any additional policy maps for QoS for your network. After creating your policy maps, attach the traffic policy or policies to an interface using the **service-policy** command.

For additional information about CAC, refer to the *System Management Configuration Guide, Cisco IOS XE Release 3SE (Catalyst 3650 Switches)*.

### Configuring Bandwidth (CLI)

This procedure explains how to configure bandwidth on your switch.

## Before You Begin

You should have created a class map for bandwidth before beginning this procedure.

## SUMMARY STEPS

1. **configure terminal**
2. **policy-map** *policy name*
3. **class** *class name*
4. **bandwidth** {*Kb/s* | **percent** *percentage* | **remaining** { **ratio** *ratio* }}
5. **end**
6. **show policy-map**

## DETAILED STEPS

|               | Command or Action                                                                                                                                                                                                                | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                                                                                                                                            | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Step 2</b> | <b>policy-map</b> <i>policy name</i><br><br><b>Example:</b><br>Switch(config)# <b>policy-map</b><br><b>policy_bandwidth01</b><br>Switch(config-pmap)#                                                                            | Enters policy map configuration mode.<br><br>Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Step 3</b> | <b>class</b> <i>class name</i><br><br><b>Example:</b><br>Switch(config-pmap)# <b>class</b><br><b>class_bandwidth01</b><br>Switch(config-pmap-c)#                                                                                 | Enters policy class map configuration mode. Specifies the name of the class whose policy you want to create or change. Command options for policy class map configuration mode include the following: <ul style="list-style-type: none"> <li>• <i>word</i>—Class map name.</li> <li>• <b>class-default</b>—System default class matching any otherwise unclassified packets.</li> </ul>                                                                                                                                                                                              |
| <b>Step 4</b> | <b>bandwidth</b> { <i>Kb/s</i>   <b>percent</b> <i>percentage</i>   <b>remaining</b> { <b>ratio</b> <i>ratio</i> }}<br><br><b>Example:</b><br>Switch(config-pmap-c)# <b>bandwidth</b><br><b>200000</b><br>Switch(config-pmap-c)# | Configures the bandwidth for the policy map. The parameters include: <ul style="list-style-type: none"> <li>• <i>Kb/s</i>—Configures a specific value in kilobits per second (from 20000 to 10000000).</li> <li>• <b>percent</b>—Allocates minimum bandwidth to a particular class based on a percentage. The queue can oversubscribe bandwidth in case other queues do not utilize the entire port bandwidth. The total sum cannot exceed 100 percent, and in case it is less than 100 percent, the rest of the bandwidth is equally divided along all bandwidth queues.</li> </ul> |

|               | Command or Action                                                                   | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------|-------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               |                                                                                     | <ul style="list-style-type: none"> <li>• <b>remaining</b>— Allocates minimum bandwidth to a particular class. The queue can oversubscribe bandwidth in case other queues do not utilize entire port bandwidth. The total sum cannot exceed 100 percent. It is preferred to use this command when the <b>priority</b> command is used for certain queues in the policy. You can also assign ratios rather than percentages to each queue; the queues will be assigned certain weights which are inline with these ratios. Ratios can range from 0 to 100. Total bandwidth ratio allocation for the policy in this case can exceed 100.</li> </ul> <p><b>Note</b> You cannot mix bandwidth types on a policy map. For example, you cannot configure bandwidth in a single policy map using both a bandwidth percent and in kilobits per second.</p> |
| <b>Step 5</b> | <b>end</b><br><br><b>Example:</b><br><pre>Switch(config-pmap-c)# end Switch#</pre>  | Saves configuration changes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Step 6</b> | <b>show policy-map</b><br><br><b>Example:</b><br><pre>Switch# show policy-map</pre> | (Optional) Displays policy configuration information for all classes configured for all service policies.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

### What to Do Next

Configure any additional policy maps for QoS for your network. After creating the policy maps, attach the traffic policy or policies to an interface using the **service-policy** command.

|               | <b>drop</b><br>Switch(config-pmap-c) #                                                 | <ul style="list-style-type: none"> <li>◦ <i>target_bit_rate</i>—Target bit rate (8000 to 10000000000).</li> <li>◦ <b>percent</b>—Percentage of interface bandwidth for CIR.</li> <li>• <b>rate</b>—Specifies the police rate, PCR for hierarchical policies, or SCR for single-level ATM 4.0 policer policies. <ul style="list-style-type: none"> <li>◦ <i>target_bit_rate</i>—Target Bit Rate (8000 to 10000000000).</li> <li>◦ <b>percent</b>—Percentage of interface bandwidth for rate.</li> </ul> </li> </ul> <p>The following <b>police conform-action transmit exceed-action</b> subcommand options are available:</p> <ul style="list-style-type: none"> <li>• <b>drop</b>—Drops the packet.</li> <li>• <b>set-cos-transmit</b>—Sets the CoS value and sends it.</li> <li>• <b>set-dscp-transmit</b>—Sets the DSCP value and sends it.</li> <li>• <b>set-prec-transmit</b>—Rewrites the packet precedence and sends it.</li> <li>• <b>transmit</b>—Transmits the packet.</li> </ul> <p><b>Note</b> Policer-based markdown actions are only supported using table maps. Only one markdown table map is allowed for each marking field in the switch.</p> |
| <b>Step 5</b> | <b>end</b><br><br><b>Example:</b><br><br>Switch(config-pmap-c) # <b>end</b><br>Switch# | Saves configuration changes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Step 6</b> | <b>show policy-map</b><br><br><b>Example:</b><br><br>Switch# <b>show policy-map</b>    | (Optional) Displays policy configuration information for all classes configured for all service policies.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

### What to Do Next

Configure any additional policy maps for QoS for your network. After creating your policy maps, attach the traffic policy or polices to an interface using the **service-policy** command.

## Configuring Priority (CLI)

This procedure explains how to configure priority on your switch.

The switch supports giving priority to specified queues. There are two priority levels available (1 and 2).

**Note** Queues supporting voice and video should be assigned a priority level of 1.

### Before You Begin

You should have created a class map for priority before beginning this procedure.

## SUMMARY STEPS

1. **configure terminal**
2. **policy-map** *policy name*
3. **class** *class name*
4. **priority** [*Kb/s* [*burst\_in\_bytes*] | **level** *level\_value* [*Kb/s* [*burst\_in\_bytes*] | **percent** *percentage* [*burst\_in\_bytes*] ] | **percent** *percentage* [*burst\_in\_bytes*] ]
5. **end**
6. **show policy-map**

## DETAILED STEPS

|               | Command or Action                                                                                                                                     | Purpose                                                                                                                                                   |

|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 3 | <p><b>class</b> <i>class name</i></p> <p><b>Example:</b></p> <pre>Switch(config-pmap) # class class_priority01 Switch(config-pmap-c) #</pre>                                                                                                                                                                                                                    | <p>Enters policy class map configuration mode. Specifies the name of the class whose policy you want to create or change. Command options for policy class map configuration mode include the following:</p> <ul style="list-style-type: none"> <li>• <i>word</i>—Class map name.</li> <li>• <b>class-default</b>—System default class matching any otherwise unclassified packets.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Step 4 | <p><b>priority</b> [<i>Kb/s</i> [<i>burst_in_bytes</i>]   <b>level</b> <i>level_value</i> [<i>Kb/s</i> [<i>burst_in_bytes</i>]   <b>percent</b> <i>percentage</i> [<i>burst_in_bytes</i>] ]   <b>percent</b> <i>percentage</i> [<i>burst_in_bytes</i>] ]</p> <p><b>Example:</b></p> <pre>Switch(config-pmap-c) # priority level 1 Switch(config-pmap-c) #</pre> | <p>The <b>priority</b> command assigns a strict scheduling priority for the class. The command options include:</p> <ul style="list-style-type: none"> <li>• <i>Kb/s</i>—Specifies the kilobits per second (from 1 to 2000000). <ul style="list-style-type: none"> <li>◦ <i>burst_in_bytes</i>—Specifies the burst in bytes (from 32 to 2000000).</li> </ul> </li> <li>• <b>level</b> <i>level_value</i>—Specifies the multilevel (1-2) priority queue. <ul style="list-style-type: none"> <li>◦ <i>Kb/s</i>—Specifies the kilobits per second (from 1 to 2000000).</li> <li>◦ <i>burst_in_bytes</i>—Specifies the burst in bytes (from 32 to 2000000).</li> <li>◦ <b>percent</b>—Percentage of the total bandwidth. <ul style="list-style-type: none"> <li>◦ <i>burst_in_bytes</i>—Specifies the burst in bytes (from 32 to 2000000).</li> </ul> </li> </ul> </li> <li>• <b>percent</b>—Percentage of the total bandwidth. <ul style="list-style-type: none"> <li>◦ <i>burst_in_bytes</i>—Specifies the burst in bytes (32 to 2000000).</li> </ul> </li> </ul> <p><b>Note</b> Priority level 1 is more important than priority level 2. Priority level 1 reserves bandwidth that is processed first for QoS, so its latency is very low. Both priority level 1 and 2 reserve bandwidth.</p> |
| Step 5 | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Switch(config-pmap-c) # end Switch#</pre>                                                                                                                                                                                                                                                                         | <p>Saves configuration changes.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Step 6 | <p><b>show policy-map</b></p> <p><b>Example:</b></p> <pre>Switch# show policy-map</pre>                                                                                                                                                                                                                                                                         | <p>(Optional) Displays policy configuration information for all classes configured for all service policies.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**What to Do Next**

Configure any additional policy maps for QoS for your network. After creating your policy maps, attach the traffic policy or polices to an interface using the **service-policy** command.

## Configuring Queues and Shaping

### Configuring Egress Queue Characteristics

Depending on the complexity of your network and your QoS solution, you may need to perform all of the procedures in this section. You need to make decisions about these characteristics:

- Which packets are mapped by DSCP, CoS, or QoS group value to each queue and threshold ID?
- What drop percentage thresholds apply to the queues, and how much reserved and maximum memory is needed for the traffic type?
- How much of the fixed buffer space is allocated to the queues?
- Does the bandwidth of the port need to be rate limited?
- How often should the egress queues be serviced and which technique (shaped, shared, or both) should be used?

---

**Note** You can only configure the egress queues on the switch.

---

### Configuring Queue Buffers (CLI)

The switch allows you to allocate buffers to queues. If there is no allocation made to buffers, then they are divided equally for all queues. You can use the queue-buffer ratio to divide it in a particular ratio. Since by default DTS (Dynamic Threshold and Scaling) is active on all queues, these are soft buffers.

---

**Note** The queue-buffer ratio is supported on both wired and wireless ports, but the queue-buffer ratio cannot be configured with a queue-limit.

---

### Before You Begin

The following are prerequisites for this procedure:

- You should have created a class map for the queue buffer before beginning this procedure.
- You must have configured either bandwidth, shape, or priority on the policy map prior to configuring the queue buffers.

## SUMMARY STEPS

1. **configure terminal**
2. **policy-map** *policy name*
3. **class** *class name*
4. **bandwidth** {*Kb/s* | **percent** *percentage* | **remaining** { **ratio** *ratio value* }}
5. **queue-buffers** {*ratio ratio value*}
6. **end**
7. **show policy-map**

| Step 1 | <p><b>configure terminal</b></p> <p><b>Example:</b></p> <pre>Switch# configure terminal</pre>                                                                                                                                        | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Step 2 | <p><b>policy-map</b> <i>policy name</i></p> <p><b>Example:</b></p> <pre>Switch(config)# policy-map policy_queuebuffer01 Switch(config-pmap)#</pre>                                                                                   | <p>Enters policy map configuration mode.</p> <p>Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Step 3 | <p><b>class</b> <i>class name</i></p> <p><b>Example:</b></p> <pre>Switch(config-pmap)# class class_queuebuffer01 Switch(config-pmap-c)#</pre>                                                                                        | <p>Enters policy class map configuration mode. Specifies the name of the class whose policy you want to create or change. Command options for policy class map configuration mode include the following:</p> <ul style="list-style-type: none"> <li>• <i>word</i>—Class map name.</li> <li>• <b>class-default</b>—System default class matching any otherwise unclassified packets.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                   |
| Step 4 | <p><b>bandwidth</b> {<i>Kb/s</i>   <b>percent</b> <i>percentage</i>   <b>remaining</b> { <b>ratio</b> <i>ratio value</i> }}</p> <p><b>Example:</b></p> <pre>Switch(config-pmap-c)# bandwidth percent 80 Switch(config-pmap-c)#</pre> | <p>Configures the bandwidth for the policy map. The command parameters include:</p> <ul style="list-style-type: none"> <li>• <i>Kb/s</i>—Use this command to configure a specific value. The range is 20000 to 10000000.</li> <li>• <b>percent</b>—Allocates a minimum bandwidth to a particular class using a percentage. The queue can oversubscribe bandwidth in case other queues do not utilize the entire port bandwidth. The total sum cannot exceed 100 percent, and in case it is less than 100 percent, the rest of the bandwidth is equally divided along all bandwidth queues.</li> <li>• <b>remaining</b>—Allocates a minimum bandwidth to a particular class. The queue can oversubscribe bandwidth in case other queues do not utilize</li> </ul> |

|               | Command or Action                                                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               |                                                                                                                                                               | <p>entire port bandwidth. The total sum cannot exceed 100 percent. It is preferred to use this command when the <b>priority</b> command is used for certain queues in the policy. You can also assign ratios rather than a percentage to each queue; the queues will be assigned certain weights that are inline with these ratios. Ratios can range from 0 to 100. Total bandwidth ratio allocation for the policy in this case can exceed 100.</p> <p><b>Note</b> You cannot mix bandwidth types on a policy map.</p> |
| <b>Step 5</b> | <p><b>queue-buffers</b> {<i>ratio ratio value</i>}</p> <p><b>Example:</b></p> <pre>Switch(config-pmap-c)# queue-buffers ratio 10 Switch(config-pmap-c)#</pre> | <p>Configures the relative buffer size for the queue.</p> <p><b>Note</b> The sum of all configured buffers in a policy must be less than or equal to 100 percent. Unallocated buffers are evenly distributed to all the remaining queues.</p>                                                                                                                                                                                                                                                                           |
| <b>Step 6</b> | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Switch(config-pmap-c)# end Switch#</pre>                                                                        | <p>Saves configuration changes.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Step 7</b> | <p><b>show policy-map</b></p> <p><b>Example:</b></p> <pre>Switch# show policy-map</pre>                                                                       | <p>(Optional) Displays policy configuration information for all classes configured for all service policies.</p>                                                                                                                                                                                                                                                                                                                                                                                                        |

### What to Do Next

Configure any additional policy maps for QoS for your network. After creating your policy maps, attach the traffic policy or polices to an interface using the **service-policy** command.

### Configuring Queue Limits (CLI)

You use queue limits to configure Weighted Tail Drop (WTD). WTD ensures the configuration of more than one threshold per queue. Each class of service is dropped at a different threshold value to provide for QoS differentiation. With the switch, each queue has 3 explicit programmable threshold classes—0, 1, 2. Therefore, the enqueue/drop decision of each packet per queue is determined by the packet's threshold class assignment, which is determined by the DSCP, CoS, or QoS group field of the frame header.

WTD also uses a soft limit, and therefore you are allowed to configure the queue limit to up to 400 percent (maximum four times the reserved buffer from common pool). This soft limit prevents overrunning the common pool without impacting other features.

**Note** You can only configure queue limits on the switch egress queues on wired ports.

### Before You Begin

The following are prerequisites for this procedure:

- You should have created a class map for the queue limits before beginning this procedure.
- You must have configured either bandwidth, shape, or priority on the policy map prior to configuring the queue limits.

## SUMMARY STEPS

1. **configure terminal**
2. **policy-map** *policy name*
3. **class** *class name*
4. **bandwidth** {*Kb/s* | **percent** *percentage* | **remaining** { **ratio** *ratio value* }}
5. **queue-limit** {*packets* **packets** | **cos** {*cos value* { *maximum threshold value* | **percent** *percentage* } | **values** {*cos value* | **percent** *percentage* } } | **dscp** {*dscp value* { *maximum threshold value* | **percent** *percentage* } | **match packet** { *maximum threshold value* | **percent** *percentage* } | **default** { *maximum threshold value* | **percent** *percentage* } | **ef** { *maximum threshold value* | **percent** *percentage* } | **dscp values** *dscp value* } | **percent** *percentage* } }
6. **end**
7. **show policy-map**

| Step 3 | <p><b>class</b> <i>class name</i></p> <p><b>Example:</b></p> <pre>Switch(config-pmap)# class class_queue-limit01 Switch(config-pmap-c)#</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | <p>Enters policy class map configuration mode. Specifies the name of the class whose policy you want to create or change. Command options for policy class map configuration mode include the following:</p> <ul style="list-style-type: none"> <li>• <i>word</i>—Class map name.</li> <li>• <b>class-default</b>—System default class matching any otherwise unclassified packets.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Step 4 | <p><b>bandwidth</b> {<i>Kb/s</i>   <b>percent</b> <i>percentage</i>   <b>remaining</b> { <i>ratio</i> <i>ratio value</i> } }</p> <p><b>Example:</b></p> <pre>Switch(config-pmap-c)# bandwidth 500000 Switch(config-pmap-c)#</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | <p>Configures the bandwidth for the policy map. The parameters include:</p> <ul style="list-style-type: none"> <li>• <i>Kb/s</i>—Use this command to configure a specific value. The range is 20000 to 10000000.</li> <li>• <b>percent</b>—Allocates a minimum bandwidth to a particular class. The queue can oversubscribe bandwidth in case other queues do not utilize the entire port bandwidth. The total sum cannot exceed 100 percent, and in case it is less than 100 percent, the rest of the bandwidth is equally divided along all bandwidth queues.</li> <li>• <b>remaining</b>—Allocates a minimum bandwidth to a particular class. The queue can oversubscribe bandwidth in case other queues do not utilize entire port bandwidth. The total sum cannot exceed 100 percent. It is preferred to use this command when the <b>priority</b> command is used for certain queues in the policy. You can also assign ratios rather than a percentage to each queue; the queues will be assigned certain weights that are inline with these ratios. Ratios can range from 0 to 100. Total bandwidth ratio allocation for the policy in this case can exceed 100.</li> </ul> <p><b>Note</b> You cannot mix bandwidth types on a policy map.</p> |
| Step 5 | <p><b>queue-limit</b> {<i>packets</i> <b>packets</b>   <b>cos</b> {<i>cos value</i>   <i>maximum threshold value</i>   <b>percent</b> <i>percentage</i> }   <b>values</b> {<i>cos value</i>   <b>percent</b> <i>percentage</i> } }   <b>dscp</b> {<i>dscp value</i>   <i>maximum threshold value</i>   <b>percent</b> <i>percentage</i> }   <b>match packet</b> {<i>maximum threshold value</i>   <b>percent</b> <i>percentage</i> }   <b>default</b> {<i>maximum threshold value</i>   <b>percent</b> <i>percentage</i> }   <b>ef</b> {<i>maximum threshold value</i>   <b>percent</b> <i>percentage</i> }   <b>dscp values</b> <i>dscp value</i> }   <b>percent</b> <i>percentage</i> } }</p> <p><b>Example:</b></p> <pre>Switch(config-pmap-c)# queue-limit dscp 3 percent 20 Switch(config-pmap-c)# queue-limit dscp 4 percent 30 Switch(config-pmap-c)# queue-limit dscp</pre> | <p>Sets the queue limit threshold percentage values.</p> <p>With every queue, there are three thresholds (0,1,2), and there are default values for each of these thresholds. Use this command to change the default or any other queue limit threshold setting. For example, if DSCP 3, 4, and 5 packets are being sent into a specific queue in a configuration, then you can use this command to set the threshold percentages for these three DSCP values. For additional information about queue limit threshold values, see <a href="#">Weighted Tail Drop</a>, on page 966.</p> <p><b>Note</b> The switch does not support absolute queue-limit percentages. The switch only supports DSCP or CoS queue-limit percentages.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|               | Command or Action                                                                       | Purpose                                                                                                   |

## Configuring Shaping (CLI)

You use the **shape** command to configure shaping (maximum bandwidth) for a particular class. The queue's bandwidth is restricted to this value even though the port has additional bandwidth left. You can configure shaping as an average percent, as well as a shape average value in bits per second.

### Before You Begin

You should have created a class map for shaping before beginning this procedure.

## SUMMARY STEPS

1. **configure terminal**
2. **policy-map** *policy name*
3. **class** *class name*
4. **shape average** {*target bit rate* | **percent** *percentage*}
5. **end**
6. **show policy-map**

## DETAILED STEPS

## Configuring QoS Policies for Multicast Traffic (CLI)

### Before You Begin

The following are the prerequisites for configuring a QoS policy for multicast traffic:

- You must have a multicast service policy configured.
- You must enable multicast-multicast mode before applying the policy.

### SUMMARY STEPS

1. **configure terminal**
2. **ap capwap multicast service-policy output** *service-policy-name*
3. **end**

## DETAILED STEPS

|               | Command or Action                                                                                                                                                                                    | Purpose                                                                                                             |

## Applying a QoS Policy on a WLAN (GUI)

- Step 1** Choose **Configuration > Wireless**.
- Step 2** Expand the **WLAN** node by clicking on the left pane and choose **WLANs**. The **WLANs** page is displayed.
- Step 3** Select the WLAN for which you want to configure the QoS policies by clicking on the **WLAN Profile**.
- Step 4** Click the QoS tab to configure the QoS policies on the WLAN. The following options are available:

| Parameter              | Description                                                                                                                                                                                                                     |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Monitoring QoS

The following commands can be used to monitor QoS on the switch.

**Note** Classification counters and statistics are not supported for any wireless targets.

**Table 89: Monitoring QoS**

| Command                                        | Description                                                                                                                                                                                             |
|------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>show class-map [class_map_name]</code>   | Displays a list of all class maps configured.                                                                                                                                                           |
| <code>show policy-map [policy_map_name]</code> | Displays a list of all policy maps configured. Command parameters include: <ul style="list-style-type: none"><li>• <b>policy map name</b></li><li>• <b>interface</b></li><li>• <b>session</b></li></ul> |

| Command                                                                                                                                                                                                                                                                                                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>show policy-map interface wireless ssid name</b> <i>ssid-name</i> <b>radio type</b> { <i>24ghz</i>   <i>5ghz</i> } <b>ap name</b> <i>ap-name</i> | Displays SSID policy configuration on an access point.                                                                                                                                                                                          |

## Configuration Examples for QoS

### Examples: Classification by Access Control Lists

This example shows how to classify packets for QoS by using access control lists (ACLs):

```
Switch# configure terminal
Switch(config)# access-list 101 permit ip host 12.4.1.1 host 15.2.1.1
Switch(config)# class-map acl-101
Switch(config-cmap)# description match on access-list 101
Switch(config-cmap)# match access-group 101
Switch(config-cmap)#
```

After creating a class map by using an ACL, you then create a policy map for the class, and apply the policy map to an interface for QoS.

[Class Maps, on page 957](#)

### Examples: Class of Service Layer 2 Classification

This example shows how to classify packets for QoS using a class of service Layer 2 classification:

```
Switch# configure terminal
Switch(config)# class-map cos
Switch(config-cmap)# match cos ?
<0-7> Enter up to 4 class-of-service values separated by white-spaces
```

```
Switch(config-cmap) # match cos 3 4 5
Switch(config-cmap) #
```

After creating a class map by using a CoS Layer 2 classification, you then create a policy map for the class, and apply the policy map to an interface for QoS.

## Examples: Class of Service DSCP Classification

This example shows how to classify packets for QoS using a class of service DSCP classification:

```
Switch# configure terminal
Switch(config) # class-map dscp
Switch(config-cmap) # match dscp af21 af22 af23
Switch(config-cmap) #
```

After creating a class map by using a DSCP classification, you then create a policy map for the class, and apply the policy map to an interface for QoS.

## Examples: VLAN ID Layer 2 Classification

This example shows how to classify for QoS using a VLAN ID Layer 2 classification:

```
Switch# configure terminal
Switch(config) # class-map vlan-120
Switch(config-cmap) # match vlan ?
    <1-4095> VLAN id
Switch(config-cmap) # match vlan 120
Switch(config-cmap) #
```

After creating a class map by using a VLAN Layer 2 classification, you then create a policy map for the class, and apply the policy map to an interface for QoS.

## Examples: Classification by DSCP or Precedence Values

This example shows how to classify packets by using DSCP or precedence values:

```
Switch# configure terminal
Switch(config) # class-map prec2
Switch(config-cmap) # description matching precedence 2 packets
Switch(config-cmap) # match ip precedence 2
Switch(config-cmap) # exit
Switch(config) # class-map ef
Switch(config-cmap) # description EF traffic
Switch(config-cmap) # match ip dscp ef
Switch(config-cmap) #
```

After creating a class map by using a DSCP or precedence values, you then create a policy map for the class, and apply the policy map to an interface for QoS.

## Examples: Hierarchical Classification

The following is an example of a hierarchical classification, where a class named parent is created, which matches another class named child. The class named child matches based on the IP precedence being set to 2.

```
Switch# configure terminal
```

```
Switch(config)# class-map child
Switch(config-cmap)# match ip precedence 2
Switch(config-cmap)# exit
Switch(config)# class-map parent
Switch(config-cmap)# match class child
Switch(config-cmap)#
```

After creating the parent class map, you then create a policy map for the class, and apply the policy map to an interface for QoS.

## Examples: Hierarchical Policy Configuration

The following is an example of a configuration using hierarchical policies:

```
Switch# configure terminal
Switch(config)# class-map c1
Switch(config-cmap)# match dscp 30
Switch(config-cmap)# exit

Switch(config)# class-map c2
Switch(config-cmap)# match precedence 4
Switch(config-cmap)# exit

Switch(config)# class-map c3
Switch(config-cmap)# exit

Switch(config)# policy-map child
Switch(config-pmap)# class c1
Switch(config-pmap-c)# priority level 1
Switch(config-pmap-c)# police rate percent 20 conform-action transmit exceed action drop
Switch(config-pmap-c-police)# exit
Switch(config-pmap-c)# exit

Switch(config-pmap)# class c2
Switch(config-pmap-c)# bandwidth 20000
Switch(config-pmap-c)# exit
Switch(config-pmap)# class class-default
Switch(config-pmap-c)# bandwidth 20000
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit

Switch(config)# policy-map parent
Switch(config-pmap)# class class-default
Switch(config-pmap-c)# shape average 1000000
Switch(config-pmap-c)# service-policy child
Switch(config-pmap-c)# end
```

## Examples: Classification for Voice and Video

This example describes how to classify packet streams for voice and video using switch specific information.

In this example, voice and video are coming in from end-point A into GigabitEthernet1/0/1 on the switch and have precedence values of 5 and 6, respectively. Additionally, voice and video are also coming from end-point B into GigabitEthernet1/0/2 on the switch with DSCP values of EF and AF11, respectively.

Assume that all the packets from the both the interfaces are sent on the uplink interface, and there is a requirement to police voice to 100 Mbps and video to 150 Mbps.

To classify per the above requirements, a class to match voice packets coming in on GigabitEthernet1/0/1 is created, named voice-interface-1, which matches precedence 5. Similarly another class for voice is created, named voice-interface-2, which will match voice packets in GigabitEthernet1/0/2. These classes are associated to two separate policies named input-interface-1, which is attached to GigabitEthernet1/0/1, and input-interface-2, which is attached to GigabitEthernet1/0/2. The action for this class is to mark the qos-group to 10. To match packets with QoS-group 10 on the output interface, a class named voice is created which matches on QoS-group 10. This is then associated to another policy named output-interface, which is associated to the uplink interface. Video is handled in the same way, but matches on QoS-group 20.

The following example shows how classify using the above switch specific information:

```
Switch(config)#
Switch(config)# class-map voice-interface-1
Switch(config-cmap)# match ip precedence 5
Switch(config-cmap)# exit

Switch(config)# class-map video-interface-1
Switch(config-cmap)# match ip precedence 6
Switch(config-cmap)# exit

Switch(config)# class-map voice-interface-2
Switch(config-cmap)# match ip dscp ef
Switch(config-cmap)# exit

Switch(config)# class-map video-interface-2
Switch(config-cmap)# match ip dscp af11
Switch(config-cmap)# exit

Switch(config)# policy-map input-interface-1
Switch(config-pmap)# class voice-interface-1
Switch(config-pmap-c)# set qos-group 10
Switch(config-pmap-c)# exit

Switch(config-pmap)# class video-interface-1
Switch(config-pmap-c)# set qos-group 20

Switch(config-pmap-c)# policy-map input-interface-2
Switch(config-pmap)# class voice-interface-2
Switch(config-pmap-c)# set qos-group 10
Switch(config-pmap-c)# class video-interface-2
Switch(config-pmap-c)# set qos-group 20
Switch(config-pmap-c)# exit
Switch(config-pmap)# exit

Switch(config)# class-map voice
Switch(config-cmap)# match qos-group 10
Switch(config-cmap)# exit

Switch(config)# class-map video
Switch(config-cmap)# match qos-group 20

Switch(config)# policy-map output-interface
Switch(config-pmap)# class voice
Switch(config-pmap-c)# police 256000 conform-action transmit exceed-action drop
Switch(config-pmap-c-police)# exit
Switch(config-pmap-c)# exit

Switch(config-pmap)# class video
Switch(config-pmap-c)# police 1024000 conform-action transmit exceed-action drop
Switch(config-pmap-c-police)# exit
Switch(config-pmap-c)# exit
```

## Examples: Wireless QoS Policy Classified by Voice, Video, and Multicast Traffic

The following example provides a template for creating a port child policy for managing quality of service for voice and video traffic.

```
Policy-map port_child_policy
  Class voice (match dscp ef)
    Priority level 1
    Police Multicast Policer
  Class video (match dscp af41)
    Priority level 2
    Police Multicast Policer
  Class mcast-data (match non-client-nrt)
    Bandwidth remaining ratio <>
  Class class-default (NRT Data)
    Bandwidth remaining ratio <>
```

### Note

Multicast Policer in the example above is not a keyword. It refers to the policing policy configured.

Two class maps with name voice and video are configured with DSCP assignments of 46 and 34. The voice traffic is assigned the priority of 1 and the video traffic is assigned the priority level 2 and is processed using Q0 and Q1. If your network receives multicast voice and video traffic, you can configure multicast policers. The non-client NRT data and NRT data are processed using the Q2 and Q3 queues.

## Examples: Configuring Downstream SSID Policy

To configure a downstream BSSID policy, you must first configure a port child policy with priority level queuing.

### Configuring a User-Defined Port Child Policy

The following is an example of configuring a user-defined port child policy:

```
policy-map port_child_policy
  class voice
    priority level 1 20000

  class video
    priority level 2 10000

  class non-client-nrt-class
    bandwidth remaining ratio 10

  class class-default
    bandwidth remaining ratio 15
```

## Configuring Downstream BSSID Policy

The following configuration example displays how to configure a downstream BSSID policy:

```
policy-map bssid-policer
  queue-buffer ratio 0
  class class-default
    shape average 30000000
  set dscp dscp table dscp2dscp
  set wlan user-priority dscp table dscp2up
  service-policy ssid_child_qos
```

The SSID child QoS policy may be defined as below:

```
Policy Map ssid-child_qos
  Class voice
    priority level 1
    police cir 5m
    admit cac wmm-tspec
      UP 6,7 / tells WCM allow 'voice' TSPEC\SIP snoop for this ssid
      rate 4000 / must be police rate value is in kbps)
  Class video
    priority level 2
    police cir 60000
```

## Examples: Client Policies

The following example shows a default client policy in the downstream direction. Any incoming traffic contains the user-priority as 0:

### Note

---

The default client policy is enabled only on WMM clients that are ACM-enabled.

---

```
Policy-map client-def-down
  class class-default
    set wlan user-priority 0
```

The following example shows the default client policy in the upstream direction. Any traffic that is sent to the wired network from wireless network will result in the DSCP value being set to 0.

### Note

---

The default client policy is enabled only on WMM clients that are ACM-enabled.

---

```
Policy-map client-def-up
  class class-default
    set dscp 0
```

The following examples shows client policies that are generated automatically and applied to the WMM client when the client authenticates to a profile in AAA with a QoS-level attribute configured.

```
Policy Map platinum-WMM
Class voice-plat
  set wlan user-priority 6
  Class video-plat
  set wlan user-priority 4
Class class-default
  set wlan user-priority 0

Policy Map gold-WMM
Class voice-gold
  set wlan user-priority 4
  Class video-gold
  set wlan user-priority 4
Class class-default
  set wlan user-priority 0
```

The following is an example of non-WMM client precious metal policies:

```
Policy Map platinum
  set wlan user-priority 6
```

Any traffic matching class voice1 the user priority is set to a pre-defined value. The class can be set to assign a DSCP or ACL.

```
Policy Map client1-down
Class voice1 //match dscp, cos
  set wlan user-priority <>
Class voice2 //match acl
  set wlan user-priority <>
Class voice3
  set wlan user-priority <>
Class class-default
  set wlan user-priority 0
```

The following is an example of a client policy based on AAA and TCLAS:

```
Policy Map client2-down[ AAA+ TCLAS pol example]
Class voice \\match dscp
  police <>
  set <>
Class class-default
  set <>
Class voice1|| voice2 [match acls]
  police <>
  class voice1
  set <>
  class voice2
  set <>
```

The following is an example of a client policy for voice and video for traffic in the downstream direction:

```
Policy Map client3-down
  class voice \\match dscp, cos
  police X
  class video
  police Y
  class class-default
  police Z
```

The following is an example of a client policy for voice and video for traffic in the upstream direction using policing:

```
Policy Map client1-up
  class voice \\match dscp, up, cos
```

```

    police X
  class video
  police Y
class class-default
  police Z

```

The following is an example of a client policy for voice and video based on DSCP:

```

Policy Map client2-up
  class voice      \match dscp, up, cos
set dscp <>
  class video
  set dscp <>
class class-default
  set dscp <>

```

## Examples: Average Rate Shaping Configuration

The following example shows how to configure average rate shaping:

```

Switch# configure terminal
Switch(config)# class-map prec1
Switch(config-cmap)# description matching precedence 1 packets
Switch(config-cmap)# match ip precedence 1
Switch(config-cmap)# end

Switch# configure terminal
Switch(config)# class-map prec2
Switch(config-cmap)# description matching precedence 2 packets
Switch(config-cmap)# match ip precedence 2
Switch(config-cmap)# exit

Switch(config)# policy-map shaper
Switch(config-pmap)# class prec1
Switch(config-pmap-c)# shape average 512000
Switch(config-pmap-c)# exit

Switch(config-pmap)# policy-map shaper
Switch(config-pmap)# class prec2
Switch(config-pmap-c)# shape average 512000
Switch(config-pmap-c)# exit

Switch(config-pmap)# class class-default
Switch(config-pmap-c)# shape average 1024000

```

After configuring the class maps, policy map, and shape averages for your configuration, proceed to then apply the policy map to the interface for QoS.

## Examples: Queue-limit Configuration

The following example shows how to configure a queue-limit policy based upon DSCP values and percentages:

```
Switch# configure terminal
Switch#(config)# policy-map port-queue
Switch#(config-pmap)# class dscp-1-2-3
Switch#(config-pmap-c)# bandwidth percent 20
Switch#(config-pmap-c)# queue-limit dscp 1 percent 80
Switch#(config-pmap-c)# queue-limit dscp 2 percent 90
Switch#(config-pmap-c)# queue-limit dscp 3 percent 100
Switch#(config-pmap-c)# exit

Switch#(config-pmap)# class dscp-4-5-6
Switch#(config-pmap-c)# bandwidth percent 20
Switch#(config-pmap-c)# queue-limit dscp 4 percent 20
Switch#(config-pmap-c)# queue-limit dscp 5 percent 30
Switch#(config-pmap-c)# queue-limit dscp 6 percent 20
Switch#(config-pmap-c)# exit

Switch#(config-pmap)# class dscp-7-8-9
Switch#(config-pmap-c)# bandwidth percent 20
Switch#(config-pmap-c)# queue-limit dscp 7 percent 20
Switch#(config-pmap-c)# queue-limit dscp 8 percent 30
Switch#(config-pmap-c)# queue-limit dscp 9 percent 20
Switch#(config-pmap-c)# exit

Switch#(config-pmap)# class dscp-10-11-12
Switch#(config-pmap-c)# bandwidth percent 20
Switch#(config-pmap-c)# queue-limit dscp 10 percent 20
Switch#(config-pmap-c)# queue-limit dscp 11 percent 30
Switch#(config-pmap-c)# queue-limit dscp 12 percent 20
Switch#(config-pmap-c)# exit

Switch#(config-pmap)# class dscp-13-14-15
Switch#(config-pmap-c)# bandwidth percent 10
Switch#(config-pmap-c)# queue-limit dscp 13 percent 20
Switch#(config-pmap-c)# queue-limit dscp 14 percent 30
Switch#(config-pmap-c)# queue-limit dscp 15 percent 20
Switch#(config-pmap-c)# end
Switch#
```

After finishing with the above policy map queue-limit configuration, you can then proceed to apply the policy map to an interface for QoS.

## Examples: Queue Buffers Configuration

The following example shows how configure a queue buffer policy and then apply it to an interface for QoS:

```
Switch# configure terminal
Switch#(config)# policy-map policy1001
Switch#(config-pmap)# class class1001
Switch#(config-pmap-c)# bandwidth remaining ratio 10
Switch#(config-pmap-c)# queue-buffer ratio ?
    <0-100> Queue-buffers ratio limit
Switch#(config-pmap-c)# queue-buffer ratio 20
Switch#(config-pmap-c)# end
```

```
Switch# configure terminal
Switch(config)# interface gigabitEthernet2/0/3
Switch(config-if)# service-policy output policy1001
Switch(config-if)# end
```

### Related Topics

## Examples: Policing Action Configuration

The following example displays the various policing actions that can be associated to the policer. These actions are accomplished using the conforming, exceeding, or violating packet configurations. You have the flexibility to drop, mark and transmit, or transmit packets that have exceeded or violated a traffic profile.

For example, a common deployment scenario is one where the enterprise customer polices traffic exiting the network towards the service provider and marks the conforming, exceeding and violating packets with different DSCP values. The service provider could then choose to drop the packets marked with the exceeded and violated DSCP values under cases of congestion, but may choose to transmit them when bandwidth is available.

### Note

The Layer 2 fields can be marked to include the CoS fields, and the Layer 3 fields can be marked to include the precedence and the DSCP fields.

One useful feature is the ability to associate multiple actions with an event. For example, you could set the precedence bit and the CoS for all conforming packets. A submode for an action configuration could then be provided by the policing feature.

This is an example of a policing action configuration:

```
Switch# configure terminal
Switch(config)# policy-map police
Switch(config-pmap)# class class-default
Switch(config-pmap-c)# police cir 1000000 pir 2000000
Switch(config-pmap-c-police)# conform-action transmit
Switch(config-pmap-c-police)# exceed-action set-dscp-transmit dscp table exceed-markdown-table
Switch(config-pmap-c-police)# violate-action set-dscp-transmit dscp table
violate-markdown-table
Switch(config-pmap-c-police)# end
```

In this example, the exceed-markdown-table and violate-mark-down-table are table maps.

### Note

Policer-based markdown actions are only supported using table maps. Only one markdown table map is allowed for each marking field in the switch.

## Examples: Policer VLAN Configuration

The following example displays a VLAN policer configuration. At the end of this configuration, the VLAN policy map is applied to an interface for QoS.

```
Switch# configure terminal
Switch(config)# class-map vlan100
Switch(config-cmap)# match vlan 100
Switch(config-cmap)# exit
Switch(config)# policy-map vlan100
Switch(config-pmap)# policy-map class vlan100
Switch(config-pmap-c)# police 100000 bc conform-action transmit exceed-action drop
Switch(config-pmap-c-police)# end
Switch# configure terminal
Switch(config)# interface gigabitEthernet1/0/5
Switch(config-if)# service-policy input vlan100
```

## Examples: Policing Units

The following examples display the various units of policing that are supported for QoS. The policing unit is the basis on which the token bucket works .

The following units of policing are supported:

- CIR and PIR are specified in bits per second. The burst parameters are specified in bytes. This is the default mode; it is the unit that is assumed when no units are specified. The CIR and PIR can also be configured in percent, in which case the burst parameters have to be configured in milliseconds.
- CIR and PIR are specified in packets per second. In this case, the burst parameters are configured in packets as well.

The following is an example of a policer configuration in bits per second:

```
Switch(config)# policy-map bps-policer
Switch(config-pmap)# class class-default
Switch(config-pmap-c) # police rate 256000 bps burst 1000 bytes
conform-action transmit exceed-action drop
```

The following is an example of a policer configuration in packets per second. In this configuration, a dual-rate three-color policer is configured where the units of measurement is packet. The burst and peak burst are all specified in packets.

```
Switch(config)# policy-map pps-policer
Switch(config-pmap)# class class-default
Switch(config-pmap-c) # police rate 5000 pps burst 100 packets
peak-rate 10000 pps peak-burst 200 packets conform-action transmit
exceed-action drop violate-action drop
```

## Examples: Dual-Rate Three-Color Policing Configuration

The following example shows how to configure a dual-rate three-color policer:

```
Switch# configure terminal
Switch(config)# policy-Map dual-rate-3color-policer
Switch(config-pmap)# class class-default
Switch(config-pmap-c)# police cir 64000 bc 2000 pir 128000 be 2000
Switch(config-pmap-c-police)# conform-action transmit
Switch(config-pmap-c-police)# exceed-action set-dscp-transmit dscp table exceed-markdown-table
Switch(config-pmap-c-police)# violate-action set-dscp-transmit dscp table
violate-markdown-table
Switch(config-pmap-c-police)# exit
Switch(config-pmap-c)#
```

In this example, the exceed-markdown-table and violate-mark-down-table are table maps.

### Note

Policer based markdown actions are only supported using table maps. Only one markdown table map is allowed for each marking field in the switch.

## Examples: Table Map Marking Configuration

The following steps and examples show how to use table map marking for your QoS configuration:

- 1 Define the table map.

Define the table-map using the **table-map** command and indicate the mapping of the values. This table does not know of the policies or classes within which it will be used. The default command in the table

map indicates the value to be copied into the 'to' field when there is no matching 'from' field. In the example, a table map named table-map1 is created. The mapping defined is to convert the value from 0 to 1 and from 2 to 3, while setting the default value to 4.

```
Switch(config)# table-map table-map1
Switch(config-tablemap)# map from 0 to 1
Switch(config-tablemap)# map from 2 to 3
Switch(config-tablemap)# default 4
Switch(config-tablemap)# exit
```

## 2 Define the policy map where the table map will be used.

In the example, the incoming CoS is mapped to the DSCP based on the mapping specified in the table table-map1. For this example, if the incoming packet has a DSCP of 0, the CoS in the packet is set 1. If no table map name is specified the command assumes a default behavior where the value is copied as is from the 'from' field (DSCP in this case) to the 'to' field (CoS in this case). Note however, that while the CoS is a 3-bit field, the DSCP is a 6-bit field, which implies that the CoS is copied to the first three bits in the DSCP.

```
Switch(config)# policy map policy1
Switch(config-pmap)# class class-default
Switch(config-pmap-c)# set cos dscp table table-map1
Switch(config-pmap-c)# exit
```

## 3 Associate the policy to an interface.

```
Switch(config)# interface GigabitEthernet1/0/1
Switch(config-if)# service-policy output policy1
Switch(config-if)# exit
```

### Related Topics

## Example: Table Map Configuration to Retain CoS Markings

The following example shows how to use table maps to retain CoS markings on an interface for your QoS configuration.

The cos-trust-policy policy (configured in the example) is enabled in the ingress direction to retain the CoS marking coming into the interface. If the policy is not enabled, only the DSCP is trusted by default. If a pure Layer 2 packet arrives at the interface, then the CoS value will be rewritten to 0 when there is no such policy in the ingress port for CoS.

```
Switch# configure terminal
Switch(config)# table-map cos2cos
Switch(config-tablemap)# default copy
Switch(config-tablemap)# exit

Switch(config)# policy map cos-trust-policy
Switch(config-pmap)# class class-default
Switch(config-pmap-c)# set cos cos table cos2cos
Switch(config-pmap-c)# exit

Switch(config)# interface GigabitEthernet1/0/2
```

```
Switch(config-if) # service-policy input cos-trust-policy
Switch(config-if) # exit
```

- [Where to Go Next for Auto-QoS, page 1087](#)
- [Additional References for Auto-QoS, page 1087](#)
- [Feature History and Information for Auto-QoS, page 1088](#)

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for Auto-QoS

The prerequisites for auto-QoS are the same as the prerequisites for standard QoS.

## Restrictions for Auto-QoS

The following are restrictions for auto-QoS:

- Auto-qos is not supported on SVI interfaces.
- Auto-qos is not supported on interfaces which are bundled in an EtherChannel.
- The **trust device** *device\_type* interface configuration command is only supported in an auto-QoS configuration, and not as a stand-alone command on the switch. When using the **trust device** *device\_type* interface configuration command in an auto-QoS configuration, if the connected peer device is not a corresponding device (defined as a device matching your trust policy), both CoS and DSCP values are set to "0" and any input policy will not take effect.
- You must exercise caution when copying a pre-3.2.2 software version to this switch. If you do copy a pre-3.2.2 software version to this switch, then you must follow the auto-QoS upgrade procedure described later in this chapter.

### Related Topics

[Upgrading Auto-QoS \(CLI\)](#), on page 1058

## Information About Configuring Auto-QoS

### Auto-QoS Overview

You can use the auto-QoS feature to simplify the deployment of QoS features. Auto-QoS determines the network design and enables QoS configurations so that the switch can prioritize different traffic flows.

The switch employs the MQC model. This means that instead of using certain global configurations, auto-QoS applied to any interface on a switch configures several global class maps and policy maps.

Auto-QoS matches traffic and assigns each matched packet to qos-groups. This allows the output policy map to put specific qos-groups into specific queues, including into the priority queue.

QoS is needed in both directions, both on inbound and outbound. When inbound, the switch port needs to trust the DSCP in the packet (done by default). When outbound, the switch port needs to give voice packets "front of line" priority. If voice is delayed too long by waiting behind other packets in the outbound queue, the end host drops the packet because it arrives outside of the receive window for that packet.

### Auto-QoS Global Configuration Templates

In general, an auto-QoS command generates a series of class maps that either match on ACLs or on DSCP and/or CoS values to differentiate traffic into application classes. An input policy is also generated, which matches the generated classes and in some cases, polices the classes to a set bandwidth. Eight egress-queue class maps are generated. The actual egress output policy assigns a queue to each one of these eight egress-queue class maps.

The auto-QoS commands only generate templates as needed. For example, the first time any new auto-QoS command is used, global configurations that define the eight queue egress service-policy are generated. From this point on, auto-QoS commands applied to other interfaces do not generate templates for egress queuing because all auto-QoS commands rely on the same eight queue models, which have already been generated from the first time a new auto-QoS command was used.

## Auto-QoS Policy and Class Maps

After entering the appropriate auto-QoS command, the following actions occur:

- Specific class maps are created.
- Specific policy maps (input and output) are created.
- Policy maps are attached to the specified interface.
- Trust level for the interface is configured.

## Effects of Auto-QoS on Running Configuration

When auto-QoS is enabled, the **auto qos** interface configuration commands and the generated global configuration are added to the running configuration.

The switch applies the auto-QoS-generated commands as if the commands were entered from the CLI. An existing user configuration can cause the application of the generated commands to fail or to be overridden by the generated commands. These actions may occur without warning. If all the generated commands are successfully applied, any user-entered configuration that was not overridden remains in the running configuration. Any user-entered configuration that was overridden can be retrieved by reloading the switch without saving the current configuration to memory. If the generated commands are not applied, the previous running configuration is restored.

## How to Configure Auto-QoS

### Configuring Auto-QoS (CLI)

For optimum QoS performance, configure auto-QoS on all the devices in your network.

## SUMMARY STEPS

1. **configure terminal**
2. **interface** *interface-id*
3. Depending on your auto-QoS configuration, use one of the following commands:
  - **auto qos voip** {**cisco-phone** | **cisco-softphone** | **trust**}
  - **auto qos video** {**cts** | **ip-camera** | **media-player**}
  - **auto qos classify** [**police**]
  - **auto qos trust** {**cos** | **dscp**}
4. **end**
5. **show auto qos interface** *interface-id*

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                                                                                                                                                                                                                                                                                                                                                                                                                | Enters the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Step 2 | <b>interface</b> <i>interface-id</i><br><br><b>Example:</b><br>Switch(config)# <b>interface</b><br><b>gigabitethernet 3/0/1</b>                                                                                                                                                                                                                                                                                                                                                                      | Specifies the port that is connected to a VoIP port, video device, or the uplink port that is connected to another trusted switch or router in the network interior, and enters the interface configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Step 3 | Depending on your auto-QoS configuration, use one of the following commands: <ul style="list-style-type: none"> <li>• <b>auto qos voip</b> {<b>cisco-phone</b>   <b>cisco-softphone</b>   <b>trust</b>}</li> <li>• <b>auto qos video</b> {<b>cts</b>   <b>ip-camera</b>   <b>media-player</b>}</li> <li>• <b>auto qos classify</b> [<b>police</b>]</li> <li>• <b>auto qos trust</b> {<b>cos</b>   <b>dscp</b>}</li> </ul> <b>Example:</b><br>Switch(config-if)# <b>auto qos</b><br><b>trust dscp</b> | The following commands enable auto-QoS for VoIP: <ul style="list-style-type: none"> <li>• <b>auto qos voip cisco-phone</b>—If the port is connected to a Cisco IP Phone, the QoS labels of incoming packets are only trusted (conditional trust through CDP) when the telephone is detected.</li> <li>• <b>auto qos voip cisco-softphone</b>—The port is connected to device running the Cisco SoftPhone feature. This command generates a QoS configuration for interfaces connected to PCs running the Cisco IP SoftPhone application and mark, as well as police traffic coming from such interfaces. Ports configured with this command are considered untrusted.</li> <li>• <b>auto qos voip trust</b>—The uplink port is connected to a trusted switch or router, and the VoIP traffic classification in the ingress packet is trusted.</li> </ul> The following commands enable auto-QoS for the specified video device (system, camera, or media player): |

|               | Command or Action                                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               |                                                                                                                                               | <ul style="list-style-type: none"> <li>• <b>auto qos video cts</b>—A port connected to a Cisco Telepresence system. QoS labels of incoming packets are only trusted (conditional trust through CDP) when a Cisco TelePresence is detected.</li> <li>• <b>auto qos video ip-camera</b>—A port connected to a Cisco video surveillance camera. QoS labels of incoming packets are only trusted (conditional trust through CDP) when a Cisco camera is detected.</li> <li>• <b>auto qos video media-player</b>—A port connected to a CDP-capable Cisco digital media player. QoS labels of incoming packets are only trusted (conditional trust through CDP) when a digital media player is detected.</li> </ul> <p>The following command enables auto-QoS for classification:</p> <ul style="list-style-type: none"> <li>• <b>auto qos classify police</b>— This command generates a QoS configuration for untrusted interfaces. The configuration places a service-policy on the interface to classify traffic coming from untrusted desktops/devices and mark them accordingly. The service-policies generated do police.</li> </ul> <p>The following commands enable auto-QoS for trusted interfaces:</p> <ul style="list-style-type: none"> <li>• <b>auto qos trust cos</b>—Class of service.</li> <li>• <b>auto qos trust dscp</b>—Differentiated Services Code Point.</li> <li>• <code>&lt;cr&gt;</code>—Trust interface.</li> </ul> |
| <b>Step 4</b> | <b>end</b><br><br><b>Example:</b><br><pre>Switch(config-if)# end</pre>                                                                        | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Step 5</b> | <b>show auto qos interface <i>interface-id</i></b><br><br><b>Example:</b><br><pre>Switch# show auto qos interface gigabitethernet 3/0/1</pre> | (Optional) Verifies your entries.<br><br>This command displays the auto-QoS command on the interface on which auto-QoS was enabled. You can use the <b>show running-config</b> privileged EXEC command to display the auto-QoS configuration and the user modifications.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Upgrading Auto-QoS (CLI)

This procedure should only be followed after copying a pre-3.2.2 software version to this switch. If you do copy a pre-3.2.2 software version to this switch, then you must follow this auto-QoS upgrade procedure.

### Before You Begin

Prior to upgrading, you need to remove all auto-QoS configurations currently on the switch. This sample procedure describes that process.

After following this sample procedure, you must then reboot the switch with the new or upgraded software image and reconfigure auto-QoS.

### SUMMARY STEPS

1. **show auto qos**
2. **no auto qos**
3. **show running-config | i autoQoS**
4. **no policy-map *policy-map\_name***
5. **show running-config | i AutoQoS**
6. **show auto qos**
7. **write memory**

### DETAILED STEPS

---

#### Step 1 **show auto qos**

##### Example:

```
Switch# show auto qos

GigabitEthernet2/0/3
auto qos voip cisco-phone

GigabitEthernet2/0/27
auto qos voip cisco-softphone
```

In privileged EXEC mode, record all current auto QoS configurations by entering this command.

#### Step 2 **no auto qos**

##### Example:

```
Switch(config-if)#no auto qos
```

In interface configuration mode, run the appropriate **no auto qos** command on each interface that has an auto QoS configuration.

**Step 3** **show running-config | i autoQos**

**Example:**

```
Switch# show running-config | i autoQos
```

Return to privileged EXEC mode, and record any remaining auto QoS maps class maps, policy maps, access lists, table maps, or other configurations by entering this command.

**Step 4** **no policy-map *policy-map\_name***

**Example:**

```
Switch) config# no policy-map pmap_101
Switch) config# no class-map cmap_101
Switch) config# no ip access-list extended AutoQos-101
Switch) config# no table-map 101
Switch) config# no table-map policed-dscp
```

In global configuration mode, remove the QoS class maps, policy maps, table maps, and any other auto QoS configurations by entering these commands:

- **no policy-map *policy-map-name***
- **no class-map *class-map-name***
- **no ip access-list extended *Auto-QoS-x***
- **no table-map *table-map-name***
- **no table-map policed-dscp**

**Step 5** **show running-config | i AutoQoS**

**Example:**

```
Switch# show running-config | i AutoQos
```

Return to privileged EXEC mode, run this command again to ensure that no auto-QoS configuration or remaining parts of the auto-QoS configuration exists

**Step 6** **show auto qos**

**Example:**

```
Switch# show auto qos
```

Run this command to ensure that no auto-QoS configuration or remaining parts of the configuration exists.

**Step 7** **write memory**

**Example:**

```
Switch# write memory
```

Write the changes to the auto QoS configuration to NV memory by entering the **write memory** command.

### What to Do Next

Reboot the switch with the new or upgraded software image.

After rebooting with the new or upgraded software image, re-configure auto-QoS for the appropriate switch interfaces as determined by running the **show auto qos** command described in step 1.

#### Note

There is only one table-map for exceed and another table-map for violate markdown per switch or stack. If the switch already has a table-map under the exceed action, then the auto-qos policy cannot be applied.

| <b>show auto qos</b> [ <b>interface</b> <i>[interface-id]</i> ] | Displays the initial auto-QoS configuration.<br><br>You can compare the <b>show auto qos</b> and the <b>show running-config</b> command output to identify the user-defined QoS settings.                                         |
| <b>show running-config</b>                                      | Displays information about the QoS configuration that might be affected by auto-QoS.<br><br>You can compare the <b>show auto qos</b> and the <b>show running-config</b> command output to identify the user-defined QoS settings. |

## Troubleshooting Auto-QoS

To troubleshoot auto-QoS, use the **debug auto qos** privileged EXEC command. For more information, see the **debug auto qos** command in the command reference for this release.

To disable auto-QoS on a port, use the **no** form of the **auto qos** command interface configuration command, such as **no auto qos voip**. Only the auto-QoS-generated interface configuration commands for this port are removed. If this is the last port on which auto-QoS is enabled and you enter the **no auto qos voip** command, auto-QoS is considered disabled even though the auto-QoS-generated global configuration commands remain (to avoid disrupting traffic on other ports affected by the global configuration).

## Configuration Examples for Auto-QoS

### Example: auto qos trust cos

The following is an example of the **auto qos trust cos** command and the applied policies and class maps.

The following policy maps are created and applied when running this command:

- AutoQos-4.0-Trust-Cos-Input-Policy
- AutoQos-4.0-Output-Policy

The following class maps are created and applied when running this command:

- class-default (match-any)
- AutoQos-4.0-Output-Priority-Queue (match-any)
- AutoQos-4.0-Output-Control-Mgmt-Queue (match-any)
- AutoQos-4.0-Output-Multimedia-Conf-Queue (match-any)
- AutoQos-4.0-Output-Trans-Data-Queue (match-any)
- AutoQos-4.0-Output-Bulk-Data-Queue (match-any)
- AutoQos-4.0-Output-Scavenger-Queue (match-any)
- AutoQos-4.0-Output-Multimedia-Strm-Queue (match-any)

```
Switch(config)# interface gigabitEthernet1/0/17

## Example: auto qos video cts

The following is an example of the **auto qos video cts** command and the applied policies and class maps.

The following policy maps are created and applied when running this command:

- AutoQos-4.0-Trust-Cos-Input-Policy
- AutoQos-4.0-Output-Policy

The following class maps are created and applied when running this command:

- class-default (match-any)
- AutoQos-4.0-Output-Priority-Queue (match-any)
- AutoQos-4.0-Output-Control-Mgmt-Queue (match-any)
- AutoQos-4.0-Output-Multimedia-Conf-Queue (match-any)
- AutoQos-4.0-Output-Trans-Data-Queue (match-any)
- AutoQos-4.0-Output-Bulk-Data-Queue (match-any)
- AutoQos-4.0-Output-Scavenger-Queue (match-any)
- AutoQos-4.0-Output-Multimedia-Strm-Queue (match-any)

```
Switch(config)# interface gigabitEthernet1/0/12
Switch(config-if)# auto qos video cts

## Example: auto qos voip cisco-softphone

The following is an example of the **auto qos voip cisco-softphone** command and the applied policies and class maps.

The following policy maps are created and applied when running this command:

- AutoQos-4.0-CiscoSoftPhone-Input-Policy
- AutoQos-4.0-Output-Policy

The following class maps are created and applied when running this command:

- AutoQos-4.0-Voip-Data-Class (match-any)
- AutoQos-4.0-Voip-Signal-Class (match-any)
- AutoQos-4.0-Multimedia-Conf-Class (match-any)
- AutoQos-4.0-Bulk-Data-Class (match-any)
- AutoQos-4.0-Transaction-Class (match-any)
- AutoQos-4.0-Scavenger-Class (match-any)
- AutoQos-4.0-Signaling-Class (match-any)
- AutoQos-4.0-Default-Class (match-any)
- class-default (match-any)
- AutoQos-4.0-Output-Priority-Queue (match-any)
- AutoQos-4.0-Output-Control-Mgmt-Queue (match-any)
- AutoQos-4.0-Output-Multimedia-Conf-Queue (match-any)
- AutoQos-4.0-Output-Trans-Data-Queue (match-any)
- AutoQos-4.0-Output-Bulk-Data-Queue (match-any)
- AutoQos-4.0-Output-Scavenger-Queue (match-any)
- AutoQos-4.0-Output-Multimedia-Strm-Queue (match-any)

```

## auto qos classify police

The following is an example of the **auto qos classify police** command and the applied policies and class maps.

The following policy maps are created and applied when running this command:

- AutoQos-4.0-Classify-Police-Input-Policy
- AutoQos-4.0-Output-Policy

The following class maps are created and applied when running this command:

- AutoQos-4.0-Multimedia-Conf-Class (match-any)
- AutoQos-4.0-Bulk-Data-Class (match-any)
- AutoQos-4.0-Transaction-Class (match-any)
- AutoQos-4.0-Scavenger-Class (match-any)
- AutoQos-4.0-Signaling-Class (match-any)
- AutoQos-4.0-Default-Class (match-any)
- class-default (match-any)
- AutoQos-4.0-Output-Priority-Queue (match-any)
- AutoQos-4.0-Output-Control-Mgmt-Queue (match-any)
- AutoQos-4.0-Output-Multimedia-Conf-Queue (match-any)
- AutoQos-4.0-Output-Trans-Data-Queue (match-any)
- AutoQos-4.0-Output-Bulk-Data-Queue (match-any)
- AutoQos-4.0-Output-Scavenger-Queue (match-any)
- AutoQos-4.0-Output-Multimedia-Strm-Queue (match-any)

```

## Finding Feature Information

Your software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Prerequisites for Configuring Radio Resource Management

The switch should be configured as a mobility controller and not a mobility anchor to configure Radio Resource Management. It may require dynamic channel assignment functionality for the home APs to be supported.

The new mobility architecture that involves mobility controller and mobility agent must be configured on the switch or controllers for RRM to work.

**Note**

---

Refer Mobility Configuration Guide for configuring mobility controller and mobility agent.

---

## Restrictions for Radio Resource Management

If an AP tries to join the RF-group that already holds the maximum number of APs it can support, the device rejects the application and throws an error.

## Information About Radio Resource Management

The Radio Resource Management (RRM) software embedded in the switch acts as a built-in RF engineer to consistently provide real-time RF management of your wireless network. RRM enables switches to continually monitor their associated lightweight access points for the following information:

- Traffic load—The total bandwidth used for transmitting and receiving traffic. It enables wireless LAN managers to track and plan network growth ahead of client demand.
- Interference—The amount of traffic coming from other 802.11 sources.
- Noise—The amount of non-802.11 traffic that is interfering with the currently assigned channel.
- Coverage—The Received Signal Strength (RSSI) and signal-to-noise ratio (SNR) for all connected clients.
- Other —The number of nearby access points.

RRM performs these functions:

- Radio resource monitoring
- Transmit power control
- Dynamic channel assignment
- Coverage hole detection and correction
- RF grouping

### Radio Resource Monitoring

RRM automatically detects and configures new switches and lightweight access points as they are added to the network. It then automatically adjusts associated and nearby lightweight access points to optimize coverage and capacity.

Lightweight access points can scan all valid channels for the country of operation as well as for channels available in other locations. The access points in local mode go “off-channel” for a period not greater than 60 ms to monitor these channels for noise and interference. Packets collected during this time are analyzed to detect rogue access points, rogue clients, ad-hoc clients, and interfering access points.

**Note**

In the presence of voice traffic or other critical traffic (in the last 100 ms), the access points can defer off-channel measurements. It also defers based on WLAN scan defer priority configurations.

Each access point spends only 0.2 percent of its time off-channel. This activity is distributed across all access points so that adjacent access points are not scanning at the same time, which could adversely affect wireless LAN performance.

RRM supports new mobility architecture for RF grouping that involves Mobility Controller (MC) and Mobility Agent (MA).

- **Mobility Controller (MC)**—The Cisco WLC 5700 Series Controllers, Cisco Catalyst 3850 Switch, or Cisco Unified Wireless Networking Solution controller can act as MC. The MC has MC functionality and MA functionality that is running internally into it.
- **Mobility Agent (MA)**—The Mobility Agent is the component that maintains client mobility state machine for a mobile client.

## Information About RF Groups

An RF group is a logical collection of Cisco WLCs that coordinate to perform RRM in a globally optimized manner to perform network calculations on a per-radio basis. An RF group exists for each 802.11 network type. Clustering Cisco WLCs into a single RF group enable the RRM algorithms to scale beyond the capabilities of a single Cisco WLC.

RF group is created based on following parameters:

- User-configured RF network name.
- Neighbor discovery performed at the radio level.
- Country list configured on MC.

RF grouping runs between MCs.

Lightweight access points periodically send out neighbor messages over the air. Access points using the same RF group name validate messages from each other.

When access points on different Cisco WLCs hear validated neighbor messages at a signal strength of  $-80$  dBm or stronger, the Cisco WLCs dynamically form an RF neighborhood in auto mode. In static mode, the leader is manually selected and the members are added to the RF Group. To know more about RF Group modes, [RF Group Leader](#).

**Note**

RF groups and mobility groups are similar in that they both define clusters of Cisco WLCs, but they are different in terms of their use. An RF group facilitates scalable, system-wide dynamic RF management while a mobility group facilitates scalable, system-wide mobility and Cisco WLC redundancy.

### RF Group Leader

Starting in the 7.0.116.0 release, the RF Group Leader can be configured in two ways as follows:

- **Auto Mode**—In this mode, the members of an RF group elect an RF group leader to maintain a “master” power and channel scheme for the group. The RF grouping algorithm dynamically chooses the RF group leader and ensures that an RF group leader is always present. Group leader assignments can and do change (for instance, if the current RF group leader becomes inoperable or if RF group members experience major changes).
- **Static Mode**—In this mode, the user selects a Cisco WLC as an RF group leader manually. In this mode, the leader and the members are manually configured and are therefore fixed. If the members are unable to join the RF group, the reason is indicated. The leader tries to establish a connection with a member every 1 minute if the member has not joined in the previous attempt.

The RF group leader analyzes real-time radio data collected by the system, calculates the power and channel assignments, and sends them to each of the Cisco WLCs in the RF group. The RRM algorithms ensure system-wide stability and restrain channel and power scheme changes to the appropriate local RF neighborhoods.

In Cisco WLC software releases prior to 6.0, the dynamic channel assignment (DCA) search algorithm attempts to find a good channel plan for the radios associated to Cisco WLCs in the RF group, but it does not adopt a new channel plan unless it is considerably better than the current plan. The channel metric of the worst radio in both plans determines which plan is adopted. Using the worst-performing radio as the single criterion for adopting a new channel plan can result in pinning or cascading problems.

Pinning occurs when the algorithm could find a better channel plan for some of the radios in an RF group but is prevented from pursuing such a channel plan change because the worst radio in the network does not have any better channel options. The worst radio in the RF group could potentially prevent other radios in the group from seeking better channel plans. The larger the network, the more likely pinning becomes.

Cascading occurs when one radio’s channel change results in successive channel changes to optimize the remaining radios in the RF neighborhood. Optimizing these radios could lead to their neighbors and their neighbors’ neighbors having a suboptimal channel plan and triggering their channel optimization. This effect could propagate across multiple floors or even multiple buildings, if all the access point radios belong to the same RF group. This change results in considerable client confusion and network instability.

The main cause of both pinning and cascading is the way in which the search for a new channel plan is performed and that any potential channel plan changes are controlled by the RF circumstances of a single radio. In Cisco WLC software release 6.0, the DCA algorithm has been redesigned to prevent both pinning and cascading. The following changes have been implemented:

- **Multiple local searches**—The DCA search algorithm performs multiple local searches initiated by different radios within the same DCA run rather than performing a single global search driven by a single radio. This change addresses both pinning and cascading while maintaining the desired flexibility and adaptability of DCA and without jeopardizing stability.
- **Multiple channel plan change initiators (CPCIs)**—Previously, the single worst radio was the sole initiator of a channel plan change. Now each radio within the RF group is evaluated and prioritized as a potential initiator. Intelligent randomization of the resulting list ensures that every radio is eventually evaluated, which eliminates the potential for pinning.
- **Limiting the propagation of channel plan changes (Localization)**—For each CPI radio, the DCA algorithm performs a local search for a better channel plan, but only the CPI radio itself and its one-hop neighboring access points are actually allowed to change their current transmit channels. The impact of an access point triggering a channel plan change is felt only to within two RF hops from that access point, and the actual channel plan changes are confined to within a one-hop RF neighborhood. Because this limitation applies across all CPI radios, cascading cannot occur.

- Non-RSSI-based cumulative cost metric—A cumulative cost metric measures how well an entire region, neighborhood, or network performs with respect to a given channel plan. The individual cost metrics of all access points in that area are considered in order to provide an overall understanding of the channel plan's quality. These metrics ensure that the improvement or deterioration of each single radio is factored into any channel plan change. The objective is to prevent channel plan changes in which a single radio improves but at the expense of multiple other radios experiencing a considerable performance decline.

The RRM algorithms run at a specified updated interval, which is 600 seconds by default. Between update intervals, the RF group leader sends keepalive messages to each of the RF group members and collects real-time RF data.

**Note**

---

Several monitoring intervals are also available. See the Configuring RRM section for details.

---

### RF Group Name

A Cisco WLC is configured with an RF group name, which is sent to all access points joined to the Cisco WLC and used by the access points as the shared secret for generating the hashed MIC in the neighbor messages. To create an RF group, you configure all of the Cisco WLCs to be included in the group with the same RF group name.

If there is any possibility that an access point joined to a Cisco WLC may hear RF transmissions from an access point on a different Cisco WLC, you should configure the Cisco WLCs with the same RF group name. If RF transmissions between access points can be heard, then system-wide RRM is recommended to avoid 802.11 interference and contention as much as possible.

### Mobility Controller

An MC can either be a group leader or a group member. One of the MCs can act as a RF group leader based on RF grouping and RF group election with other MCs. The order of priority to elect the RF leader is based on the maximum number of APs the controller or switch can support. The highest priority being 1 and the least being 5.

- 1 WiSM 2 Controllers
- 2 Cisco WLC 5700 Series Controllers
- 3 WiSM 1 Controllers
- 4 Catalyst 3850 Series Switches
- 5 Catalyst 3650 Series Switches

When one of the MCs becomes the RRM group leader, the remaining MCs become RRM group members. RRM group members send their RF information to the Group Leader. The group leader determines a channel and Tx power plan for the network and passes the information back to the RF group members. The MCs push the power plan to MA for the radios that belong to MA. These channel and power plans are ultimately pushed down to individual radios.

**Note**

---

MC has MA functionality within it.

---

## Mobility Agent

The MA communicates with the MC. The MC includes MAC or IP address of the switch/controller while communicating with the MA.

The MA provides the following information when polled by the MC:

- Interference or noise data.
- Neighbor data.
- Radio capabilities (supported channels, power levels).
- Radio configuration (power, channel, channel width).
- Radar data.

The MC exchanges the following information with the switch/controller (MA). The message includes:

- Configurations (channel/power/channel width) for individual radios.
- Polling requests for current configurations and RF measurements for individual radios
- Group Leader Update

In turn, the MA communicates the following messages with the MC:

- RF measurements from radios (e.g. load, noise and neighbor information)
- RF capabilities and configurations of individual radios

The MA sets channel, power, and channel width on the radios when directed by the MC. The DFS, coverage hole detection/mitigation, static channel/power configurations are performed by the MA.

## Information About Rogue Access Point Detection in RF Groups

After you have created an RF group of Cisco WLCs, you need to configure the access points connected to the Cisco WLCs to detect rogue access points. The access points will then select the beacon/probe-response frames in neighboring access point messages to see if they contain an authentication information element (IE) that matches that of the RF group. If the select is successful, the frames are authenticated. Otherwise, the authorized access point reports the neighboring access point as a rogue, records its BSSID in a rogue table, and sends the table to the Cisco WLC.

## Transmit Power Control

The switch dynamically controls access point transmit power based on real-time wireless LAN conditions.

The Transmit Power Control (TPC) algorithm both increases and decreases an access point's power in response to changes in the RF environment. In most instances, TPC seeks to lower an access point's power to reduce interference, but in the case of a sudden change in the RF coverage—for example, if an access point fails or becomes disabled—TPC can also increase power on surrounding access points. This feature is different from coverage hole detection, which is primarily concerned with clients. TPC provides enough RF power to achieve desired coverage levels while avoiding channel interference between access points.

## Overriding the TPC Algorithm with Minimum and Maximum Transmit Power Settings

The TPC algorithm balances RF power in many diverse RF environments. However, it is possible that automatic power control will not be able to resolve some scenarios in which an adequate RF design was not possible to implement due to architectural restrictions or site restrictions—for example, when all access points must be mounted in a central hallway, placing the access points close together, but requiring coverage out to the edge of the building.

In these scenarios, you can configure maximum and minimum transmit power limits to override TPC recommendations. The maximum and minimum TPC power settings apply to all access points through RF profiles in a RF network.

To set the Maximum Power Level Assignment and Minimum Power Level Assignment, enter the maximum and minimum transmit power used by RRM in the text boxes in the Tx Power Control page. The range for these parameters is -10 to 30 dBm. The minimum value cannot be greater than the maximum value; the maximum value cannot be less than the minimum value.

If you configure a maximum transmit power, RRM does not allow any access point attached to the switch to exceed this transmit power level (whether the power is set by RRM TPC or by coverage hole detection). For example, if you configure a maximum transmit power of 11 dBm, then no access point would transmit above 11 dBm, unless the access point is configured manually.

## Dynamic Channel Assignment

Two adjacent access points on the same channel can cause either signal contention or signal collision. In a collision, data is not received by the access point. This functionality can become a problem, for example, when someone reading e-mail in a café affects the performance of the access point in a neighboring business. Even though these are completely separate networks, someone sending traffic to the café on channel 1 can disrupt communication in an enterprise using the same channel. Switches can dynamically allocate access point channel assignments to avoid conflict and to increase capacity and performance. Channels are “reused” to avoid wasting scarce RF resources. In other words, channel 1 is allocated to a different access point far from the café, which is more effective than not using channel 1 altogether.

The switch’s Dynamic Channel Assignment (DCA) capabilities are also useful in minimizing adjacent channel interference between access points. For example, two overlapping channels in the 802.11b/g band, such as 1 and 2, cannot both simultaneously use 11/54 Mbps. By effectively reassigning channels, the switch keeps adjacent channels separated.

### Note

We recommend that you use only non-overlapping channels (1, 6, 11, and so on).

The switch examines a variety of real-time RF characteristics to efficiently handle channel assignments as follows:

- Access point received energy—The received signal strength measured between each access point and its nearby neighboring access points. Channels are optimized for the highest network capacity.
- Noise—Noise can limit signal quality at the client and access point. An increase in noise reduces the effective cell size and degrades user experience. By optimizing channels to avoid noise sources, the switch can optimize coverage while maintaining system capacity. If a channel is unusable due to excessive noise, that channel can be avoided.

- **802.11 Interference**—Interference is any 802.11 traffic that is not part of your wireless LAN, including rogue access points and neighboring wireless networks. Lightweight access points constantly scan all channels looking for sources of interference. If the amount of 802.11 interference exceeds a predefined configurable threshold (the default is 10 percent), the access point sends an alert to the switch. Using the RRM algorithms, the switch may then dynamically rearrange channel assignments to increase system performance in the presence of the interference. Such an adjustment could result in adjacent lightweight access points being on the same channel, but this setup is preferable to having the access points remain on a channel that is unusable due to an interfering foreign access point.

In addition, if other wireless networks are present, the switch shifts the usage of channels to complement the other networks. For example, if one network is on channel 6, an adjacent wireless LAN is assigned to channel 1 or 11. This arrangement increases the capacity of the network by limiting the sharing of frequencies. If a channel has virtually no capacity remaining, the switch may choose to avoid this channel. In very dense deployments in which all nonoverlapping channels are occupied, the switch does its best, but you must consider RF density when setting expectations.

- **Load and utilization**—When utilization monitoring is enabled, capacity calculations can consider that some access points are deployed in ways that carry more traffic than other access points (for example, a lobby versus an engineering area). The switch can then assign channels to improve the access point with the worst performance reported. The load is taken into account when changing the channel structure to minimize the impact on clients currently in the wireless LAN. This metric keeps track of every access point's transmitted and received packet counts to determine how busy the access points are. New clients avoid an overloaded access point and associate to a new access point. This parameter is disabled by default.

The switch combines this RF characteristic information with RRM algorithms to make system-wide decisions. Conflicting demands are resolved using soft-decision metrics that guarantee the best choice for minimizing network interference. The end result is optimal channel configuration in a three-dimensional space, where access points on the floor above and below play a major factor in an overall wireless LAN configuration.

**Note**

---

Radios using 40-MHz channels in the 2.4-GHz band or 80MHz channels are not supported by DCA.

---

The RRM startup mode is invoked in the following conditions:

- In a single-switch environment, the RRM startup mode is invoked after the switch is rebooted.
- In a multiple-switch environment, the RRM startup mode is invoked after an RF Group leader is elected.

You can trigger RRM startup mode from CLI.

RRM startup mode runs for 100 minutes (10 iterations at 10-minute intervals). The duration of the RRM startup mode is independent of the DCA interval, sensitivity, and network size. The startup mode consists of 10 DCA runs with high sensitivity (making channel changes easy and sensitive to the environment) to converge to a steady state channel plan. After the startup mode is finished, DCA continues to run at the specified interval and sensitivity.

## Coverage Hole Detection and Correction

The RRM coverage hole detection algorithm can detect areas of radio coverage in a wireless LAN that are below the level needed for robust radio performance. This feature can alert you to the need for an additional (or relocated) lightweight access point.

If clients on a lightweight access point are detected at threshold levels (RSSI, failed client count, percentage of failed packets, and number of failed packets) lower than those specified in the RRM configuration, the access point sends a “coverage hole” alert to the switch. The alert indicates the existence of an area where clients are continually experiencing poor signal coverage, without having a viable access point to which to roam. The switch discriminates between coverage holes that can and cannot be corrected. For coverage holes that can be corrected, the switch mitigates the coverage hole by increasing the transmit power level for that specific access point. The switch does not mitigate coverage holes caused by clients that are unable to increase their transmit power or are statically set to a power level because increasing their downstream transmit power might increase interference in the network.

## How to Configure RRM

### Configuring Advanced RRM CCX Parameters (CLI)

#### SUMMARY STEPS

1. **configure terminal**
2. **ap dot11 24ghz | 5ghz rrm ccx location-measurement *interval***
3. **end**

#### DETAILED STEPS

|               | Command or Action                                                                                                                                                         | Purpose                                                                                                             |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                                                                                     | Enters global configuration mode.                                                                                   |
| <b>Step 2</b> | <b>ap dot11 24ghz   5ghz rrm ccx location-measurement <i>interval</i></b><br><br><b>Example:</b><br>Switch(config)# <b>ap dot11 24ghz rrm ccx location-measurement 15</b> | Configures the interval for 802.11 CCX client location measurements. The range is from 10 to 32400 seconds.         |
| <b>Step 3</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b>                                                                                                           | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode. |

## Configuring Neighbor Discovery Type (CLI)

### SUMMARY STEPS

1. `configure terminal`
2. `ap dot11 24ghz | 5ghz rrm ndp-type {protected | transparent}`
3. `end`

### DETAILED STEPS

|               | Command or Action                                                                                                                                                                                                                                | Purpose                                                                                                                                                                                                                                                                                                                               |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <code>configure terminal</code><br><br><b>Example:</b><br><code>Switch# configure terminal</code>                                                                                                                                                | Enters global configuration mode.                                                                                                                                                                                                                                                                                                     |

By default, the mode is set to “transparent”. <ul style="list-style-type: none"> <li>• <b>protected</b>—Sets the neighbor discover type to protected. Packets are encrypted.</li> <li>• <b>transparent</b>—Sets the neighbor discover type to transparent. Packets are sent as is.</li> </ul> |
| <b>Step 3</b> | <code>end</code><br><br><b>Example:</b><br><code>Switch(config)# end</code>                                                                                                                                                                      | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode.                                                                                                                                                                                                                   |

## Configuring RRM Profile Thresholds, Monitoring Channels, and Monitoring Intervals (GUI)

- Step 1** Choose **Configuration > Wireless > 802.11a/n/ac > RRM > General** or **Configuration > Wireless > 802.11b/g/n > RRM > General** to open RRM General page.
- Step 2** Configure profile thresholds used for alarming as follows:
- Note** The profile thresholds have no bearing on the functionality of the RRM algorithms. Switches send an SNMP trap (or an alert) to the Cisco Prime Infrastructure or another trap receiver when individual APs values set for these threshold parameters are exceeded.
- a) In the **Interference** text box, enter the percentage of interference (802.11 traffic from sources outside of your wireless network) on a single access point. The valid range is 0 to 100%, and the default value is 10%.
  - b) In the **Clients** text box, enter the number of clients on a single access point. The valid range is 1 to 75, and the default value is 12.

- c) In the **Noise** text box, enter the level of noise (non-802.11 traffic) on a single access point. The valid range is  $-127$  to  $0$  dBm, and the default value is  $-70$  dBm.
- d) In the **Utilization** text box, enter the percentage of RF bandwidth being used by a single access point. The valid range is  $0$  to  $100\%$ , and the default value is  $80\%$ .
- e) In the **Throughput** text box, enter the level of Throughput being used by a single access point. The valid range is  $1000$  to  $10000000$ , and the default value is  $1000000$ .

**Step 3**

From the **Channel List** drop-down list, choose one of the following options to specify the set of channels that the access point uses for RRM scanning:

- **All Channels**—RRM channel scanning occurs on all channels supported by the selected radio, which includes channels not allowed in the country of operation.
- **Country Channels**—RRM channel scanning occurs only on the data channels in the country of operation. This is the default value.
- **DCA Channels**—RRM channel scanning occurs only on the channel set used by the DCA algorithm, which by default includes all of the non-overlapping channels allowed in the country of operation. However, you can specify the channel set to be used by DCA if desired. To do so, follow instructions in the [Dynamic Channel Assignment](#).

**Step 4**

Configure monitor intervals as follows:

- 1 In the **Channel Scan Interval** text box, enter (in seconds) the sum of the time between scans for each channel within a radio band. The entire scanning process takes  $50$  ms per channel, per radio and runs at the interval configured here. The time spent listening on each channel is determined by the non-configurable  $50$ -ms scan time and the number of channels to be scanned. For example, in the U.S. all  $11$   $802.11b/g$  channels are scanned for  $50$  ms each within the default  $180$ -second interval. So every  $16$  seconds,  $50$  ms is spent listening on each scanned channel ( $180/11 = \sim 16$  seconds). The Channel Scan Interval parameter determines the interval at which the scanning occurs. The valid range is  $60$  to  $3600$  seconds, and the default value for  $802.11a/n/ac$  and  $802.11b/g/n$  radios is  $180$  seconds.
- 2 In the **Neighbor Packet Frequency** text box, enter (in seconds) how frequently neighbor packets (messages) are sent, which eventually builds the neighbor list. The valid range is  $60$  to  $3600$  seconds, and the default value is  $60$  seconds.

**Note** If the access point radio does not receive a neighbor packet from an existing neighbor within  $60$  minutes, the Cisco WLC deletes that neighbor from the neighbor list.

**Step 5**

Click **Apply**.

**Step 6**

Click **Save Configuration**.

**Note** Click **Set to Factory Default** if you want to return all of the Cisco WLC's RRM parameters to their factory-default values.

## Configuring RF Groups

This section describes how to configure RF groups through either the GUI or the CLI.

**Note**

The RF group name is generally set at deployment time through the Startup Wizard. However, you can change it as necessary.

---

**Note** When the multiple-country feature is being used, all Cisco WLCs intended to join the same RF group must be configured with the same set of countries, configured in the same order.

---

---

**Note** You can also configure RF groups using the Cisco Prime Infrastructure.

---

## Configuring the RF Group Mode (GUI)

- 
- Step 1** Choose **Configuration > Wireless > 802.11a/n/ac > RRM > RF Grouping** or **Configuration > Wireless > 802.11b/g/n > RRM > RF Grouping** to open the RF Grouping page.
- Step 2** From the **Group Mode** drop-down list, choose the mode that you want to configure for this Cisco WLC. You can configure RF grouping in the following modes:
- auto—Sets the RF group selection to automatic update mode.
    - Note** A configured static leader cannot become a member of another RF group until its mode is set to “auto”.
  - leader—Sets the RF group selection to static mode, and sets this Cisco WLC as the group leader.
  - off—Sets the RF group selection off. Every Cisco WLC optimizes its own access point parameters.
    - Note** A Cisco WLC with a lower priority cannot assume the role of a group leader if a Cisco WLC with a higher priority is available. Here, priority is related to the processing power of the Cisco WLC.
    - Note** We recommend that Cisco WLCs participate in automatic RF grouping. You can override RRM settings without disabling automatic RF group participation.
- Step 3** Click **Apply** to save the configuration and click **Restart** to restart the RRM RF Grouping algorithm.
- Step 4** If you configured RF Grouping mode for this Cisco WLC as a static leader, you can add group members from the Group Members section as follows:
- 1 In the switch Name text box, enter the Cisco WLC that you want to add as a member to this group.
  - 2 In the IP Address text box, enter the IP address of the Cisco WLC.
  - 3 Click **Add** to add the member to this group.
    - Note** If the member has not joined the static leader, the reason of the failure is shown in parentheses.
- Step 5** Click **Apply**.
- Step 6** Click **Save Configuration**.
-

## Configuring RF Group Selection Mode (CLI)

### SUMMARY STEPS

1. `configure terminal`
2. `ap dot11 24ghz | 5ghz rrm group-mode {auto | leader | off}`
3. `end`

### DETAILED STEPS

|               | Command or Action                                                                                                                                                           | Purpose                                                                                                                                                                                                                                                                                                                            |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <p><code>configure terminal</code></p> <p><b>Example:</b><br/>Switch# <code>configure terminal</code></p>                                                                   | Enters global configuration mode.                                                                                                                                                                                                                                                                                                  |
| <b>Step 2</b> | <p><code>ap dot11 24ghz   5ghz rrm group-mode {auto   leader   off}</code></p> <p><b>Example:</b><br/>Switch(config)# <code>ap dot11 24ghz rrm group-mode leader</code></p> | <p>Configures RF group selection mode for 802.11 bands.</p> <ul style="list-style-type: none"> <li>• <b>auto</b>—Sets the 802.11 RF group selection to automatic update mode.</li> <li>• <b>leader</b>—Sets the 802.11 RF group selection to leader mode.</li> <li>• <b>off</b>—Disables the 802.11 RF group selection.</li> </ul> |
| <b>Step 3</b> | <p><code>end</code></p> <p><b>Example:</b><br/>Switch(config)# <code>end</code></p>                                                                                         | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode.                                                                                                                                                                                                                |

## Configuring an RF Group Name (CLI)

### SUMMARY STEPS

1. `configure terminal`
2. `wireless rf-network name`
3. `end`
4. `show network profile profile_number`

## DETAILED STEPS

|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                                                                                                                        | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                       |
| <b>Step 2</b> | <b>ap dot11 24ghz   5ghz rrm txpower</b> { <i>trans_power_level</i>   <b>auto</b>   <b>max</b>   <b>min</b>   <b>once</b> }<br><br><b>Example:</b><br>Switch(config)# <b>ap dot11 24ghz rrm txpower auto</b> | Configures the 802.11 tx-power level <ul style="list-style-type: none"> <li>• <b>trans_power_level</b>—Sets the transmit power level.</li> <li>• <b>auto</b>—Enables auto-RF.</li> <li>• <b>max</b>—Configures the maximum auto-RF tx-power.</li> <li>• <b>min</b>—Configures the minimum auto-RF tx-power.</li> <li>• <b>once</b>—Enables one-time auto-RF.</li> </ul> |
| <b>Step 3</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b>                                                                                                                                              | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode.                                                                                                                                                                                                                                                     |

## Configuring Transmit Power Control (GUI)

- Step 1** Choose **Configuration > Wireless > 802.11a/n/ac > RRM > TPC** or **Configuration > Wireless > 802.11b/g/n > RRM > TPC** to open RRM Tx Power Control (TPC) page.
- Step 2** Choose the Transmit Power Control.  
Coverage Optimal Mode (TPCv1)— Offers strong signal coverage and stability. In this mode, power can be kept low to gain extra capacity and reduce interference.
- Step 3** Choose one of the following options from the Power Level Assignment Method list to specify the Cisco WLC's dynamic power assignment mode:
- **Automatic**—Causes the Cisco WLC to periodically evaluate and, if necessary, update the transmit power for all joined access points. This is the default value.
  - **On Demand**—Causes the Cisco WLC to periodically evaluate the transmit power for all joined access points. However, the Cisco WLC updates the power, if necessary, only when you click **Apply** after choosing **On Demand**.
 

**Note** The Cisco WLC does not evaluate and update the transmit power immediately when you click **Apply** after choosing **On Demand**. It waits for the next 600-second interval. This value is not configurable.
  - **Fixed**—Prevents the Cisco WLC from evaluating and, if necessary, updating the transmit power for joined access points. The power level is set to the fixed value chosen from the drop-down list. The corresponding option for **Fixed** when you try to configure from CLI is **once**.
 

**Note** The transmit power level is assigned an integer value instead of a value in mW or dBm. The integer corresponds to a power level that varies depending on the regulatory domain, channel, and antennas in which the access points are deployed.

**Note** For optimal performance, we recommend that you use the Automatic setting.
- Step 4** Enter the maximum and minimum power level assignment values in the Maximum Power Level Assignment and Minimum Power Level Assignment text boxes.  
The range for the Maximum Power Level Assignment is –10 to 30 dBm.  
The range for the Minimum Power Level Assignment is –10 to 30 dBm.
- Step 5** In the Power Threshold text box, enter the cutoff signal level used by RRM when determining whether to reduce an access point's power. The default value for this parameter is –70 dBm for TPCv1, but can be changed when access points are transmitting at higher (or lower) than desired power levels.  
The range for this parameter is –80 to –50 dBm. Increasing this value (between –65 and –50 dBm) causes the access points to operate at a higher transmit power. Decreasing the value has the opposite effect.
- In applications with a dense population of access points, it may be useful to decrease the threshold to –80 or –75 dBm to reduce the number of BSSIDs (access points) and beacons seen by the wireless clients. Some wireless clients might have difficulty processing a large number of BSSIDs or a high beacon rate and might exhibit problematic behavior with the default threshold.
- This page also shows the following nonconfigurable transmit power level parameter settings:
- **Power Neighbor Count**—The minimum number of neighbors an access point must have for the transmit power control algorithm to run.

- Power Assignment Leader—The MAC address of the RF group leader, which is responsible for power level assignment.
- Last Power Level Assignment—The last time RRM evaluated the current transmit power level assignments.

**Step 6** Click **Apply**.

**Step 7** Click **Save Configuration**.

## Configuring 802.11 RRM Parameters

### Configuring Advanced 802.11 Channel Assignment Parameters (CLI)

#### SUMMARY STEPS

1. `configure terminal`
2. `ap dot11 24ghz | 5ghz rrm channel cleanair-event sensitivity {high | low | medium}`
3. `ap dot11 24ghz | 5ghz rrm channel dca {channel number} anchor-time | global {auto| once} | interval | min-metric | sensitivity {high | low | medium} }`
4. `ap dot11 5ghz rrm channel dca chan-width-11n {20 | 40}`
5. `ap dot11 24ghz | 5ghz rrm channel device`
6. `ap dot11 24ghz | 5ghz rrm channel foreign`
7. `ap dot11 24ghz | 5ghz rrm channel load`
8. `ap dot11 24ghz | 5ghz rrm channel noise`
9. `end`

| <b>Step 6</b> | <p><b>ap dot11 24ghz   5ghz rrm channel foreign</b></p> <p><b>Example:</b></p> <pre>Switch(config)#ap dot11 24ghz rrm channel foreign</pre>                                                                                                                                                       | <p>Configures the foreign AP 802.11 interference avoidance in the channel assignment.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|               | Command or Action                                                                                                         | Purpose                                                                                                             |
|---------------|---------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| <b>Step 7</b> | <b>ap dot11 24ghz   5ghz rrm channel load</b><br><br><b>Example:</b><br>Switch(config) #ap dot11 24ghz rrm channel load   | Configures the Cisco AP 802.11 load avoidance in the channel assignment.                                            |
| <b>Step 8</b> | <b>ap dot11 24ghz   5ghz rrm channel noise</b><br><br><b>Example:</b><br>Switch(config) #ap dot11 24ghz rrm channel noise | Configures the 802.11 noise avoidance in the channel assignment.                                                    |
| <b>Step 9</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config) # end                                                                 | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode. |

### Configuring Dynamic Channel Assignment (GUI)

You can specify the channels that the Dynamic Channel Assignment (DCA) algorithm considers when selecting the channels to be used for RRM scanning by using the Cisco WLC GUI.

**Note** This functionality is helpful when you know that the clients do not support certain channels because they are legacy devices or they have certain regulatory restrictions.

- 
- Step 1** Disable the 802.11a/n/ac or 802.11b/g/n network as follows:
- Choose **Configuration > Wireless > 802.11a/n/ac > Network** or **Configuration > Wireless > 802.11b/g/n > Network** to open the Global Parameters page.
  - Unselect the **802.11a/n/ac** (or **802.11b/g/n**) **Network Status** check box.
  - Click **Apply**.
- Step 2** Choose **Configuration > Wireless > 802.11a/n/ac > RRM > DCA** or **Configuration > Wireless > 802.11b/g/n > RRM > DCA** to open the Dynamic Channel Assignment (DCA) page.
- Step 3** Choose one of the following options from the **Channel Assignment Method** drop-down list to specify the Cisco WLC's DCA mode:
- **Automatic**—Causes the Cisco WLC to periodically evaluate and, if necessary, update the channel assignment for all joined access points. This is the default value.
  - **Freeze**—Causes the Cisco WLC to evaluate and update the channel assignment for all joined access points, if necessary, only when you click **Apply** after selecting the **Freeze** option.
- Note** The Cisco WLC does not evaluate and update the channel assignment immediately when you click **Apply** after selecting the **Freeze** option. It waits for the next interval to elapse.

- **OFF**—Turns off DCA and sets all access point radios to the first channel of the band. If you choose this option, you must manually assign channels on all radios.

**Note** For optimal performance, we recommend that you use the Automatic setting. See the [Disabling Dynamic Channel and Power Assignment \(GUI\)](#) section for instructions on how to disable the Cisco WLC's dynamic channel and power settings.

**Step 4** From the Interval drop-down list, choose one of the following options to specify how often the DCA algorithm is allowed to run: **10 minutes**, **1 hour**, **2 hours**, **3 hours**, **4 hours**, **6 hours**, **8 hours**, **12 hours**, or **24 hours**. The default value is 10 minutes.

**Step 5** From the AnchorTime drop-down list, choose a number to specify the time of day when the DCA algorithm is to start. The options are numbers between 0 and 23 (inclusive) representing the hour of the day from 12:00 a.m. to 11:00 p.m.

**Step 6** From the **DCA Channel Sensitivity** drop-down list, choose one of the following options to specify how sensitive the DCA algorithm is to environmental changes such as signal, load, noise, and interference when determining whether to change channels:

- **Low**—The DCA algorithm is not particularly sensitive to environmental changes.
- **Medium**—The DCA algorithm is moderately sensitive to environmental changes.
- **High**—The DCA algorithm is highly sensitive to environmental changes.

The default value is Medium. The DCA sensitivity thresholds vary by radio band, as noted in the following table:

**Table 91: DCA Sensitivity Thresholds**

| Option | 2.4-GHz DCA Sensitivity Threshold | 5-GHz DCA Sensitivity Threshold |
|--------|-----------------------------------|---------------------------------|
| High   | 5 dB                              | 5 dB                            |
| Medium | 10 dB                             | 15 dB                           |
| Low    | 20 dB                             | 20 dB                           |

**Step 7** This page also shows the following nonconfigurable channel parameter settings:

- Channel Assignment Leader—The MAC address of the RF group leader, which is responsible for channel assignment.

**Step 8** In the DCA Channel List area, the DCA Channels text box shows the channels that are currently selected. To choose a channel, select its check box in the Select column. To exclude a channel, unselect its check box.

The ranges are as follows:

- 802.11a—36, 40, 44, 48, 52, 56, 60, 64, 100, 104, 108, 112, 116, 132, 136, 140, 149, 153, 157, 161, 165 (depending on countries).
- 802.11b/g—1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14 (depending on countries).

The defaults are as follows:

- 802.11a—36, 40, 44, 48, 52, 56, 60, 64, 100, 104, 108, 112, 116, 132, 136, 140, 149, 153, 157, 161

- 802.11b/g—1, 6, 11

**Step 9** Click **Apply**.

**Step 10** Reenable the 802.11 networks as follows:

- 1 Choose **Configuration > Wireless > 802.11a/n/ac > Network** or **Configuration > Wireless > 802.11b/g/n > Network** to open the Global Parameters page.
- 2 Select the **802.11a/n/ac** (or **802.11b/g/n**) **Network Status** check box.
- 3 Click **Apply**.

**Step 11** Click **Save Configuration**.

## Configuring 802.11 Coverage Hole Detection (CLI)

### SUMMARY STEPS

1. `configure terminal`
2. `ap dot11 24ghz | 5ghz rrm coverage data {fail-percentage | packet-count | rssi-threshold}`
3. `ap dot11 24ghz | 5ghz rrm coverage exception global exception level`
4. `ap dot11 24ghz | 5ghz rrm coverage level global cli_min exception level`
5. `ap dot11 24ghz | 5ghz rrm coverage voice {fail-percentage | packet-count | rssi-threshold}`
6. `end`

## Configuring Coverage Hole Detection (GUI)

### Step 1

Disable the 802.11 network as follows:

- Choose **Configuration > Wireless > 802.11a/n/ac** or **Configuration > Wireless > 802.11b/g/n** to open the 802.11a/n/ac (or 802.11b/g/n) Global Parameters page.
- Unselect the **802.11a/n/ac** (or **802.11b/g/n**) **Network Status** check box.

c) Click **Apply**.

- Step 2** Choose **Configuration > Wireless > 802.11a/n/ac > RRM > Coverage Thresholds** or **Configuration > Wireless > 802.11b/g/n > RRM > Coverage Thresholds** to open coverage page.
- Step 3** Select the **Enable Coverage Hole Detection** check box to enable coverage hole detection, or unselect it to disable this feature. If you enable coverage hole detection, the Cisco WLC automatically determines, based on data received from the access points, if any access points have clients that are potentially located in areas with poor coverage. The default value is selected.
- Step 4** In the **Data RSSI** text box, enter the minimum Receive Signal Strength Indication (RSSI) value for data packets received by the access point. The value that you enter is used to identify coverage holes (or areas of poor coverage) within your network. If the access point receives a packet in the data queue with an RSSI value below the value that you enter here, a potential coverage hole has been detected. The valid range is –90 to –60 dBm, and the default value is –80 dBm. The access point takes data RSSI measurements every 5 seconds and reports them to the Cisco WLC in 90-second intervals.
- Step 5** In the **Voice RSSI** text box, enter the minimum Receive Signal Strength Indication (RSSI) value for voice packets received by the access point. The value that you enter is used to identify coverage holes within your network. If the access point receives a packet in the voice queue with an RSSI value below the value that you enter here, a potential coverage hole has been detected. The valid range is –90 to –60 dBm, and the default value is –80 dBm. The access point takes voice RSSI measurements every 5 seconds and reports them to the Cisco WLC in 90-second intervals.
- Step 6** In the **Min Failed Client Count per AP** text box, enter the minimum number of clients on an access point with an RSSI value at or below the data or voice RSSI threshold. The valid range is 1 to 75, and the default value is 3.
- Step 7** In the **Coverage Exception Level per AP** text box, enter the percentage of clients on an access point that are experiencing a low signal level but cannot roam to another access point. The valid range is 0 to 100%, and the default value is 25%.
- Note** If both the number and percentage of failed packets exceed the values configured for Failed Packet Count and Failed Packet Percentage (configurable through the Cisco WLC CLI) for a 5-second period, the client is considered to be in a pre-alarm condition. The Cisco WLC uses this information to distinguish between real and false coverage holes. False positives are generally due to the poor roaming logic implemented on most clients. A coverage hole is detected if both the number and percentage of failed clients meet or exceed the values entered in the Min Failed Client Count per AP and Coverage Exception Level per AP text boxes over two 90-second periods (a total of 180 seconds). The Cisco WLC determines if the coverage hole can be corrected and, if appropriate, mitigates the coverage hole by increasing the transmit power level for that specific access point.
- Step 8** Click **Apply**.
- Step 9** Reenable the 802.11 network as follows:
- Choose **Configuration > Wireless > 802.11a/n/ac > Network** or **Configuration > Wireless > 802.11b/g/n > Network** to open the 802.11a (or 802.11b/g) Global Parameters page.
  - Select the **802.11a/n/ac** (or **802.11b/g/n**) **Network Status** check box.
  - Click **Apply**.
- Step 10** Click **Save Configuration**.
-

## Configuring 802.11 Event Logging (CLI)

### SUMMARY STEPS

1. `configure terminal`
2. `ap dot11 24ghz | 5ghz rrm logging {channel | coverage | foreign | load | noise | performance | txpower}`
3. `end`

### DETAILED STEPS

|               | Command or Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Configuring 802.11 Statistics Monitoring (CLI)

### SUMMARY STEPS

1. `configure terminal`
2. `ap dot11 24ghz | 5ghz rrm monitor channel-list {all | country | dca}`
3. `ap dot11 24ghz | 5ghz rrm monitor coverage interval`
4. `ap dot11 24ghz | 5ghz rrm monitor load interval`
5. `ap dot11 24ghz | 5ghz rrm monitor noise interval`
6. `ap dot11 24ghz | 5ghz rrm monitor signal interval`
7. `end`

### DETAILED STEPS

|        | Command or Action                                                                                                                                                                           | Purpose                                                                                                                                                                                                                                                                                                                                         |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <p><code>configure terminal</code></p> <p><b>Example:</b><br/>Switch# <code>configure terminal</code></p>                                                                                   | Enters global configuration mode.                                                                                                                                                                                                                                                                                                               |
| Step 2 | <p><code>ap dot11 24ghz   5ghz rrm monitor channel-list {all   country   dca}</code></p> <p><b>Example:</b><br/>Switch(config)#<code>ap dot11 24ghz rrm monitor channel-list all</code></p> | <p>Sets the 802.11 monitoring channel-list for parameters such as noise/interference/rogue.</p> <ul style="list-style-type: none"> <li>• <b>all</b>— Monitors all channels.</li> <li>• <b>country</b>— Monitor channels used in configured country code.</li> <li>• <b>dca</b>— Monitor channels used by dynamic channel assignment.</li> </ul> |
| Step 3 | <p><code>ap dot11 24ghz   5ghz rrm monitor coverage interval</code></p> <p><b>Example:</b><br/>Switch(config)#<code>ap dot11 24ghz rrm monitor coverage 600</code></p>                      | Configures the 802.11 coverage measurement interval in seconds that ranges from 60 to 3600.                                                                                                                                                                                                                                                     |
| Step 4 | <p><code>ap dot11 24ghz   5ghz rrm monitor load interval</code></p> <p><b>Example:</b><br/>Switch(config)#<code>ap dot11 24ghz rrm monitor load 180</code></p>                              | Configures the 802.11 load measurement interval in seconds that ranges from 60 to 3600.                                                                                                                                                                                                                                                         |
| Step 5 | <p><code>ap dot11 24ghz   5ghz rrm monitor noise interval</code></p> <p><b>Example:</b><br/>Switch(config)#<code>ap dot11 24ghz rrm monitor noise 360</code></p>                            | Configures the 802.11 noise measurement interval (channel scan interval) in seconds that ranges from 60 to 3600.                                                                                                                                                                                                                                |

|               | Command or Action                                                                                                                                      | Purpose                                                                                                               |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <b>Step 6</b> | <b>ap dot11 24ghz   5ghz rrm monitor signal <i>interval</i></b><br><br><b>Example:</b><br>Switch(config)# <b>ap dot11 24ghz rrm monitor signal 480</b> | Configures the 802.11 signal measurement interval (neighbor packet frequency) in seconds that ranges from 60 to 3600. |
| <b>Step 7</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b>                                                                                        | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode.   |

### Configuring the 802.11 Performance Profile (CLI)

#### SUMMARY STEPS

1. **configure terminal**
2. **ap dot11 24ghz | 5ghz rrm profile clients *cli\_threshold\_value***
3. **ap dot11 24ghz | 5ghz rrm profile foreign *int\_threshold\_value***
4. **ap dot11 24ghz | 5ghz rrm profile noise *for\_noise\_threshold\_value***
5. **ap dot11 24ghz | 5ghz rrm profile throughput *throughput\_threshold\_value***
6. **ap dot11 24ghz | 5ghz rrm profile utilization *rf\_util\_threshold\_value***
7. **end**

#### DETAILED STEPS

|               | Command or Action                                                                                                                                                  | Purpose                                                                                   |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                                                                              | Enters global configuration mode.                                                         |
| <b>Step 2</b> | <b>ap dot11 24ghz   5ghz rrm profile clients <i>cli_threshold_value</i></b><br><br><b>Example:</b><br>Switch(config)# <b>ap dot11 24ghz rrm profile clients 20</b> | Sets the threshold value for 802.11 Cisco AP clients that range between 1 and 75 clients. |

|               | Command or Action                                                                                                                                                                             | Purpose                                                                                                             |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| <b>Step 3</b> | <p><b>ap dot11 24ghz   5ghz rrm profile foreign</b><br/><i>int_threshold_value</i></p> <p><b>Example:</b></p> <pre>Switch(config)#ap dot11 24ghz rrm profile foreign 50</pre>                 | Sets the threshold value for 802.11 foreign interference that ranges between 0 and 100%.                            |
| <b>Step 4</b> | <p><b>ap dot11 24ghz   5ghz rrm profile noise</b><br/><i>for_noise_threshold_value</i></p> <p><b>Example:</b></p> <pre>Switch(config)#ap dot11 24ghz rrm profile noise -65</pre>              | Sets the threshold value for 802.11 foreign noise ranges between -127 and 0 dBm.                                    |

Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode. |

## Configuring Rogue Access Point Detection in RF Groups

### Configuring Rogue Access Point Detection in RF Groups (CLI)

#### Before You Begin

Ensure that each Cisco WLC in the RF group has been configured with the same RF group name.

#### Note

The name is used to verify the authentication IE in all beacon frames. If the Cisco WLCs have different names, false alarms will occur.

## SUMMARY STEPS

1. `ap name Cisco_AP mode {local | monitor}`
2. `end`
3. `configure terminal`
4. `wireless wps ap-authentication`
5. `wireless wps ap-authentication threshold value`

## DETAILED STEPS

|        | Command or Action                                                                                                                                               | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <code>ap name Cisco_AP mode {local   monitor}</code><br><br><b>Example:</b><br><code>Switch# ap name ap1 mode local</code>                                      | Configures a particular access point for local (normal) mode or monitor (listen-only) mode. Perform this step for every access point connected to the Cisco WLC.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Step 2 | <code>end</code><br><br><b>Example:</b><br><code>Switch(config)# end</code>                                                                                     | Returns to privileged EXEC mode. Alternatively, you can also press <b>Ctrl-Z</b> to exit global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Step 3 | <code>configure terminal</code><br><br><b>Example:</b><br><code>Switch# configure terminal</code>                                                               | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Step 4 | <code>wireless wps ap-authentication</code><br><br><b>Example:</b><br><code>Switch (config)# wireless wps ap-authentication</code>                              | Enables rogue access point detection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Step 5 | <code>wireless wps ap-authentication threshold value</code><br><br><b>Example:</b><br><code>Switch (config)# wireless wps ap-authentication threshold 50</code> | <p>Specifies when a rogue access point alarm is generated. An alarm occurs when the threshold value (which specifies the number of access point frames with an invalid authentication IE) is met or exceeded within the detection period.</p> <p>The valid threshold range is from 1 to 255, and the default threshold value is 1. To avoid false alarms, you may want to set the threshold to a higher value.</p> <p><b>Note</b> Enable rogue access point detection and threshold value on every Cisco WLC in the RF group.</p> <p><b>Note</b> If rogue access point detection is not enabled on every Cisco WLC in the RF group, the access points on the Cisco WLCs with this feature disabled are reported as rogues.</p> |

## Enabling Rogue Access Point Detection in RF Groups (GUI)

- 
- Step 1** Make sure that each Cisco WLC in the RF group has been configured with the same RF group name.  
**Note** The name is used to verify the authentication IE in all beacon frames. If the Cisco WLCs have different names, false alarms will occur.
- Step 2** Choose **Configuration > Wireless > Access Points > All APs** to open the All APs page.
- Step 3** Click the name of an access point to open the All APs > Edit page.
- Step 4** Choose either **local** or **monitor** from the AP Mode drop-down list and click **Apply** to commit your changes.
- Step 5** Click **Save Configuration** to save your changes.
- Step 6** Repeat [Step 2](#) through [Step 5](#) for every access point connected to the Cisco WLC.
- Step 7** Choose **Configuration > Security > Wireless Protection Policies > AP Authentication/MFP** to open the AP Authentication Policy page.  
 The name of the RF group to which this Cisco WLC belongs appears at the top of the page.
- Step 8** Choose **AP Authentication** from the Protection Type drop-down list to enable rogue access point detection.
- Step 9** Enter a number in the Alarm Trigger Threshold edit box to specify when a rogue access point alarm is generated. An alarm occurs when the threshold value (which specifies the number of access point frames with an invalid authentication IE) is met or exceeded within the detection period.  
**Note** The valid threshold range is from 1 to 255, and the default threshold value is 1. To avoid false alarms, you may want to set the threshold to a higher value.
- Step 10** Click **Apply** to commit your changes.
- Step 11** Click **Save Configuration** to save your changes.
- Step 12** Repeat this procedure on every Cisco WLC in the RF group.  
**Note** If rogue access point detection is not enabled on every Cisco WLC in the RF group, the access points on the Cisco WLCs with this feature disabled are reported as rogues.
- 

## Monitoring RRM Parameters and RF Group Status

### Monitoring RRM Parameters

*Table 92: Commands for monitoring Radio Resource Management*

| Commands                     | Description                                                                  |
|------------------------------|------------------------------------------------------------------------------|
| show ap dot11 24ghz ccx      | Displays the 802.11b CCX information for all Cisco APs.                      |
| show ap dot11 24ghz channel  | Displays the configuration and statistics of the 802.11b channel assignment. |
| show ap dot11 24ghz coverage | Displays the configuration and statistics of the 802.11b coverage.           |

| Commands                     | Description                                                                      |
|------------------------------|----------------------------------------------------------------------------------|
| show ap dot11 24ghz group    | Displays the configuration and statistics of the 802.11b grouping.               |
| show ap dot11 24ghz l2roam   | Displays 802.11b l2roam information.                                             |
| show ap dot11 24ghz logging  | Displays the configuration and statistics of the 802.11b event logging.          |
| show ap dot11 24ghz monitor  | Displays the configuration and statistics of the 802.11b monitoring.             |
| show ap dot11 24ghz profile  | Displays 802.11b profiling information for all Cisco APs.                        |
| show ap dot11 24ghz receiver | Displays the configuration and statistics of the 802.11b receiver.               |
| show ap dot11 24ghz summary  | Displays the configuration and statistics of the 802.11b Cisco APs.              |
| show ap dot11 24ghz txpower  | Displays the configuration and statistics of the 802.11b transmit power control. |
| show ap dot11 5ghz ccx       | Displays 802.11a CCX information for all Cisco APs.                              |
| show ap dot11 5ghz channel   | Displays the configuration and statistics of the 802.11a channel assignment.     |
| show ap dot11 5ghz coverage  | Displays the configuration and statistics of the 802.11a coverage.               |
| show ap dot11 5ghz group     | Displays the configuration and statistics of the 802.11a grouping.               |
| show ap dot11 5ghz l2roam    | Displays 802.11a l2roam information.                                             |
| show ap dot11 5ghz logging   | Displays the configuration and statistics of the 802.11a event logging.          |
| show ap dot11 5ghz monitor   | Displays the configuration and statistics of the 802.11a monitoring.             |
| show ap dot11 5ghz profile   | Displays 802.11a profiling information for all Cisco APs.                        |
| show ap dot11 5ghz receiver  | Displays the configuration and statistics of the 802.11a receiver.               |

| Commands                   | Description                                                                      |
|----------------------------|----------------------------------------------------------------------------------|
| show ap dot11 5ghz summary | Displays the configuration and statistics of the 802.11a Cisco APs.              |
| show ap dot11 5ghz txpower | Displays the configuration and statistics of the 802.11a transmit power control. |

## Monitoring RF Group Status (CLI)

This section describes the new commands for RF group status.

The following commands can be used to monitor RF group status on the switch.

**Table 93: Monitoring Aggressive Load Balancing Command**

| Command                   | Purpose                                                                                |
|---------------------------|----------------------------------------------------------------------------------------|
| show ap dot11 5ghz group  | Displays the Cisco WLC name which is the RF group leader for the 802.11a RF network.   |
| show ap dot11 24ghz group | Displays the Cisco WLC name which is the RF group leader for the 802.11b/g RF network. |

## Monitoring RF Group Status (GUI)

**Step 1** Choose **Configuration > Wireless > 802.11a/n > or 802.11b/g/n > RRM > RF Grouping** to open the RF Grouping Algorithm page.

This page shows the details of the RF group, displaying the configurable parameter **Group mode**, the **Group role** of this Cisco WLC, the **Group Update Interval** and the Cisco WLC name and IP address of the **Group Leader** to this Cisco WLC.

**Note** RF grouping mode can be set using the **Group Mode** drop-down list.

**Tip** Once a Cisco WLC has joined as a static member and you want to change the grouping mode, we recommend that you remove the member from the configured static-leader and also make sure that a member Cisco WLC has not been configured to be a member on multiple static leaders. This is to avoid repeated join attempts from one or more RF static leaders.

**Step 2** (Optional) Repeat this procedure for the network type that you did not select (802.11a/n or 802.11b/g/n).

## Examples: RF Group Configuration

This example shows how to configure RF group name:

```
Switch# configure terminal
Switch(config)# wireless rf-network test1
Switch(config)# ap dot11 24ghz shutdown
Switch(config)# end
Switch # show network profile 5
```

This example shows how to configure rogue access point detection in RF groups:

```
Switch# ap name ap1 mode local
Switch# end
Switch# configure terminal
Switch(config)# wireless wps ap-authentication
Switch(config)# wireless wps ap-authentication threshold 50
Switch(config)# end
```

### Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

### Information About Configuring MSDP

This section describes how to configure the Multicast Source Discovery Protocol (MSDP) on the switch. The MSDP connects multiple Protocol-Independent Multicast sparse-mode (PIM-SM) domains.

MSDP is not fully supported in this software release because of a lack of support for Multicast Border Gateway Protocol (MBGP), which works closely with MSDP. However, it is possible to create default peers that MSDP can operate with if MBGP is not running.

To use this feature, the active switch must be running the IP services feature set.

### Understanding MSDP

MSDP allows multicast sources for a group to be known to all rendezvous points (RPs) in different domains. Each PIM-SM domain uses its own RPs and does not depend on RPs in other domains. An RP runs MSDP over the Transmission Control Protocol (TCP) to discover multicast sources in other domains.

An RP in a PIM-SM domain has an MSDP peering relationship with MSDP-enabled devices in another domain. The peering relationship occurs over a TCP connection, primarily exchanging a list of sources sending to multicast groups. The TCP connections between RPs are achieved by the underlying routing system. The receiving RP uses the source lists to establish a source path.

The purpose of this topology is to have domains discover multicast sources in other domains. If the multicast sources are of interest to a domain that has receivers, multicast data is delivered over the normal, source-tree building mechanism in PIM-SM. MSDP is also used to announce sources sending to a group. These announcements must originate at the domain's RP.

MSDP depends heavily on the Border Gateway Protocol (BGP) or MBGP for interdomain operation. We recommend that you run MSDP in RPs in your domain that are RPs for sources sending to global groups to be announced to the Internet.

## MSDP Operation

When a source sends its first multicast packet, the first-hop router (*designated router* or RP) directly connected to the source sends a PIM register message to the RP. The RP uses the register message to register the active source and to forward the multicast packet down the shared tree in the local domain. With MSDP configured, the RP also forwards a source-active (SA) message to all MSDP peers. The SA message identifies the source, the group the source is sending to, and the address of the RP or the originator ID (the IP address of the interface used as the RP address), if configured.

Each MSDP peer receives and forwards the SA message away from the originating RP to achieve peer reverse-path flooding (RPF). The MSDP device examines the BGP or MBGP routing table to discover which peer is the next hop toward the originating RP of the SA message. Such a peer is called an *RPF peer* (reverse-path forwarding peer). The MSDP device forwards the message to all MSDP peers other than the RPF peer. For information on how to configure an MSDP peer when BGP and MBGP are not supported, see the [Configuring a Default MSDP Peer](#), on page 1129.

If the MSDP peer receives the same SA message from a non-RPF peer toward the originating RP, it drops the message. Otherwise, it forwards the message to all its MSDP peers.

The RP for a domain receives the SA message from an MSDP peer. If the RP has any join requests for the group the SA message describes and if the (\*,G) entry exists with a nonempty outgoing interface list, the domain is interested in the group, and the RP triggers an (S,G) join toward the source. After the (S,G) join reaches the source's DR, a branch of the source tree has been built from the source to the RP in the remote domain. Multicast traffic can now flow from the source across the source tree to the RP and then down the shared tree in the remote domain to the receiver.

## MSDP Benefits

MSDP has these benefits:

- It breaks up the shared multicast distribution tree. You can make the shared tree local to your domain. Your local members join the local tree, and join messages for the shared tree never need to leave your domain.
- PIM sparse-mode domains can rely only on their own RPs, decreasing reliance on RPs in another domain. This increases security because you can prevent your sources from being known outside your domain.
- Domains with only receivers can receive data without globally advertising group membership.
- Global source multicast routing table state is not required, saving memory.

# How to Configure MSDP

## Default MSDP Configuration

MSDP is not enabled, and no default MSDP peer exists.

## Configuring a Default MSDP Peer

In this software release, because BGP and MBGP are not supported, you cannot configure an MSDP peer on the local switch by using the **ip msdp peer** global configuration command. Instead, you define a default MSDP peer (by using the **ip msdp default-peer** global configuration command) from which to accept all SA messages for the switch. The default MSDP peer must be a previously configured MSDP peer. Configure a default MSDP peer when the switch is not BGP- or MBGP-peering with an MSDP peer. If a single MSDP peer is configured, the switch always accepts all SA messages from that peer.

This figure shows a network in which default MSDP peers might be used. A customer who owns Switch B is connected to the Internet through two Internet service providers (ISPs), one owning Router A and the other owning Router C. They are not running BGP or MBGP between them. To learn about sources in the ISP's domain or in other domains, Switch B at the customer site identifies Router A as its default MSDP peer. Switch B advertises SA messages to both Router A and Router C but accepts SA messages only from Router A or only from Router C. If Router A is first in the configuration file, it is used if it is running. If Router A is not running, only then does Switch B accept SA messages from Router C. This is the default behavior without a prefix list.

If you specify a prefix list, the peer is a default peer only for the prefixes in the list. You can have multiple active default peers when you have a prefix list associated with each. When you do not have any prefix lists, you can configure multiple default peers, but only the first one is the active default peer as long as the router has connectivity to this peer and the peer is alive. If the first configured peer fails or the connectivity to this peer fails, the second configured peer becomes the active default, and so on.

The ISP probably uses a prefix list to define which prefixes it accepts from the customer's router.

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# <b>configure terminal</b>                                                                                                                        | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Step 2 | <b>ip msdp default-peer</b> <i>ip-address</i>   <i>name</i><br><b>[prefix-list</b> <i>list</i> ]<br><br><b>Example:</b><br>Router(config)# <b>ip msdp default-peer</b><br><b>10.1.1.1 prefix-list site-a</b> | Defines a default peer from which to accept all MSDP SA messages. <ul style="list-style-type: none"> <li>• For <i>ip-address</i>   <i>name</i>, enter the IP address or Domain Name System (DNS) server name of the MSDP default peer.</li> <li>• (Optional) For <b>prefix-list</b> <i>list</i>, enter the list name that specifies the peer to be the default peer only for the listed prefixes. You can have multiple active default peers when you have a prefix list associated with each.</li> </ul> |

|               | Command or Action                                                                                                                                                                                                                                           | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|               |                                                                                                                                                                                                                                                             | <p>When you enter multiple <b>ip msdp default-peer</b> commands with the <b>prefix-list</b> keyword, you use all the default peers at the same time for different RP prefixes. This syntax is typically used in a service provider cloud that connects stub site clouds.</p> <p>When you enter multiple <b>ip msdp default-peer</b> commands without the <b>prefix-list</b> keyword, a single active peer accepts all SA messages. If that peer fails, the next configured default peer accepts all SA messages. This syntax is typically used at a stub site.</p>                                                                                     |
| <b>Step 3</b> | <p><b>ip prefix-list</b> <i>name</i> [<i>description string</i>]   <b>seq</b> <i>number</i> {<b>permit</b>   <b>deny</b>} <i>network length</i></p> <p><b>Example:</b></p> <pre>Router(config)# prefix-list site-a seq 3 permit 12 network length 128</pre> | <p>(Optional) Creates a prefix list using the name specified in Step 2.</p> <ul style="list-style-type: none"> <li>• (Optional) For <b>description string</b>, enter a description of up to 80 characters to describe this prefix list.</li> <li>• For <b>seq number</b>, enter the sequence number of the entry. The range is 1 to 4294967294.</li> <li>• The <b>deny</b> keyword denies access to matching conditions.</li> <li>• The <b>permit</b> keyword permits access to matching conditions.</li> <li>• For <i>network length</i>, specify the network number and length (in bits) of the network mask that is permitted or denied.</li> </ul> |
| <b>Step 4</b> | <p><b>ip msdp description</b> {<i>peer-name</i>   <i>peer-address</i>} <i>text</i></p> <p><b>Example:</b></p> <pre>Router(config)# ip msdp description peer-name site-b</pre>                                                                               | <p>(Optional) Configures a description for the specified peer to make it easier to identify in a configuration or in <b>show</b> command output.</p> <p>By default, no description is associated with an MSDP peer.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Step 5</b> | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Router(config)# end</pre>                                                                                                                                                                                     | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Step 6</b> | <p><b>show running-config</b></p> <p><b>Example:</b></p> <pre>Router# show running-config</pre>                                                                                                                                                             | Verifies your entries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Step 7</b> | <p><b>copy running-config startup-config</b></p> <p><b>Example:</b></p> <pre>Router# copy running-config startup-config</pre>                                                                                                                               | (Optional) Saves your entries in the configuration file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Caching Source-Active State

By default, the switch does not cache source/group pairs from received SA messages. When the switch forwards the MSDP SA information, it does not store it in memory. Therefore, if a member joins a group soon after a SA message is received by the local RP, that member needs to wait until the next SA message to hear about the source. This delay is known as join latency.

If you want to sacrifice some memory in exchange for reducing the latency of the source information, you can configure the switch to cache SA messages.

Beginning in privileged EXEC mode, follow these steps to enable the caching of source/group pairs. This procedure is optional.

### DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <p><b>configure terminal</b></p> <p><b>Example:</b></p> <pre>Switch# configure terminal</pre>                                                                                                                                                          | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Step 2 | <p><b>ip msdp cache-sa-state [list access-list-number]</b></p> <p><b>Example:</b></p> <pre>Switch(config)# ip msdp cache-sa-state 100</pre>                                                                                                            | <p>Enables the caching of source/group pairs (create an SA state). Those pairs that pass the access list are cached.</p> <p>For <b>list access-list-number</b>, the range is 100 to 199.</p> <p><b>Note</b> An alternative to this command is the <b>ip msdp sa-reques</b> global configuration command, which causes the switch to send an SA request message to the MSDP peer when a new member for a group becomes active.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Step 3 | <p><b>access-list access-list-number {deny   permit} protocol source source-wildcard destination destination-wildcard</b></p> <p><b>Example:</b></p> <pre>Switch(config)# access-list 100 permit ip 171.69.0.0 0.0.255.255 224.2.0.0 0.0.255.255</pre> | <p>Creates an IP extended access list, repeating the command as many times as necessary.</p> <ul style="list-style-type: none"> <li>For <i>access-list-number</i>, the range is 100 to 199. Enter the same number created in Step 2.</li> <li>The <b>deny</b> keyword denies access if the conditions are matched. The <b>permit</b> keyword permits access if the conditions are matched.</li> <li>For <i>protocol</i>, enter <b>ip</b> as the protocol name.</li> <li>For <i>source</i>, enter the number of the network or host from which the packet is being sent.</li> <li>For <i>source-wildcard</i>, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.</li> <li>For <i>destination</i>, enter the number of the network or host to which the packet is being sent.</li> </ul> |

|               | Command or Action                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                |
|---------------|-----------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               |                                                                                                                       | <ul style="list-style-type: none"> <li>For <i>destination-wildcard</i>, enter the wildcard bits in dotted decimal notation to be applied to the destination. Place ones in the bit positions that you want to ignore.</li> </ul> <p>Recall that the access list is always terminated by an implicit deny statement for everything.</p> |
| <b>Step 4</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b>                                                       | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                       |
| <b>Step 5</b> | <b>show running-config</b><br><br><b>Example:</b><br>Switch# <b>show running-config</b>                               | Verifies your entries.                                                                                                                                                                                                                                                                                                                 |
| <b>Step 6</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# <b>copy running-config startup-config</b> | (Optional) Saves your entries in the configuration file.                                                                                                                                                                                                                                                                               |

## Requesting Source Information from an MSDP Peer

Local RPs can send SA requests and get immediate responses for all active sources for a given group. By default, the switch does not send any SA request messages to its MSDP peers when a new member joins a group and wants to receive multicast traffic. The new member waits to receive the next periodic SA message.

If you want a new member of a group to learn the active multicast sources in a connected PIM sparse-mode domain that are sending to a group, configure the switch to send SA request messages to the specified MSDP peer when a new member joins a group. The peer replies with the information in its SA cache. If the peer does not have a cache configured, this command has no result. Configuring this feature reduces join latency but sacrifices memory.

This task is optional.

## DETAILED STEPS

|        | Command or Action                                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                       |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                                                                  | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                             |
| Step 2 | <b>ip msdp sa-request</b> { <i>ip-address</i>   <i>name</i> }<br><br><b>Example:</b><br>Switch(config)# <b>ip msdp sa-request</b><br><b>171.69.1.1</b> | Configure the switch to send SA request messages to the specified MSDP peer.<br><br>For <i>ip-address</i>   <i>name</i> , enter the IP address or name of the MSDP peer from which the local switch requests SA messages when a new member for a group becomes active.<br><br>Repeat the command for each MSDP peer that you want to supply with SA messages. |
| Step 3 | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b>                                                                                        | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                              |
| Step 4 | <b>show running-config</b><br><br><b>Example:</b><br>Switch# <b>show running-config</b>                                                                | Verifies your entries.                                                                                                                                                                                                                                                                                                                                        |
| Step 5 | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# <b>copy running-config startup-config</b>                                  | (Optional) Saves your entries in the configuration file.                                                                                                                                                                                                                                                                                                      |

## Controlling Source Information that Your Switch Originates

You can control the multicast source information that originates with your switch:

- Sources you advertise (based on your sources)
- Receivers of source information (based on knowing the requestor)

For more information, see the [Redistributing Sources](#), on page 1134 and the [Filtering Source-Active Request Messages](#), on page 1135.

## Redistributing Sources

SA messages originate on RPs to which sources have registered. By default, any source that registers with an RP is advertised. The *A flag* is set in the RP when a source is registered, which means the source is advertised in an SA unless it is filtered.

This task is optional.

### DETAILED STEPS

|               | Command or Action                                                                                                                                                                                                                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <p><b>configure terminal</b></p> <p><b>Example:</b></p> <pre>Switch# configure terminal</pre>                                                                                                                                                                                                                                        | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Step 2</b> | <p><b>ip msdp redistribute</b> [<i>list access-list-name</i>] [<i>asn aspath-access-list-number</i>] [<i>route-map map</i>]</p> <p><b>Example:</b></p> <pre>Switch(config)# ip msdp redistribute list 21</pre>                                                                                                                       | <p>Configures which (S,G) entries from the multicast routing table are advertised in SA messages.</p> <p>By default, only sources within the local domain are advertised.</p> <ul style="list-style-type: none"> <li>• (Optional) <b>list</b> <i>access-list-name</i>— Enters the name or number of an IP standard or extended access list. The range is 1 to 99 for standard access lists and 100 to 199 for extended lists. The access list controls which local sources are advertised and to which groups they send.</li> <li>• (Optional) <b>asn</b> <i>aspath-access-list-number</i>—Enters the IP standard or extended access list number in the range 1 to 199. This access list number must also be configured in the <b>ip as-path access-list</b> command.</li> <li>• (Optional) <b>route-map</b> <i>map</i>—Enters the IP standard or extended access list number in the range 1 to 199. This access list number must also be configured in the <b>ip as-path access-list</b> command.</li> </ul> <p>The switch advertises (S,G) pairs according to the access list or autonomous system path access list.</p> |
| <b>Step 3</b> | <p>Use one of the following:</p> <ul style="list-style-type: none"> <li>• <b>access-list</b><i>access-list-number</i> {deny  permit} <i>source</i> [<i>source-wildcard</i>]</li> <li>• <b>access-list</b><i>access-list-number</i> {deny  permit} <i>protocol source source-wildcard destination destination-wildcard</i></li> </ul> | <p>Creates an IP standard access list, repeating the command as many times as necessary.</p> <p>or</p> <p>Creates an IP extended access list, repeating the command as many times as necessary.</p> <ul style="list-style-type: none"> <li>• <i>access-list-number</i>—Enters the same number created in Step 2. The range is 1 to 99 for standard access lists and 100 to 199 for extended lists.</li> <li>• <b>deny</b>—Denies access if the conditions are matched. The <b>permit</b> keyword permits access if the conditions are matched.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|               | Command or Action                                                                                                                                                                         | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | <p><b>Example:</b><br/>Switch(config)# <b>access list 21 permit 194.1.22.0</b></p> <p>OR</p> <p>Switch(config)# <b>access list 21 permit ip 194.1.22.0 1.1.1.1 194.3.44.0 1.1.1.1</b></p> | <ul style="list-style-type: none"> <li>• <i>protocol</i>—Enters <b>ip</b> as the protocol name.</li> <li>• <i>source</i>—Enters the number of the network or host from which the packet is being sent.</li> <li>• <i>source-wildcard</i>—Enters the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.</li> <li>• <i>destination</i>—Enters the number of the network or host to which the packet is being sent.</li> <li>• <i>destination-wildcard</i>—Enters the wildcard bits in dotted decimal notation to be applied to the destination. Place ones in the bit positions that you want to ignore.</li> </ul> <p>Recall that the access list is always terminated by an implicit deny statement for everything.</p> |
| <b>Step 4</b> | <p><b>end</b></p> <p><b>Example:</b><br/>Switch(config)# <b>end</b></p>                                                                                                                   | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Step 5</b> | <p><b>show running-config</b></p> <p><b>Example:</b><br/>Switch# <b>show running-config</b></p>                                                                                           | Verifies your entries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Step 6</b> | <p><b>copy running-config startup-config</b></p> <p><b>Example:</b><br/>Switch# <b>copy running-config startup-config</b></p>                                                             | (Optional) Saves your entries in the configuration file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

### Filtering Source-Active Request Messages

By default, only switches that are caching SA information can respond to SA requests. By default, such a switch honors all SA request messages from its MSDP peers and supplies the IP addresses of the active sources.

However, you can configure the switch to ignore all SA requests from an MSDP peer. You can also honor only those SA request messages from a peer for groups described by a standard access list. If the groups in the access list pass, SA request messages are accepted. All other such messages from the peer for other groups are ignored.

This task is optional.

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                                                                                                                                                              | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Step 1 | <p><b>configure terminal</b></p> <p><b>Example:</b></p> <pre>Switch# configure terminal</pre>                                                                                                                                                                                                                                                                  | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Step 2 | <p>Use one of the following:</p> <ul style="list-style-type: none"> <li>• <b>ip msdp filter-sa-request</b><br/><i>{ip-address  name}</i></li> <li>• <b>ip msdp filter-sa-request</b><br/><i>{ip-address  name}</i><br/><b>list</b> <i>access-list-number</i></li> </ul> <p><b>Example:</b></p> <pre>Switch(config)# ip msdp filter sa-request 171.69.2.2</pre> | <p>Filters all SA request messages from the specified MSDP peer.</p> <p>or</p> <p>Filters SA request messages from the specified MSDP peer for groups that pass the standard access list. The access list describes a multicast group address. The range for the access-list-number is 1 to 99.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Step 3 | <p><b>access-list</b> <i>access-list-number</i> {deny   permit}<br/><i>source</i> [<i>source-wildcard</i>]</p> <p><b>Example:</b></p> <pre>Switch(config)# access-list 1 permit 192.4.22.0 0.0.0.255</pre>                                                                                                                                                     | <p>Creates an IP standard access list, repeating the command as many times as necessary.</p> <ul style="list-style-type: none"> <li>• For <i>access-list-number</i>, the range is 1 to 99.</li> <li>• The <b>deny</b> keyword denies access if the conditions are matched. The <b>permit</b> keyword permits access if the conditions are matched.</li> <li>• For <i>source</i>, enter the number of the network or host from which the packet is being sent.</li> <li>• (Optional) For <i>source-wildcard</i>, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore.</li> </ul> <p>Recall that the access list is always terminated by an implicit deny statement for everything.</p> |
| Step 4 | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Switch(config)# end</pre>                                                                                                                                                                                                                                                                                        | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|        | Command or Action                                                                                                     | Purpose                                                  |
|--------|-----------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| Step 5 | <b>show running-config</b><br><br><b>Example:</b><br>Switch# <b>show running-config</b>                               | Verifies your entries.                                   |
| Step 6 | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# <b>copy running-config startup-config</b> | (Optional) Saves your entries in the configuration file. |

## Controlling Source Information that Your Switch Forwards

By default, the switch forwards all SA messages it receives to all its MSDP peers. However, you can prevent outgoing messages from being forwarded to a peer by using a filter or by setting a time-to-live (TTL) value.

### Using a Filter

By creating a filter, you can perform one of these actions:

- Filter all source/group pairs
- Specify an IP extended access list to pass only certain source/group pairs
- Filter based on match criteria in a route map

This task is optional.

### Using TTL to Limit the Multicast Data Sent in SA Messages

You can use a TTL value to control what data is encapsulated in the first SA message for every source. Only multicast packets with an IP-header TTL greater than or equal to the *tll* argument are sent to the specified MSDP peer. For example, you can limit internal traffic to a TTL of 8. If you want other groups to go to external locations, you must send those packets with a TTL greater than 8.

This task is optional.

## Controlling Source Information that Your Switch Receives

By default, the switch receives all SA messages that its MSDP RPF peers send to it. However, you can control the source information that you receive from MSDP peers by filtering incoming SA messages. In other words, you can configure the switch to not accept them.

You can perform one of these actions:

- Filter all incoming SA messages from an MSDP peer
- Specify an IP extended access list to pass certain source/group pairs
- Filter based on match criteria in a route map

This task is optional.

## Configuring an MSDP Mesh Group

An MSDP mesh group is a group of MSDP speakers that have fully meshed MSDP connectivity among one another. Any SA messages received from a peer in a mesh group are not forwarded to other peers in the same mesh group. Thus, you reduce SA message flooding and simplify peer-RPF flooding. Use the **ip msdp mesh-group** global configuration command when there are multiple RPs within a domain. It is especially used to send SA messages across a domain. You can configure multiple mesh groups (with different names) in a single switch.

This task is optional.

### DETAILED STEPS

## Shutting Down an MSDP Peer

If you want to configure many MSDP commands for the same peer and you do not want the peer to become active, you can shut down the peer, configure it, and later bring it up. When a peer is shut down, the TCP connection is terminated and is not restarted. You can also shut down an MSDP session without losing configuration information for the peer.

This task is optional.

## DETAILED STEPS

## Including a Bordering PIM Dense-Mode Region in MSDP

You can configure MSDP on a switch that borders a PIM sparse-mode region with a dense-mode region. By default, active sources in the dense-mode region do not participate in MSDP.

### Note

We do not recommend using the **ip msdp border sa-address** global configuration command. It is better to configure the border router in the sparse-mode domain to proxy-register sources in the dense-mode domain to the RP of the sparse-mode domain and have the sparse-mode domain use standard MSDP procedures to advertise these sources.

The **ip msdp originator-id** global configuration command also identifies an interface to be used as the RP address. If both the **ip msdp border sa-address** and the **ip msdp originator-id** global configuration commands are configured, the address derived from the **ip msdp originator-id** command specifies the RP address.

This task is optional.

| <b>Step 4</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b>                                                                                                                    | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Step 5</b> | <b>show running-config</b><br><br><b>Example:</b><br>Switch# <b>show running-config</b>                                                                                            | Verifies your entries.                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Step 6</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# <b>copy running-config startup-config</b>                                                              | (Optional) Saves your entries in the configuration file.                                                                                                                                                                                                                                                                                                                                                  |

## Configuring an Originating Address other than the RP Address

You can allow an MSDP speaker that originates an SA message to use the IP address of the interface as the RP address in the SA message by changing the Originator ID. You might change the Originator ID in one of these cases:

- If you configure a logical RP on multiple switches in an MSDP mesh group.
- If you have a switch that borders a PIM sparse-mode domain and a dense-mode domain. If a switch borders a dense-mode domain for a site, and sparse-mode is being used externally, you might want dense-mode sources to be known to the outside world. Because this switch is not an RP, it would not have an RP address to use in an SA message. Therefore, this command provides the RP address by specifying the address of the interface.

If both the **ip msdp border sa-address** and the **ip msdp originator-id** global configuration commands are configured, the address derived from the **ip msdp originator-id** command specifies the address of the RP.

This task is optional.

### DETAILED STEPS

|               | Command or Action                                                                                                     | Purpose                                                                                                                                                                     |
|---------------|-----------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                                 | Enters global configuration mode.                                                                                                                                           |
| <b>Step 2</b> | <b>ip msdp originator-id interface-id</b><br><br><b>Example:</b><br>Switch(config)# <b>ip msdp originator-id 0/1</b>  | Configures the RP address in SA messages to be the address of the originating device interface.<br><br>For <i>interface-id</i> , specify the interface on the local switch. |
| <b>Step 3</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b>                                                       | Returns to privileged EXEC mode.                                                                                                                                            |
| <b>Step 4</b> | <b>show running-config</b><br><br><b>Example:</b><br>Switch# <b>show running-config</b>                               | Verifies your entries.                                                                                                                                                      |
| <b>Step 5</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# <b>copy running-config startup-config</b> | (Optional) Saves your entries in the configuration file.                                                                                                                    |

## Monitoring and Maintaining MSDP

Commands that monitor MSDP SA messages, peers, state, and peer status:

**Table 94: Commands for Monitoring and Maintaining MSDP**

| Command                                                                                                                                                          | Purpose                                                                                                                                                                                               |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>debug ip msdp</b> [ <i>peer-address</i>   <i>name</i> ] [ <b>detail</b> ]<br>[ <b>routes</b> ]                                                                | Debugs an MSDP activity.                                                                                                                                                                              |
| <b>debug ip msdp resets</b>                                                                                                                                      | Debugs MSDP peer reset reasons.                                                                                                                                                                       |
| <b>show ip msdp count</b> [ <i>autonomous-system-number</i> ]                                                                                                    | Displays the number of sources and groups originated in SA messages from each autonomous system. The <b>ip msdp cache-sa-state</b> command must be configured for this command to produce any output. |
| <b>show ip msdp peer</b> [ <i>peer-address</i>   <i>name</i> ]                                                                                                   | Displays detailed information about an MSDP peer.                                                                                                                                                     |
| <b>show ip msdp sa-cache</b> [ <i>group-address</i>  <br><i>source-address</i>   <i>group-name</i>   <i>source-name</i> ]<br>[ <i>autonomous-system-number</i> ] | Displays (S,G) state learned from MSDP peers.                                                                                                                                                         |
| <b>show ip msdp summary</b>                                                                                                                                      | Displays MSDP peer status and SA message counts.                                                                                                                                                      |

Commands that clear MSDP connections, statistics, and SA cache entries:

**Table 95: Commands for Clearing MSDP Connections, Statistics, or SA Cache Entries**

| Command                                                               | Purpose                                                                                                                         |
|-----------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>clear ip msdp peer</b> <i>peer-address</i>   <i>name</i>           | Clears the TCP connection to the specified MSDP peer, resetting all MSDP message counters.                                      |
| <b>clear ip msdp statistics</b> [ <i>peer-address</i>   <i>name</i> ] | Clears statistics counters for one or all the MSDP peers without resetting the sessions.                                        |
| <b>clear ip msdp sa-cache</b> [ <i>group-address</i>   <i>name</i> ]  | Clears the SA cache entries for all entries, all sources for a specific group, or all entries for a specific source/group pair. |

## Configuration Examples for Configuring MSDP

### Configuring a Default MSDP Peer: Example

This example shows a partial configuration of Router A and Router C in . Each of these ISPs have more than one customer (like the customer in ) who use default peering (no BGP or MBGP). In that case, they might have similar configurations. That is, they accept SAs only from a default peer if the SA is permitted by the corresponding prefix list.

Router A

```
Router(config)# ip msdp default-peer 10.1.1.1
Router(config)# ip msdp default-peer 10.1.1.1 prefix-list site-a
Router(config)# ip prefix-list site-b permit 10.0.0.0/1
```

Router C

```
Router(config)# ip msdp default-peer 10.1.1.1 prefix-list site-a
Router(config)# ip prefix-list site-b permit 10.0.0.0/1
```

### Caching Source-Active State: Example

This example shows how to enable the cache state for all sources in 171.69.0.0/16 sending to groups 224.2.0.0/16:

```
Switch(config)# ip msdp cache-sa-state 100
Switch(config)# access-list 100 permit ip 171.69.0.0 0.0.255.255 224.2.0.0 0.0.255.255
```

### Requesting Source Information from an MSDP Peer: Example

This example shows how to configure the switch to send SA request messages to the MSDP peer at 171.69.1.1:

```
Switch(config)# ip msdp sa-request 171.69.1.1
```

### Controlling Source Information that Your Switch Originates: Example

This example shows how to configure the switch to filter SA request messages from the MSDP peer at 171.69.2.2. SA request messages from sources on network 192.4.22.0 pass access list 1 and are accepted; all others are ignored.

```
Switch(config)# ip msdp filter sa-request 171.69.2.2 list 1
Switch(config)# access-list 1 permit 192.4.22.0 0.0.0.255
```

## Controlling Source Information that Your Switch Forwards: Example

This example shows how to allow only (S,G) pairs that pass access list 100 to be forwarded in an SA message to the peer named *switch.cisco.com*:

```
Switch(config)# ip msdp peer switch.cisco.com connect-source gigabitethernet1/0/1
Switch(config)# ip msdp sa-filter out switch.cisco.com list 100
Switch(config)# access-list 100 permit ip 171.69.0.0 0.0.255.255 224.20 0 0.0.255.255
```

## Controlling Source Information that Your Switch Receives: Example

This example shows how to filter all SA messages from the peer named *switch.cisco.com*:

```
Switch(config)# ip msdp peer switch.cisco.com connect-source gigabitethernet1/0/1
Switch(config)# ip msdp sa-filter in switch.cisco.com
```

## Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

## Information About Configuring IP Unicast Routing

This module describes how to configure IP Version 4 (IPv4) unicast routing on the switch.

### Note

On switches running the LAN base feature, static routing on VLANs is supported only with this release.

A switch stack operates and appears as a single router to the rest of the routers in the network. Basic routing functions, including static routing and the Routing Information Protocol (RIP), are available with both the IP base feature set and the IP services feature set. To use advanced routing features and other routing protocols, you must have the IP services feature set enabled on the standalone switch or on the active switch.

### Note

In addition to IPv4 traffic, you can also enable IP Version 6 (IPv6) unicast routing and configure interfaces to forward IPv6 traffic if the switch or switch stack is running the IP base or IP services feature set.

## Information About IP Routing

In some network environments, VLANs are associated with individual networks or subnetworks. In an IP network, each subnetwork is mapped to an individual VLAN. Configuring VLANs helps control the size of the broadcast domain and keeps local traffic local. However, network devices in different VLANs cannot communicate with one another without a Layer 3 device (router) to route traffic between the VLAN, referred to as inter-VLAN routing. You configure one or more routers to route traffic to the appropriate destination VLAN.

This figure shows a basic routing topology. Switch A is in VLAN 10, and Switch B is in VLAN 20. The router has an interface in each VLAN.

**Figure 64: Routing Topology Example**

When Host A in VLAN 10 needs to communicate with Host B in VLAN 10, it sends a packet addressed to that host. Switch A forwards the packet directly to Host B, without sending it to the router.

When Host A sends a packet to Host C in VLAN 20, Switch A forwards the packet to the router, which receives the traffic on the VLAN 10 interface. The router checks the routing table, finds the correct outgoing interface, and forwards the packet on the VLAN 20 interface to Switch B. Switch B receives the packet and forwards it to Host C.

## Types of Routing

Routers and Layer 3 switches can route packets in these ways:

- By using default routing
- By using preprogrammed static routes for the traffic
- By dynamically calculating routes by using a routing protocol

Default routing refers to sending traffic with a destination unknown to the router to a default outlet or destination.

Static unicast routing forwards packets from predetermined ports through a single path into and out of a network. Static routing is secure and uses little bandwidth, but does not automatically respond to changes in the network, such as link failures, and therefore, might result in unreachable destinations. As networks grow, static routing becomes a labor-intensive liability.

Switches running the LAN base feature set support 16 user-configured static routes, in addition to any default routes used for the management interface. The LAN base image supports static routing only on SVIs.

Dynamic routing protocols are used by routers to dynamically calculate the best route for forwarding traffic. There are two types of dynamic routing protocols:

- Routers using distance-vector protocols maintain routing tables with distance values of networked resources, and periodically pass these tables to their neighbors. Distance-vector protocols use one or a series of metrics for calculating the best routes. These protocols are easy to configure and use.
- Routers using link-state protocols maintain a complex database of network topology, based on the exchange of link-state advertisements (LSAs) between routers. LSAs are triggered by an event in the network, which speeds up the convergence time or time required to respond to these changes. Link-state protocols respond quickly to topology changes, but require greater bandwidth and more resources than distance-vector protocols.

Distance-vector protocols supported by the switch are Routing Information Protocol (RIP), which uses a single distance metric (cost) to determine the best path and Border Gateway Protocol (BGP), which adds a path vector mechanism. The switch also supports the Open Shortest Path First (OSPF) link-state protocol and Enhanced IGRP (EIGRP), which adds some link-state routing features to traditional Interior Gateway Routing Protocol (IGRP) to improve efficiency.

**Note**

On a switch or switch stack, the supported protocols are determined by the software running on the active switch. If the active switch is running the IP base feature set, only default routing, static routing and RIP are supported. If the active switch is running the IP services feature set, only default routing, static routing and RIP are supported. If the switch is running the LAN base feature set, you can configure 16 static routes on SVIs. All other routing protocols require the IP services feature set.

## IP Routing and Switch Stacks

A switch stack appears to the network as a single switch, regardless of which switch in the stack is connected to a routing peer.

The active switch performs these functions:

- It initializes and configures the routing protocols.
- It sends routing protocol messages and updates to other routers.
- It processes routing protocol messages and updates received from peer routers.
- It generates, maintains, and distributes the distributed Cisco Express Forwarding (dCEF) database to all stack members. The routes are programmed on all switches in the stack bases on this database.
- The MAC address of the active switch is used as the router MAC address for the whole stack, and all outside devices use this address to send IP packets to the stack.
- All IP packets that require software forwarding or processing go through the CPU of the active switch.

Stack members perform these functions:

- They act as routing standby switches, ready to take over in case they are elected as the new active switch if the active switch fails.
- They program the routes into hardware.

If a active switch fails, the stack detects that the active switch is down and elects one of the stack members to be the new active switch. During this period, except for a momentary interruption, the hardware continues to forward packets with no active protocols.

However, even though the switch stack maintains the hardware identification after a failure, the routing protocols on the router neighbors might flap during the brief interruption before the active switch restarts. Routing protocols such as OSPF and EIGRP need to recognize neighbor transitions. The router uses two levels of nonstop forwarding (NSF) to detect a switchover, to continue forwarding network traffic, and to recover route information from peer devices:

- NSF-aware routers tolerate neighboring router failures. After the neighbor router restarts, an NSF-aware router supplies information about its state and route adjacencies on request.

- NSF-capable routers support NSF. When they detect a active switch change, they rebuild routing information from NSF-aware or NSF-capable neighbors and do not wait for a restart.

The switch stack supports NSF-capable routing for OSPF and EIGRP.

Upon election, the new active switch performs these functions:

- It starts generating, receiving, and processing routing updates.
- It builds routing tables, generates the CEF database, and distributes it to stack members.
- It uses its MAC address as the router MAC address. To notify its network peers of the new MAC address, it periodically (every few seconds for 5 minutes) sends a gratuitous ARP reply with the new router MAC address.

---

**Note** If you configure the persistent MAC address feature on the stack and the active switch changes, the stack MAC address does not change for the configured time period. If the previous active switch rejoins the stack as a member switch during that time period, the stack MAC address remains the MAC address of the previous active switch.

---

- It attempts to determine the reachability of every proxy ARP entry by sending an ARP request to the proxy ARP IP address and receiving an ARP reply. For each reachable proxy ARP IP address, it generates a gratuitous ARP reply with the new router MAC address. This process is repeated for 5 minutes after a new active switch election.

---

**Note** When a active switch is running the IP services feature set, the stack can run all supported protocols, including Open Shortest Path First (OSPF), Enhanced IGRP (EIGRP), and Border Gateway Protocol (BGP). If the active switch fails and the new elected active switch is running the IP base or LAN base feature set, these protocols will no longer run in the stack.

---

---

**Caution** Partitioning of the switch stack into two or more stacks might lead to undesirable behavior in the network.

---

If the switch is reloaded, then all the ports on that switch go down and there is a loss of traffic for the interfaces involved in routing, despite NSF/SSO capability

## Classless Routing

By default, classless routing behavior is enabled on the switch when it is configured to route. With classless routing, if a router receives packets for a subnet of a network with no default route, the router forwards the packet to the best supernet route. A supernet consists of contiguous blocks of Class C address spaces used to simulate a single, larger address space and is designed to relieve the pressure on the rapidly depleting Class B address space.

In Figure 41-2, classless routing is enabled. When the host sends a packet to 120.20.4.1, instead of discarding the packet, the router forwards it to the best supernet route. If you disable classless routing and a router receives packets destined for a subnet of a network with no network default route, the router discards the packet.

**Figure 65: IP Classless Routing**

In Figure 41-3, the router in network 128.20.0.0 is connected to subnets 128.20.1.0, 128.20.2.0, and 128.20.3.0. If the host sends a packet to 120.20.4.1, because there is no network default route, the router discards the packet.

**Figure 66: No IP Classless Routing**

## Address Resolution

You can control interface-specific handling of IP by using address resolution. A device using IP can have both a local address or MAC address, which uniquely defines the device on its local segment or LAN, and a network address, which identifies the network to which the device belongs.

**Note**

In a switch stack, network communication uses a single MAC address and the IP address of the stack.

The local address or MAC address is known as a data link address because it is contained in the data link layer (Layer 2) section of the packet header and is read by data link (Layer 2) devices. To communicate with a device on Ethernet, the software must learn the MAC address of the device. The process of learning the MAC address from an IP address is called address resolution. The process of learning the IP address from the MAC address is called reverse address resolution.

The switch can use these forms of address resolution:

- Address Resolution Protocol (ARP) is used to associate IP address with MAC addresses. Taking an IP address as input, ARP learns the associated MAC address and then stores the IP address/MAC address association in an ARP cache for rapid retrieval. Then the IP datagram is encapsulated in a link-layer frame and sent over the network. Encapsulation of IP datagrams and ARP requests or replies on IEEE 802 networks other than Ethernet is specified by the Subnetwork Access Protocol (SNAP).
- Proxy ARP helps hosts with no routing tables learn the MAC addresses of hosts on other networks or subnets. If the switch (router) receives an ARP request for a host that is not on the same interface as the ARP request sender, and if the router has all of its routes to the host through other interfaces, it generates a proxy ARP packet giving its own local data link address. The host that sent the ARP request then sends its packets to the router, which forwards them to the intended host.

The switch also uses the Reverse Address Resolution Protocol (RARP), which functions the same as ARP does, except that the RARP packets request an IP address instead of a local MAC address. Using RARP requires a RARP server on the same network segment as the router interface. Use the **ip rarp-server address** interface configuration command to identify the server.

For more information on RARP, see the *Cisco IOS Configuration Fundamentals Configuration Guide, Release 12.4*.

## Proxy ARP

Proxy ARP, the most common method for learning about other routes, enables an Ethernet host with no routing information to communicate with hosts on other networks or subnets. The host assumes that all hosts are on the same local Ethernet and that they can use ARP to learn their MAC addresses. If a switch receives an ARP request for a host that is not on the same network as the sender, the switch evaluates whether it has the best route to that host. If it does, it sends an ARP reply packet with its own Ethernet MAC address, and the host that sent the request sends the packet to the switch, which forwards it to the intended host. Proxy ARP treats all networks as if they are local and performs ARP requests for every IP address.

## ICMP Router Discovery Protocol

Router discovery allows the switch to dynamically learn about routes to other networks using ICMP router discovery protocol (IRDP). IRDP allows hosts to locate routers. When operating as a client, the switch generates router discovery packets. When operating as a host, the switch receives router discovery packets. The switch can also listen to Routing Information Protocol (RIP) routing updates and use this information to infer locations of routers. The switch does not actually store the routing tables sent by routing devices; it merely keeps track of which systems are sending the data. The advantage of using IRDP is that it allows each router to specify both a priority and the time after which a device is assumed to be down if no further packets are received.

Each device discovered becomes a candidate for the default router, and a new highest-priority router is selected when a higher priority router is discovered, when the current default router is declared down, or when a TCP connection is about to time out because of excessive retransmissions.

## UDP Broadcast Packets and Protocols

User Datagram Protocol (UDP) is an IP host-to-host layer protocol, as is TCP. UDP provides a low-overhead, connectionless session between two end systems and does not provide for acknowledgment of received datagrams. Network hosts occasionally use UDP broadcasts to find address, configuration, and name information. If such a host is on a network segment that does not include a server, UDP broadcasts are normally not forwarded. You can remedy this situation by configuring an interface on a router to forward certain classes of broadcasts to a helper address. You can use more than one helper address per interface.

You can specify a UDP destination port to control which UDP services are forwarded. You can specify multiple UDP protocols. You can also specify the Network Disk (ND) protocol, which is used by older diskless Sun workstations and the network security protocol SDNS.

By default, both UDP and ND forwarding are enabled if a helper address has been defined for an interface. The description for the **ip forward-protocol** interface configuration command in the *Cisco IOS IP Command Reference, Volume 1 of 3: Addressing and Services, Release 12.4* lists the ports that are forwarded by default if you do not specify any UDP ports.

## Broadcast Packet Handling

After configuring an IP interface address, you can enable routing and configure one or more routing protocols, or you can configure the way the switch responds to network broadcasts. A broadcast is a data packet destined for all hosts on a physical network. The switch supports two kinds of broadcasting:

- A directed broadcast packet is sent to a specific network or series of networks. A directed broadcast address includes the network or subnet fields.
- A flooded broadcast packet is sent to every network.

---

**Note** You can also limit broadcast, unicast, and multicast traffic on Layer 2 interfaces by using the **storm-control** interface configuration command to set traffic suppression levels.

---

Routers provide some protection from broadcast storms by limiting their extent to the local cable. Bridges (including intelligent bridges), because they are Layer 2 devices, forward broadcasts to all network segments, thus propagating broadcast storms. The best solution to the broadcast storm problem is to use a single broadcast address scheme on a network. In most modern IP implementations, you can set the address to be used as the broadcast address. Many implementations, including the one in the switch, support several addressing schemes for forwarding broadcast messages.

## IP Broadcast Flooding

You can allow IP broadcasts to be flooded throughout your internetwork in a controlled fashion by using the database created by the bridging STP. Using this feature also prevents loops. To support this capability, bridging must be configured on each interface that is to participate in the flooding. If bridging is not configured

on an interface, it still can receive broadcasts. However, the interface never forwards broadcasts it receives, and the router never uses that interface to send broadcasts received on a different interface.

Packets that are forwarded to a single network address using the IP helper-address mechanism can be flooded. Only one copy of the packet is sent on each network segment.

To be considered for flooding, packets must meet these criteria. (Note that these are the same conditions used to consider packet forwarding using IP helper addresses.)

- The packet must be a MAC-level broadcast.
- The packet must be an IP-level broadcast.
- The packet must be a TFTP, DNS, Time, NetBIOS, ND, or BOOTP packet, or a UDP specified by the **ip forward-protocol udp** global configuration command.
- The time-to-live (TTL) value of the packet must be at least two.

A flooded UDP datagram is given the destination address specified with the **ip broadcast-address** interface configuration command on the output interface. The destination address can be set to any address. Thus, the destination address might change as the datagram propagates through the network. The source address is never changed. The TTL value is decremented.

When a flooded UDP datagram is sent out an interface (and the destination address possibly changed), the datagram is handed to the normal IP output routines and is, therefore, subject to access lists, if they are present on the output interface.

In the switch, the majority of packets are forwarded in hardware; most packets do not go through the switch CPU. For those packets that do go to the CPU, you can speed up spanning tree-based UDP flooding by a factor of about four to five times by using turbo-flooding. This feature is supported over Ethernet interfaces configured for ARP encapsulation.

## How to Configure IP Routing

By default, IP routing is disabled on the switch, and you must enable it before routing can take place. For detailed IP routing configuration information, see the *Cisco IOS IP Configuration Guide, Release 12.4*

In the following procedures, the specified interface must be one of these Layer 3 interfaces:

- A routed port: a physical port configured as a Layer 3 port by using the **no switchport** interface configuration command.
- A switch virtual interface (SVI): a VLAN interface created by using the **interface vlan *vlan\_id*** global configuration command and by default a Layer 3 interface.
- An EtherChannel port channel in Layer 3 mode: a port-channel logical interface created by using the **interface port-channel *port-channel-number*** global configuration command and binding the Ethernet interface into the channel group. For more information, see the “Configuring Layer 3 EtherChannels” section on page 39-15.

---

**Note** The switch does not support tunnel interfaces for unicast routed traffic.

---

All Layer 3 interfaces on which routing will occur must have IP addresses assigned to them. See the “Assigning IP Addresses to Network Interfaces” section on page 41-7.

**Note**

A Layer 3 switch can have an IP address assigned to each routed port and SVI. The number of routed ports and SVIs that you can configure is limited to 128, exceeding the recommended number and volume of features being implemented might impact CPU utilization because of hardware limitations.

Configuring routing consists of several main procedures:

- To support VLAN interfaces, create and configure VLANs on the switch or switch stack, and assign VLAN membership to Layer 2 interfaces. For more information, see Chapter 14, “Configuring VLANs.”
- Configure Layer 3 interfaces.
- Enable IP routing on the switch.
- Assign IP addresses to the Layer 3 interfaces.
- Enable selected routing protocols on the switch.
- Configure routing protocol parameters (optional).

## How to Configure IP Addressing

A required task for configuring IP routing is to assign IP addresses to Layer 3 network interfaces to enable the interfaces and allow communication with the hosts on those interfaces that use IP. The following sections describe how to configure various IP addressing features. Assigning IP addresses to the interface is required; the other procedures are optional.

### Default IP Addressing Configuration

*Table 96: Default Addressing Configuration*

| Feature               | Default Setting                                                                                                                                          |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| IP address            | None defined.                                                                                                                                            |
| ARP                   | No permanent entries in the Address Resolution Protocol (ARP) cache.<br>Encapsulation: Standard Ethernet-style ARP.<br>Timeout: 14400 seconds (4 hours). |
| IP broadcast address  | 255.255.255.255 (all ones).                                                                                                                              |
| IP classless routing  | Enabled.                                                                                                                                                 |
| IP default gateway    | Disabled.                                                                                                                                                |
| IP directed broadcast | Disabled (all IP directed broadcasts are dropped).                                                                                                       |

| Feature             | Default Setting                                                                                                                                                                                                                                                                               |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IP domain           | Domain list: No domain names defined.<br>Domain lookup: Enabled.<br>Domain name: Enabled.                                                                                                                                                                                                     |
| IP forward-protocol | If a helper address is defined or User Datagram Protocol (UDP) flooding is configured, UDP forwarding is enabled on default ports.<br>Any-local-broadcast: Disabled.<br>Spanning Tree Protocol (STP): Disabled.<br>Turbo-flood: Disabled.                                                     |
| IP helper address   | Disabled.                                                                                                                                                                                                                                                                                     |
| IP host             | Disabled.                                                                                                                                                                                                                                                                                     |
| IRDP                | Disabled.<br>Defaults when enabled: <ul style="list-style-type: none"> <li>• Broadcast IRDP advertisements.</li> <li>• Maximum interval between advertisements: 600 seconds.</li> <li>• Minimum interval between advertisements: 0.75 times max interval</li> <li>• Preference: 0.</li> </ul> |
| IP proxy ARP        | Enabled.                                                                                                                                                                                                                                                                                      |
| IP routing          | Disabled.                                                                                                                                                                                                                                                                                     |
| IP subnet-zero      | Disabled.                                                                                                                                                                                                                                                                                     |

## Assigning IP Addresses to Network Interfaces

An IP address identifies a location to which IP packets can be sent. Some IP addresses are reserved for special uses and cannot be used for host, subnet, or network addresses. RFC 1166, "Internet Numbers," contains the official description of IP addresses.

An interface can have one primary IP address. A mask identifies the bits that denote the network number in an IP address. When you use the mask to subnet a network, the mask is referred to as a subnet mask. To receive an assigned network number, contact your Internet service provider.

## DETAILED STEPS

|        | Command or Action                                                                                                                                | Purpose                                                                                |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| Step 1 | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                                                   | Enters global configuration mode.                                                      |
| Step 2 | <b>interface <i>interface-id</i></b><br><br><b>Example:</b><br>Switch(config)# interface gigabitethernet 1/0/1                                   | Enters interface configuration mode, and specifies the Layer 3 interface to configure. |
| Step 3 | <b>no switchport</b><br><br><b>Example:</b><br>Switch(config-if)# no switchport                                                                  | Removes the interface from Layer 2 configuration mode (if it is a physical interface). |
| Step 4 | <b>ip address <i>ip-address subnet-mask</i></b><br><br><b>Example:</b><br>Switch(config-if)# ip address 10.1.5.1 255.255.255.0                   | Configures the IP address and IP subnet mask.                                          |
| Step 5 | <b>no shutdown</b><br><br><b>Example:</b><br>Switch(config-if)# no shutdown                                                                      | Enables the physical interface.                                                        |
| Step 6 | <b>end</b><br><br><b>Example:</b><br>Switch(config-if)# end                                                                                      | Returns to privileged EXEC mode.                                                       |
| Step 7 | <b>show ip route</b><br><br><b>Example:</b><br>Switch# show ip route                                                                             | Verifies your entries.                                                                 |
| Step 8 | <b>show ip interface [<i>interface-id</i>]</b><br><br><b>Example:</b><br>Switch# show ip interface gigabitethernet 1/0/1                         | Verifies your entries.                                                                 |
| Step 9 | <b>show running-config interface [<i>interface-id</i>]</b><br><br><b>Example:</b><br>Switch# show running-config interface gigabitethernet 1/0/1 | Verifies your entries.                                                                 |

|                | Command or Action                                                                                              | Purpose                                                  |
|----------------|----------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| <b>Step 10</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

### Using Subnet Zero

Subnetting with a subnet address of zero is strongly discouraged because of the problems that can arise if a network and a subnet have the same addresses. For example, if network 131.108.0.0 is subnetted as 255.255.255.0, subnet zero would be written as 131.108.0.0, which is the same as the network address.

You can use the all ones subnet (131.108.255.0) and even though it is discouraged, you can enable the use of subnet zero if you need the entire subnet space for your IP address.

### DETAILED STEPS

|               | Command or Action                                                                                              | Purpose                                                                     |
|---------------|----------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                 | Enters global configuration mode.                                           |
| <b>Step 2</b> | <b>ip subnet-zero</b><br><br><b>Example:</b><br>Switch(config)# ip subnet-zero                                 | Enables the use of subnet zero for interface addresses and routing updates. |
| <b>Step 3</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config)# end                                                       | Returns to privileged EXEC mode.                                            |
| <b>Step 4</b> | <b>show running-config</b><br><br><b>Example:</b><br>Switch# show running-config                               | Verifies your entry.                                                        |
| <b>Step 5</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config | (Optional) Saves your entry in the configuration file.                      |

## Enabling Classless Routing

To prevent the switch from forwarding packets destined for unrecognized subnets to the best supernet route possible, you can disable classless routing behavior.

### DETAILED STEPS

|               | Command or Action                                                                                              | Purpose                                                |
|---------------|----------------------------------------------------------------------------------------------------------------|--------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                 | Enters global configuration mode.                      |
| <b>Step 2</b> | <b>no ip classless</b><br><br><b>Example:</b><br>Switch(config)#no ip classless                                | Disables classless routing behavior.                   |
| <b>Step 3</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config)# end                                                       | Returns to privileged EXEC mode.                       |
| <b>Step 4</b> | <b>show running-config</b><br><br><b>Example:</b><br>Switch# show running-config                               | Verifies your entry.                                   |
| <b>Step 5</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config | (Optional) Saves your entry in the configuration file. |

## Configuring Address Resolution Methods

You can perform the following tasks to configure address resolution.

### Defining a Static ARP Cache

ARP and other address resolution protocols provide dynamic mapping between IP addresses and MAC addresses. Because most hosts support dynamic address resolution, you usually do not need to specify static ARP cache entries. If you must define a static ARP cache entry, you can do so globally, which installs a permanent entry in the ARP cache that the switch uses to translate IP addresses into MAC addresses. Optionally, you can also specify that the switch respond to ARP requests as if it were the owner of the specified IP address. If you do not want the ARP entry to be permanent, you can specify a timeout period for the ARP entry.

## DETAILED STEPS

|        | Command or Action                                                                                                                                  | Purpose                                                                                                                                                                                                                                                                                                                                                                             |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <p><b>configure terminal</b></p> <p><b>Example:</b></p> <pre>Switch# configure terminal</pre>                                                      | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                   |
| Step 2 | <p><b>arp ip-address hardware-address type</b></p> <p><b>Example:</b></p> <pre>Switch(config)# ip 10.1.5.1 c2f3.220a.12f4 arpa</pre>               | <p>Associates an IP address with a MAC (hardware) address in the ARP cache, and specifies encapsulation type as one of these:</p> <ul style="list-style-type: none"> <li>• <b>arpa</b>—ARP encapsulation for Ethernet interfaces</li> <li>• <b>snap</b>—Subnetwork Address Protocol encapsulation for Token Ring and FDDI interfaces</li> <li>• <b>sap</b>—HP's ARP type</li> </ul> |
| Step 3 | <p><b>arp ip-address hardware-address type [alias]</b></p> <p><b>Example:</b></p> <pre>Switch(config)# ip 10.1.5.3 d7f3.220d.12f5 arpa alias</pre> | (Optional) Specifies that the switch respond to ARP requests as if it were the owner of the specified IP address.                                                                                                                                                                                                                                                                   |
| Step 4 | <p><b>interface interface-id</b></p> <p><b>Example:</b></p> <pre>Switch(config)# interface gigabitethernet 1/0/1</pre>                             | Enters interface configuration mode, and specifies the interface to configure.                                                                                                                                                                                                                                                                                                      |
| Step 5 | <p><b>arp timeout seconds</b></p> <p><b>Example:</b></p> <pre>Switch(config-if)# arp 20000</pre>                                                   | (Optional) Sets the length of time an ARP cache entry will stay in the cache. The default is 14400 seconds (4 hours). The range is 0 to 2147483 seconds.                                                                                                                                                                                                                            |
| Step 6 | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Switch(config-if)# end</pre>                                                                         | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                    |
| Step 7 | <p><b>show interfaces [interface-id]</b></p> <p><b>Example:</b></p> <pre>Switch# show interfaces gigabitethernet 1/0/1</pre>                       | Verifies the type of ARP and the timeout value used on all interfaces or a specific interface.                                                                                                                                                                                                                                                                                      |
| Step 8 | <p><b>show arp</b></p> <p><b>Example:</b></p> <pre>Switch# show arp</pre>                                                                          | Views the contents of the ARP cache.                                                                                                                                                                                                                                                                                                                                                |

|                | Command or Action                                                                                            | Purpose                                                  |
|----------------|--------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| <b>Step 9</b>  | <b>show ip arp</b><br><br><b>Example:</b><br>Switch# show ip arp                                             | Views the contents of the ARP cache.                     |
| <b>Step 10</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config start-config | (Optional) Saves your entries in the configuration file. |

### Setting ARP Encapsulation

By default, Ethernet ARP encapsulation (represented by the **arpa** keyword) is enabled on an IP interface. You can change the encapsulation methods to SNAP if required by your network.

#### DETAILED STEPS

|               | Command or Action                                                                                              | Purpose                                                                                                                                                                                |

| <b>Step 5</b> | <b>show interfaces [<i>interface-id</i>]</b><br><br><b>Example:</b><br>Switch# show interfaces                 | Verifies ARP encapsulation configuration on all interfaces or the specified interface.                                                                                                 |

|               | Command or Action                                                                                              | Purpose                                                  |
|---------------|----------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| <b>Step 6</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

### Enabling Proxy ARP

By default, the switch uses proxy ARP to help hosts learn MAC addresses of hosts on other networks or subnets.

#### DETAILED STEPS

|               | Command or Action                                                                                                        | Purpose                                                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                           | Enters global configuration mode.                                                      |
| <b>Step 2</b> | <b>interface <i>interface-id</i></b><br><br><b>Example:</b><br>Switch(config)# interface gigabitethernet 1/0/2           | Enters interface configuration mode, and specifies the Layer 3 interface to configure. |
| <b>Step 3</b> | <b>ip proxy-arp</b><br><br><b>Example:</b><br>Switch(config-if)# ip proxy-arp                                            | Enables proxy ARP on the interface.                                                    |
| <b>Step 4</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config-if)# end                                                              | Returns to privileged EXEC mode.                                                       |
| <b>Step 5</b> | <b>show ip interface [<i>interface-id</i>]</b><br><br><b>Example:</b><br>Switch# show ip interface gigabitethernet 1/0/2 | Verifies the configuration on the interface or all interfaces.                         |
| <b>Step 6</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config           | (Optional) Saves your entries in the configuration file.                               |

## Routing Assistance When IP Routing is Disabled

These mechanisms allow the switch to learn about routes to other networks when it does not have IP routing enabled:

- Proxy ARP
- Default Gateway
- ICMP Router Discovery Protocol (IRDP)

### Proxy ARP

Proxy ARP is enabled by default. To enable it after it has been disabled, see the “Enabling Proxy ARP” section. Proxy ARP works as long as other routers support it.

### Default Gateway

Another method for locating routes is to define a default router or default gateway. All non-local packets are sent to this router, which either routes them appropriately or sends an IP Control Message Protocol (ICMP) redirect message back, defining which local router the host should use. The switch caches the redirect messages and forwards each packet as efficiently as possible. A limitation of this method is that there is no means of detecting when the default router has gone down or is unavailable.

## DETAILED STEPS

|               | Command or Action                                                                                                              | Purpose                             |
|---------------|--------------------------------------------------------------------------------------------------------------------------------|-------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <code>configure terminal</code>                                    | Enters global configuration mode.   |
| <b>Step 2</b> | <b>ip default-gateway <i>ip-address</i></b><br><br><b>Example:</b><br>Switch(config)# <code>ip default gateway 10.1.5.1</code> | Sets up a default gateway (router). |
| <b>Step 3</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <code>end</code>                                                          | Returns to privileged EXEC mode.    |

|               | Command or Action                                                                                              | Purpose                                                                   |
|---------------|----------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------|
| <b>Step 4</b> | <b>show ip redirects</b><br><br><b>Example:</b><br>Switch# show ip redirects                                   | Displays the address of the default gateway router to verify the setting. |
| <b>Step 5</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config | (Optional) Saves your entries in the configuration file.                  |

### ICMP Router Discovery Protocol (IRDP)

The only required task for IRDP routing on an interface is to enable IRDP processing on that interface. When enabled, the default parameters apply.

You can optionally change any of these parameters. If you change the **maxadvertinterval** value, the **holdtime** and **minadvertinterval** values also change, so it is important to first change the **maxadvertinterval** value, before manually changing either the **holdtime** or **minadvertinterval** values.

#### DETAILED STEPS

|               | Command or Action                                                                                              | Purpose                                                                                             |
|---------------|----------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                 | Enters global configuration mode.                                                                   |
| <b>Step 2</b> | <b>interface <i>interface-id</i></b><br><br><b>Example:</b><br>Switch(config)# interface gigabitethernet 1/0/1 | Enters interface configuration mode, and specifies the Layer 3 interface to configure.              |
| <b>Step 3</b> | <b>ip irdp</b><br><br><b>Example:</b><br>Switch(config-if)# ip irdp                                            | Enables IRDP processing on the interface.                                                           |
| <b>Step 4</b> | <b>ip irdp multicast</b><br><br><b>Example:</b><br>Switch(config-if)# ip irdp multicast                        | (Optional) Sends IRDP advertisements to the multicast address (224.0.0.1) instead of IP broadcasts. |

|                | Command or Action                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                 |
|----------------|-------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                |                                                                                                                               | <b>Note</b> This command allows for compatibility with Sun Microsystems Solaris, which requires IRDP packets to be sent out as multicasts. Many implementations cannot receive these multicasts; ensure end-host ability before using this command.                                                     |
| <b>Step 5</b>  | <b>ip irdp holdtime</b> <i>seconds</i><br><br><b>Example:</b><br>Switch(config-if)# ip irdp holdtime 1000                     | (Optional) Sets the IRDP period for which advertisements are valid. The default is three times the <b>maxadvertinterval</b> value. It must be greater than <b>maxadvertinterval</b> and cannot be greater than 9000 seconds. If you change the <b>maxadvertinterval</b> value, this value also changes. |
| <b>Step 6</b>  | <b>ip irdp maxadvertinterval</b> <i>seconds</i><br><br><b>Example:</b><br>Switch(config-if)# ip irdp<br>maxadvertinterval 650 | (Optional) Sets the IRDP maximum interval between advertisements. The default is 600 seconds.                                                                                                                                                                                                           |
| <b>Step 7</b>  | <b>ip irdp minadvertinterval</b> <i>seconds</i><br><br><b>Example:</b><br>Switch(config-if)# ip irdp<br>minadvertinterval 500 | (Optional) Sets the IRDP minimum interval between advertisements. The default is 0.75 times the <b>maxadvertinterval</b> . If you change the <b>maxadvertinterval</b> , this value changes to the new default (0.75 of <b>maxadvertinterval</b> ).                                                      |
| <b>Step 8</b>  | <b>ip irdp preference</b> <i>number</i><br><br><b>Example:</b><br>Switch(config-if)# ip irdp preference 2                     | (Optional) Sets a device IRDP preference level. The allowed range is -231 to 231. The default is 0. A higher value increases the router preference level.                                                                                                                                               |
| <b>Step 9</b>  | <b>ip irdp address</b> <i>address [number]</i><br><br><b>Example:</b><br>Switch(config-if)# ip irdp address<br>10.1.10.10     | (Optional) Specifies an IRDP address and preference to proxy-advertise.                                                                                                                                                                                                                                 |
| <b>Step 10</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config-if)# end                                                                   | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                        |
| <b>Step 11</b> | <b>show ip irdp</b><br><br><b>Example:</b><br>Switch# show ip irdp                                                            | Verifies settings by displaying IRDP values.                                                                                                                                                                                                                                                            |

|         | Command or Action                                                                                                         | Purpose                                                  |
|---------|---------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| Step 12 | <b>copy running-config startup-config</b><br><br><b>Example:</b><br><pre>Switch# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

## Configuring Broadcast Packet Handling

Perform the tasks in these sections to enable these schemes:

- Enabling Directed Broadcast-to-Physical Broadcast Translation, page 41-19
- Forwarding UDP Broadcast Packets and Protocols, page 41-20
- Establishing an IP Broadcast Address, page 41-22
- Flooding IP Broadcasts, page 41-23

### Enabling Directed Broadcast-to-Physical Broadcast Translation

By default, IP directed broadcasts are dropped; they are not forwarded. Dropping IP-directed broadcasts makes routers less susceptible to denial-of-service attacks.

You can enable forwarding of IP-directed broadcasts on an interface where the broadcast becomes a physical (MAC-layer) broadcast. Only those protocols configured by using the **ip forward-protocol** global configuration command are forwarded.

You can specify an access list to control which broadcasts are forwarded. When an access list is specified, only those IP packets permitted by the access list are eligible to be translated from directed broadcasts to physical broadcasts. For more information on access lists, see Chapter 36, “Configuring Network Security with ACLs.”

### DETAILED STEPS

|        | Command or Action                                                                                                         | Purpose                                                                        |
|--------|---------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------|
| Step 1 | <b>configure terminal</b><br><br><b>Example:</b><br><pre>Switch# configure terminal</pre>                                 | Enters global configuration mode.                                              |
| Step 2 | <b>interface <i>interface-id</i></b><br><br><b>Example:</b><br><pre>Switch(config)# interface gigabitethernet 1/0/2</pre> | Enters interface configuration mode, and specifies the interface to configure. |

|               | Command or Action                                                                                                                                               | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 3</b> | <p><b>ip directed-broadcast</b> [<i>access-list-number</i>]</p> <p><b>Example:</b></p> <pre>Switch(config-if)# ip directed-broadcast 103</pre>                  | <p>Enables directed broadcast-to-physical broadcast translation on the interface. You can include an access list to control which broadcasts are forwarded. When an access list, only IP packets permitted by the access list can be translated.</p> <p><b>Note</b> The <b>ip directed-broadcast</b> interface configuration command can be configured on a VPN routing/forwarding(VRF) interface and is VRF aware. Directed broadcast traffic is routed only within the VRF.</p> |
| <b>Step 4</b> | <p><b>exit</b></p> <p><b>Example:</b></p> <pre>Switch(config-if)# exit</pre>                                                                                    | Returns to global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Step 5</b> | <p><b>ip forward-protocol</b> {<b>udp</b> [<i>port</i>]   <b>nd</b>   <b>sdns</b>}</p> <p><b>Example:</b></p> <pre>Switch(config)# ip forward-protocol nd</pre> | <p>Specifies which protocols and ports the router forwards when forwarding broadcast packets.</p> <ul style="list-style-type: none"> <li>• <b>udp</b>—Forward UDP datagrams.</li> </ul> <p>port: (Optional) Destination port that controls which UDP services are forwarded.</p> <ul style="list-style-type: none"> <li>• <b>nd</b>—Forward ND datagrams.</li> <li>• <b>sdns</b>—Forward SDNS datagrams</li> </ul>                                                                |
| <b>Step 6</b> | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Switch(config)# end</pre>                                                                                         | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Step 7</b> | <p><b>show ip interface</b> [<i>interface-id</i>]</p> <p><b>Example:</b></p> <pre>Switch# show ip interface</pre>                                               | Verifies the configuration on the interface or all interfaces                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Step 8</b> | <p><b>show running-config</b></p> <p><b>Example:</b></p> <pre>Switch# show running-config</pre>                                                                 | Verifies the configuration on the interface or all interfaces                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Step 9</b> | <p><b>copy running-config startup-config</b></p> <p><b>Example:</b></p> <pre>Switch# copy running-config startup-config</pre>                                   | (Optional) Saves your entries in the configuration file.                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Forwarding UDP Broadcast Packets and Protocols

If you do not specify any UDP ports when you configure the forwarding of UDP broadcasts, you are configuring the router to act as a BOOTP forwarding agent. BOOTP packets carry DHCP information.

### DETAILED STEPS

|               | Command or Action                                                                                                             | Purpose                                                                                                         |
|---------------|-------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                                | Enters global configuration mode.                                                                               |
| <b>Step 2</b> | <b>interface <i>interface-id</i></b><br><br><b>Example:</b><br>Switch(config)# interface gigabitethernet 1/0/1                | Enters interface configuration mode, and specifies the Layer 3 interface to configure.                          |
| <b>Step 3</b> | <b>ip helper-address <i>address</i></b><br><br><b>Example:</b><br>Switch(config-if)# ip helper address 10.1.10.1              | Enables forwarding and specifies the destination address for forwarding UDP broadcast packets, including BOOTP. |
| <b>Step 4</b> | <b>exit</b><br><br><b>Example:</b><br>Switch(config-if)# exit                                                                 | Returns to global configuration mode.                                                                           |
| <b>Step 5</b> | <b>ip forward-protocol {udp [<i>port</i>]   nd   sdns}</b><br><br><b>Example:</b><br>Switch(config)# ip forward-protocol sdns | Specifies which protocols the router forwards when forwarding broadcast packets.                                |
| <b>Step 6</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config)# end                                                                      | Returns to privileged EXEC mode.                                                                                |
| <b>Step 7</b> | <b>show ip interface [<i>interface-id</i>]</b><br><br><b>Example:</b><br>Switch# show ip interface gigabitethernet 1/0/1      | Verifies the configuration on the interface or all interfaces.                                                  |
| <b>Step 8</b> | <b>show running-config</b><br><br><b>Example:</b><br>Switch# show running-config                                              | Verifies the configuration on the interface or all interfaces.                                                  |

|               | Command or Action                                                                                              | Purpose                                                  |
|---------------|----------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| <b>Step 9</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

### Establishing an IP Broadcast Address

The most popular IP broadcast address (and the default) is an address consisting of all ones (255.255.255.255). However, the switch can be configured to generate any form of IP broadcast address.

#### DETAILED STEPS

|               | Command or Action                                                                                                             | Purpose                                                                           |
|---------------|-------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                                | Enters global configuration mode.                                                 |
| <b>Step 2</b> | <b>interface <i>interface-id</i></b><br><br><b>Example:</b><br>Switch(config)# interface gigabitethernet 1/0/1                | Enters interface configuration mode, and specifies the interface to configure.    |
| <b>Step 3</b> | <b>ip broadcast-address <i>ip-address</i></b><br><br><b>Example:</b><br>Switch(config-if)# ip broadcast-address 128.1.255.255 | Enters a broadcast address different from the default, for example 128.1.255.255. |
| <b>Step 4</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config-if)# end                                                                   | Returns to privileged EXEC mode.                                                  |
| <b>Step 5</b> | <b>show ip interface [<i>interface-id</i>]</b><br><br><b>Example:</b><br>Switch# show ip interface                            | Verifies the broadcast address on the interface or all interfaces.                |
| <b>Step 6</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config                | (Optional) Saves your entries in the configuration file.                          |

## Flooding IP Broadcasts

### DETAILED STEPS

|        | Command or Action                                                                                                    | Purpose                                                                |
|--------|----------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------|
| Step 1 | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                       | Enters global configuration mode.                                      |
| Step 2 | <b>ip forward-protocol spanning-tree</b><br><br><b>Example:</b><br>Switch(config)# ip forward-protocol spanning-tree | Uses the bridging spanning-tree database to flood UDP datagrams.       |
| Step 3 | <b>end</b><br><br><b>Example:</b><br>Switch(config)# end                                                             | Returns to privileged EXEC mode.                                       |
| Step 4 | <b>show running-config</b><br><br><b>Example:</b><br>Switch# show running-config                                     | Verifies your entry.                                                   |
| Step 5 | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config       | (Optional) Saves your entry in the configuration file.                 |
| Step 6 | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                       | Enters global configuration mode                                       |
| Step 7 | <b>ip forward-protocol turbo-flood</b><br><br><b>Example:</b><br>Switch(config)# ip forward-protocol turbo-flood     | Uses the spanning-tree database to speed up flooding of UDP datagrams. |
| Step 8 | <b>end</b><br><br><b>Example:</b><br>Switch(config)# end                                                             | Returns to privileged EXEC mode.                                       |

|         | Command or Action                                                                                              | Purpose                                                |
|---------|----------------------------------------------------------------------------------------------------------------|--------------------------------------------------------|
| Step 9  | <b>show running-config</b><br><br><b>Example:</b><br>Switch# show running-config                               | Verifies your entry.                                   |
| Step 10 | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config | (Optional) Saves your entry in the configuration file. |

## Monitoring and Maintaining IP Addressing

When the contents of a particular cache, table, or database have become or are suspected to be invalid, you can remove all its contents by using the **clear** privileged EXEC commands. Table 41-2 lists the commands for clearing contents.

**Table 97: Commands to Clear Caches, Tables, and Databases**

|                                                             |                                                                     |
|-------------------------------------------------------------|---------------------------------------------------------------------|
| <b>clear arp-cache</b>                                      | Clears the IP ARP cache and the fast-switching cache.               |
| <b>clear host</b> { <i>name</i>   *}                        | Removes one or all entries from the hostname and the address cache. |
| <b>clear ip route</b> { <b>network</b> [ <i>mask</i> ]   *} | Removes one or more routes from the IP routing table.               |

You can display specific statistics, such as the contents of IP routing tables, caches, and databases; the reachability of nodes; and the routing path that packets are taking through the network. Table 41-3 lists the privileged EXEC commands for displaying IP statistics.

**Table 98: Commands to Display Caches, Tables, and Databases**

|                                                  |                                                                                                                               |
|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>show arp</b>                                  | Displays the entries in the ARP table.                                                                                        |
| <b>show hosts</b>                                | Displays the default domain name, style of lookup service, name server hosts, and the cached list of hostnames and addresses. |
| <b>show ip aliases</b>                           | Displays IP addresses mapped to TCP ports (aliases).                                                                          |
| <b>show ip arp</b>                               | Displays the IP ARP cache.                                                                                                    |
| <b>show ip interface</b> [ <i>interface-id</i> ] | Displays the IP status of interfaces.                                                                                         |

|                                                                              |                                                                                          |
|------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| <b>show ip irdp</b>                                                          | Displays IRDP values.                                                                    |
| <b>show ip masks</b> <i>address</i>                                          | Displays the masks used for network addresses and the number of subnets using each mask. |
| <b>show ip redirects</b>                                                     | Displays the address of a default gateway.                                               |
| <b>show ip route</b> [ <i>address</i> [ <i>mask</i> ]]   [ <i>protocol</i> ] | Displays the current state of the routing table.                                         |
| <b>show ip route summary</b>                                                 | Displays the current state of the routing table in summary form.                         |

## How to Configure IP Unicast Routing

### Enabling IP Unicast Routing

By default, the switch is in Layer 2 switching mode and IP routing is disabled. To use the Layer 3 capabilities of the switch, you must enable IP routing.

#### DETAILED STEPS

|               | Command or Action                                                                                          | Purpose                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <code>configure terminal</code>                | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Step 2</b> | <b>ip routing</b><br><br><b>Example:</b><br>Switch(config)# <code>ip routing</code>                        | Enables IP routing.                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Step 3</b> | <b>router</b> <i>ip_routing_protocol</i><br><br><b>Example:</b><br>Switch(config)# <code>router rip</code> | Specifies an IP routing protocol. This step might include other commands, such as specifying the networks to route with the <b>network</b> (RIP) router configuration command. For information on specific protocols, see sections later in this chapter and to the <i>Cisco IOS IP Configuration Guide, Release 12.4</i> .<br><br><b>Note</b> The IP base feature set supports only RIP as a routing protocol. |
| <b>Step 4</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <code>end</code>                                      | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                |

|               | Command or Action                                                                                              | Purpose                                                  |
|---------------|----------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| <b>Step 5</b> | <b>show running-config</b><br><br><b>Example:</b><br>Switch# show running-config                               | Verifies your entries.                                   |
| <b>Step 6</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

## Example of Enabling IP Routing

This example shows how to enable IP routing using RIP as the routing protocol :

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# ip routing
Switch(config)# router rip
Switch(config-router)# network 10.0.0.0
Switch(config-router)# end
```

## What to Do Next

You can now set up parameters for the selected routing protocols as described in these sections:

- RIP
- OSPF,
- EIGRP
- BGP
- Unicast Reverse Path Forwarding
- Protocol-Independent Features (optional)

## Information About RIP

The Routing Information Protocol (RIP) is an interior gateway protocol (IGP) created for use in small, homogeneous networks. It is a distance-vector routing protocol that uses broadcast User Datagram Protocol (UDP) data packets to exchange routing information. The protocol is documented in RFC 1058. You can find detailed information about RIP in *IP Routing Fundamentals*, published by Cisco Press.

**Note** RIP is supported in the IP Base.

Using RIP, the switch sends routing information updates (advertisements) every 30 seconds. If a router does not receive an update from another router for 180 seconds or more, it marks the routes served by that router as unusable. If there is still no update after 240 seconds, the router removes all routing table entries for the non-updating router.

RIP uses hop counts to rate the value of different routes. The hop count is the number of routers that can be traversed in a route. A directly connected network has a hop count of zero; a network with a hop count of 16 is unreachable. This small range (0 to 15) makes RIP unsuitable for large networks.

If the router has a default network path, RIP advertises a route that links the router to the pseudonetwork 0.0.0.0. The 0.0.0.0 network does not exist; it is treated by RIP as a network to implement the default routing feature. The switch advertises the default network if a default was learned by RIP or if the router has a gateway of last resort and RIP is configured with a default metric. RIP sends updates to the interfaces in specified networks. If an interface's network is not specified, it is not advertised in any RIP update.

## Summary Addresses and Split Horizon

Routers connected to broadcast-type IP networks and using distance-vector routing protocols normally use the split-horizon mechanism to reduce the possibility of routing loops. Split horizon blocks information about routes from being advertised by a router on any interface from which that information originated. This feature usually optimizes communication among multiple routers, especially when links are broken.

# How to Configure RIP

## Default RIP Configuration

*Table 99: Default RIP Configuration*

| Feature                         | Default Setting                                        |
|---------------------------------|--------------------------------------------------------|
| Auto summary                    | Enabled.                                               |
| Default-information originate   | Disabled.                                              |
| Default metric                  | Built-in; automatic metric translations.               |
| IP RIP authentication key-chain | No authentication.<br>Authentication mode: clear text. |
| IP RIP triggered                | Disabled                                               |
| IP split horizon                | Varies with media.                                     |
| Neighbor                        | None defined.                                          |
| Network                         | None specified.                                        |
| Offset list                     | Disabled.                                              |

| Feature                | Default Setting                                                                                                                                                            |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Output delay           | 0 milliseconds.                                                                                                                                                            |
| Timers basic           | <ul style="list-style-type: none"> <li>• Update: 30 seconds.</li> <li>• Invalid: 180 seconds.</li> <li>• Hold-down: 180 seconds.</li> <li>• Flush: 240 seconds.</li> </ul> |
| Validate-update-source | Enabled.                                                                                                                                                                   |
| Version                | Receives RIP Version 1 and 2 packets; sends Version 1 packets.                                                                                                             |

## Configuring Basic RIP Parameters

To configure RIP, you enable RIP routing for a network and optionally configure other parameters. On the switches, RIP configuration commands are ignored until you configure the network number.

### DETAILED STEPS

|               | Command or Action                                                                                | Purpose                                                                                                                                                                                                                                                                             |
|---------------|--------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>            | Enters global configuration mode.                                                                                                                                                                                                                                                   |
| <b>Step 2</b> | <b>ip routing</b><br><br><b>Example:</b><br>Switch(config)# <b>ip routing</b>                    | Enables IP routing. (Required only if IP routing is disabled.)                                                                                                                                                                                                                      |
| <b>Step 3</b> | <b>router rip</b><br><br><b>Example:</b><br>Switch(config)# <b>router rip</b>                    | Enables a RIP routing process, and enter router configuration mode.                                                                                                                                                                                                                 |
| <b>Step 4</b> | <b>network <i>network number</i></b><br><br><b>Example:</b><br>Switch(config)# <b>network 12</b> | Associates a network with a RIP routing process. You can specify multiple <b>network</b> commands. RIP routing updates are sent and received through interfaces only on these networks.<br><br><b>Note</b> You must configure a network number for the RIP commands to take effect. |

|         | Command or Action                                                                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 5  | <b>neighbor</b> <i>ip-address</i><br><br><b>Example:</b><br>Switch(config)# <b>neighbor</b> 10.2.5.1                                                                                  | (Optional) Defines a neighboring router with which to exchange routing information. This step allows routing updates from RIP (normally a broadcast protocol) to reach nonbroadcast networks.                                                                                                                                                                                                                                                                                                                                                                                          |
| Step 6  | <b>offset-list</b> [ <i>access-list number   name</i> ] { <b>in</b>   <b>out</b> } <i>offset [type number]</i><br><br><b>Example:</b><br>Switch(config)# <b>offset-list</b> 103 in 10 | (Optional) Applies an offset list to routing metrics to increase incoming and outgoing metrics to routes learned through RIP. You can limit the offset list with an access list or an interface.                                                                                                                                                                                                                                                                                                                                                                                       |
| Step 7  | <b>timers basic</b> <i>update invalid holddown flush</i><br><br><b>Example:</b><br>Switch(config)# <b>timers basic</b> 45 360 400 300                                                 | (Optional) Adjusts routing protocol timers. Valid ranges for all timers are 0 to 4294967295 seconds. <ul style="list-style-type: none"> <li>• <i>update</i>—The time between sending routing updates. The default is 30 seconds.</li> <li>• <i>invalid</i>—The timer after which a route is declared invalid. The default is 180 seconds.</li> <li>• <i>holddown</i>—The time before a route is removed from the routing table. The default is 180 seconds.</li> <li>• <i>flush</i>—The amount of time for which routing updates are postponed. The default is 240 seconds.</li> </ul> |
| Step 8  | <b>version</b> { <b>1</b>   <b>2</b> }<br><br><b>Example:</b><br>Switch(config)# <b>version</b> 2                                                                                     | (Optional) Configures the switch to receive and send only RIP Version 1 or RIP Version 2 packets. By default, the switch receives Version 1 and 2 but sends only Version 1. You can also use the interface commands <b>ip rip {send   receive} version 1   2   1 2</b> to control what versions are used for sending and receiving on interfaces.                                                                                                                                                                                                                                      |
| Step 9  | <b>no auto summary</b><br><br><b>Example:</b><br>Switch(config)# <b>no auto summary</b>                                                                                               | (Optional) Disables automatic summarization. By default, the switch summarizes subprefixes when crossing classful network boundaries. Disable summarization (RIP Version 2 only) to advertise subnet and host routing information to classful network boundaries.                                                                                                                                                                                                                                                                                                                      |
| Step 10 | <b>no validate-update-source</b><br><br><b>Example:</b><br>Switch(config)# <b>no validate-update-source</b>                                                                           | (Optional) Disables validation of the source IP address of incoming RIP routing updates. By default, the switch validates the source IP address of incoming RIP routing updates and discards the update if the source address is not valid. Under normal circumstances, disabling this feature is not recommended. However, if you have a router that is off-network and you want to receive its updates, you can use this command.                                                                                                                                                    |
| Step 11 | <b>output-delay</b> <i>delay</i><br><br><b>Example:</b><br>Switch(config)# <b>output-delay</b> 8                                                                                      | (Optional) Adds interpacket delay for RIP updates sent. By default, packets in a multiple-packet RIP update have no delay added between packets. If you are sending packets to a lower-speed device, you can add an interpacket delay in the range of 8 to 50 milliseconds.                                                                                                                                                                                                                                                                                                            |

|         | Command or Action                                                                                                     | Purpose                                                  |
|---------|-----------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| Step 12 | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b>                                                       | Returns to privileged EXEC mode.                         |
| Step 13 | <b>show ip protocols</b><br><br><b>Example:</b><br>Switch# <b>show ip protocols</b>                                   | Verifies your entries.                                   |
| Step 14 | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# <b>copy running-config startup-config</b> | (Optional) Saves your entries in the configuration file. |

## Configuring RIP Authentication

RIP Version 1 does not support authentication. If you are sending and receiving RIP Version 2 packets, you can enable RIP authentication on an interface. The key chain specifies the set of keys that can be used on the interface. If a key chain is not configured, no authentication is performed.

The switch supports two modes of authentication on interfaces for which RIP authentication is enabled: plain text and MD5. The default is plain text.

### DETAILED STEPS

|        | Command or Action                                                                                                                                     | Purpose                                                                        |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------|
| Step 1 | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                                                                 | Enters global configuration mode.                                              |
| Step 2 | <b>interface <i>interface-id</i></b><br><br><b>Example:</b><br>Switch(config)# <b>interface gigabitethernet 1/0/1</b>                                 | Enters interface configuration mode, and specifies the interface to configure. |
| Step 3 | <b>ip rip authentication key-chain <i>name-of-chain</i></b><br><br><b>Example:</b><br>Switch(config-if)# <b>ip rip authentication key-chain trees</b> | Enables RIP authentication.                                                    |

|        | Command or Action                                                                                                                 | Purpose                                                                                               |
|--------|-----------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|
| Step 4 | <b>ip rip authentication mode</b> {text   md5}<br><br><b>Example:</b><br>Switch(config-if)# <b>ip rip authentication mode md5</b> | Configures the interface to use plain text authentication (the default) or MD5 digest authentication. |
| Step 5 | <b>end</b><br><br><b>Example:</b><br>Switch(config-if)# <b>end</b>                                                                | Returns to privileged EXEC mode.                                                                      |
| Step 6 | <b>show running-config interface</b> [interface-id]<br><br><b>Example:</b><br>Switch# <b>show running-config</b>                  | Verifies your entries.                                                                                |
| Step 7 | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# <b>copy running-config startup-config</b>             | (Optional) Saves your entries in the configuration file.                                              |

## Configuring Summary Addresses and Split Horizon

**Note** In general, disabling split horizon is not recommended unless you are certain that your application requires it to properly advertise routes.

If you want to configure an interface running RIP to advertise a summarized local IP address pool on a network access server for dial-up clients, use the **ip summary-address rip** interface configuration command.

**Note** If split horizon is enabled, neither autosummary nor interface IP summary addresses are advertised.

### DETAILED STEPS

|        | Command or Action                                                                     | Purpose                           |
|--------|---------------------------------------------------------------------------------------|-----------------------------------|
| Step 1 | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b> | Enters global configuration mode. |

|               | Command or Action                                                                                                                                                             | Purpose                                                                                |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| <b>Step 2</b> | <b>interface</b> <i>interface-id</i><br><br><b>Example:</b><br>Switch(config)# <b>interface</b> gigabitethernet 1/0/1                                                         | Enters interface configuration mode, and specifies the Layer 3 interface to configure. |
| <b>Step 3</b> | <b>ip address</b> <i>ip-address subnet-mask</i><br><br><b>Example:</b><br>Switch(config-if)# <b>ip address</b> 10.1.1.10 255.255.255.0                                        | Configures the IP address and IP subnet.                                               |
| <b>Step 4</b> | <b>ip summary-address rip ip address</b> <i>ip-network mask</i><br><br><b>Example:</b><br>Switch(config-if)# <b>ip summary-address rip ip address</b> 10.1.1.30 255.255.255.0 | Configures the IP address to be summarized and the IP network mask.                    |
| <b>Step 5</b> | <b>no ip split horizon</b><br><br><b>Example:</b><br>Switch(config-if)# <b>no ip split horizon</b>                                                                            | Disables split horizon on the interface.                                               |
| <b>Step 6</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config-if)# <b>end</b>                                                                                                            | Returns to privileged EXEC mode.                                                       |
| <b>Step 7</b> | <b>show ip interface</b> <i>interface-id</i><br><br><b>Example:</b><br>Switch# <b>show ip interface</b> gigabitethernet 1/0/1                                                 | Verifies your entries.                                                                 |
| <b>Step 8</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# <b>copy running-config startup-config</b>                                                         | (Optional) Saves your entries in the configuration file.                               |

## Configuring Split Horizon

Routers connected to broadcast-type IP networks and using distance-vector routing protocols normally use the split-horizon mechanism to reduce the possibility of routing loops. Split horizon blocks information about routes from being advertised by a router on any interface from which that information originated. This feature can optimize communication among multiple routers, especially when links are broken.

**Note** In general, we do not recommend disabling split horizon unless you are certain that your application requires it to properly advertise routes.

## DETAILED STEPS

|               | Command or Action                                                                                                               | Purpose                                                                        |
|---------------|---------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                                  | Enters global configuration mode.                                              |
| <b>Step 2</b> | <b>interface <i>interface-id</i></b><br><br><b>Example:</b><br>Switch(config)# interface gigabitethernet 1/0/1                  | Enters interface configuration mode, and specifies the interface to configure. |
| <b>Step 3</b> | <b>ip address <i>ip-address subnet-mask</i></b><br><br><b>Example:</b><br>Switch(config-if)# ip address 10.1.1.10 255.255.255.0 | Configures the IP address and IP subnet.                                       |
| <b>Step 4</b> | <b>no ip split-horizon</b><br><br><b>Example:</b><br>Switch(config-if)# no ip split-horizon                                     | Disables split horizon on the interface.                                       |
| <b>Step 5</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config-if)# end                                                                     | Returns to privileged EXEC mode.                                               |
| <b>Step 6</b> | <b>show ip interface <i>interface-id</i></b><br><br><b>Example:</b><br>Switch# show ip interface gigabitethernet 1/0/1          | Verifies your entries.                                                         |
| <b>Step 7</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config                  | (Optional) Saves your entries in the configuration file.                       |

## Configuration Example for Summary Addresses and Split Horizon

In this example, the major net is 10.0.0.0. The summary address 10.2.0.0 overrides the autosummary address of 10.0.0.0 so that 10.2.0.0 is advertised out interface Gigabit Ethernet port 2, and 10.0.0.0 is not advertised. In the example, if the interface is still in Layer 2 mode (the default), you must enter a **no switchport** interface configuration command before entering the **ip address** interface configuration command.

### Note

If split horizon is enabled, neither autosummary nor interface summary addresses (those configured with the **ip summary-address rip** router configuration command) are advertised.

```
Switch(config)# router rip
Switch(config-router)# interface gigabitethernet1/0/2
Switch(config-if)# ip address 10.1.5.1 255.255.255.0
Switch(config-if)# ip summary-address rip 10.2.0.0 255.255.0.0
Switch(config-if)# no ip split-horizon
Switch(config-if)# exit
Switch(config)# router rip
Switch(config-router)# network 10.0.0.0
Switch(config-router)# neighbor 2.2.2.2 peer-group mygroup
Switch(config-router)# end
```

## Information About OSPF

OSPF is an Interior Gateway Protocol (IGP) designed expressly for IP networks, supporting IP subnetting and tagging of externally derived routing information. OSPF also allows packet authentication and uses IP multicast when sending and receiving packets. The Cisco implementation supports RFC 1253, OSPF management information base (MIB).

### Note

OSPF is supported in IP Base.

The Cisco implementation conforms to the OSPF Version 2 specifications with these key features:

- Definition of stub areas is supported.
- Routes learned through any IP routing protocol can be redistributed into another IP routing protocol. At the intradomain level, this means that OSPF can import routes learned through EIGRP and RIP. OSPF routes can also be exported into RIP.
- Plain text and MD5 authentication among neighboring routers within an area is supported.
- Configurable routing interface parameters include interface output cost, retransmission interval, interface transmit delay, router priority, router dead and hello intervals, and authentication key.
- Virtual links are supported.
- Not-so-stubby-areas (NSSAs) per RFC 1587 are supported.

OSPF typically requires coordination among many internal routers, area border routers (ABRs) connected to multiple areas, and autonomous system boundary routers (ASBRs). The minimum configuration would use all default parameter values, no authentication, and interfaces assigned to areas. If you customize your environment, you must ensure coordinated configuration of all routers.

## OSPF Nonstop Forwarding

The switch or switch stack supports two levels of nonstop forwarding (NSF):

- [OSPF NSF Awareness](#), on page 1187
- [OSPF NSF Capability](#), on page 1187

### OSPF NSF Awareness

The IP-services feature set supports OSPF NSF Awareness supported for IPv4. When the neighboring router is NSF-capable, the Layer 3 switch continues to forward packets from the neighboring router during the interval between the primary Route Processor (RP) in a router crashing and the backup RP taking over, or while the primary RP is manually reloaded for a non-disruptive software upgrade.

This feature cannot be disabled.

### OSPF NSF Capability

The IP services feature set supports the OSPFv2 NSF IETF format in addition to the OSPFv2 NSF Cisco format that is supported in earlier releases. For information about this feature, see *NSF—OSPF (RFC 3623 OSPF Graceful Restart)*:

[http://www.cisco.com/en/US/docs/ios/ha/configuration/guide/ha-ospf\\_grrs.html#wp1055692](http://www.cisco.com/en/US/docs/ios/ha/configuration/guide/ha-ospf_grrs.html#wp1055692).

The IP-services feature set also supports OSPF NSF-capable routing for IPv4 for better convergence and lower traffic loss following a stack master change. When a stack master change occurs in an OSPF NSF-capable stack, the new stack master must do two things to resynchronize its link-state database with its OSPF neighbors:

- Release the available OSPF neighbors on the network without resetting the neighbor relationship.
- Reacquire the contents of the link-state database for the network.

After a stack master change, the new master sends an OSPF NSF signal to neighboring NSF-aware devices. A device recognizes this signal to mean that it should not reset the neighbor relationship with the stack. As the NSF-capable stack master receives signals from other routes on the network, it begins to rebuild its neighbor list.

When the neighbor relationships are reestablished, the NSF-capable stack master resynchronizes its database with its NSF-aware neighbors, and routing information is exchanged between the OSPF neighbors. The new stack master uses this routing information to remove stale routes, to update the routing information database (RIB), and to update the forwarding information base (FIB) with the new information. The OSPF protocols then fully converge.

#### Note

OSPF NSF requires that all neighbor networking devices be NSF-aware. If an NSF-capable router discovers non-NSF aware neighbors on a network segment, it disables NSF capabilities for that segment. Other network segments where all devices are NSF-aware or NSF-capable continue to provide NSF capabilities.

Use the **nsf** OSPF routing configuration command to enable OSPF NSF routing. Use the **show ip ospf** privileged EXEC command to verify that it is enabled.

For more information, see *Cisco Nonstop Forwarding*: [http://www.cisco.com/en/US/docs/ios/ha/configuration/guide/ha-nonstp\\_fwdg.html](http://www.cisco.com/en/US/docs/ios/ha/configuration/guide/ha-nonstp_fwdg.html)

## OSPF Area Parameters

You can optionally configure several OSPF area parameters. These parameters include authentication for password-based protection against unauthorized access to an area, stub areas, and not-so-stubby-areas (NSSAs). Stub areas are areas into which information on external routes is not sent. Instead, the area border router (ABR) generates a default external route into the stub area for destinations outside the autonomous system (AS). An NSSA does not flood all LSAs from the core into the area, but can import AS external routes within the area by redistribution.

Route summarization is the consolidation of advertised addresses into a single summary route to be advertised by other areas. If network numbers are contiguous, you can use the **area range** router configuration command to configure the ABR to advertise a summary route that covers all networks in the range.

## Other OSPF Parameters

You can optionally configure other OSPF parameters in router configuration mode.

- **Route summarization:** When redistributing routes from other protocols as described in the “Using Route Maps to Redistribute Routing Information” section on page 41-124, each route is advertised individually in an external LSA. To help decrease the size of the OSPF link state database, you can use the **summary-address** router configuration command to advertise a single router for all the redistributed routes included in a specified network address and mask.
- **Virtual links:** In OSPF, all areas must be connected to a backbone area. You can establish a virtual link in case of a backbone-continuity break by configuring two Area Border Routers as endpoints of a virtual link. Configuration information includes the identity of the other virtual endpoint (the other ABR) and the nonbackbone link that the two routers have in common (the transit area). Virtual links cannot be configured through a stub area.
- **Default route:** When you specifically configure redistribution of routes into an OSPF routing domain, the route automatically becomes an autonomous system boundary router (ASBR). You can force the ASBR to generate a default route into the OSPF routing domain.
- **Domain Name Server (DNS) names for use in all OSPF **show** privileged EXEC command displays** makes it easier to identify a router than displaying it by router ID or neighbor ID.
- **Default Metrics:** OSPF calculates the OSPF metric for an interface according to the bandwidth of the interface. The metric is calculated as  $ref\text{-}bw$  divided by bandwidth, where  $ref$  is 10 by default, and bandwidth ( $bw$ ) is specified by the **bandwidth** interface configuration command. For multiple links with high bandwidth, you can specify a larger number to differentiate the cost on those links.
- **Administrative distance** is a rating of the trustworthiness of a routing information source, an integer between 0 and 255, with a higher value meaning a lower trust rating. An administrative distance of 255 means the routing information source cannot be trusted at all and should be ignored. OSPF uses three different administrative distances: routes within an area (interarea), routes to another area (interarea), and routes from another routing domain learned through redistribution (external). You can change any of the distance values.
- **Passive interfaces:** Because interfaces between two devices on an Ethernet represent only one network segment, to prevent OSPF from sending hello packets for the sending interface, you must configure the sending device to be a passive interface. Both devices can identify each other through the hello packet for the receiving interface.

- Route calculation timers: You can configure the delay time between when OSPF receives a topology change and when it starts the shortest path first (SPF) calculation and the hold time between two SPF calculations.
- Log neighbor changes: You can configure the router to send a syslog message when an OSPF neighbor state changes, providing a high-level view of changes in the router.

## LSA Group Pacing

The OSPF LSA group pacing feature allows the router to group OSPF LSAs and pace the refreshing, check-summing, and aging functions for more efficient router use. This feature is enabled by default with a 4-minute default pacing interval, and you will not usually need to modify this parameter. The optimum group pacing interval is inversely proportional to the number of LSAs the router is refreshing, check-summing, and aging. For example, if you have approximately 10,000 LSAs in the database, decreasing the pacing interval would benefit you. If you have a very small database (40 to 100 LSAs), increasing the pacing interval to 10 to 20 minutes might benefit you slightly.

## Loopback Interfaces

OSPF uses the highest IP address configured on the interfaces as its router ID. If this interface is down or removed, the OSPF process must recalculate a new router ID and resend all its routing information out its interfaces. If a loopback interface is configured with an IP address, OSPF uses this IP address as its router ID, even if other interfaces have higher IP addresses. Because loopback interfaces never fail, this provides greater stability. OSPF automatically prefers a loopback interface over other interfaces, and it chooses the highest IP address among all loopback interfaces.

# How to Configure OSPF

## Default OSPF Configuration

*Table 100: Default OSPF Configuration*

| Feature              | Default Setting                                                                                                                                                                                                                                       |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Interface parameters | Cost: 1.<br>Retransmit interval: 5 seconds.<br>Transmit delay: 1 second.<br>Priority: 1.<br>Hello interval: 10 seconds.<br>Dead interval: 4 times the hello interval.<br>No authentication.<br>No password specified.<br>MD5 authentication disabled. |

| Feature                            | Default Setting                                                                                                                                   |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| Area                               | Authentication type: 0 (no authentication).<br>Default cost: 1.<br>Range: Disabled.<br>Stub: No stub area defined.<br>NSSA: No NSSA area defined. |
| Auto cost                          | 100 Mb/s.                                                                                                                                         |
| Default-information originate      | Disabled. When enabled, the default metric setting is 10, and the external route type default is Type 2.                                          |
| Default metric                     | Built-in, automatic metric translation, as appropriate for each routing protocol.                                                                 |
| Distance OSPF                      | dist1 (all routes within an area): 110. dist2 (all routes from one area to another): 110. and dist3 (routes from other routing domains): 110.     |
| OSPF database filter               | Disabled. All outgoing link-state advertisements (LSAs) are flooded to the interface.                                                             |
| IP OSPF name lookup                | Disabled.                                                                                                                                         |
| Log adjacency changes              | Enabled.                                                                                                                                          |
| Neighbor                           | None specified.                                                                                                                                   |
| Neighbor database filter           | Disabled. All outgoing LSAs are flooded to the neighbor.                                                                                          |
| Network area                       | Disabled.                                                                                                                                         |
| Nonstop Forwarding (NSF) awareness | Enabled. Allows Layer 3 switches to continue forwarding packets from a neighboring NSF-capable router during hardware or software changes.        |
| NSF capability                     | Disabled.<br><b>Note</b> The switch stack supports OSPF NSF-capable routing for IPv4.                                                             |
| Router ID                          | No OSPF routing process defined.                                                                                                                  |
| Summary address                    | Disabled.                                                                                                                                         |
| Timers LSA group pacing            | 240 seconds.                                                                                                                                      |
| Timers shortest path first (spf)   | spf delay: 5 seconds.; spf-holdtime: 10 seconds.                                                                                                  |

| Feature      | Default Setting                                                                                                                                                                                                                                         |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Virtual link | No area ID or router ID defined.<br>Hello interval: 10 seconds.<br>Retransmit interval: 5 seconds.<br>Transmit delay: 1 second.<br>Dead interval: 40 seconds.<br>Authentication key: no key predefined.<br>Message-digest key (MD5): no key predefined. |

## Configuring Basic OSPF Parameters

To enable OSPF, create an OSPF routing process, specify the range of IP addresses to associate with the routing process, and assign area IDs to be associated with that range. For switches running the IP services image, you can configure either the Cisco OSPFv2 NSF format or the IETF OSPFv2 NSF format.

### DETAILED STEPS

|               | Command or Action                                                                                                              | Purpose                                                                                                                                                                                                                                                                                                                                                                              |
|---------------|--------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <code>configure terminal</code>                                    | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                    |
| <b>Step 2</b> | <b>router ospf process-id</b><br><br><b>Example:</b><br>Switch(config)# <code>router ospf 15</code>                            | Enables OSPF routing, and enter router configuration mode. The process ID is an internally used identification parameter that is locally assigned and can be any positive integer. Each OSPF routing process has a unique value.<br><br><b>Note</b> OSPF for Routed Access supports only one OSPFv2 and one OSPFv3 instance with a maximum number of 200 dynamically learned routes. |
| <b>Step 3</b> | <b>nsf cisco [enforce global]</b><br><br><b>Example:</b><br>Switch(config)# <code>nsf cisco enforce global</code>              | (Optional) Enables Cisco NSF operations for OSPF. The <b>enforce global</b> keyword cancels NSF restart when non-NSF-aware neighboring networking devices are detected.<br><br><b>Note</b> Enter the command in Step 3 or Step 4, and go to Step 5.                                                                                                                                  |
| <b>Step 4</b> | <b>nsf ietf [restart-interval seconds]</b><br><br><b>Example:</b><br>Switch(config)# <code>nsf ietf restart-interval 60</code> | (Optional) Enables IETF NSF operations for OSPF. The <b>restart-interval</b> keyword specifies the length of the graceful restart interval, in seconds. The range is from 1 to 1800. The default is 120.<br><br><b>Note</b> Enter the command in Step 3 or Step 4, and go to Step 5.                                                                                                 |

|               | Command or Action                                                                                                                           | Purpose                                                                                                                                                                                                                                                                     |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 5</b> | <b>network</b> address wildcard-mask area area-id<br><br><b>Example:</b><br><pre>Switch(config)# network 10.1.1.1 255.240.0.0 area 20</pre> | Define an interface on which OSPF runs and the area ID for that interface. You can use the wildcard-mask to use a single command to define one or more multiple interfaces to be associated with a specific OSPF area. The area ID can be a decimal value or an IP address. |
| <b>Step 6</b> | <b>end</b><br><br><b>Example:</b><br><pre>Switch(config)# end</pre>                                                                         | Returns to privileged EXEC mode.                                                                                                                                                                                                                                            |
| <b>Step 7</b> | <b>show ip protocols</b><br><br><b>Example:</b><br><pre>Switch# show ip protocols</pre>                                                     | Verifies your entries.                                                                                                                                                                                                                                                      |
| <b>Step 8</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br><pre>Switch# copy running-config startup-config</pre>                   | (Optional) Saves your entries in the configuration file.                                                                                                                                                                                                                    |

## Configuring OSPF Interfaces

You can use the **ip ospf** interface configuration commands to modify interface-specific OSPF parameters. You are not required to modify any of these parameters, but some interface parameters (hello interval, dead interval, and authentication key) must be consistent across all routers in an attached network. If you modify these parameters, be sure all routers in the network have compatible values.

**Note** The **ip ospf** interface configuration commands are all optional.

### DETAILED STEPS

|               | Command or Action                                                                         | Purpose                           |
|---------------|-------------------------------------------------------------------------------------------|-----------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br><pre>Switch# configure terminal</pre> | Enters global configuration mode. |

|                | Command or Action                                                                                                      | Purpose                                                                                                                                                                                                                                                                       |
|----------------|------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 2</b>  | <b>interface</b> interface-id<br><br><b>Example:</b><br>Switch(config)# interface gigabitethernet 1/0/1                | Enters interface configuration mode, and specifies the Layer 3 interface to configure.                                                                                                                                                                                        |
| <b>Step 3</b>  | <b>ip ospf cost</b><br><br><b>Example:</b><br>Switch(config-if)# ip ospf 8                                             | (Optional) Explicitly specifies the cost of sending a packet on the interface.                                                                                                                                                                                                |
| <b>Step 4</b>  | <b>ip ospf retransmit-interval</b> seconds<br><br><b>Example:</b><br>Switch(config-if)# ip ospf transmit-interval 10   | (Optional) Specifies the number of seconds between link state advertisement transmissions. The range is 1 to 65535 seconds. The default is 5 seconds.                                                                                                                         |
| <b>Step 5</b>  | <b>ip ospf transmit-delay</b> seconds<br><br><b>Example:</b><br>Switch(config-if)# ip ospf transmit-delay 2            | (Optional) Sets the estimated number of seconds to wait before sending a link state update packet. The range is 1 to 65535 seconds. The default is 1 second.                                                                                                                  |
| <b>Step 6</b>  | <b>ip ospf priority</b> number<br><br><b>Example:</b><br>Switch(config-if)# ip ospf priority 5                         | (Optional) Sets priority to help find the OSPF designated router for a network. The range is from 0 to 255. The default is 1.                                                                                                                                                 |
| <b>Step 7</b>  | <b>ip ospf hello-interval</b> seconds<br><br><b>Example:</b><br>Switch(config-if)# ip ospf hello-interval 12           | (Optional) Sets the number of seconds between hello packets sent on an OSPF interface. The value must be the same for all nodes on a network. The range is 1 to 65535 seconds. The default is 10 seconds.                                                                     |
| <b>Step 8</b>  | <b>ip ospf dead-interval</b> seconds<br><br><b>Example:</b><br>Switch(config-if)# ip ospf dead-interval 8              | (Optional) Sets the number of seconds after the last device hello packet was seen before its neighbors declare the OSPF router to be down. The value must be the same for all nodes on a network. The range is 1 to 65535 seconds. The default is 4 times the hello interval. |
| <b>Step 9</b>  | <b>ip ospf authentication-key</b> key<br><br><b>Example:</b><br>Switch(config-if)# ip ospf authentication-key password | (Optional) Assign a password to be used by neighboring OSPF routers. The password can be any string of keyboard-entered characters up to 8 bytes in length. All neighboring routers on the same network must have the same password to exchange OSPF information.             |
| <b>Step 10</b> | <b>ip ospf message-digest-key</b> keyid md5 key                                                                        | (Optional) Enables MDS authentication.                                                                                                                                                                                                                                        |

|                | Command or Action                                                                                                                  | Purpose                                                                                                                                                                                                                                                                                                                                                                    |
|----------------|------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | <p><b>Example:</b></p> <pre>Switch(config-if)# ip ospf message digest-key 16 md5 yourlpass</pre>                                   | <ul style="list-style-type: none"> <li>• <i>keyid</i>—An identifier from 1 to 255.</li> <li>• <i>key</i>—An alphanumeric password of up to 16 bytes.</li> </ul>                                                                                                                                                                                                            |
| <b>Step 11</b> | <p><b>ip ospf database-filter all out</b></p> <p><b>Example:</b></p> <pre>Switch(config-if)# ip ospf database-filter all out</pre> | (Optional) Block flooding of OSPF LSA packets to the interface. By default, OSPF floods new LSAs over all interfaces in the same area, except the interface on which the LSA arrives.                                                                                                                                                                                      |
| <b>Step 12</b> | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Switch(config-if)# end</pre>                                                         | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                           |
| <b>Step 13</b> | <p><b>show ip ospf interface [interface-name]</b></p> <p><b>Example:</b></p> <pre>Switch# show ip ospf interface</pre>             | Displays OSPF-related interface information.                                                                                                                                                                                                                                                                                                                               |
| <b>Step 14</b> | <p><b>show ip ospf neighbor detail</b></p> <p><b>Example:</b></p> <pre>Switch# show ip ospf neighbor detail</pre>                  | <p>Displays NSF awareness status of neighbor switch. The output matches one of these examples:</p> <ul style="list-style-type: none"> <li>• <i>Options is 0x52</i><br/><i>LLS Options is 0x1 (LR)</i><br/>When both of these lines appear, the neighbor switch is NSF aware.</li> <li>• <i>Options is 0x42</i>—This means the neighbor switch is not NSF aware.</li> </ul> |
| <b>Step 15</b> | <p><b>copy running-config startup-config</b></p> <p><b>Example:</b></p> <pre>Switch# copy running-config startup-config</pre>      | (Optional) Saves your entries in the configuration file.                                                                                                                                                                                                                                                                                                                   |

## Configuring OSPF Area Parameters

### Before You Begin

**Note** The OSPF **area** router configuration commands are all optional.

### DETAILED STEPS

|               | Command or Action                                                                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                                                                                       | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Step 2</b> | <b>router ospf process-id</b><br><br><b>Example:</b><br>Switch(config)# router ospf 109                                                                                              | Enables OSPF routing, and enter router configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Step 3</b> | <b>area area-id authentication</b><br><br><b>Example:</b><br>Switch(config-router)# area 1 authentication                                                                            | (Optional) Allow password-based protection against unauthorized access to the identified area. The identifier can be either a decimal value or an IP address.                                                                                                                                                                                                                                                                                                                                   |
| <b>Step 4</b> | <b>area area-id authentication message-digest</b><br><br><b>Example:</b><br>Switch(config-router)# area 1 authentication message-digest                                              | (Optional) Enables MD5 authentication on the area.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Step 5</b> | <b>area area-id stub [no-summary]</b><br><br><b>Example:</b><br>Switch(config-router)# area 1 stub                                                                                   | (Optional) Define an area as a stub area. The <b>no-summary</b> keyword prevents an ABR from sending summary link advertisements into the stub area.                                                                                                                                                                                                                                                                                                                                            |
| <b>Step 6</b> | <b>area area-id nssa [no-redistribution] [default-information-originate] [no-summary]</b><br><br><b>Example:</b><br>Switch(config-router)# area 1 nssa default-information-originate | (Optional) Defines an area as a not-so-stubby-area. Every router within the same area must agree that the area is NSSA. Select one of these keywords: <ul style="list-style-type: none"> <li>• <b>no-redistribution</b>—Select when the router is an NSSA ABR and you want the <b>redistribute</b> command to import routes into normal areas, but not into the NSSA.</li> <li>• <b>default-information-originate</b>—Select on an ABR to allow importing type 7 LSAs into the NSSA.</li> </ul> |

|                | Command or Action                                                                                                                     | Purpose                                                                                                                       |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
|                |                                                                                                                                       | <ul style="list-style-type: none"> <li>• <b>no-redistribution</b>—Select to not send summary LSAs into the NSSA.</li> </ul>   |
| <b>Step 7</b>  | <b>area</b> <i>area-id</i> <b>range</b> <i>address mask</i><br><br><b>Example:</b><br>Switch(config-router)# area 1 range 255.240.0.0 | (Optional) Specifies an address range for which a single route is advertised. Use this command only with area border routers. |
| <b>Step 8</b>  | <b>end</b><br><br><b>Example:</b><br>Switch(config-router)# end                                                                       | Returns to privileged EXEC mode.                                                                                              |
| <b>Step 9</b>  | <b>show ip ospf</b> [ <i>process-id</i> ]<br><br><b>Example:</b><br>Switch# show ip ospf                                              | Displays information about the OSPF routing process in general or for a specific process ID to verify configuration.          |
| <b>Step 10</b> | <b>show ip ospf</b> [ <i>process-id</i> [ <i>area-id</i> ]] <b>database</b><br><br><b>Example:</b><br>Switch# show ip ospf database   | Displays lists of information related to the OSPF database for a specific router.                                             |
| <b>Step 11</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config                        | (Optional) Saves your entries in the configuration file.                                                                      |

## Configuring Other OSPF Parameters

### DETAILED STEPS

|               | Command or Action                                                              | Purpose                           |
|---------------|--------------------------------------------------------------------------------|-----------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal | Enters global configuration mode. |

|               | Command or Action                                                                                                                                                                                                                                                                                                                  | Purpose                                                                                                                                                                                                     |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 2</b> | <b>router ospf <i>process-id</i></b><br><br><b>Example:</b><br>Switch(config)# router ospf 10                                                                                                                                                                                                                                      | Enables OSPF routing, and enter router configuration mode.                                                                                                                                                  |
| <b>Step 3</b> | <b>summary-address <i>address mask</i></b><br><br><b>Example:</b><br>Switch(config)# summary-address 10.1.1.1<br>255.255.255.0                                                                                                                                                                                                     | (Optional) Specifies an address and IP subnet mask for redistributed routes so that only one summary route is advertised.                                                                                   |
| <b>Step 4</b> | <b>area <i>area-id</i> virtual-link <i>router-id</i> [hello-interval <i>seconds</i>] [retransmit-interval <i>seconds</i>] [trans<br/> [[<i>authentication-key key</i>]   message-digest-key <i>keyid</i><br/> md5 <i>key</i>]]</b><br><br><b>Example:</b><br>Switch(config)# area 2 virtual-link<br>192.168.255.1 hello-interval 5 | (Optional) Establishes a virtual link and set its parameters. See the “Configuring OSPF Interfaces” section on page 41-39 for parameter definitions and Table 41-5 on page 41-35 for virtual link defaults. |
| <b>Step 5</b> | <b>default-information originate [always] [metric <i>metric-value</i>] [metric-type <i>type-value</i>] [route-map <i>map-name</i>]</b><br><br><b>Example:</b><br>Switch(config)# default-information originate<br>metric 100 metric-type 1                                                                                         | (Optional) Forces the ASBR to generate a default route into the OSPF routing domain. Parameters are all optional.                                                                                           |
| <b>Step 6</b> | <b>ip ospf name-lookup</b><br><br><b>Example:</b><br>Switch(config)# ip ospf name-lookup                                                                                                                                                                                                                                           | (Optional) Configures DNS name lookup. The default is disabled.                                                                                                                                             |
| <b>Step 7</b> | <b>ip auto-cost reference-bandwidth <i>ref-bw</i></b><br><br><b>Example:</b><br>Switch(config)# ip auto-cost<br>reference-bandwidth 5                                                                                                                                                                                              | (Optional) Specifies an address range for which a single route will be advertised. Use this command only with area border routers.                                                                          |
| <b>Step 8</b> | <b>distance ospf {[<i>inter-area dist1</i>] [<i>inter-area dist2</i>] [<i>external dist3</i>]}</b><br><br><b>Example:</b><br>Switch(config)# distance ospf inter-area 150                                                                                                                                                          | (Optional) Changes the OSPF distance values. The default distance for each type of route is 110. The range is 1 to 255.                                                                                     |

|                | Command or Action                                                                                                                                          | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 9</b>  | <p><b>passive-interface</b> <i>type number</i></p> <p><b>Example:</b></p> <pre>Switch(config)# passive-interface gigabitethernet 1/0/6</pre>               | (Optional) Suppresses the sending of hello packets through the specified interface.                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Step 10</b> | <p><b>timers throttle spf</b> <i>spf-delay spf-holdtime spf-wait</i></p> <p><b>Example:</b></p> <pre>Switch(config)# timers throttle spf 200 100 100</pre> | <p>(Optional) Configures route calculation timers.</p> <ul style="list-style-type: none"> <li>• <i>spf-delay</i>—Delay between receiving a change to SPF calculation. The range is from 1 to 600000 milliseconds.</li> <li>• <i>spf-holdtime</i>—Delay between first and second SPF calculation. The range is from 1 to 600000 in milliseconds.</li> <li>• <i>spf-wait</i>—Maximum wait time in milliseconds for SPF calculations. The range is from 1 to 600000 in milliseconds.</li> </ul> |
| <b>Step 11</b> | <p><b>ospf log-adj-changes</b></p> <p><b>Example:</b></p> <pre>Switch(config)# ospf log-adj-changes</pre>                                                  | (Optional) Sends syslog message when a neighbor state changes.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Step 12</b> | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Switch(config)# end</pre>                                                                                    | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Step 13</b> | <p><b>show ip ospf</b> [<i>process-id</i> [<i>area-id</i>]] <b>database</b></p> <p><b>Example:</b></p> <pre>Switch# show ip ospf database</pre>            | Displays lists of information related to the OSPF database for a specific router. For some of the keyword options, see the “Monitoring OSPF” section on page 41-47.                                                                                                                                                                                                                                                                                                                          |
| <b>Step 14</b> | <p><b>copy running-config startup-config</b></p> <p><b>Example:</b></p> <pre>Switch# copy running-config startup-config</pre>                              | (Optional) Saves your entries in the configuration file.                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Changing LSA Group Pacing

### DETAILED STEPS

|               | Command or Action                                                                                                         | Purpose                                                    |
|---------------|---------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                            | Enters global configuration mode.                          |
| <b>Step 2</b> | <b>router ospf <i>process-id</i></b><br><br><b>Example:</b><br>Switch(config)# router ospf 25                             | Enables OSPF routing, and enter router configuration mode. |
| <b>Step 3</b> | <b>timers lsa-group-pacing <i>seconds</i></b><br><br><b>Example:</b><br>Switch(config-router)# timers lsa-group-pacing 15 | Changes the group pacing of LSAs.                          |
| <b>Step 4</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config)# end                                                                  | Returns to privileged EXEC mode.                           |
| <b>Step 5</b> | <b>show running-config</b><br><br><b>Example:</b><br>Switch# show running-config                                          | Verifies your entries.                                     |
| <b>Step 6</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config            | (Optional) Saves your entries in the configuration file.   |

## Configuring a Loopback Interface

### DETAILED STEPS

|               | Command or Action                                                                                              | Purpose                                                               |
|---------------|----------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                 | Enters global configuration mode.                                     |
| <b>Step 2</b> | <b>interface loopback 0</b><br><br><b>Example:</b><br>Switch(config)# interface loopback 0                     | Creates a loopback interface, and enter interface configuration mode. |
| <b>Step 3</b> | <b>ip address address mask</b><br><br><b>Example:</b><br>Switch(config-if)# ip address 10.1.1.5 255.255.240.0  | Assign an IP address to this interface.                               |
| <b>Step 4</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config-if)# end                                                    | Returns to privileged EXEC mode.                                      |
| <b>Step 5</b> | <b>show ip interface</b><br><br><b>Example:</b><br>Switch# show ip interface                                   | Verifies your entries.                                                |
| <b>Step 6</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config | (Optional) Saves your entries in the configuration file.              |

## Monitoring OSPF

You can display specific statistics such as the contents of IP routing tables, caches, and databases.

**Table 101: Show IP OSPF Statistics Commands**

|                                           |                                                            |
|-------------------------------------------|------------------------------------------------------------|
| <b>show ip ospf</b> [ <i>process-id</i> ] | Displays general information about OSPF routing processes. |
|-------------------------------------------|------------------------------------------------------------|

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                                                                |

| <pre> <b>show ip ospf virtual-links</b> </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Displays OSPF-related virtual links information.               |

## Configuration Examples for OSPF

### Example: Configuring Basic OSPF Parameters

This example shows how to configure an OSPF routing process and assign it a process number of 109:

```

Switch(config)# router ospf 109
Switch(config-router)# network 131.108.0.0 255.255.255.0 area 24

```

## Information About EIGRP

Enhanced IGRP (EIGRP) is a Cisco proprietary enhanced version of the IGRP. EIGRP uses the same distance vector algorithm and distance information as IGRP; however, the convergence properties and the operating efficiency of EIGRP are significantly improved.

The convergence technology employs an algorithm referred to as the Diffusing Update Algorithm (DUAL), which guarantees loop-free operation at every instant throughout a route computation and allows all devices involved in a topology change to synchronize at the same time. Routers that are not affected by topology changes are not involved in recomputations.

IP EIGRP provides increased network width. With RIP, the largest possible width of your network is 15 hops. Because the EIGRP metric is large enough to support thousands of hops, the only barrier to expanding the network is the transport-layer hop counter. EIGRP increments the transport control field only when an IP packet has traversed 15 routers and the next hop to the destination was learned through EIGRP. When a RIP route is used as the next hop to the destination, the transport control field is incremented as usual.

## EIGRP Features

EIGRP offers these features:

- Fast convergence.
- Incremental updates when the state of a destination changes, instead of sending the entire contents of the routing table, minimizing the bandwidth required for EIGRP packets.
- Less CPU usage because full update packets need not be processed each time they are received.
- Protocol-independent neighbor discovery mechanism to learn about neighboring routers.
- Variable-length subnet masks (VLSMs).
- Arbitrary route summarization.
- EIGRP scales to large networks.

## EIGRP Components

EIGRP has these four basic components:

- Neighbor discovery and recovery is the process that routers use to dynamically learn of other routers on their directly attached networks. Routers must also discover when their neighbors become unreachable or inoperative. Neighbor discovery and recovery is achieved with low overhead by periodically sending small hello packets. As long as hello packets are received, the Cisco IOS software can learn that a neighbor is alive and functioning. When this status is determined, the neighboring routers can exchange routing information.
- The reliable transport protocol is responsible for guaranteed, ordered delivery of EIGRP packets to all neighbors. It supports intermixed transmission of multicast and unicast packets. Some EIGRP packets must be sent reliably, and others need not be. For efficiency, reliability is provided only when necessary. For example, on a multiaccess network that has multicast capabilities (such as Ethernet), it is not necessary to send hellos reliably to all neighbors individually. Therefore, EIGRP sends a single multicast hello with an indication in the packet informing the receivers that the packet need not be acknowledged. Other types of packets (such as updates) require acknowledgment, which is shown in the packet. The reliable transport has a provision to send multicast packets quickly when there are unacknowledged packets pending. Doing so helps ensure that convergence time remains low in the presence of varying speed links.
- The DUAL finite state machine embodies the decision process for all route computations. It tracks all routes advertised by all neighbors. DUAL uses the distance information (known as a metric) to select efficient, loop-free paths. DUAL selects routes to be inserted into a routing table based on feasible successors. A successor is a neighboring router used for packet forwarding that has a least-cost path to a destination that is guaranteed not to be part of a routing loop. When there are no feasible successors, but there are neighbors advertising the destination, a recomputation must occur. This is the process whereby a new successor is determined. The amount of time it takes to recompute the route affects the

convergence time. Recomputation is processor-intensive; it is advantageous to avoid recomputation if it is not necessary. When a topology change occurs, DUAL tests for feasible successors. If there are feasible successors, it uses any it finds to avoid unnecessary recomputation.

- The protocol-dependent modules are responsible for network layer protocol-specific tasks. An example is the IP EIGRP module, which is responsible for sending and receiving EIGRP packets that are encapsulated in IP. It is also responsible for parsing EIGRP packets and informing DUAL of the new information received. EIGRP asks DUAL to make routing decisions, but the results are stored in the IP routing table. EIGRP is also responsible for redistributing routes learned by other IP routing protocols.

---

**Note** To enable EIGRP, the switch or stack master must be running the IP services feature set.

---

## EIGRP Nonstop Forwarding

The switch stack supports two levels of EIGRP nonstop forwarding:

- EIGRP NSF Awareness
- EIGRP NSF Capability

### EIGRP NSF Awareness

The IP-services feature set supports EIGRP NSF Awareness for IPv4. When the neighboring router is NSF-capable, the Layer 3 switch continues to forward packets from the neighboring router during the interval between the primary Route Processor (RP) in a router failing and the backup RP taking over, or while the primary RP is manually reloaded for a nondisruptive software upgrade.

This feature cannot be disabled. For more information on this feature, see the “EIGRP Nonstop Forwarding (NSF) Awareness” section of the *Cisco IOS IP Routing Protocols Configuration Guide, Release 12.4*.

### EIGRP NSF Capability

The IP services feature set supports EIGRP Cisco NSF routing to speed up convergence and to eliminate traffic loss after a stack master change. For details about this NSF capability, see the “Configuring Nonstop Forwarding” chapter in the *High Availability Configuration Guide, Cisco IOS XE Release 3S*: [http://www.cisco.com/en/US/docs/ios/ios\\_xe/ha/configuration/guide/ha-nonstp\\_fwdg\\_xe.html](http://www.cisco.com/en/US/docs/ios/ios_xe/ha/configuration/guide/ha-nonstp_fwdg_xe.html).

The IP-services feature set also supports EIGRP NSF-capable routing for IPv4 for better convergence and lower traffic loss following a stack master change. When an EIGRP NSF-capable stack master restarts or a new stack master starts up and NSF restarts, the switch has no neighbors, and the topology table is empty. The switch must bring up the interfaces, reacquire neighbors, and rebuild the topology and routing tables without interrupting the traffic directed toward the switch stack. EIGRP peer routers maintain the routes learned from the new stack master and continue forwarding traffic through the NSF restart process.

To prevent an adjacency reset by the neighbors, the new stack master uses a new Restart (RS) bit in the EIGRP packet header to show the restart. When the neighbor receives this, it synchronizes the stack in its peer list and maintains the adjacency with the stack. The neighbor then sends its topology table to the stack master with the RS bit set to show that it is NSF-aware and is aiding the new stack master.

If at least one of the stack peer neighbors is NSF-aware, the stack master receives updates and rebuilds its database. Each NSF-aware neighbor sends an end of table (EOT) marker in the last update packet to mark the end of the table content. The stack master recognizes the convergence when it receives the EOT marker, and it then begins sending updates. When the stack master has received all EOT markers from its neighbors or when the NSF converge timer expires, EIGRP notifies the routing information database (RIB) of convergence and floods its topology table to all NSF-aware peers.

## EIGRP Stub Routing

The EIGRP stub routing feature, available in all feature sets, reduces resource utilization by moving routed traffic closer to the end user.

### Note

The IP base feature set contains EIGRP stub routing capability, which only advertises connected or summary routes from the routing tables to other switches in the network. The switch uses EIGRP stub routing at the access layer to eliminate the need for other types of routing advertisements. For enhanced capability and complete EIGRP routing, the switch must be running the IP services feature set. On a switch running the IP base feature set, if you try to configure multi-VRF-CE and EIGRP stub routing at the same time, the configuration is not allowed. IPv6 EIGRP stub routing is not supported with the IP base feature set.

In a network using EIGRP stub routing, the only allowable route for IP traffic to the user is through a switch that is configured with EIGRP stub routing. The switch sends the routed traffic to interfaces that are configured as user interfaces or are connected to other devices.

When using EIGRP stub routing, you need to configure the distribution and remote routers to use EIGRP and to configure only the switch as a stub. Only specified routes are propagated from the switch. The switch responds to all queries for summaries, connected routes, and routing updates.

Any neighbor that receives a packet informing it of the stub status does not query the stub router for any routes, and a router that has a stub peer does not query that peer. The stub router depends on the distribution router to send the proper updates to all peers.

In Figure 41-4, switch B is configured as an EIGRP stub router. Switches A and C are connected to the rest of the WAN. Switch B advertises connected, static, redistribution, and summary routes to switch A and C. Switch B does not advertise any routes learned from switch A (and the reverse).

**Figure 67: EIGRP Stub Router Configuration**

For more information about EIGRP stub routing, see “Configuring EIGRP Stub Routing” section of the *Cisco IOS IP Configuration Guide, Volume 2 of 3: Routing Protocols, Release 12.4*.

## How to Configure EIGRP

To create an EIGRP routing process, you must enable EIGRP and associate networks. EIGRP sends updates to the interfaces in the specified networks. If you do not specify an interface network, it is not advertised in any EIGRP update.

### Note

If you have routers on your network that are configured for IGRP, and you want to change to EIGRP, you must designate transition routers that have both IGRP and EIGRP configured. In these cases, perform Steps 1 through 3 in the next section and also see the “Configuring Split Horizon” section. You must use the same AS number for routes to be automatically redistributed.

## Default EIGRP Configuration

**Table 102: Default EIGRP Configuration**

| Feature             | Default Setting                                                                                                   |
|---------------------|-------------------------------------------------------------------------------------------------------------------|
| Auto summary        | Disabled.                                                                                                         |
| Default-information | Exterior routes are accepted and default information is passed between EIGRP processes when doing redistribution. |

| Feature                            | Default Setting                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Default metric                     | <p>Only connected routes and interface static routes can be redistributed without a default metric. The metric includes:</p> <ul style="list-style-type: none"> <li>• Bandwidth: 0 or greater kb/s.</li> <li>• Delay (tens of microseconds): 0 or any positive number that is a multiple of 39.1 nanoseconds.</li> <li>• Reliability: any number between 0 and 255 (255 means 100 percent reliability).</li> <li>• Loading: effective bandwidth as a number between 0 and 255 (255 is 100 percent loading).</li> <li>• MTU: maximum transmission unit size of the route in bytes. 0 or any positive integer.</li> </ul> |
| Distance                           | <p>Internal distance: 90.<br/>External distance: 170.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| EIGRP log-neighbor changes         | Disabled. No adjacency changes logged.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Nonstop Forwarding (NSF) Awareness | Enabled for IPv4 on switches running the IP services feature set. Allows Layer 3 switches to continue forwarding packets from a neighboring NSF-capable router during hardware or software changes.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| NSF capability                     | <p>Disabled.</p> <p><b>Note</b> The switch supports EIGRP NSF-capable routing for IPv4.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Feature       | Default Setting                                           |
|---------------|-----------------------------------------------------------|
| Offset-list   | Disabled.                                                 |
| Router EIGRP  | Disabled.                                                 |
| Set metric    | No metric set in the route map.                           |
| Traffic-share | Distributed proportionately to the ratios of the metrics. |
| Variance      | 1 (equal-cost load-balancing).                            |

## Configuring Basic EIGRP Parameters

### Before You Begin

#### DETAILED STEPS

|               | Command or Action                                                                                             | Purpose                                                                                                                                                                   |
|---------------|---------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <b>configure terminal</b>                         | Enters global configuration mode.                                                                                                                                         |
| <b>Step 2</b> | <b>router eigrp</b> autonomous-system<br><br><b>Example:</b><br>Switch(config)# <b>router eigrp 10</b>        | Enables an EIGRP routing process, and enter router configuration mode. The AS number identifies the routes to other EIGRP routers and is used to tag routing information. |
| <b>Step 3</b> | <b>nsf</b><br><br><b>Example:</b><br>Switch(config)# <b>nsf</b>                                               | (Optional) Enables EIGRP NSF. Enter this command on the stack master and on all of its peers.                                                                             |
| <b>Step 4</b> | <b>network</b> network-number<br><br><b>Example:</b><br>Switch(config)# <b>network 192.168.0.0</b>            | Associate networks with an EIGRP routing process. EIGRP sends updates to the interfaces in the specified networks.                                                        |
| <b>Step 5</b> | <b>eigrp log-neighbor-changes</b><br><br><b>Example:</b><br>Switch(config)# <b>eigrp log-neighbor-changes</b> | (Optional) Enables logging of EIGRP neighbor changes to monitor routing system stability.                                                                                 |

|                | Command or Action                                                                                                                                                                             | Purpose                                                                                                                                                                                                                                                                 |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 6</b>  | <b>metric weights</b> <i>tos k1 k2 k3 k4 k5</i><br><br><b>Example:</b><br>Switch(config)# <b>metric weights 0 2 0 2 0 0</b>                                                                   | (Optional) Adjust the EIGRP metric. Although the defaults have been carefully set to provide excellent operation in most networks, you can adjust them.<br><br>Setting metrics is complex and is not recommended without guidance from an experienced network designer. |
| <b>Step 7</b>  | <b>offset-list</b> [ <i>access-list number   name</i> ] { <b>in</b>   <b>out</b> }<br><i>offset [type number]</i><br><br><b>Example:</b><br>Switch(config)# <b>offset-list 21 out 10</b>      | (Optional) Applies an offset list to routing metrics to increase incoming and outgoing metrics to routes learned through EIGRP. You can limit the offset list with an access list or an interface.                                                                      |
| <b>Step 8</b>  | <b>auto-summary</b><br><br><b>Example:</b><br>Switch(config)# <b>auto-summary</b>                                                                                                             | (Optional) Enables automatic summarization of subnet routes into network-level routes.                                                                                                                                                                                  |
| <b>Step 9</b>  | <b>ip summary-address eigrp</b><br><i>autonomous-system-number address mask</i><br><br><b>Example:</b><br>Switch(config)# <b>ip summary-address eigrp 1</b><br><b>192.168.0.0 255.255.0.0</b> | (Optional) Configures a summary aggregate.                                                                                                                                                                                                                              |
| <b>Step 10</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config)# <b>end</b>                                                                                                                               | Returns to privileged EXEC mode.                                                                                                                                                                                                                                        |
| <b>Step 11</b> | <b>show ip protocols</b><br><br><b>Example:</b><br>Switch# <b>show ip protocols</b>                                                                                                           | Verifies your entries.<br><br>For NSF awareness, the output shows:<br>*** IP Routing is NSF aware *** EIGRP NSF enabled                                                                                                                                                 |
| <b>Step 12</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# <b>copy running-config startup-config</b>                                                                         | (Optional) Saves your entries in the configuration file.                                                                                                                                                                                                                |

## Configuring EIGRP Interfaces

Other optional EIGRP parameters can be configured on an interface basis.

## DETAILED STEPS

|               | Command or Action                                                                                                                                                              | Purpose                                                                                                                                                                                                                                                                              |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                                                                                 | Enters global configuration mode.                                                                                                                                                                                                                                                    |
| <b>Step 2</b> | <b>interface <i>interface-id</i></b><br><br><b>Example:</b><br>Switch(config)# interface gigabitethernet 1/0/1                                                                 | Enters interface configuration mode, and specifies the Layer 3 interface to configure.                                                                                                                                                                                               |
| <b>Step 3</b> | <b>ip bandwidth-percent eigrp <i>percent</i></b><br><br><b>Example:</b><br>Switch(config-if)# ip bandwidth-percent eigrp 60                                                    | (Optional) Configures the percentage of bandwidth that can be used by EIGRP on an interface. The default is 50 percent.                                                                                                                                                              |
| <b>Step 4</b> | <b>ip summary-address eigrp <i>autonomous-system-number address mask</i></b><br><br><b>Example:</b><br>Switch(config-if)# ip summary-address eigrp 109 192.161.0.0 255.255.0.0 | (Optional) Configures a summary aggregate address for a specified interface (not usually necessary if auto-summary is enabled).                                                                                                                                                      |
| <b>Step 5</b> | <b>ip hello-interval eigrp <i>autonomous-system-number seconds</i></b><br><br><b>Example:</b><br>Switch(config-if)# ip hello-interval eigrp 109 10                             | (Optional) Change the hello time interval for an EIGRP routing process. The range is 1 to 65535 seconds. The default is 60 seconds for low-speed NBMA networks and 5 seconds for all other networks.                                                                                 |
| <b>Step 6</b> | <b>ip hold-time eigrp <i>autonomous-system-number seconds</i></b><br><br><b>Example:</b><br>Switch(config-if)# ip hold-time eigrp 109 40                                       | (Optional) Change the hold time interval for an EIGRP routing process. The range is 1 to 65535 seconds. The default is 180 seconds for low-speed NBMA networks and 15 seconds for all other networks.<br><br>Do not adjust the hold time without consulting Cisco technical support. |
| <b>Step 7</b> | <b>no ip split-horizon eigrp <i>autonomous-system-number</i></b><br><br><b>Example:</b><br>Switch(config-if)# no ip split-horizon eigrp 109                                    | (Optional) Disables split horizon to allow route information to be advertised by a router out any interface from which that information originated.                                                                                                                                  |

|                | Command or Action                                                                                              | Purpose                                                                                                |
|----------------|----------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------|
| <b>Step 8</b>  | <b>end</b><br><br><b>Example:</b><br>Switch(config-if) # end                                                   | Returns to privileged EXEC mode.                                                                       |
| <b>Step 9</b>  | <b>show ip eigrp interface</b><br><br><b>Example:</b><br>Switch# show ip eigrp interface                       | Displays which interfaces EIGRP is active on and information about EIGRP relating to those interfaces. |
| <b>Step 10</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config | (Optional) Saves your entries in the configuration file.                                               |

## Configuring EIGRP Route Authentication

EIGRP route authentication provides MD5 authentication of routing updates from the EIGRP routing protocol to prevent the introduction of unauthorized or false routing messages from unapproved sources.

### DETAILED STEPS

|               | Command or Action                                                                                                                                  | Purpose                                                                                |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                                                     | Enters global configuration mode.                                                      |
| <b>Step 2</b> | <b>interface interface-id</b><br><br><b>Example:</b><br>Switch(config)# interface gigabitethernet 1/0/1                                            | Enters interface configuration mode, and specifies the Layer 3 interface to configure. |
| <b>Step 3</b> | <b>ip authentication mode eigrp <i>autonomous-system</i> md5</b><br><br><b>Example:</b><br>Switch(config-if)# ip authentication mode eigrp 104 md5 | Enables MD5 authentication in IP EIGRP packets.                                        |
| <b>Step 4</b> | <b>ip authentication key-chain eigrp <i>autonomous-system</i> <i>key-chain</i></b>                                                                 | Enables authentication of IP EIGRP packets.                                            |

|                | Command or Action                                                                                                                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                                                                        |

|                | <p><b>Example:</b></p> <pre>Switch(config-if)# ip authentication key-chain eigrp 105 chain1</pre>                                                                                                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Step 5</b>  | <p><b>exit</b></p> <p><b>Example:</b></p> <pre>Switch(config-if)# exit</pre>                                                                                                                                                           | Returns to global configuration mode.                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Step 6</b>  | <p><b>key chain</b> <i>name-of-chain</i></p> <p><b>Example:</b></p> <pre>Switch(config)# key chain chain1</pre>                                                                                                                        | Identify a key chain and enter key-chain configuration mode. Match the name configured in Step 4.                                                                                                                                                                                                                                                                                                              |
| <b>Step 7</b>  | <p><b>key</b> <i>number</i></p> <p><b>Example:</b></p> <pre>Switch(config-keychain)# key 1</pre>                                                                                                                                       | In key-chain configuration mode, identify the key number.                                                                                                                                                                                                                                                                                                                                                      |
| <b>Step 8</b>  | <p><b>key-string</b> <i>text</i></p> <p><b>Example:</b></p> <pre>Switch(config-keychain-key)# key-string key1</pre>                                                                                                                    | In key-chain key configuration mode, identify the key string.                                                                                                                                                                                                                                                                                                                                                  |
| <b>Step 9</b>  | <p><b>accept-lifetime</b> <i>start-time</i> {<b>infinite</b>   <i>end-time</i>   <b>duration</b> <i>seconds</i>}</p> <p><b>Example:</b></p> <pre>Switch(config-keychain-key)# accept-lifetime 13:30:00 Jan 25 2011 duration 7200</pre> | <p>(Optional) Specifies the time period during which the key can be received.</p> <p>The <i>start-time</i> and <i>end-time</i> syntax can be either <i>hh:mm:ss Month date year</i> or <i>hh:mm:ss date Month year</i>. The default is forever with the default <i>start-time</i> and the earliest acceptable date as January 1, 1993. The default <i>end-time</i> and <b>duration</b> is <b>infinite</b>.</p> |
| <b>Step 10</b> | <p><b>send-lifetime</b> <i>start-time</i> {<b>infinite</b>   <i>end-time</i>   <b>duration</b> <i>seconds</i>}</p> <p><b>Example:</b></p> <pre>Switch(config-keychain-key)# send-lifetime 14:00:00 Jan 25 2011 duration 3600</pre>     | <p>(Optional) Specifies the time period during which the key can be sent.</p> <p>The <i>start-time</i> and <i>end-time</i> syntax can be either <i>hh:mm:ss Month date year</i> or <i>hh:mm:ss date Month year</i>. The default is forever with the default <i>start-time</i> and the earliest acceptable date as January 1, 1993. The default <i>end-time</i> and <b>duration</b> is <b>infinite</b>.</p>     |
| <b>Step 11</b> | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Switch(config-keychain-key)# exit</pre>                                                                                                                                                  | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                               |

|                | Command or Action                                                                                              | Purpose                                                  |
|----------------|----------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| <b>Step 12</b> | <b>show key chain</b><br><br><b>Example:</b><br>Switch# show key chain                                         | Displays authentication key information.                 |
| <b>Step 13</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

## Monitoring and Maintaining EIGRP

You can delete neighbors from the neighbor table. You can also display various EIGRP routing statistics. Table 41-8 lists the privileged EXEC commands for deleting neighbors and displaying statistics. For explanations of fields in the resulting display, see the *Cisco IOS IP Command Reference, Volume 2 of 3: Routing Protocols, Release 12.4*.

**Table 103: IP EIGRP Clear and Show Commands**

|                                                                                                                 |                                                                                        |
|-----------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| <b>clear ip eigrp neighbors</b> [ <i>if-address</i>   <i>interface</i> ]                                        | Deletes neighbors from the neighbor table.                                             |
| <b>show ip eigrp interface</b> [ <i>interface</i> ] [ <i>as number</i> ]                                        | Displays information about interfaces configured for EIGRP.                            |
| <b>show ip eigrp neighbors</b> [ <i>type-number</i> ]                                                           | Displays EIGRP discovered neighbors.                                                   |
| <b>show ip eigrp topology</b><br>[ <i>autonomous-system-number</i> ]   [[ <i>ip-address</i> ]<br><i>mask</i> ]] | Displays the EIGRP topology table for a given process.                                 |
| <b>show ip eigrp traffic</b><br>[ <i>autonomous-system-number</i> ]                                             | Displays the number of packets sent and received for all or a specified EIGRP process. |

## Information About BGP

The Border Gateway Protocol (BGP) is an exterior gateway protocol used to set up an interdomain routing system that guarantees the loop-free exchange of routing information between autonomous systems. Autonomous systems are made up of routers that operate under the same administration and that run Interior Gateway Protocols (IGPs), such as RIP or OSPF, within their boundaries and that interconnect by using an Exterior Gateway Protocol (EGP). BGP Version 4 is the standard EGP for interdomain routing in the Internet. The protocol is defined in RFCs 1163, 1267, and 1771. You can find detailed information about BGP in

*Internet Routing Architectures*, published by Cisco Press, and in the “Configuring BGP” chapter in the *Cisco IP and IP Routing Configuration Guide*.

For details about BGP commands and keywords, see the “IP Routing Protocols” part of the *Cisco IOS IP Command Reference, Volume 2 of 3: Routing Protocols*.

## BGP Network Topology

Routers that belong to the same autonomous system (AS) and that exchange BGP updates run internal BGP (IBGP), and routers that belong to different autonomous systems and that exchange BGP updates run external BGP (EBGP). Most configuration commands are the same for configuring EBGP and IBGP. The difference is that the routing updates are exchanged either between autonomous systems (EBGP) or within an AS (IBGP). Figure 41-5 shows a network that is running both EBGP and IBGP.

**Figure 68: EBGP, IBGP, and Multiple Autonomous Systems**

Before exchanging information with an external AS, BGP ensures that networks within the AS can be reached by defining internal BGP peering among routers within the AS and by redistributing BGP routing information to IGP that run within the AS, such as IGRP and OSPF.

Routers that run a BGP routing process are often referred to as BGP speakers. BGP uses the Transmission Control Protocol (TCP) as its transport protocol (specifically port 179). Two BGP speakers that have a TCP connection to each other for exchanging routing information are known as peers or neighbors. In Figure 41-5, Routers A and B are BGP peers, as are Routers B and C and Routers C and D. The routing information is a series of AS numbers that describe the full path to the destination network. BGP uses this information to construct a loop-free map of autonomous systems.

The network has these characteristics:

- Routers A and B are running EBGP, and Routers B and C are running IBGP. Note that the EBGP peers are directly connected and that the IBGP peers are not. As long as there is an IGP running that allows the two neighbors to reach one another, IBGP peers do not have to be directly connected.
- All BGP speakers within an AS must establish a peer relationship with each other. That is, the BGP speakers within an AS must be fully meshed logically. BGP4 provides two techniques that reduce the requirement for a logical full mesh: confederations and route reflectors.
- AS 200 is a transit AS for AS 100 and AS 300—that is, AS 200 is used to transfer packets between AS 100 and AS 300.

BGP peers initially exchange their full BGP routing tables and then send only incremental updates. BGP peers also exchange keepalive messages (to ensure that the connection is up) and notification messages (in response to errors or special conditions).

In BGP, each route consists of a network number, a list of autonomous systems that information has passed through (the autonomous system path), and a list of other path attributes. The primary function of a BGP system is to exchange network reachability information, including information about the list of AS paths, with other BGP systems. This information can be used to determine AS connectivity, to prune routing loops, and to enforce AS-level policy decisions.

A router or switch running Cisco IOS does not select or use an IBGP route unless it has a route available to the next-hop router and it has received synchronization from an IGP (unless IGP synchronization is disabled). When multiple routes are available, BGP bases its path selection on attribute values. See the “Configuring BGP Decision Attributes” section for information about BGP attributes.

BGP Version 4 supports classless interdomain routing (CIDR) so you can reduce the size of your routing tables by creating aggregate routes, resulting in supernets. CIDR eliminates the concept of network classes within BGP and supports the advertising of IP prefixes.

## Nonstop Forwarding Awareness

The BGP NSF Awareness feature is supported for IPv4 in the IP services feature set. To enable this feature with BGP routing, you need to enable Graceful Restart. When the neighboring router is NSF-capable, and this feature is enabled, the Layer 3 switch continues to forward packets from the neighboring router during the interval between the primary Route Processor (RP) in a router failing and the backup RP taking over, or while the primary RP is manually reloaded for a nondisruptive software upgrade.

For more information, see the “BGP Nonstop Forwarding (NSF) Awareness” section of the *Cisco IOS IP Routing Protocols Configuration Guide, Release 12.4*.

## Information About BGP Routing

To enable BGP routing, you establish a BGP routing process and define the local network. Because BGP must completely recognize the relationships with its neighbors, you must also specify a BGP neighbor.

BGP supports two kinds of neighbors: internal and external. Internal neighbors are in the same AS; external neighbors are in different autonomous systems. External neighbors are usually adjacent to each other and share a subnet, but internal neighbors can be anywhere in the same AS.

The switch supports the use of private AS numbers, usually assigned by service providers and given to systems whose routes are not advertised to external neighbors. The private AS numbers are from 64512 to 65535. You can configure external neighbors to remove private AS numbers from the AS path by using the **neighbor remove-private-as** router configuration command. Then when an update is passed to an external neighbor, if the AS path includes private AS numbers, these numbers are dropped.

If your AS will be passing traffic through it from another AS to a third AS, it is important to be consistent about the routes it advertises. If BGP advertised a route before all routers in the network had learned about the route through the IGP, the AS might receive traffic that some routers could not yet route. To prevent this from happening, BGP must wait until the IGP has propagated information across the AS so that BGP is synchronized with the IGP. Synchronization is enabled by default. If your AS does not pass traffic from one AS to another AS, or if all routers in your autonomous systems are running BGP, you can disable synchronization, which allows your network to carry fewer routes in the IGP and allows BGP to converge more quickly.

## Routing Policy Changes

Routing policies for a peer include all the configurations that might affect inbound or outbound routing table updates. When you have defined two routers as BGP neighbors, they form a BGP connection and exchange routing information. If you later change a BGP filter, weight, distance, version, or timer, or make a similar configuration change, you must reset the BGP sessions so that the configuration changes take effect.

There are two types of reset, hard reset and soft reset. Cisco IOS Releases 12.1 and later support a soft reset without any prior configuration. To use a soft reset without preconfiguration, both BGP peers must support the soft route refresh capability, which is advertised in the OPEN message sent when the peers establish a TCP session. A soft reset allows the dynamic exchange of route refresh requests and routing information between BGP routers and the subsequent re-advertisement of the respective outbound routing table.

- When soft reset generates inbound updates from a neighbor, it is called dynamic inbound soft reset.
- When soft reset sends a set of updates to a neighbor, it is called outbound soft reset.

A soft inbound reset causes the new inbound policy to take effect. A soft outbound reset causes the new local outbound policy to take effect without resetting the BGP session. As a new set of updates is sent during outbound policy reset, a new inbound policy can also take effect.

Table 41-10 lists the advantages and disadvantages hard reset and soft reset.

**Table 104: Advantages and Disadvantages of Hard and Soft Resets**

| Type of Reset              | Advantages                                                                                                               | Disadvantages                                                                                     |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------|
| Hard reset                 | No memory overhead                                                                                                       | The prefixes in the BGP, IP, and FIB tables provided by the neighbor are lost. Not recommended.   |
| Outbound soft reset        | No configuration, no storing of routing table updates                                                                    | Does not reset inbound routing table updates.                                                     |
| Dynamic inbound soft reset | Does not clear the BGP session and cache<br>Does not require storing of routing table updates and has no memory overhead | Both BGP routers must support the route refresh capability (in Cisco IOS Release 12.1 and later). |

## BGP Decision Attributes

When a BGP speaker receives updates from multiple autonomous systems that describe different paths to the same destination, it must choose the single best path for reaching that destination. When chosen, the selected path is entered into the BGP routing table and propagated to its neighbors. The decision is based on the value of attributes that the update contains and other BGP-configurable factors.

When a BGP peer learns two EBGp paths for a prefix from a neighboring AS, it chooses the best path and inserts that path in the IP routing table. If BGP multipath support is enabled and the EBGp paths are learned from the same neighboring autonomous systems, instead of a single best path, multiple paths are installed in the IP routing table. Then, during packet switching, per-packet or per-destination load-balancing is performed among the multiple paths. The **maximum-paths** router configuration command controls the number of paths allowed.

These factors summarize the order in which BGP evaluates the attributes for choosing the best path:

If the path specifies a next hop that is inaccessible, drop the update. The BGP next-hop attribute, automatically determined by the software, is the IP address of the next hop that is going to be used to reach a destination. For EBGP, this is usually the IP address of the neighbor specified by the **neighbor remote-as router** configuration command. You can disable next-hop processing by using route maps or the **neighbor next-hop-self** router configuration command.

- 1 Prefer the path with the largest weight (a Cisco proprietary parameter). The weight attribute is local to the router and not propagated in routing updates. By default, the weight attribute is 32768 for paths that the router originates and zero for other paths. Routes with the largest weight are preferred. You can use access lists, route maps, or the **neighbor weight** router configuration command to set weights.
- 2 Prefer the route with the highest local preference. Local preference is part of the routing update and exchanged among routers in the same AS. The default value of the local preference attribute is 100. You can set local preference by using the **bgp default local-preference** router configuration command or by using a route map.
- 3 Prefer the route that was originated by BGP running on the local router.
- 4 Prefer the route with the shortest AS path.
- 5 Prefer the route with the lowest origin type. An interior route or IGP is lower than a route learned by EGP, and an EGP-learned route is lower than one of unknown origin or learned in another way.
- 6 Prefer the route with the lowest multi-exit discriminator (MED) metric attribute if the neighboring AS is the same for all routes considered. You can configure the MED by using route maps or by using the **default-metric** router configuration command. When an update is sent to an IBGP peer, the MED is included.
- 7 Prefer the external (EBGP) path over the internal (IBGP) path.
- 8 Prefer the route that can be reached through the closest IGP neighbor (the lowest IGP metric). This means that the router will prefer the shortest internal path within the AS to reach the destination (the shortest path to the BGP next-hop).
- 9 If the following conditions are all true, insert the route for this path into the IP routing table:
  - Both the best route and this route are external.
  - Both the best route and this route are from the same neighboring autonomous system.
  - maximum-paths is enabled.
- 10 If multipath is not enabled, prefer the route with the lowest IP address value for the BGP router ID. The router ID is usually the highest IP address on the router or the loopback (virtual) address, but might be implementation-specific.

## Route Maps

Within BGP, route maps can be used to control and to modify routing information and to define the conditions by which routes are redistributed between routing domains. See the “Using Route Maps to Redistribute Routing Information” section on page 41-124 for more information about route maps. Each route map has a name that identifies the route map (*map tag*) and an optional sequence number.

## BGP Filtering

You can filter BGP advertisements by using AS-path filters, such as the **as-path access-list** global configuration command and the **neighbor filter-list** router configuration command. You can also use access lists with the **neighbor distribute-list** router configuration command. Distribute-list filters are applied to network numbers. See the “Controlling Advertising and Processing in Routing Updates” section on page 41-135 for information about the **distribute-list** command.

You can use route maps on a per-neighbor basis to filter updates and to modify various attributes. A route map can be applied to either inbound or outbound updates. Only the routes that pass the route map are sent or accepted in updates. On both inbound and outbound updates, matching is supported based on AS path, community, and network numbers. Autonomous system path matching requires the **match as-path access-list** route-map command, community based matching requires the **match community-list** route-map command, and network-based matching requires the **ip access-list** global configuration command.

## Prefix List for BGP Filtering

You can use prefix lists as an alternative to access lists in many BGP route filtering commands, including the **neighbor distribute-list** router configuration command. The advantages of using prefix lists include performance improvements in loading and lookup of large lists, incremental update support, easier CLI configuration, and greater flexibility.

Filtering by a prefix list involves matching the prefixes of routes with those listed in the prefix list, as when matching access lists. When there is a match, the route is used. Whether a prefix is permitted or denied is based upon these rules:

- An empty prefix list permits all prefixes.
- An implicit deny is assumed if a given prefix does not match any entries in a prefix list.
- When multiple entries of a prefix list match a given prefix, the sequence number of a prefix list entry identifies the entry with the lowest sequence number.

By default, sequence numbers are generated automatically and incremented in units of five. If you disable the automatic generation of sequence numbers, you must specify the sequence number for each entry. You can specify sequence values in any increment. If you specify increments of one, you cannot insert additional entries into the list; if you choose very large increments, you might run out of values.

## BGP Community Filtering

One way that BGP controls the distribution of routing information based on the value of the COMMUNITIES attribute. The attribute is a way to groups destinations into communities and to apply routing decisions based on the communities. This method simplifies configuration of a BGP speaker to control distribution of routing information.

A community is a group of destinations that share some common attribute. Each destination can belong to multiple communities. AS administrators can define to which communities a destination belongs. By default, all destinations belong to the general Internet community. The community is identified by the COMMUNITIES attribute, an optional, transitive, global attribute in the numerical range from 1 to 4294967200. These are some predefined, well-known communities:

- **internet**—Advertise this route to the Internet community. All routers belong to it.

- **no-export**—Do not advertise this route to EBGp peers.
- **no-advertise**—Do not advertise this route to any peer (internal or external).
- **local-as**—Do not advertise this route to peers outside the local autonomous system.

Based on the community, you can control which routing information to accept, prefer, or distribute to other neighbors. A BGP speaker can set, append, or modify the community of a route when learning, advertising, or redistributing routes. When routes are aggregated, the resulting aggregate has a COMMUNITIES attribute that contains all communities from all the initial routes.

You can use community lists to create groups of communities to use in a match clause of a route map. As with an access list, a series of community lists can be created. Statements are checked until a match is found. As soon as one statement is satisfied, the test is concluded.

To set the COMMUNITIES attribute and match clauses based on communities, see the **match community-list** and **set community** route-map configuration commands in the “Using Route Maps to Redistribute Routing Information” section.

## BGP Neighbors and Peer Groups

Often many BGP neighbors are configured with the same update policies (that is, the same outbound route maps, distribute lists, filter lists, update source, and so on). Neighbors with the same update policies can be grouped into peer groups to simplify configuration and to make updating more efficient. When you have configured many peers, we recommend this approach.

To configure a BGP peer group, you create the peer group, assign options to the peer group, and add neighbors as peer group members. You configure the peer group by using the **neighbor** router configuration commands. By default, peer group members inherit all the configuration options of the peer group, including the remote-as (if configured), version, update-source, out-route-map, out-filter-list, out-dist-list, minimum-advertisement-interval, and next-hop-self. All peer group members also inherit changes made to the peer group. Members can also be configured to override the options that do not affect outbound updates.

## Aggregate Routes

Classless interdomain routing (CIDR) enables you to create aggregate routes (or supernets) to minimize the size of routing tables. You can configure aggregate routes in BGP either by redistributing an aggregate route into BGP or by creating an aggregate entry in the BGP routing table. An aggregate address is added to the BGP table when there is at least one more specific entry in the BGP table.

## Routing Domain Confederations

One way to reduce the IBGP mesh is to divide an autonomous system into multiple subautonomous systems and to group them into a single confederation that appears as a single autonomous system. Each autonomous system is fully meshed within itself and has a few connections to other autonomous systems in the same confederation. Even though the peers in different autonomous systems have EBGp sessions, they exchange routing information as if they were IBGP peers. Specifically, the next hop, MED, and local preference information is preserved. You can then use a single IGP for all of the autonomous systems.

## BGP Route Reflectors

BGP requires that all of the IBGP speakers be fully meshed. When a router receives a route from an external neighbor, it must advertise it to all internal neighbors. To prevent a routing information loop, all IBGP speakers must be connected. The internal neighbors do not send routes learned from internal neighbors to other internal neighbors.

With route reflectors, all IBGP speakers need not be fully meshed because another method is used to pass learned routes to neighbors. When you configure an internal BGP peer to be a route reflector, it is responsible for passing IBGP learned routes to a set of IBGP neighbors. The internal peers of the route reflector are divided into two groups: client peers and nonclient peers (all the other routers in the autonomous system). A route reflector reflects routes between these two groups. The route reflector and its client peers form a cluster. The nonclient peers must be fully meshed with each other, but the client peers need not be fully meshed. The clients in the cluster do not communicate with IBGP speakers outside their cluster.

When the route reflector receives an advertised route, it takes one of these actions, depending on the neighbor:

- A route from an external BGP speaker is advertised to all clients and nonclient peers.
- A route from a nonclient peer is advertised to all clients.
- A route from a client is advertised to all clients and nonclient peers. Hence, the clients need not be fully meshed.

Usually a cluster of clients have a single route reflector, and the cluster is identified by the route reflector router ID. To increase redundancy and to avoid a single point of failure, a cluster might have more than one route reflector. In this case, all route reflectors in the cluster must be configured with the same 4-byte cluster ID so that a route reflector can recognize updates from route reflectors in the same cluster. All the route reflectors serving a cluster should be fully meshed and should have identical sets of client and nonclient peers.

## Route Dampening

Route flap dampening is a BGP feature designed to minimize the propagation of flapping routes across an internetwork. A route is considered to be flapping when it is repeatedly available, then unavailable, then available, then unavailable, and so on. When route dampening is enabled, a numeric penalty value is assigned to a route when it flaps. When a route's accumulated penalties reach a configurable limit, BGP suppresses advertisements of the route, even if the route is running. The reuse limit is a configurable value that is compared with the penalty. If the penalty is less than the reuse limit, a suppressed route that is up is advertised again.

Dampening is not applied to routes that are learned by IBGP. This policy prevents the IBGP peers from having a higher penalty for routes external to the AS.

## More BGP Information

For detailed descriptions of BGP configuration, see the "Configuring BGP" chapter in the "IP Routing Protocols" part of the *Cisco IOS IP Configuration Guide, Release 12.4*. For details about specific commands, see the *Cisco IOS IP Command Reference, Volume 2 of 3: Routing Protocols, Release 12.4*.

# How to Configure BGP

## Default BGP Configuration

Table 41-9 shows the basic default BGP configuration. For the defaults for all characteristics, see the specific commands in the *Cisco IOS IP Command Reference, Volume 2 of 3: Routing Protocols, Release 12.4*.

**Table 105: Default BGP Configuration**

| Feature                            | Default Setting                                                                                                                                                                                                                                                             |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Aggregate address                  | Disabled: None defined.                                                                                                                                                                                                                                                     |
| AS path access list                | None defined.                                                                                                                                                                                                                                                               |
| Auto summary                       | Disabled.                                                                                                                                                                                                                                                                   |
| Best path                          | <ul style="list-style-type: none"> <li>The router considers <i>as-path</i> in choosing a route and does not compare similar routes from external BGP peers.</li> <li>Compare router ID: Disabled.</li> </ul>                                                                |
| BGP community list                 | <ul style="list-style-type: none"> <li>Number: None defined. When you permit a value for the community number, the list defaults to an implicit deny for everything else that has not been permitted.</li> <li>Format: Cisco default format (32-bit number).</li> </ul>     |
| BGP confederation identifier/peers | <ul style="list-style-type: none"> <li>Identifier: None configured.</li> <li>Peers: None identified.</li> </ul>                                                                                                                                                             |
| BGP Fast external fallover         | Enabled.                                                                                                                                                                                                                                                                    |
| BGP local preference               | 100. The range is 0 to 4294967295 with the higher value preferred.                                                                                                                                                                                                          |
| BGP network                        | None specified; no backdoor route advertised.                                                                                                                                                                                                                               |
| BGP route dampening                | Disabled by default. When enabled: <ul style="list-style-type: none"> <li>Half-life is 15 minutes.</li> <li>Re-use is 750 (10-second increments).</li> <li>Suppress is 2000 (10-second increments).</li> <li>Max-suppress-time is 4 times half-life; 60 minutes.</li> </ul> |

| Feature                                                            | Default Setting                                                                                                                                                                                                                                                                                                                |
|--------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BGP router ID                                                      | The IP address of a loopback interface if one is configured or the highest IP address configured for a physical interface on the router.                                                                                                                                                                                       |
| Default information originate (protocol or network redistribution) | Disabled.                                                                                                                                                                                                                                                                                                                      |
| Default metric                                                     | Built-in, automatic metric translations.                                                                                                                                                                                                                                                                                       |

| Timers  | Keepalive: 60 seconds; holdtime: 180 seconds. |

<sup>8</sup> Nonstop Forwarding

<sup>9</sup> NSF Awareness can be enabled for IPv4 on switches with the IP services feature set by enabling Graceful Restart.

## Enabling BGP Routing

### Before You Begin

**Note** To enable BGP, the switch or stack master must be running the IP services feature set.

### DETAILED STEPS

|               | Command or Action                                                                                                                                                               | Purpose                                                                                                                                                                                                                                                                                                                                                              |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                                                                                  | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                    |
| <b>Step 2</b> | <b>ip routing</b><br><br><b>Example:</b><br>Switch(config)# ip routing                                                                                                          | Enables IP routing.                                                                                                                                                                                                                                                                                                                                                  |
| <b>Step 3</b> | <b>router bgp <i>autonomous-system</i></b><br><br><b>Example:</b><br>Switch(config)# router bgp 45000                                                                           | Enables a BGP routing process, assign it an AS number, and enter router configuration mode. The AS number can be from 1 to 65535, with 64512 to 65535 designated as private autonomous numbers.                                                                                                                                                                      |
| <b>Step 4</b> | <b>network <i>network-number</i> [mask <i>network-mask</i>]</b><br><b>[route-map <i>route-map-name</i>]</b><br><br><b>Example:</b><br>Switch(config)# network 10.108.0.0        | Configures a network as local to this AS, and enter it in the BGP table.                                                                                                                                                                                                                                                                                             |
| <b>Step 5</b> | <b>neighbor {<i>ip-address</i>   <i>peer-group-name</i>}</b><br><b>remote-as <i>number</i></b><br><br><b>Example:</b><br>Switch(config)# neighbor 10.108.1.2<br>remote-as 65200 | Adds an entry to the BGP neighbor table specifying that the neighbor identified by the IP address belongs to the specified AS.<br><br>For EBGP, neighbors are usually directly connected, and the IP address is the address of the interface at the other end of the connection.<br><br>For IBGP, the IP address can be the address of any of the router interfaces. |

|                | Command or Action                                                                                                                                              | Purpose                                                                                                                                                                                                                                                                                                                                                                               |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 6</b>  | <b>neighbor</b> {ip-address   peer-group-name}<br><b>remove-private-as</b><br><br><b>Example:</b><br>Switch(config)# neighbor 172.16.2.33<br>remove-private-as | (Optional) Removes private AS numbers from the AS-path in outbound routing updates.                                                                                                                                                                                                                                                                                                   |
| <b>Step 7</b>  | <b>synchronization</b><br><br><b>Example:</b><br>Switch(config)# synchronization                                                                               | (Optional) Enables synchronization between BGP and an IGP.                                                                                                                                                                                                                                                                                                                            |
| <b>Step 8</b>  | <b>auto-summary</b><br><br><b>Example:</b><br>Switch(config)# auto-summary                                                                                     | (Optional) Enables automatic network summarization. When a subnet is redistributed from an IGP into BGP, only the network route is inserted into the BGP table.                                                                                                                                                                                                                       |
| <b>Step 9</b>  | <b>bgp graceful-restart</b><br><br><b>Example:</b><br>Switch(config)# bgp graceful-start                                                                       | (Optional) Enables NSF awareness on switch. By default, NSF awareness is disabled.                                                                                                                                                                                                                                                                                                    |
| <b>Step 10</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config)# end                                                                                                       | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                      |
| <b>Step 11</b> | <b>show ip bgp network</b> network-number<br><br><b>Example:</b><br>Switch# show ip bgp network 10.108.0.0                                                     | Verifies the configuration.                                                                                                                                                                                                                                                                                                                                                           |
| <b>Step 12</b> | <b>show ip bgp neighbor</b><br><br><b>Example:</b><br>Switch# show ip bgp neighbor                                                                             | Verifies that NSF awareness (Graceful Restart) is enabled on the neighbor.<br><br>If NSF awareness is enabled on the switch and the neighbor, this message appears:<br><i>Graceful Restart Capability: advertised and received</i><br><br>If NSF awareness is enabled on the switch, but not on the neighbor, this message appears:<br><i>Graceful Restart Capability: advertised</i> |
| <b>Step 13</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config                                                 | (Optional) Saves your entries in the configuration file.                                                                                                                                                                                                                                                                                                                              |

## Managing Routing Policy Changes

To learn if a BGP peer supports the route refresh capability and to reset the BGP session:

### DETAILED STEPS

|               | Command or Action                                                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>show ip bgp neighbors</b><br><br><b>Example:</b><br>Switch# show ip bgp neighbors                                                         | Displays whether a neighbor supports the route refresh capability. When supported, this message appears for the router:<br><br><i>Received route refresh capability from peer.</i>                                                                                                                                                                                                                               |
| <b>Step 2</b> | <b>clear ip bgp</b> {*   <i>address</i>   <i>peer-group-name</i> }<br><br><b>Example:</b><br>Switch# clear ip bgp *                          | Resets the routing table on the specified connection. <ul style="list-style-type: none"> <li>• Enter an asterisk (*) to specify that all connections be reset.</li> <li>• Enter an IP address to specify the connection to be reset.</li> <li>• Enter a peer group name to reset the peer group.</li> </ul>                                                                                                      |
| <b>Step 3</b> | <b>clear ip bgp</b> {*   <i>address</i>   <i>peer-group-name</i> } <b>soft out</b><br><br><b>Example:</b><br>Switch# clear ip bgp * soft out | (Optional) Performs an outbound soft reset to reset the inbound routing table on the specified connection. Use this command if route refresh is supported. <ul style="list-style-type: none"> <li>• Enter an asterisk (*) to specify that all connections be reset.</li> <li>• Enter an IP address to specify the connection to be reset.</li> <li>• Enter a peer group name to reset the peer group.</li> </ul> |
| <b>Step 4</b> | <b>show ip bgp</b><br><br><b>Example:</b><br>Switch# show ip bgp                                                                             | Verifies the reset by checking information about the routing table and about BGP neighbors.                                                                                                                                                                                                                                                                                                                      |
| <b>Step 5</b> | <b>show ip bgp neighbors</b><br><br><b>Example:</b><br>Switch# show ip bgp neighbors                                                         | Verifies the reset by checking information about the routing table and about BGP neighbors.                                                                                                                                                                                                                                                                                                                      |

## Configuring BGP Decision Attributes

### DETAILED STEPS

|               | Command or Action                                                                                                                                                 | Purpose                                                                                                                                                                                                                                                                       |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                                                                    | Enters global configuration mode.                                                                                                                                                                                                                                             |
| <b>Step 2</b> | <b>router bgp <i>autonomous-system</i></b><br><br><b>Example:</b><br>Switch(config)# router bgp 4500                                                              | Enables a BGP routing process, assign it an AS number, and enter router configuration mode.                                                                                                                                                                                   |
| <b>Step 3</b> | <b>bgp best-path as-path ignore</b><br><br><b>Example:</b><br>Switch(config-router)# bgp bestpath as-path ignore                                                  | (Optional) Configures the router to ignore AS path length in selecting a route.                                                                                                                                                                                               |
| <b>Step 4</b> | <b>neighbor {<i>ip-address</i>   <i>peer-group-name</i>} next-hop-self</b><br><br><b>Example:</b><br>Switch(config-router)# neighbor 10.108.1.1 next-hop-self     | (Optional) Disables next-hop processing on BGP updates to a neighbor by entering a specific IP address to be used instead of the next-hop address.                                                                                                                            |
| <b>Step 5</b> | <b>neighbor {<i>ip-address</i>   <i>peer-group-name</i>} weight <i>weight</i></b><br><br><b>Example:</b><br>Switch(config-router)# neighbor 172.16.12.1 weight 50 | (Optional) Assign a weight to a neighbor connection. Acceptable values are from 0 to 65535; the largest weight is the preferred route. Routes learned through another BGP peer have a default weight of 0; routes sourced by the local router have a default weight of 32768. |
| <b>Step 6</b> | <b>default-metric <i>number</i></b><br><br><b>Example:</b><br>Switch(config-router)# default-metric 300                                                           | (Optional) Sets a MED metric to set preferred paths to external neighbors. All routes without a MED will also be set to this value. The range is 1 to 4294967295. The lowest value is the most desirable.                                                                     |
| <b>Step 7</b> | <b>bgp bestpath med missing-as-worst</b><br><br><b>Example:</b><br>Switch(config-router)# bgp bestpath med missing-as-worst                                       | (Optional) Configures the switch to consider a missing MED as having a value of infinity, making the path without a MED value the least desirable path.                                                                                                                       |

|                | Command or Action                                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                                                           |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 8</b>  | <b>bgp always-compare med</b><br><br><b>Example:</b><br><pre>Switch(config-router)# bgp always-compare-med</pre>                              | (Optional) Configures the switch to compare MEDs for paths from neighbors in different autonomous systems. By default, MED comparison is only done among paths in the same AS.                                                                                                                                                                                                    |
| <b>Step 9</b>  | <b>bgp bestpath med confed</b><br><br><b>Example:</b><br><pre>Switch(config-router)# bgp bestpath med confed</pre>                            | (Optional) Configures the switch to consider the MED in choosing a path from among those advertised by different subautonomous systems within a confederation.                                                                                                                                                                                                                    |
| <b>Step 10</b> | <b>bgp deterministic med</b><br><br><b>Example:</b><br><pre>Switch(config-router)# bgp deterministic med</pre>                                | (Optional) Configures the switch to consider the MED variable when choosing among routes advertised by different peers in the same AS.                                                                                                                                                                                                                                            |
| <b>Step 11</b> | <b>bgp default local-preference <i>value</i></b><br><br><b>Example:</b><br><pre>Switch(config-router)# bgp default local-preference 200</pre> | (Optional) Change the default local preference value. The range is 0 to 4294967295; the default value is 100. The highest local preference value is preferred.                                                                                                                                                                                                                    |
| <b>Step 12</b> | <b>maximum-paths <i>number</i></b><br><br><b>Example:</b><br><pre>Switch(config-router)# maximum-paths 8</pre>                                | (Optional) Configures the number of paths to be added to the IP routing table. The default is to only enter the best path in the routing table. The range is from 1 to 16. Having multiple paths allows load-balancing among the paths. (Although the switch software allows a maximum of 32 equal-cost routes, the switch hardware will never use more than 16 paths per route.) |
| <b>Step 13</b> | <b>end</b><br><br><b>Example:</b><br><pre>Switch(config-router)# end</pre>                                                                    | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                  |
| <b>Step 14</b> | <b>show ip bgp</b><br><br><b>Example:</b><br><pre>Switch# show ip bgp</pre>                                                                   | Verifies the reset by checking information about the routing table and about BGP neighbors.                                                                                                                                                                                                                                                                                       |
| <b>Step 15</b> | <b>show ip bgp neighbors</b><br><br><b>Example:</b><br><pre>Switch# show ip bgp neighbors</pre>                                               | Verifies the reset by checking information about the routing table and about BGP neighbors.                                                                                                                                                                                                                                                                                       |

|                | Command or Action                                                                                                         | Purpose                                                  |
|----------------|---------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| <b>Step 16</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br><pre>Switch# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

## Configuring BGP Filtering with Route Maps

### DETAILED STEPS

|               | Command or Action                                                                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br><pre>Switch# configure terminal</pre>                                                                                     | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Step 2</b> | <b>route-map <i>map-tag</i> [permit   deny]</b><br><b>[<i>sequence-number</i>]</b><br><br><b>Example:</b><br><pre>Switch(config)# route-map set-peer-address permit 10</pre>  | Creates a route map, and enter route-map configuration mode.                                                                                                                                                                                                                                                                                                                                          |
| <b>Step 3</b> | <b>set ip next-hop <i>ip-address</i> [...<i>ip-address</i>]</b><br><b>[<i>peer-address</i>]</b><br><br><b>Example:</b><br><pre>Switch(config)# set ip next-hop 10.1.1.3</pre> | (Optional) Sets a route map to disable next-hop processing <ul style="list-style-type: none"> <li>• In an inbound route map, set the next hop of matching routes to be the neighbor peering address, overriding third-party next hops.</li> <li>• In an outbound route map of a BGP peer, set the next hop to the peering address of the local router, disabling the next-hop calculation.</li> </ul> |
| <b>Step 4</b> | <b>end</b><br><br><b>Example:</b><br><pre>Switch(config)# end</pre>                                                                                                           | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Step 6</b> | <b>show ip bgp neighbors</b><br><br><b>Example:</b><br>Switch# show ip bgp neighbors                           | Verifies the configuration.                              |
| <b>Step 7</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

## Configuring BGP Filtering by Access Lists and Neighbors

Another method of filtering is to specify an access list filter on both incoming and outbound updates, based on the BGP autonomous system paths. Each filter is an access list based on regular expressions. (See the “Regular Expressions” appendix in the *Cisco IOS Dial Technologies Command Reference, Release 12.4* for more information on forming regular expressions.) To use this method, define an autonomous system path access list, and apply it to updates to and from particular neighbors.

### DETAILED STEPS

|               | Command or Action                                                                                                                                                                                                                          | Purpose                                           |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                                                                                                                                             | Enters global configuration mode.                 |
| <b>Step 2</b> | <b>ip as-path access-list <i>access-list-number</i> {permit   deny} <i>as-regular-expressions</i></b><br><br><b>Example:</b><br>Switch(config)# ip as-path access-list 1 deny _65535_                                                      | Defines a BGP-related access list.                |
| <b>Step 3</b> | <b>router bgp <i>autonomous-system</i></b><br><br><b>Example:</b><br>Switch(config)# router bgp 110                                                                                                                                        | Enters BGP router configuration mode.             |
| <b>Step 4</b> | <b>neighbor {<i>ip-address</i>   <i>peer-group name</i>} filter-list {<i>access-list-number</i>   <i>name</i>} {in   out} weight <i>weight</i>}</b><br><br><b>Example:</b><br>Switch(config-router)# neighbor 172.16.1.1 filter-list 1 out | Establishes a BGP filter based on an access list. |

|        | Command or Action                                                                                               | Purpose                                                  |
|--------|-----------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| Step 5 | <b>end</b><br><br><b>Example:</b><br>Switch(config-router)# end                                                 | Returns to privileged EXEC mode.                         |
| Step 6 | <b>show ip bgp neighbors [paths regular-expression]</b><br><br><b>Example:</b><br>Switch# show ip bgp neighbors | Verifies the configuration.                              |
| Step 7 | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config  | (Optional) Saves your entries in the configuration file. |

## Configuring Prefix Lists for BGP Filtering

You do not need to specify a sequence number when removing a configuration entry. **Show** commands include the sequence numbers in their output.

Before using a prefix list in a command, you must set up the prefix list.

### DETAILED STEPS

|        | Command or Action                                                                                                                                                                        | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                                                                                           | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Step 2 | <b>ip prefix-list list-name [seq seq-value] deny   permit network/len [ge ge-value] [le le-value]</b><br><br><b>Example:</b><br>Switch(config)# ip prefix-list BLUE permit 172.16.1.0/24 | Creates a prefix list with an optional sequence number to <b>deny</b> or <b>permit</b> access for matching conditions. You must enter at least one <b>permit</b> or <b>deny</b> clause. <ul style="list-style-type: none"> <li>• <i>network/len</i> is the network number and length (in bits) of the network mask.</li> <li>• (Optional) <b>ge</b> and <b>le</b> values specify the range of the prefix length to be matched. The specified <i>ge-value</i> and <i>le-value</i> must satisfy this condition: <math>len &lt; ge-value &lt; le-value &lt; 32</math></li> </ul> |

|        | Command or Action                                                                                                                                                                                                                                                                  | Purpose                                                                                          |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
| Step 3 | <p><b>ip prefix-list</b> <i>list-name</i> <b>seq</b> <i>seq-value</i> <b>deny</b>   <b>permit</b> <i>network/len</i> [<b>ge</b> <i>ge-value</i>] [<b>le</b> <i>le-value</i>]</p> <p><b>Example:</b></p> <pre>Switch(config)# ip prefix-list BLUE seq 10 permit 172.24.1.0/24</pre> | (Optional) Adds an entry to a prefix list, and assign a sequence number to the entry.            |
| Step 4 | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Switch(config)# end</pre>                                                                                                                                                                                                            | Returns to privileged EXEC mode.                                                                 |
| Step 5 | <p><b>show ip prefix list</b> [<b>detail</b>   <b>summary</b>] <i>name</i> [<i>network/len</i>] [<b>seq</b> <i>seq-num</i>] [<b>longer</b>] [<b>first-match</b>]</p> <p><b>Example:</b></p> <pre>Switch# show ip prefix list summary test</pre>                                    | Verifies the configuration by displaying information about a prefix list or prefix list entries. |
| Step 6 | <p><b>copy running-config startup-config</b></p> <p><b>Example:</b></p> <pre>Switch# copy running-config startup-config</pre>                                                                                                                                                      | (Optional) Saves your entries in the configuration file.                                         |

## Configuring BGP Community Filtering

By default, no COMMUNITIES attribute is sent to a neighbor. You can specify that the COMMUNITIES attribute be sent to the neighbor at an IP address by using the **neighbor send-community** router configuration command.

### SUMMARY STEPS

1. **configure terminal**
2. **ip community-list** *community-list-number* {**permit** | **deny**} *community-number*
3. **router bgp** *autonomous-system*
4. **neighbor** {*ip-address* | *peer-group name*} **send-community**
5. **set comm-list** *list-num* **delete**
6. **exit**
7. **ip bgp-community new-format**
8. **end**
9. **show ip bgp community**
10. **copy running-config startup-config**

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                        |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>configure terminal</b><br><br><b>Example:</b><br><pre>Switch# configure terminal</pre>                                                                                              | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                              |
| Step 2 | <b>ip community-list <i>community-list-number</i> {permit   deny} <i>community-number</i></b><br><br><b>Example:</b><br><pre>Switch(config)# ip community-list 1 permit 50000:10</pre> | Creates a community list, and assign it a number. <ul style="list-style-type: none"> <li>• The <i>community-list-number</i> is an integer from 1 to 99 that identifies one or more permit or deny groups of communities.</li> <li>• The <i>community-number</i> is the number configured by a <b>set community</b> route-map configuration command.</li> </ul> |
| Step 3 | <b>router bgp <i>autonomous-system</i></b><br><br><b>Example:</b><br><pre>Switch(config)# router bgp 108</pre>                                                                         | Enters BGP router configuration mode.                                                                                                                                                                                                                                                                                                                          |
| Step 4 | <b>neighbor {<i>ip-address</i>   <i>peer-group name</i>} send-community</b><br><br><b>Example:</b><br><pre>Switch(config-router)# neighbor 172.16.70.23 send-community</pre>           | Specifies that the COMMUNITIES attribute be sent to the neighbor at this IP address.                                                                                                                                                                                                                                                                           |
| Step 5 | <b>set comm-list <i>list-num</i> delete</b><br><br><b>Example:</b><br><pre>Switch(config-router)# set comm-list 500 delete</pre>                                                       | (Optional) Removes communities from the community attribute of an inbound or outbound update that match a standard or extended community list specified by a route map.                                                                                                                                                                                        |
| Step 6 | <b>exit</b><br><br><b>Example:</b><br><pre>Switch(config-router)# end</pre>                                                                                                            | Returns to global configuration mode.                                                                                                                                                                                                                                                                                                                          |
| Step 7 | <b>ip bgp-community new-format</b><br><br><b>Example:</b><br><pre>Switch(config)# ip bgp-community new format</pre>                                                                    | (Optional) Displays and parses BGP communities in the format AA:NN.<br><br>A BGP community is displayed in a two-part format 2 bytes long. The Cisco default community format is in the format NNAA. In the most recent RFC for BGP, a community takes the form AA:NN, where the first part is the AS number and the second part is a 2-byte number.           |

|         | Command or Action                                                                                              | Purpose                                                  |
|---------|----------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| Step 8  | <b>end</b><br><br><b>Example:</b><br>Switch(config)# end                                                       | Returns to privileged EXEC mode.                         |
| Step 9  | <b>show ip bgp community</b><br><br><b>Example:</b><br>Switch# show ip bgp community                           | Verifies the configuration.                              |
| Step 10 | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

## Configuring BGP Neighbors and Peer Groups

To assign configuration options to an individual neighbor, specify any of these router configuration commands by using the neighbor IP address. To assign the options to a peer group, specify any of the commands by using the peer group name. You can disable a BGP peer or peer group without removing all the configuration information by using the **neighbor shutdown** router configuration command.

### DETAILED STEPS

|        | Command or Action                                                                                                               | Purpose                                                                                                                                                                                        |
|--------|---------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>configure terminal</b>                                                                                                       | Enters global configuration mode.                                                                                                                                                              |
| Step 2 | <b>router bgp</b> <i>autonomous-system</i>                                                                                      | Enters BGP router configuration mode.                                                                                                                                                          |
| Step 3 | <b>neighbor</b> <i>peer-group-name</i> <b>peer-group</b>                                                                        | Creates a BGP peer group.                                                                                                                                                                      |
| Step 4 | <b>neighbor</b> <i>ip-address</i> <b>peer-group</b><br><i>peer-group-name</i>                                                   | Makes a BGP neighbor a member of the peer group.                                                                                                                                               |
| Step 5 | <b>neighbor</b> { <i>ip-address</i>   <i>peer-group-name</i> }<br><b>remote-as</b> <i>number</i>                                | Specifies a BGP neighbor. If a peer group is not configured with a <b>remote-as</b> <i>number</i> , use this command to create peer groups containing EBGp neighbors. The range is 1 to 65535. |
| Step 6 | <b>neighbor</b> { <i>ip-address</i>   <i>peer-group-name</i> }<br><b>description</b> <i>text</i>                                | (Optional) Associates a description with a neighbor.                                                                                                                                           |
| Step 7 | <b>neighbor</b> { <i>ip-address</i>   <i>peer-group-name</i> }<br><b>default-originate</b> [ <b>route-map</b> <i>map-name</i> ] | (Optional) Allows a BGP speaker (the local router) to send the default route 0.0.0.0 to a neighbor for use as a default route.                                                                 |

|         | Command or Action                                                                                                                                               | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 8  | <b>neighbor</b> { <i>ip-address</i>   <i>peer-group-name</i> }<br><b>send-community</b>                                                                         | (Optional) Specifies that the COMMUNITIES attribute be sent to the neighbor at this IP address.                                                                                                                                                                                                                                                                                                                                                                |
| Step 9  | <b>neighbor</b> { <i>ip-address</i>   <i>peer-group-name</i> }<br><b>update-source</b> <i>interface</i>                                                         | (Optional) Allows internal BGP sessions to use any operational interface for TCP connections.                                                                                                                                                                                                                                                                                                                                                                  |
| Step 10 | <b>neighbor</b> { <i>ip-address</i>   <i>peer-group-name</i> }<br><b>ebgp-multihop</b>                                                                          | (Optional) Allows BGP sessions, even when the neighbor is not on a directly connected segment. The multihop session is not established if the only route to the multihop peer's address is the default route (0.0.0.0).                                                                                                                                                                                                                                        |
| Step 11 | <b>neighbor</b> { <i>ip-address</i>   <i>peer-group-name</i> }<br><b>local-as</b> <i>number</i>                                                                 | (Optional) Specifies an AS number to use as the local AS. The range is 1 to 65535.                                                                                                                                                                                                                                                                                                                                                                             |
| Step 12 | <b>neighbor</b> { <i>ip-address</i>   <i>peer-group-name</i> }<br><b>advertisement-interval</b> <i>seconds</i>                                                  | (Optional) Sets the minimum interval between sending BGP routing updates.                                                                                                                                                                                                                                                                                                                                                                                      |
| Step 13 | <b>neighbor</b> { <i>ip-address</i>   <i>peer-group-name</i> }<br><b>maximum-prefix</b> <i>maximum</i> [ <i>threshold</i> ]                                     | (Optional) Controls how many prefixes can be received from a neighbor. The range is 1 to 4294967295. The <i>threshold</i> (optional) is the percentage of maximum at which a warning message is generated. The default is 75 percent.                                                                                                                                                                                                                          |
| Step 14 | <b>neighbor</b> { <i>ip-address</i>   <i>peer-group-name</i> }<br><b>next-hop-self</b>                                                                          | (Optional) Disables next-hop processing on the BGP updates to a neighbor.                                                                                                                                                                                                                                                                                                                                                                                      |
| Step 15 | <b>neighbor</b> { <i>ip-address</i>   <i>peer-group-name</i> }<br><b>password</b> <i>string</i>                                                                 | (Optional) Sets MD5 authentication on a TCP connection to a BGP peer. The same password must be configured on both BGP peers, or the connection between them is not made.                                                                                                                                                                                                                                                                                      |
| Step 16 | <b>neighbor</b> { <i>ip-address</i>   <i>peer-group-name</i> }<br><b>route-map</b> <i>map-name</i> { <b>in</b>   <b>out</b> }                                   | (Optional) Applies a route map to incoming or outgoing routes.                                                                                                                                                                                                                                                                                                                                                                                                 |
| Step 17 | <b>neighbor</b> { <i>ip-address</i>   <i>peer-group-name</i> }<br><b>send-community</b>                                                                         | (Optional) Specifies that the COMMUNITIES attribute be sent to the neighbor at this IP address.                                                                                                                                                                                                                                                                                                                                                                |
| Step 18 | <b>neighbor</b> { <i>ip-address</i>   <i>peer-group-name</i> } <b>timers</b><br><i>keepalive holdtime</i>                                                       | (Optional) Sets timers for the neighbor or peer group. <ul style="list-style-type: none"> <li>The <i>keepalive</i> interval is the time within which keepalive messages are sent to peers. The range is 1 to 4294967295 seconds; the default is 60.</li> <li>The <i>holdtime</i> is the interval after which a peer is declared inactive after not receiving a keepalive message from it. The range is 1 to 4294967295 seconds; the default is 180.</li> </ul> |
| Step 19 | <b>neighbor</b> { <i>ip-address</i>   <i>peer-group-name</i> } <b>weight</b><br><i>weight</i>                                                                   | (Optional) Specifies a weight for all routes from a neighbor.                                                                                                                                                                                                                                                                                                                                                                                                  |
| Step 20 | <b>neighbor</b> { <i>ip-address</i>   <i>peer-group-name</i> }<br><b>distribute-list</b> { <i>access-list-number</i>   <i>name</i> } { <b>in</b>   <b>out</b> } | (Optional) Filter BGP routing updates to or from neighbors, as specified in an access list.                                                                                                                                                                                                                                                                                                                                                                    |

|         | Command or Action                                                                                                                                                       | Purpose                                                                         |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| Step 21 | <b>neighbor</b> { <i>ip-address</i>   <i>peer-group-name</i> }<br><b>filter-list</b> <i>access-list-number</i> { <b>in</b>   <b>out</b>   <b>weight</b> <i>weight</i> } | (Optional) Establish a BGP filter.                                              |
| Step 22 | <b>neighbor</b> { <i>ip-address</i>   <i>peer-group-name</i> } <b>version</b> <i>value</i>                                                                              | (Optional) Specifies the BGP version to use when communicating with a neighbor. |
| Step 23 | <b>neighbor</b> { <i>ip-address</i>   <i>peer-group-name</i> }<br><b>soft-reconfiguration inbound</b>                                                                   | (Optional) Configures the software to start storing received updates.           |
| Step 24 | <b>end</b>                                                                                                                                                              | Returns to privileged EXEC mode.                                                |
| Step 25 | <b>show ip bgp neighbors</b>                                                                                                                                            | Verifies the configuration.                                                     |
| Step 26 | <b>copy running-config startup-config</b>                                                                                                                               | (Optional) Saves your entries in the configuration file.                        |

## Configuring Aggregate Addresses in a Routing Table

### DETAILED STEPS

|        | Command or Action                                                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                                |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# <code>configure terminal</code>                                                                   | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                      |
| Step 2 | <b>router bgp</b> <i>autonomous-system</i><br><br><b>Example:</b><br>Switch(config)# <code>router bgp 106</code>                                              | Enters BGP router configuration mode.                                                                                                                                                                                                                                                                                                                  |
| Step 3 | <b>aggregate-address</b> <i>address mask</i><br><br><b>Example:</b><br>Switch(config-router)# <code>aggregate-address 10.0.0.0 255.0.0.0</code>               | Creates an aggregate entry in the BGP routing table. The aggregate route is advertised as coming from the AS, and the atomic aggregate attribute is set to indicate that information might be missing.                                                                                                                                                 |
| Step 4 | <b>aggregate-address</b> <i>address mask as-set</i><br><br><b>Example:</b><br>Switch(config-router)# <code>aggregate-address 10.0.0.0 255.0.0.0 as-set</code> | (Optional) Generates AS set path information. This command creates an aggregate entry following the same rules as the previous command, but the advertised path will be an AS_SET consisting of all elements contained in all paths. Do not use this keyword when aggregating many paths because this route must be continually withdrawn and updated. |

|                | Command or Action                                                                                                                                                                             | Purpose                                                                           |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| <b>Step 5</b>  | <b>aggregate-address</b> <i>address-mask</i> <b>summary-only</b><br><br><b>Example:</b><br>Switch(config-router)# aggregate-address 10.0.0.0<br>255.0.0.0 summary-only                        | (Optional) Advertises summary addresses only.                                     |
| <b>Step 6</b>  | <b>aggregate-address</b> <i>address mask</i> <b>suppress-map</b> <i>map-name</i><br><br><b>Example:</b><br>Switch(config-router)# aggregate-address 10.0.0.0<br>255.0.0.0 suppress-map map1   | (Optional) Suppresses selected, more specific routes.                             |
| <b>Step 7</b>  | <b>aggregate-address</b> <i>address mask</i> <b>advertise-map</b> <i>map-name</i><br><br><b>Example:</b><br>Switch(config-router)# aggregate-address 10.0.0.0<br>255.0.0.0 advertise-map map2 | (Optional) Generates an aggregate based on conditions specified by the route map. |
| <b>Step 8</b>  | <b>aggregate-address</b> <i>address mask</i> <b>attribute-map</b> <i>map-name</i><br><br><b>Example:</b><br>Switch(config-router)# aggregate-address 10.0.0.0<br>255.0.0.0 attribute-map map3 | (Optional) Generates an aggregate with attributes specified in the route map.     |
| <b>Step 9</b>  | <b>end</b><br><br><b>Example:</b><br>Switch(config-router)# end                                                                                                                               | Returns to privileged EXEC mode.                                                  |
| <b>Step 10</b> | <b>show ip bgp neighbors</b> [ <i>advertised-routes</i> ]<br><br><b>Example:</b><br>Switch# show ip bgp neighbors                                                                             | Verifies the configuration.                                                       |
| <b>Step 11</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config                                                                                | (Optional) Saves your entries in the configuration file.                          |

## Configuring Routing Domain Confederations

You must specify a confederation identifier that acts as the autonomous system number for the group of autonomous systems.

## DETAILED STEPS

|               | Command or Action                                                                                                                                                                  | Purpose                                                                                                           |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                                                                                     | Enters global configuration mode.                                                                                 |
| <b>Step 2</b> | <b>router bgp <i>autonomous-system</i></b><br><br><b>Example:</b><br>Switch(config)# router bgp 100                                                                                | Enters BGP router configuration mode.                                                                             |
| <b>Step 3</b> | <b>bgp confederation identifier <i>autonomous-system</i></b><br><br><b>Example:</b><br>Switch(config)# bgp confederation identifier 50007                                          | Configures a BGP confederation identifier.                                                                        |
| <b>Step 4</b> | <b>bgp confederation peers <i>autonomous-system</i></b><br>[ <i>autonomous-system ...</i> ]<br><br><b>Example:</b><br>Switch(config)# bgp confederation peers 51000 51001<br>51002 | Specifies the autonomous systems that belong to the confederation and that will be treated as special EBGP peers. |
| <b>Step 5</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config)# end                                                                                                                           | Returns to privileged EXEC mode.                                                                                  |
| <b>Step 6</b> | <b>show ip bgp neighbor</b><br><br><b>Example:</b><br>Switch# show ip bgp neighbor                                                                                                 | Verifies the configuration.                                                                                       |

| <b>Step 8</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config                                                                     | (Optional) Saves your entries in the configuration file.                                                          |

## Configuring BGP Route Reflectors

### DETAILED STEPS

|               | Command or Action                                                                                                                                                                        | Purpose                                                                                                                                                                                                                                               |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                                                                                           | Enters global configuration mode.                                                                                                                                                                                                                     |
| <b>Step 2</b> | <b>router bgp <i>autonomous-system</i></b><br><br><b>Example:</b><br>Switch(config)# router bgp 101                                                                                      | Enters BGP router configuration mode.                                                                                                                                                                                                                 |
| <b>Step 3</b> | <b>neighbor {<i>ip-address</i>   <i>peer-group-name</i>}<br/>route-reflector-client</b><br><br><b>Example:</b><br>Switch(config-router)# neighbor 172.16.70.24<br>route-reflector-client | Configures the local router as a BGP route reflector and the specified neighbor as a client.                                                                                                                                                          |
| <b>Step 4</b> | <b>bgp cluster-id <i>cluster-id</i></b><br><br><b>Example:</b><br>Switch(config-router)# bgp cluster-id 10.0.1.2                                                                         | (Optional) Configures the cluster ID if the cluster has more than one route reflector.                                                                                                                                                                |
| <b>Step 5</b> | <b>no bgp client-to-client reflection</b><br><br><b>Example:</b><br>Switch(config-router)# no bgp client-to-client<br>reflection                                                         | (Optional) Disables client-to-client route reflection. By default, the routes from a route reflector client are reflected to other clients. However, if the clients are fully meshed, the route reflector does not need to reflect routes to clients. |
| <b>Step 6</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config-router)# end                                                                                                                          | Returns to privileged EXEC mode.                                                                                                                                                                                                                      |
| <b>Step 7</b> | <b>show ip bgp</b><br><br><b>Example:</b><br>Switch# show ip bgp                                                                                                                         | Verifies the configuration. Displays the originator ID and the cluster-list attributes.                                                                                                                                                               |
| <b>Step 8</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config                                                                           | (Optional) Saves your entries in the configuration file.                                                                                                                                                                                              |

## Configuring Route Dampening

### DETAILED STEPS

|               | Command or Action                                                                                                                                                                                   | Purpose                                                                                                                                  |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                                                                                                      | Enters global configuration mode.                                                                                                        |
| <b>Step 2</b> | <b>router bgp <i>autonomous-system</i></b><br><br><b>Example:</b><br>Switch(config)# router bgp 100                                                                                                 | Enters BGP router configuration mode.                                                                                                    |
| <b>Step 3</b> | <b>bgp dampening</b><br><br><b>Example:</b><br>Switch(config-router)# bgp dampening                                                                                                                 | Enables BGP route dampening.                                                                                                             |
| <b>Step 4</b> | <b>bgp dampening <i>half-life reuse suppress max-suppress</i></b><br><b>[<i>route-map map</i>]</b><br><br><b>Example:</b><br>Switch(config-router)# bgp dampening 30 1500 10000<br>120              | (Optional) Changes the default values of route dampening factors.                                                                        |
| <b>Step 5</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config-router)# end                                                                                                                                     | Returns to privileged EXEC mode.                                                                                                         |
| <b>Step 6</b> | <b>show ip bgp flap-statistics</b> [{ <i>regexp regexp</i> }   { <i>filter-list list</i> }   { <i>address mask [longer-prefix]</i> }]<br><br><b>Example:</b><br>Switch# show ip bgp flap-statistics | (Optional) Monitors the flaps of all paths that are flapping. The statistics are deleted when the route is not suppressed and is stable. |
| <b>Step 7</b> | <b>show ip bgp dampened-paths</b><br><br><b>Example:</b><br>Switch# show pi bgp dampened-paths                                                                                                      | (Optional) Displays the dampened routes, including the time remaining before they are suppressed.                                        |

|                | Command or Action                                                                                                                                                                                 | Purpose                                                                                     |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|
| <b>Step 8</b>  | <b>clear ip bgp flap-statistics</b> [ <i>{regexp regexp}</i>   <i>{filter-list list}</i>   <i>{address mask [longer-prefix]}</i> ]<br><br><b>Example:</b><br>Switch# clear ip bgp flap-statistics | (Optional) Clears BGP flap statistics to make it less likely that a route will be dampened. |
| <b>Step 9</b>  | <b>clear ip bgp dampening</b><br><br><b>Example:</b><br>Switch# clear ip bgp dampening                                                                                                            | (Optional) Clears route dampening information, and unsuppress the suppressed routes.        |
| <b>Step 10</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config                                                                                    | (Optional) Saves your entries in the configuration file.                                    |

## Monitoring and Maintaining BGP

You can remove all contents of a particular cache, table, or database. This might be necessary when the contents of the particular structure have become or are suspected to be invalid.

You can display specific statistics, such as the contents of BGP routing tables, caches, and databases. You can use the information to get resource utilization and solve network problems. You can also display information about node reachability and discover the routing path your device's packets are taking through the network.

Table 41-8 lists the privileged EXEC commands for clearing and displaying BGP. For explanations of the display fields, see the *Cisco IOS IP Command Reference, Volume 2 of 3: Routing Protocols, Release 12.4*.

**Table 106: IP BGP Clear and Show Commands**

|                                           |                                                                                                                                                                      |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>clear ip bgp</b> <i>address</i>        | Resets a particular BGP connection.                                                                                                                                  |
| <b>clear ip bgp</b> *                     | Resets all BGP connections.                                                                                                                                          |
| <b>clear ip bgp peer-group</b> <i>tag</i> | Removes all members of a BGP peer group.                                                                                                                             |
| <b>show ip bgp</b> <i>prefix</i>          | Displays peer groups and peers not in peer groups to which the prefix has been advertised. Also display prefix attributes such as the next hop and the local prefix. |
| <b>show ip bgp cidr-only</b>              | Displays all BGP routes that contain subnet and supernet network masks.                                                                                              |

|                                                                                                                                                                                                                           |                                                                                                                     |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| <b>show ip bgp community</b> [ <i>community-number</i> ]<br>[ <b>exact</b> ]                                                                                                                                              | Displays routes that belong to the specified communities.                                                           |
| <b>show ip bgp community-list</b><br><i>community-list-number</i> [ <b>exact-match</b> ]                                                                                                                                  | Displays routes that are permitted by the community list.                                                           |
| <b>show ip bgp filter-list</b> <i>access-list-number</i>                                                                                                                                                                  | Displays routes that are matched by the specified AS path access list.                                              |
| <b>show ip bgp inconsistent-as</b>                                                                                                                                                                                        | Displays the routes with inconsistent originating autonomous systems.                                               |
| <b>show ip bgp regexp</b> <i>regular-expression</i>                                                                                                                                                                       | Displays the routes that have an AS path that matches the specified regular expression entered on the command line. |
| <b>show ip bgp</b>                                                                                                                                                                                                        | Displays the contents of the BGP routing table.                                                                     |
| <b>show ip bgp neighbors</b> [ <i>address</i> ]                                                                                                                                                                           | Displays detailed information on the BGP and TCP connections to individual neighbors.                               |
| <b>show ip bgp neighbors</b> [ <i>address</i> ]<br>[ <b>advertised-routes</b>   <b>dampened-routes</b>  <br><b>flap-statistics</b>   <b>paths</b> <i>regular-expression</i>  <br><b>received-routes</b>   <b>routes</b> ] | Displays routes learned from a particular BGP neighbor.                                                             |
| <b>show ip bgp paths</b>                                                                                                                                                                                                  | Displays all BGP paths in the database.                                                                             |
| <b>show ip bgp peer-group</b> [ <i>tag</i> ] [ <b>summary</b> ]                                                                                                                                                           | Displays information about BGP peer groups.                                                                         |
| <b>show ip bgp summary</b>                                                                                                                                                                                                | Displays the status of all BGP connections.                                                                         |

The **bgp log-neighbor changes** command is enabled by default. It allows to log messages that are generated when a BGP neighbor resets, comes up, or goes down.

## Configuration Examples for BGP

### Example: Configuring BGP on Routers

In Figure 41-5

Router A:

```
Switch(config)# router bgp 100
Switch(config-router)# neighbor 129.213.1.1 remote-as 200
```

Router B:

```
Switch(config)# router bgp 200
```

```
Switch(config-router)# neighbor 129.213.1.2 remote-as 100
Switch(config-router)# neighbor 175.220.1.2 remote-as 200
```

Router C:

```
Switch(config)# router bgp 200
Switch(config-router)# neighbor 175.220.212.1 remote-as 200
Switch(config-router)# neighbor 192.208.10.1 remote-as 300
```

Router D:

```
Switch(config)# router bgp 300
Switch(config-router)# neighbor 192.208.10.2 remote-as 200
```

To verify that BGP peers are running, use the `show ip bgp neighbors` privileged EXEC command. This is the output of this command on Router A:

```
Switch# show ip bgp neighbors

BGP neighbor is 129.213.1.1, remote AS 200, external link
BGP version 4, remote router ID 175.220.212.1
BGP state = established, table version = 3, up for 0:10:59
Last read 0:00:29, hold time is 180, keepalive interval is 60 seconds
Minimum time between advertisement runs is 30 seconds
Received 2828 messages, 0 notifications, 0 in queue
Sent 2826 messages, 0 notifications, 0 in queue
Connections established 11; dropped 10
```

Anything other than *state = established* means that the peers are not running. The remote router ID is the highest IP address on that router (or the highest loopback interface). Each time the table is updated with new information, the table version number increments. A table version number that continually increments means that a route is flapping, causing continual routing updates.

For exterior protocols, a reference to an IP network from the **network** router configuration command controls only which networks are advertised. This is in contrast to Interior Gateway Protocols (IGPs), such as EIGRP, which also use the **network** command to specify where to send updates.

For detailed descriptions of BGP configuration, see the “IP Routing Protocols” part of the *Cisco IOS IP Configuration Guide, Release 12.4*. For details about specific commands, see the *Cisco IOS IP Command Reference, Volume 2 of 3: Routing Protocols, Release 12.4*.

## Information About ISO CLNS Routing

### Connectionless Routing

The International Organization for Standardization (ISO) Connectionless Network Service (CLNS) protocol is a standard for the network layer of the Open System Interconnection (OSI) model. Addresses in the ISO network architecture are referred to as network service access point (NSAP) addresses and network entity titles (NETs). Each node in an OSI network has one or more NETs. In addition, each node has many NSAP addresses.

When you enable connectionless routing on the switch by using the **clns routing** global configuration command, the switch makes only forwarding decisions, with no routing-related functionality. For dynamic routing, you must also enable a routing protocol. The switch supports the Intermediate System-to-Intermediate System (IS-IS) dynamic routing protocol that is based on the OSI routing protocol for ISO CLNS networks.

When dynamically routing, you use IS-IS. This routing protocol supports the concept of areas. Within an area, all routers know how to reach all the system IDs. Between areas, routers know how to reach the proper area. IS-IS supports two levels of routing: station routing (within an area) and area routing (between areas).

The key difference between the ISO IGRP and IS-IS NSAP addressing schemes is in the definition of area addresses. Both use the system ID for Level 1 routing (routing within an area). However, they differ in the way addresses are specified for area routing. An ISO IGRP NSAP address includes three separate fields for routing: the domain, area, and system ID. An IS-IS address includes two fields: a single continuous area field (comprising the domain and area fields) and the system ID.

**Note**

For more detailed information about ISO CLNS, see the *Cisco IOS Apollo Domain, Banyan VINES, DECnet, ISO CLNS and XNS Configuration Guide, Release 12.4*. For complete syntax and usage information for the commands used in this chapter, see the *Cisco IOS Apollo Domain, Banyan VINES, DECnet, ISO CLNS and XNS Command Reference, Release 12.4*, use the IOS command reference master index, or search online.

## IS-IS Dynamic Routing

IS-IS is an ISO dynamic routing protocol (described in ISO 105890). Unlike other routing protocols, enabling IS-IS requires that you create an IS-IS routing process and assign it to a specific interface, rather than to a network. You can specify more than one IS-IS routing process per Layer 3 switch or router by using the multiarea IS-IS configuration syntax. You then configure the parameters for each instance of the IS-IS routing process.

Small IS-IS networks are built as a single area that includes all the routers in the network. As the network grows larger, it is usually reorganized into a backbone area made up of the connected set of all Level 2 routers from all areas, which is in turn connected to local areas. Within a local area, routers know how to reach all system IDs. Between areas, routers know how to reach the backbone, and the backbone routers know how to reach other areas.

Routers establish Level 1 adjacencies to perform routing within a local area (station routing). Routers establish Level 2 adjacencies to perform routing between Level 1 areas (area routing).

A single Cisco router can participate in routing in up to 29 areas and can perform Level 2 routing in the backbone. In general, each routing process corresponds to an area. By default, the first instance of the routing process configured performs both Level 1 and Level 2 routing. You can configure additional router instances, which are automatically treated as Level 1 areas. You must configure the parameters for each instance of the IS-IS routing process individually.

For IS-IS multiarea routing, you can configure only one process to perform Level 2 routing, although you can define up to 29 Level 1 areas for each Cisco unit. If Level 2 routing is configured on any process, all additional processes are automatically configured as Level 1. You can configure this process to perform Level 1 routing at the same time. If Level 2 routing is not desired for a router instance, remove the Level 2 capability using the **is-type** global configuration command. Use the **is-type** command also to configure a different router instance as a Level 2 router.

**Note**

For more detailed information about IS-IS, see the “IP Routing Protocols” chapter of the *Cisco IOS IP Configuration Guide, Release 12.4*. For complete syntax and usage information for the commands used in this section, see the *Cisco IOS IP Command Reference, Release 12.4*.

## Nonstop Forwarding Awareness

The integrated IS-IS NSF Awareness feature is supported for IPv4G. The feature allows customer premises equipment (CPE) routers that are NSF-aware to help NSF-capable routers perform nonstop forwarding of packets. The local router is not necessarily performing NSF, but its awareness of NSF allows the integrity and accuracy of the routing database and link-state database on the neighboring NSF-capable router to be maintained during the switchover process.

This feature is automatically enabled and requires no configuration. For more information on this feature, see the *Integrated IS-IS Nonstop Forwarding (NSF) Awareness Feature Guide*.

## IS-IS Global Parameters

These are some optional IS-IS global parameters that you can configure:

- You can force a default route into an IS-IS routing domain by configuring a default route controlled by a route map. You can also specify other filtering options configurable under a route map.
- You can configure the router to ignore IS-IS LSPs that are received with internal checksum errors or to purge corrupted LSPs, which causes the initiator of the LSP to regenerate it.
- You can assign passwords to areas and domains.
- You can create aggregate addresses that are represented in the routing table by a summary address (route-summarization). Routes learned from other routing protocols can also be summarized. The metric used to advertise the summary is the smallest metric of all the specific routes.
- You can set an overload bit.
- You can configure the LSP refresh interval and the maximum time that an LSP can remain in the router database without a refresh.
- You can set the throttling timers for LSP generation, shortest path first computation, and partial route computation.
- You can configure the switch to generate a log message when an IS-IS adjacency changes state (up or down).
- If a link in the network has a maximum transmission unit (MTU) size of less than 1500 bytes, you can lower the LSP MTU so that routing will still occur.
- The partition avoidance router configuration command prevents an area from becoming partitioned when full connectivity is lost among a Level1-2 border router, adjacent Level 1 routers, and end hosts.

## IS-IS Interface Parameters

You can optionally configure certain interface-specific IS-IS parameters, independently from other attached routers. However, if you change some values from the defaults, such as multipliers and time intervals, it makes sense to also change them on multiple routers and interfaces. Most of the interface parameters can be configured for level 1, level 2, or both.

These are some interface level parameters you can configure:

- The default metric on the interface, which is used as a value for the IS-IS metric and assigned when there is no quality of service (QoS) routing performed.

- The hello interval (length of time between hello packets sent on the interface) or the default hello packet multiplier used on the interface to determine the hold time sent in IS-IS hello packets. The hold time determines how long a neighbor waits for another hello packet before declaring the neighbor down. This determines how quickly a failed link or neighbor is detected so that routes can be recalculated. Change the hello-multiplier in circumstances where hello packets are lost frequently and IS-IS adjacencies are failing unnecessarily. You can raise the hello multiplier and lower the hello interval correspondingly to make the hello protocol more reliable without increasing the time required to detect a link failure.
- Other time intervals:
  - Complete sequence number PDU (CSNP) interval. CSNPs are sent by the designated router to maintain database synchronization
  - Retransmission interval. This is the time between retransmission of IS-IS LSPs for point-to-point links.
  - IS-IS LSP retransmission throttle interval. This is the maximum rate (number of milliseconds between packets) at which IS-IS LSPs are re-sent on point-to-point links. This interval is different from the retransmission interval, which is the time between successive retransmissions of the same LSP
- Designated router election priority, which allows you to reduce the number of adjacencies required on a multiaccess network, which in turn reduces the amount of routing protocol traffic and the size of the topology database.
- The interface circuit type, which is the type of adjacency desired for neighbors on the specified interface
- Password authentication for the interface

## How to Configure ISO CLNS Routing

### Default IS-IS Configuration

**Table 107: Default IS-IS Configuration**

| Feature                            | Default Setting                                                                                                                                                                                                                      |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Ignore link-state PDU (LSP) errors | Enabled.                                                                                                                                                                                                                             |
| IS-IS type                         | Conventional IS-IS: the router acts as both a Level 1 (station) and a Level 2 (area) router.<br><br>Multiarea IS-IS: the first instance of the IS-IS routing process is a Level 1-2 router. Remaining instances are Level 1 routers. |
| Default-information originate      | Disabled.                                                                                                                                                                                                                            |
| Log IS-IS adjacency state changes. | Disabled.                                                                                                                                                                                                                            |

| Feature                                           | Default Setting                                                                                                                                                                        |
|---------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LSP generation throttling timers                  | Maximum interval between two consecutive occurrences: 5 seconds.<br>Initial LSP generation delay: 50 ms.<br>Hold time between the first and second LSP generation: 5000 ms.            |
| LSP maximum lifetime (without a refresh)          | 1200 seconds (20 minutes) before the LSP packet is deleted.                                                                                                                            |
| LSP refresh interval                              | Send LSP refreshes every 900 seconds (15 minutes).                                                                                                                                     |
| Maximum LSP packet size                           | 1497 bytes.                                                                                                                                                                            |
| NSF Awareness                                     | Enabled. Allows Layer 3 switches to continue forwarding packets from a neighboring NSF-capable router during hardware or software changes.                                             |
| Partial route computation (PRC) throttling timers | Maximum PRC wait interval: 5 seconds.<br>Initial PRC calculation delay after a topology change: 2000 ms.<br>Hold time between the first and second PRC calculation: 5000 ms.           |
| Partition avoidance                               | Disabled.                                                                                                                                                                              |
| Password                                          | No area or domain password is defined, and authentication is disabled.                                                                                                                 |
| Set-overload-bit                                  | Disabled. When enabled, if no arguments are entered, the overload bit is set immediately and remains set until you enter the <b>no set-overload-bit</b> command.                       |
| Shortest path first (SPF) throttling timers       | Maximum interval between consecutive SFPS: 10 seconds.<br>Initial SFP calculation after a topology change: 5500 ms.<br>Holdtime between the first and second SFP calculation: 5500 ms. |
| Summary-address                                   | Disabled.                                                                                                                                                                              |

## Enabling IS-IS Routing

To enable IS-IS, you specify a name and NET for each routing process. You then enable IS-IS routing on the interface and specify the area for each instance of the routing process.

## DETAILED STEPS

|               | Command or Action                                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------|------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                               | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Step 2</b> | <b>clns routing</b><br><br><b>Example:</b><br>Switch(config)# clns routing                                                   | Enables ISO connectionless routing on the switch.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Step 3</b> | <b>router isis [area tag]</b><br><br><b>Example:</b><br>Switch(config)# router isis tag1                                     | Enables the IS-IS routing for the specified routing process and enter IS-IS routing configuration mode.<br><br>(Optional) Use the <i>area tag</i> argument to identify the area to which the IS-IS router is assigned. You must enter a value if you are configuring multiple IS-IS areas.<br><br>The first IS-IS instance configured is Level 1-2 by default. Later instances are automatically Level 1. You can change the level of routing by using the <b>is-type</b> global configuration command. |
| <b>Step 4</b> | <b>net network-entity-title</b><br><br><b>Example:</b><br>Switch(config-router)# net<br>47.0004.004d.0001.0001.0c11.1111.00  | Configures the NETs for the routing process. If you are configuring multiarea IS-IS, specify a NET for each routing process. You can specify a name for a NET and for an address.                                                                                                                                                                                                                                                                                                                       |
| <b>Step 5</b> | <b>is-type {level-1   level-1-2   level-2-only}</b><br><br><b>Example:</b><br>Switch(config-router)# is-type<br>level-2-only | (Optional) Configures the router to act as a Level 1 (station) router, a Level 2 (area) router for multi-area routing, or both (the default): <ul style="list-style-type: none"> <li>• <b>level-1</b>—act as a station router only</li> <li>• <b>level-1-2</b>—act as both a station router and an area router</li> <li>• <b>level 2</b>—act as an area router only</li> </ul>                                                                                                                          |
| <b>Step 6</b> | <b>exit</b><br><br><b>Example:</b><br>Switch(config-router)# end                                                             | Returns to global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Step 7</b> | <b>interface interface-id</b><br><br><b>Example:</b><br>Switch(config)# interface gigabitethernet<br>1/0/1                   | Specifies an interface to route IS-IS, and enter interface configuration mode. If the interface is not already configured as a Layer 3 interface, enter the <b>no switchport</b> command to put it into Layer 3 mode.                                                                                                                                                                                                                                                                                   |

|                | Command or Action                                                                                                          | Purpose                                                                                                                                                                 |
|----------------|----------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 8</b>  | <b>ip router isis</b> [ <i>area tag</i> ]<br><br><b>Example:</b><br>Switch(config-if)# ip router isis tag1                 | Configures an IS-IS routing process for ISO CLNS on the interface and attach an area designator to the routing process.                                                 |
| <b>Step 9</b>  | <b>clns router isis</b> [ <i>area tag</i> ]<br><br><b>Example:</b><br>Switch(config-if)# clns router isis tag1             | Enables ISO CLNS on the interface.                                                                                                                                      |
| <b>Step 10</b> | <b>ip address</b> <i>ip-address-mask</i><br><br><b>Example:</b><br>Switch(config-if)# ip address 10.0.0.5<br>255.255.255.0 | Define the IP address for the interface. An IP address is required on all interfaces in an area enabled for IS-IS if any one interface is configured for IS-IS routing. |
| <b>Step 11</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config-if)# end                                                                | Returns to privileged EXEC mode.                                                                                                                                        |
| <b>Step 12</b> | <b>show isis</b> [ <i>area tag</i> ] <b>database detail</b><br><br><b>Example:</b><br>Switch# show isis database detail    | Verifies your entries.                                                                                                                                                  |
| <b>Step 13</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config<br>startup-config          | (Optional) Saves your entries in the configuration file.                                                                                                                |

## Configuring IS-IS Global Parameters

### DETAILED STEPS

|               | Command or Action                                                              | Purpose                           |
|---------------|--------------------------------------------------------------------------------|-----------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal | Enters global configuration mode. |

|               | Command or Action                                                                                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                                                              |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 2</b> | <b>clns routing</b><br><br><b>Example:</b><br><pre>Switch(config)# clns routing</pre>                                                                                        | Enables ISO connectionless routing on the switch.                                                                                                                                                                                                                                                                                                                                    |
| <b>Step 3</b> | <b>router isis</b><br><br><b>Example:</b><br><pre>Switch(config)# router isis</pre>                                                                                          | Specifies the IS-IS routing protocol and enter router configuration mode.                                                                                                                                                                                                                                                                                                            |
| <b>Step 4</b> | <b>default-information originate [route-map map-name]</b><br><br><b>Example:</b><br><pre>Switch(config-router)# default-information originate route-map map1</pre>           | (Optional) Forces a default route into the IS-IS routing domain. If you enter <b>route-map map-name</b> , the routing process generates the default route if the route map is satisfied.                                                                                                                                                                                             |
| <b>Step 5</b> | <b>ignore-lsp-errors</b><br><br><b>Example:</b><br><pre>Switch(config-router)# ignore-lsp-errors</pre>                                                                       | (Optional) Configures the router to ignore LSPs with internal checksum errors, instead of purging the LSPs. This command is enabled by default (corrupted LSPs are dropped). To purge the corrupted LSPs, enter the <b>no ignore-lsp-errors</b> router configuration command.                                                                                                        |
| <b>Step 6</b> | <b>area-password password</b><br><br><b>Example:</b><br><pre>Switch(config-router)# area-password 1password</pre>                                                            | (Optional) Configures the area authentication password, which is inserted in Level 1 (station router level) LSPs.                                                                                                                                                                                                                                                                    |
| <b>Step 7</b> | <b>domain-password password</b><br><br><b>Example:</b><br><pre>Switch(config-router)# domain-password 2password</pre>                                                        | (Optional) Configures the routing domain authentication password, which is inserted in Level 2 (area router level) LSPs.                                                                                                                                                                                                                                                             |
| <b>Step 8</b> | <b>summary-address address mask [level-1   level-1-2   level-2]</b><br><br><b>Example:</b><br><pre>Switch(config-router)# summary-address 10.1.0.0 255.255.0.0 level-2</pre> | (Optional) Creates a summary of addresses for a given level.                                                                                                                                                                                                                                                                                                                         |
| <b>Step 9</b> | <b>set-overload-bit [on-startup {seconds   wait-for-bgp}]</b><br><br><b>Example:</b><br><pre>Switch(config-router)#</pre>                                                    | (Optional) Sets an overload bit (a hippity bit) to allow other routers to ignore the router in their shortest path first (SPF) calculations if the router is having problems. <ul style="list-style-type: none"> <li>• (Optional) <b>on-startup</b>—sets the overload bit only on startup. If <b>on-startup</b> is not specified, the overload bit is set immediately and</li> </ul> |

|                | Command or Action                                                                                                                                                                                                                        | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | <pre>set-overload-bit on-startup wait-for-bgp</pre>                                                                                                                                                                                      | <p>remains set until you enter the <b>no set-overload-bit</b> command. If <b>on-startup</b> is specified, you must enter a number of seconds or <b>wait-for-bgp</b>.</p> <ul style="list-style-type: none"> <li>• <b>seconds</b>—When the <b>on-startup</b> keyword is configured, causes the overload bit to be set upon system startup and remain set for this number of seconds. The range is from 5 to 86400 seconds.</li> <li>• <b>wait-for-bgp</b>—When the <b>on-startup</b> keyword is configured, causes the overload bit to be set upon system startup and remain set until BGP has converged. If BGP does not signal IS-IS that it is converged, IS-IS will turn off the overload bit after 10 minutes.</li> </ul> |
| <b>Step 10</b> | <p><b>lsp-refresh-interval</b> <i>seconds</i></p> <p><b>Example:</b></p> <pre>Switch(config-router)# lsp-refresh-interval 1080</pre>                                                                                                     | (Optional) Sets an LSP refresh interval in seconds. The range is from 1 to 65535 seconds. The default is to send LSP refreshes every 900 seconds (15 minutes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Step 11</b> | <p><b>max-lsp-lifetime</b> <i>seconds</i></p> <p><b>Example:</b></p> <pre>Switch(config-router)# max-lsp-lifetime 1000</pre>                                                                                                             | (Optional) Sets the maximum time that LSP packets remain in the router database without being refreshed. The range is from 1 to 65535 seconds. The default is 1200 seconds (20 minutes). After the specified time interval, the LSP packet is deleted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Step 12</b> | <p><b>lsp-gen-interval</b> [<b>level-1</b>   <b>level-2</b>]<br/><i>lsp-max-wait</i> [<i>lsp-initial-wait</i><br/><i>lsp-second-wait</i>]</p> <p><b>Example:</b></p> <pre>Switch(config-router)# lsp-gen-interval level-2 2 50 100</pre> | (Optional) Sets the IS-IS LSP generation throttling timers: <ul style="list-style-type: none"> <li>• <i>lsp-max-wait</i>—the maximum interval (in seconds) between two consecutive occurrences of an LSP being generated. The range is 1 to 120, the default is 5.</li> <li>• <i>lsp-initial-wait</i>—the initial LSP generation delay (in milliseconds). The range is 1 to 10000; the default is 50.</li> <li>• <i>lsp-second-wait</i>—the hold time between the first and second LSP generation (in milliseconds). The range is 1 to 10000; the default is 5000.</li> </ul>                                                                                                                                                 |
| <b>Step 13</b> | <p><b>spf-interval</b> [<b>level-1</b>   <b>level-2</b>] <i>spf-max-wait</i><br/>[<i>spf-initial-wait</i> <i>spf-second-wait</i>]</p> <p><b>Example:</b></p> <pre>Switch(config-router)# spf-interval level-2 5 10 20</pre>              | (Optional) Sets IS-IS shortest path first (SPF) throttling timers. <ul style="list-style-type: none"> <li>• <i>spf-max-wait</i>—the maximum interval between consecutive SFPs (in seconds). The range is 1 to 120, the default is 10.</li> <li>• <i>spf-initial-wait</i>—the initial SFP calculation after a topology change (in milliseconds). The range is 1 to 10000; the default is 5500.</li> <li>• <i>spf-second-wait</i>—the holdtime between the first and second SFP calculation (in milliseconds). The range is 1 to 10000; the default is 5500.</li> </ul>                                                                                                                                                         |

|         | Command or Action                                                                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 14 | <p><b>pre-interval</b> <i>prc-max-wait</i> [<i>prc-initial-wait</i> <i>prc-second-wait</i>]</p> <p><b>Example:</b></p> <pre>Switch(config-router)# pre-interval 5 10 20</pre> | <p>(Optional) Sets IS-IS partial route computation (PRC) throttling timers.</p> <ul style="list-style-type: none"> <li>• <i>prc-max-wait</i>—the maximum interval (in seconds) between two consecutive PRC calculations. The range is 1 to 120; the default is 5.</li> <li>• <i>prc-initial-wait</i>—the initial PRC calculation delay (in milliseconds) after a topology change. The range is 1 to 10,000; the default is 2000.</li> <li>• <i>prc-second-wait</i>—the hold time between the first and second PRC calculation (in milliseconds). The range is 1 to 10,000; the default is 5000.</li> </ul> |
| Step 15 | <p><b>log-adjacency-changes</b> [<b>all</b>]</p> <p><b>Example:</b></p> <pre>Switch(config-router)# log-adjacency-changes all</pre>                                           | <p>(Optional) Sets the router to log IS-IS adjacency state changes. Enter <b>all</b> to include all changes generated by events that are not related to the Intermediate System-to-Intermediate System Hellos, including End System-to-Intermediate System PDUs and link state packets (LSPs).</p>                                                                                                                                                                                                                                                                                                         |
| Step 16 | <p><b>lsp-mtu</b> <i>size</i></p> <p><b>Example:</b></p> <pre>Switch(config-router)# lsp mtu 1560</pre>                                                                       | <p>(Optional) Specifies the maximum LSP packet size in bytes. The range is 128 to 4352; the default is 1497 bytes.</p> <p><b>Note</b> If any link in the network has a reduced MTU size, you must change the LSP MTU size on all routers in the network.</p>                                                                                                                                                                                                                                                                                                                                               |
| Step 17 | <p><b>partition avoidance</b></p> <p><b>Example:</b></p> <pre>Switch(config-router)# partition avoidance</pre>                                                                | <p>(Optional) Causes an IS-IS Level 1-2 border router to stop advertising the Level 1 area prefix into the Level 2 backbone when full connectivity is lost among the border router, all adjacent level 1 routers, and end hosts.</p>                                                                                                                                                                                                                                                                                                                                                                       |
| Step 18 | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Switch(config-router)# end</pre>                                                                                                | <p>Returns to privileged EXEC mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Step 19 | <p><b>show clns</b></p> <p><b>Example:</b></p> <pre>Switch# show clns</pre>                                                                                                   | <p>Verifies your entries.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Step 20 | <p><b>copy running-config startup-config</b></p> <p><b>Example:</b></p> <pre>Switch# copy running-config startup-config</pre>                                                 | <p>(Optional) Saves your entries in the configuration file.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Configuring IS-IS Interface Parameters

### DETAILED STEPS

|               | Command or Action                                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                                                        | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Step 2</b> | <b>interface <i>interface-id</i></b><br><br><b>Example:</b><br>Switch(config)# interface<br>gigabitethernet 1/0/1                                     | Specifies the interface to be configured and enter interface configuration mode. If the interface is not already configured as a Layer 3 interface, enter the <b>no switchport</b> command to put it into Layer 3 mode.                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Step 3</b> | <b>isis metric <i>default-metric</i> [level-1   level-2]</b><br><br><b>Example:</b><br>Switch(config-if)# isis metric 15                              | (Optional) Configures the metric (or cost) for the specified interface. The range is from 0 to 63. The default is 10. If no level is entered, the default is to apply to both Level 1 and Level 2 routers.                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Step 4</b> | <b>isis hello-interval {<i>seconds</i>   minimal} [level-1   level-2]</b><br><br><b>Example:</b><br>Switch(config-if)# isis hello-interval<br>minimal | (Optional) Specifies the length of time between hello packets sent by the switch. By default, a value three times the hello interval <i>seconds</i> is advertised as the <i>holdtime</i> in the hello packets sent. With smaller hello intervals, topological changes are detected faster, but there is more routing traffic. <ul style="list-style-type: none"> <li>• <b>minimal</b>—causes the system to compute the hello interval based on the hello multiplier so that the resulting hold time is 1 second.</li> <li>• <b>seconds</b>—the range is from 1 to 65535. The default is 10 seconds.</li> </ul> |
| <b>Step 5</b> | <b>isis hello-multiplier <i>multiplier</i> [level-1   level-2]</b><br><br><b>Example:</b><br>Switch(config-if)# isis<br>hello-multiplier 5            | (Optional) Specifies the number of IS-IS hello packets a neighbor must miss before the router should declare the adjacency as down. The range is from 3 to 1000. The default is 3. Using a smaller hello-multiplier causes fast convergence, but can result in more routing instability.                                                                                                                                                                                                                                                                                                                       |
| <b>Step 6</b> | <b>isis csnp-interval <i>seconds</i> [level-1   level-2]</b><br><br><b>Example:</b><br>Switch(config-if)# isis csnp-interval<br>15                    | (Optional) Configures the IS-IS complete sequence number PDU (CSNP) interval for the interface. The range is from 0 to 65535. The default is 10 seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|                | Command or Action                                                                                                                                                        | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 7</b>  | <b>isis retransmit-interval</b> <i>seconds</i><br><br><b>Example:</b><br><pre>Switch(config-if)# isis retransmit-interval 7</pre>                                        | (Optional) Configures the number of seconds between retransmission of IS-IS LSPs for point-to-point links. The value you specify should be an integer greater than the expected round-trip delay between any two routers on the network. The range is from 0 to 65535. The default is 5 seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Step 8</b>  | <b>isis retransmit-throttle-interval</b> <i>milliseconds</i><br><br><b>Example:</b><br><pre>Switch(config-if)# isis retransmit-throttle-interval 4000</pre>              | (Optional) Configures the IS-IS LSP retransmission throttle interval, which is the maximum rate (number of milliseconds between packets) at which IS-IS LSPs will be re-sent on point-to-point links. The range is from 0 to 65535. The default is determined by the <b>isis lsp-interval</b> command.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Step 9</b>  | <b>isis priority</b> <i>value</i> [ <b>level-1</b>   <b>level-2</b> ]<br><br><b>Example:</b><br><pre>Switch(config-if)# isis priority 50</pre>                           | (Optional) Configures the priority to use for designated router election. The range is from 0 to 127. The default is 64.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Step 10</b> | <b>isis circuit-type</b> { <b>level-1</b>   <b>level-1-2</b>   <b>level-2-only</b> }<br><br><b>Example:</b><br><pre>Switch(config-if)# isis circuit-type level-1-2</pre> | (Optional) Configures the type of adjacency desired for neighbors on the specified interface (specify the interface circuit type). <ul style="list-style-type: none"> <li>• <b>level-1</b>—a Level 1 adjacency is established if there is at least one area address common to both this node and its neighbors.</li> <li>• <b>level-1-2</b>—a Level 1 and 2 adjacency is established if the neighbor is also configured as both Level 1 and Level 2 and there is at least one area in common. If there is no area in common, a Level 2 adjacency is established. This is the default.</li> <li>• <b>level 2</b>—a Level 2 adjacency is established. If the neighbor router is a Level 1 router, no adjacency is established.</li> </ul> |
| <b>Step 11</b> | <b>isis password</b> <i>password</i> [ <b>level-1</b>   <b>level-2</b> ]<br><br><b>Example:</b><br><pre>Switch(config-if)# isis password secret</pre>                    | (Optional) Configures the authentication password for an interface. By default, authentication is disabled. Specifying Level 1 or Level 2 enables the password only for Level 1 or Level 2 routing, respectively. If you do not specify a level, the default is Level 1 and Level 2.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Step 12</b> | <b>end</b><br><br><b>Example:</b><br><pre>Switch(config-if)# end</pre>                                                                                                   | Returns to privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Step 13</b> | <b>show clns interface</b> <i>interface-id</i><br><br><b>Example:</b><br><pre>Switch# show clns interface gigabitethernet 1/0/1</pre>                                    | Verifies your entries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|         | Command or Action                                                                                                         | Purpose                                                  |
|---------|---------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| Step 14 | <b>copy running-config startup-config</b><br><br><b>Example:</b><br><pre>Switch# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

## Monitoring and Maintaining ISO IGRP and IS-IS

You can remove all contents of a CLNS cache or remove information for a particular neighbor or route. You can display specific CLNS or IS-IS statistics, such as the contents of routing tables, caches, and databases. You can also display information about specific interfaces, filters, or neighbors.

Table 41-13 lists the privileged EXEC commands for clearing and displaying ISO CLNS and IS-IS routing. For explanations of the display fields, see the *Cisco IOS Apollo Domain, Banyan VINES, DECnet, ISO CLNS and XNS Command Reference, Release 12.4*, use the Cisco IOS command reference master index, or search online.

**Table 108: ISO CLNS and IS-IS Clear and Show Commands**

|                                                  |                                                                                    |
|--------------------------------------------------|------------------------------------------------------------------------------------|
| <b>clear clns cache</b>                          | Clears and reinitializes the CLNS routing cache.                                   |
| <b>clear clns es-neighbors</b>                   | Removes end system (ES) neighbor information from the adjacency database.          |
| <b>clear clns is-neighbors</b>                   | Removes intermediate system (IS) neighbor information from the adjacency database. |
| <b>clear clns neighbors</b>                      | Removes CLNS neighbor information from the adjacency database.                     |
| <b>clear clns route</b>                          | Removes dynamically derived CLNS routing information.                              |
| <b>show clns</b>                                 | Displays information about the CLNS network.                                       |
| <b>show clns cache</b>                           | Displays the entries in the CLNS routing cache.                                    |
| <b>show clns es-neighbors</b>                    | Displays ES neighbor entries, including the associated areas.                      |
| <b>show clns filter-expr</b>                     | Displays filter expressions.                                                       |
| <b>show clns filter-set</b>                      | Displays filter sets.                                                              |
| <b>show clns interface</b> <i>[interface-id]</i> | Displays the CLNS-specific or ES-IS information about each interface.              |

|                                                               |                                                                                                   |
|---------------------------------------------------------------|---------------------------------------------------------------------------------------------------|
| <b>show clns neighbor</b>                                     | Displays information about IS-IS neighbors.                                                       |
| <b>show clns protocol</b>                                     | List the protocol-specific information for each IS-IS or ISO IGRP routing process in this router. |
| <b>show clns route</b>                                        | Displays all the destinations to which this router knows how to route CLNS packets.               |
| <b>show clns traffic</b>                                      | Displays information about the CLNS packets this router has seen.                                 |
| <b>show ip route isis</b>                                     | Displays the current state of the ISIS IP routing table.                                          |
| <b>show isis database</b>                                     | Displays the IS-IS link-state database.                                                           |
| <b>show isis routes</b>                                       | Displays the IS-IS Level 1 routing table.                                                         |
| <b>show isis spf-log</b>                                      | Displays a history of the shortest path first (SPF) calculations for IS-IS.                       |
| <b>show isis topology</b>                                     | Displays a list of all connected routers in all areas.                                            |
| <b>show route-map</b>                                         | Displays all route maps configured or only the one specified.                                     |
| <b>trace clns destination</b>                                 | Discover the paths taken to a specified destination by packets in the network.                    |
| <b>which-route</b> { <i>nsap-address</i>   <i>clns-name</i> } | Displays the routing table in which the specified CLNS destination is found.                      |

## Configuration Examples for ISO CLNS Routing

### Example: Configuring IS-IS Routing

This example shows how to configure three routers to run conventional IS-IS as an IP routing protocol. In conventional IS-IS, all routers act as Level 1 and Level 2 routers (by default).

Router A:

```
Switch(config)# clns routing
Switch(config)# router isis
Switch(config-router)# net 49.0001.0000.0000.000a.00
Switch(config-router)# exit
Switch(config)# interface gigabitethernet1/0/1
Switch(config-if)# ip router isis
Switch(config-if)# clns router isis
Switch(config)# interface gigabitethernet1/0/2
Switch(config-if)# ip router isis
Switch(config-if)# clns router isis
Switch(config-router)# exit
```

**Router B:**

```
Switch(config)# clns routing
Switch(config)# router isis
Switch(config-router)# net 49.0001.0000.0000.000b.00
Switch(config-router)# exit
Switch(config)# interface gigabitethernet1/0/1
Switch(config-if)# ip router isis
Switch(config-if)# clns router isis
Switch(config)# interface gigabitethernet1/0/2
Switch(config-if)# ip router isis
Switch(config-if)# clns router isis
Switch(config-router)# exit
```

**Router C:**

```
Switch(config)# clns routing
Switch(config)# router isis
Switch(config-router)# net 49.0001.0000.0000.000c.00
Switch(config-router)# exit
Switch(config)# interface gigabitethernet1/0/1
Switch(config-if)# ip router isis
Switch(config-if)# clns router isis
Switch(config)# interface gigabitethernet1/0/2
Switch(config-if)# ip router isis
Switch(config-if)# clns router isis
Switch(config-router)# exit
```

## Information About Multi-VRF CE

Virtual Private Networks (VPNs) provide a secure way for customers to share bandwidth over an ISP backbone network. A VPN is a collection of sites sharing a common routing table. A customer site is connected to the service-provider network by one or more interfaces, and the service provider associates each interface with a VPN routing table, called a VPN routing/forwarding (VRF) table.

The switch supports multiple VPN routing/forwarding (multi-VRF) instances in customer edge (CE) devices (multi-VRF CE) when it is running the IP services or advanced IP services feature set. Multi-VRF CE allows a service provider to support two or more VPNs with overlapping IP addresses.

**Note**

---

The switch does not use Multiprotocol Label Switching (MPLS) to support VPNs. For information about MPLS VRF, see the *Cisco IOS Switching Services Configuration Guide, Release 12.4*.

---

## Understanding Multi-VRF CE

Multi-VRF CE is a feature that allows a service provider to support two or more VPNs, where IP addresses can be overlapped among the VPNs. Multi-VRF CE uses input interfaces to distinguish routes for different VPNs and forms virtual packet-forwarding tables by associating one or more Layer 3 interfaces with each VRF. Interfaces in a VRF can be either physical, such as Ethernet ports, or logical, such as VLAN SVIs, but an interface cannot belong to more than one VRF at any time.

**Note**

---

Multi-VRF CE interfaces must be Layer 3 interfaces.

---

Multi-VRF CE includes these devices:

- Customer edge (CE) devices provide customers access to the service-provider network over a data link to one or more provider edge routers. The CE device advertises the site's local routes to the router and learns the remote VPN routes from it. A switch can be a CE.
- Provider edge (PE) routers exchange routing information with CE devices by using static routing or a routing protocol such as BGP, RIPv2, OSPF, or EIGRP. The PE is only required to maintain VPN routes for those VPNs to which it is directly attached, eliminating the need for the PE to maintain all of the service-provider VPN routes. Each PE router maintains a VRF for each of its directly connected sites. Multiple interfaces on a PE router can be associated with a single VRF if all of these sites participate in the same VPN. Each VPN is mapped to a specified VRF. After learning local VPN routes from CEs, a PE router exchanges VPN routing information with other PE routers by using internal BGP (IBGP).
- Provider routers or core routers are any routers in the service provider network that do not attach to CE devices.

With multi-VRF CE, multiple customers can share one CE, and only one physical link is used between the CE and the PE. The shared CE maintains separate VRF tables for each customer and switches or routes packets for each customer based on its own routing table. Multi-VRF CE extends limited PE functionality to a CE device, giving it the ability to maintain separate VRF tables to extend the privacy and security of a VPN to the branch office.

## Network Topology

Figure 41-6 shows a configuration using switches as multiple virtual CEs. This scenario is suited for customers who have low bandwidth requirements for their VPN service, for example, small companies. In this case, multi-VRF CE support is required in the switches. Because multi-VRF CE is a Layer 3 feature, each interface in a VRF must be a Layer 3 interface.

**Figure 69: Switches Acting as Multiple Virtual CEs**

When the CE switch receives a command to add a Layer 3 interface to a VRF, it sets up the appropriate mapping between the VLAN ID and the policy label (PL) in multi-VRF-CE-related data structures and adds the VLAN ID and PL to the VLAN database.

When multi-VRF CE is configured, the Layer 3 forwarding table is conceptually partitioned into two sections:

- The multi-VRF CE routing section contains the routes from different VPNs.
- The global routing section contains routes to non-VPN networks, such as the Internet.

VLAN IDs from different VRFs are mapped into different policy labels, which are used to distinguish the VRFs during processing. For each new VPN route learned, the Layer 3 setup function retrieves the policy label by using the VLAN ID of the ingress port and inserts the policy label and new route to the multi-VRF CE routing section. If the packet is received from a routed port, the port internal VLAN ID number is used; if the packet is received from an SVI, the VLAN number is used.

### Packet-Forwarding Process

This is the packet-forwarding process in a multi-VRF-CE-enabled network:

- When the switch receives a packet from a VPN, the switch looks up the routing table based on the input policy label number. When a route is found, the switch forwards the packet to the PE.
- When the ingress PE receives a packet from the CE, it performs a VRF lookup. When a route is found, the router adds a corresponding MPLS label to the packet and sends it to the MPLS network.
- When an egress PE receives a packet from the network, it strips the label and uses the label to identify the correct VPN routing table. Then it performs the normal route lookup. When a route is found, it forwards the packet to the correct adjacency.
- When a CE receives a packet from an egress PE, it uses the input policy label to look up the correct VPN routing table. If a route is found, it forwards the packet within the VPN.

### Network Components

To configure VRF, you create a VRF table and specify the Layer 3 interface associated with the VRF. Then configure the routing protocols in the VPN and between the CE and the PE. BGP is the preferred routing protocol used to distribute VPN routing information across the provider's backbone. The multi-VRF CE network has three major components:

- VPN route target communities—lists of all other members of a VPN community. You need to configure VPN route targets for each VPN community member.
- Multiprotocol BGP peering of VPN community PE routers—propagates VRF reachability information to all members of a VPN community. You need to configure BGP peering in all PE routers within a VPN community.
- VPN forwarding—transports all traffic between all VPN community members across a VPN service-provider network.

### VRF-Aware Services

IP services can be configured on global interfaces, and these services run within the global routing instance. IP services are enhanced to run on multiple routing instances; they are VRF-aware. Any configured VRF in the system can be specified for a VRF-aware service.

VRF-Aware services are implemented in platform-independent modules. VRF means multiple routing instances in Cisco IOS. Each platform has its own limit on the number of VRFs it supports.

VRF-aware services have the following characteristics:

- The user can ping a host in a user-specified VRF.
- ARP entries are learned in separate VRFs. The user can display Address Resolution Protocol (ARP) entries for specific VRFs.

# How to Configure Multi-VRF CE

## Default Multi-VRF CE Configuration

*Table 109: Default VRF Configuration*

| Feature            | Default Setting                                                |
|--------------------|----------------------------------------------------------------|
| VRF                | Disabled. No VRFs are defined.                                 |
| Maps               | No import maps, export maps, or route maps are defined.        |
| VRF maximum routes | Fast Ethernet switches: 8000 Gigabit Ethernet switches: 12000. |
| Forwarding table   | The default for an interface is the global routing table.      |

## Multi-VRF CE Configuration Guidelines

### Note

To use multi-VRF CE, you must have the IP services or advanced IP services feature set enabled on your switch.

- A switch with multi-VRF CE is shared by multiple customers, and each customer has its own routing table.
- Because customers use different VRF tables, the same IP addresses can be reused. Overlapped IP addresses are allowed in different VPNs.
- Multi-VRF CE lets multiple customers share the same physical link between the PE and the CE. Trunk ports with multiple VLANs separate packets among customers. Each customer has its own VLAN.
- Multi-VRF CE does not support all MPLS-VRF functionality. It does not support label exchange, LDP adjacency, or labeled packets.
- For the PE router, there is no difference between using multi-VRF CE or using multiple CEs. In Figure 41-6, multiple virtual Layer 3 interfaces are connected to the multi-VRF CE device.
- The switch supports configuring VRF by using physical ports, VLAN SVIs, or a combination of both. The SVIs can be connected through an access port or a trunk port.
- A customer can use multiple VLANs as long as they do not overlap with those of other customers. A customer's VLANs are mapped to a specific routing table ID that is used to identify the appropriate routing tables stored on the switch.
- The switch supports one global network and up to 26 VRFs.
- Most routing protocols (BGP, OSPF, RIP, and static routing) can be used between the CE and the PE. However, we recommend using external BGP (EBGP) for these reasons:
  - BGP does not require multiple algorithms to communicate with multiple CEs.
  - BGP is designed for passing routing information between systems run by different administrations.
  - BGP makes it easy to pass attributes of the routes to the CE.
- Multi-VRF CE does not affect the packet switching rate.
- VPN multicast is not supported.
- You can enable VRF on a private VLAN, and the reverse.
- You cannot enable VRF when policy-based routing (PBR) is enabled on an interface, and the reverse.
- You cannot enable VRF when Web Cache Communication Protocol (WCCP) is enabled on an interface, and the reverse.

## Configuring VRFs

For complete syntax and usage information for the commands, see the switch command reference for this release and the *Cisco IOS Switching Services Command Reference, Release 12.4*.

### DETAILED STEPS

|               | Command or Action                                                                                                                                       | Purpose                                                                                                                                                                                                                                                                                                                                     |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                                                          | Enters global configuration mode.                                                                                                                                                                                                                                                                                                           |
| <b>Step 2</b> | <b>ip routing</b><br><br><b>Example:</b><br>Switch(config)# ip routing                                                                                  | Enables IP routing.                                                                                                                                                                                                                                                                                                                         |
| <b>Step 3</b> | <b>ip vrf vrf-name</b><br><br><b>Example:</b><br>Switch(config)# ip vrf vpn1                                                                            | Names the VRF, and enter VRF configuration mode.                                                                                                                                                                                                                                                                                            |
| <b>Step 4</b> | <b>rd route-distinguisher</b><br><br><b>Example:</b><br>Switch(config-vrf)# rd 100:2                                                                    | Creates a VRF table by specifying a route distinguisher. Enter either an AS number and an arbitrary number (xxx:y) or an IP address and arbitrary number (A.B.C.D:y)                                                                                                                                                                        |
| <b>Step 5</b> | <b>route-target {export   import   both}</b><br><i>route-target-ext-community</i><br><br><b>Example:</b><br>Switch(config-vrf)# route-target both 100:2 | Creates a list of import, export, or import and export route target communities for the specified VRF. Enter either an AS system number and an arbitrary number (xxx:y) or an IP address and an arbitrary number (A.B.C.D:y). The <i>route-target-ext-community</i> should be the same as the <i>route-distinguisher</i> entered in Step 4. |
| <b>Step 6</b> | <b>import map route-map</b><br><br><b>Example:</b><br>Switch(config-vrf)# import map importmap1                                                         | (Optional) Associates a route map with the VRF.                                                                                                                                                                                                                                                                                             |
| <b>Step 7</b> | <b>interface interface-id</b><br><br><b>Example:</b><br>Switch(config-vrf)# interface gigabitethernet 1/0/1                                             | Specifies the Layer 3 interface to be associated with the VRF, and enter interface configuration mode. The interface can be a routed port or SVI.                                                                                                                                                                                           |

|                | Command or Action                                                                                                                                         | Purpose                                                                     |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------|
| <b>Step 8</b>  | <b>ip vrf forwarding</b> <i>vrf-name</i><br><br><b>Example:</b><br>Switch(config-if)# ip vrf forwarding vpn1                                              | Associates the VRF with the Layer 3 interface.                              |
| <b>Step 9</b>  | <b>end</b><br><br><b>Example:</b><br>Switch(config-if)# end                                                                                               | Returns to privileged EXEC mode.                                            |
| <b>Step 10</b> | <b>show ip vrf</b> [ <b>brief</b>   <b>detail</b>   <b>interfaces</b> ] [ <i>vrf-name</i> ]<br><br><b>Example:</b><br>Switch# show ip vrf interfaces vpn1 | Verifies the configuration. Displays information about the configured VRFs. |
| <b>Step 11</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config                                            | (Optional) Saves your entries in the configuration file.                    |

## Configuring VRF-Aware Services

These services are VRF-Aware:

- ARP
- Ping
- Simple Network Management Protocol (SNMP)
- Unicast Reverse Path Forwarding (uRPF)
- Syslog
- Traceroute
- FTP and TFTP

**Note** The switch does not support VRF-aware services for Unicast Reverse Path Forwarding (uRPF) or Network Time Protocol (NTP).

### Configuring VRF-Aware Services for ARP

For complete syntax and usage information for the commands, see the switch command reference for this release and the *Cisco IOS Switching Services Command Reference, Release 12.4*.

```
show ip arp vrf vrf-name
```

## DETAILED STEPS

|               | Command or Action                                                                                           | Purpose |
|---------------|-------------------------------------------------------------------------------------------------------------|---------|
| <b>Step 1</b> | <p><b>Example:</b></p> <pre>Switch# show ip arp vrf vpn1</pre> Displays the ARP table in the specified VRF. |         |

### Configuring VRF-Aware Services for Ping

For complete syntax and usage information for the commands, see the switch command reference for this release and the *Cisco IOS Switching Services Command Reference, Release 12.4*.

## DETAILED STEPS

|               | Command or Action                                                                                    | Purpose                                      |
|---------------|------------------------------------------------------------------------------------------------------|----------------------------------------------|
| <b>Step 1</b> | <pre>ping vrf vrf-name ip-host</pre> <p><b>Example:</b></p> <pre>Switch# ping vrf vpn1 ip-host</pre> | Displays the ARP table in the specified VRF. |

### Configuring VRF-Aware Services for SNMP

For complete syntax and usage information for the commands, refer to the switch command reference for this release and the *Cisco IOS Switching Services Command Reference, Release 12.4*.

## DETAILED STEPS

|               | Command or Action                                                                                                                    | Purpose                                  |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------|
| <b>Step 1</b> | <pre>configure terminal</pre> <p><b>Example:</b></p> <pre>Switch# configure terminal</pre>                                           | Enters global configuration mode.        |
| <b>Step 2</b> | <pre>snmp-server trap authentication vrf</pre> <p><b>Example:</b></p> <pre>Switch(config)# snmp-server trap authentication vrf</pre> | Enables SNMP traps for packets on a VRF. |

|               | Command or Action                                                                                                                                                                                                 | Purpose                                                                                                              |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| <b>Step 3</b> | <b>snmp-server engineID remote</b> <i>host vrf vpn-instance engine-id string</i><br><br><b>Example:</b><br><br>Switch(config)# snmp-server engineID remote<br>172.16.20.3 vrf vpn1 80000009030000B064EFE100       | Configures a name for the remote SNMP engine on a switch.                                                            |
| <b>Step 4</b> | <b>snmp-server host</b> <i>host vrf vpn-instance traps community</i><br><br><b>Example:</b><br><br>Switch(config)# snmp-server host 172.16.20.3 vrf vpn1<br>traps comaccess                                       | Specifies the recipient of an SNMP trap operation and specifies the VRF table to be used for sending SNMP traps.     |
| <b>Step 5</b> | <b>snmp-server host</b> <i>host vrf vpn-instance informs community</i><br><br><b>Example:</b><br><br>Switch(config)# snmp-server host 172.16.20.3 vrf vpn1<br>informs comaccess                                   | Specifies the recipient of an SNMP inform operation and specifies the VRF table to be used for sending SNMP informs. |
| <b>Step 6</b> | <b>snmp-server user</b> <i>user group remote host vrf vpn-instance security model</i><br><br><b>Example:</b><br><br>Switch(config)# snmp-server user abcd remote<br>172.16.20.3 vrf vpn1 priv v2c 3des secure3des | Adds a user to an SNMP group for a remote host on a VRF for SNMP access.                                             |
| <b>Step 7</b> | <b>end</b><br><br><b>Example:</b><br><br>Switch(config)# end                                                                                                                                                      | Returns to privileged EXEC mode.                                                                                     |

### Configuring VRF-Aware Services for uRPF

uRPF can be configured on an interface assigned to a VRF, and source lookup is done in the VRF table.

For complete syntax and usage information for the commands, refer to the switch command reference for this release and the *Cisco IOS Switching Services Command Reference, Release 12.4*.

#### DETAILED STEPS

|               | Command or Action                                                                  | Purpose                           |
|---------------|------------------------------------------------------------------------------------|-----------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br><br>Switch# configure terminal | Enters global configuration mode. |

|               | Command or Action                                                                                                  | Purpose                                                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| <b>Step 2</b> | <b>interface</b> interface-id Switch(config)# interface gigabitethernet 1/0/1                                      | Enters interface configuration mode, and specifies the Layer 3 interface to configure. |
| <b>Step 3</b> | <b>no switchport</b><br><br><b>Example:</b><br>Switch(config-if) # no switchport                                   | Removes the interface from Layer 2 configuration mode if it is a physical interface.   |
| <b>Step 4</b> | <b>ip vrf forwarding</b> vrf-name<br><br><b>Example:</b><br>Switch(config-if) # ip vrf forwarding vpn2             | Configures VRF on the interface.                                                       |
| <b>Step 5</b> | <b>ip address</b> ip-address<br><br><b>Example:</b><br>Switch(config-if) # ip address 10.1.5.1                     | Enters the IP address for the interface.                                               |
| <b>Step 6</b> | <b>ip verify unicast reverse-path</b><br><br><b>Example:</b><br>Switch(config-if) # ip verify unicast reverse-path | Enables uRPF on the interface.                                                         |
| <b>Step 7</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config-if) # end                                                       | Returns to privileged EXEC mode.                                                       |

### Configuring VRF-Aware RADIUS

To configure VRF-Aware RADIUS, you must first enable AAA on a RADIUS server. The switch supports the **ip vrf forwarding** *vrf-name* server-group configuration and the **ip radius source-interface** global configuration commands, as described in the Per VRF AAA Feature Guide.

### Configuring VRF-Aware Services for Syslog

For complete syntax and usage information for the commands, refer to the switch command reference for this release and the *Cisco IOS Switching Services Command Reference, Release 12.4*.

## DETAILED STEPS

|        | Command or Action                                                                                                                          | Purpose                                                                                |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| Step 1 | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                                             | Enters global configuration mode.                                                      |
| Step 2 | <b>logging on</b><br><br><b>Example:</b><br>Switch(config)# logging on                                                                     | Enables or temporarily disables logging of storage router event message.               |
| Step 3 | <b>logging host ip-address vrf vrf-name</b><br><br><b>Example:</b><br>Switch(config)# logging host 10.10.1.0 vrf vpn1                      | Specifies the host address of the syslog server where logging messages are to be sent. |
| Step 4 | <b>logging buffered logging buffered size debugging</b><br><br><b>Example:</b><br>Switch(config)# logging buffered critical 6000 debugging | Logs messages to an internal buffer.                                                   |
| Step 5 | <b>logging trap debugging</b><br><br><b>Example:</b><br>Switch(config)# logging trap debugging                                             | Limits the logging messages sent to the syslog server.                                 |
| Step 6 | <b>logging facility facility</b><br><br><b>Example:</b><br>Switch(config)# logging facility user                                           | Sends system logging messages to a logging facility.                                   |
| Step 7 | <b>end</b><br><br><b>Example:</b><br>Switch(config)# end                                                                                   | Returns to privileged EXEC mode.                                                       |

**Configuring VRF-Aware Services for Traceroute**

For complete syntax and usage information for the commands, refer to the switch command reference for this release and the Cisco IOS Switching Services Command Reference, Release 12.4.

## DETAILED STEPS

|               | Command or Action                                                                                                              | Purpose                                                                   |
|---------------|--------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------|
| <b>Step 1</b> | <b>traceroute vrf</b> <i>vrf-name</i> <i>ipaddress</i><br><br><b>Example:</b><br>Switch(config)# traceroute vrf vpn2 10.10.1.1 | Specifies the name of a VPN VRF in which to find the destination address. |

## Configuring VRF-Aware Services for FTP and TFTP

So that FTP and TFTP are VRF-aware, you must configure some FTP/TFTP CLIs. For example, if you want to use a VRF table that is attached to an interface, say E1/0, you need to configure the `ip tftp source-interface E1/0` or the `ip ftp source-interface E1/0` command to inform TFTP or FTP server to use a specific routing table. In this example, the VRF table is used to look up the destination IP address. These changes are backward-compatible and do not affect existing behavior. That is, you can use the source-interface CLI to send packets out a particular interface even if no VRF is configured on that interface.

## DETAILED STEPS

|               | Command or Action                                                                                                                                                       | Purpose                                              |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                                                                          | Enters global configuration mode.                    |
| <b>Step 2</b> | <b>ip ftp source-interface</b> <i>interface-type</i> <i>interface-number</i><br><br><b>Example:</b><br>Switch(config)# ip ftp source-interface<br>gigabitethernet 1/0/2 | Specifies the source IP address for FTP connections. |
| <b>Step 3</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config)#end                                                                                                                 | Returns to privileged EXEC mode.                     |
| <b>Step 4</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                                                                          | Enters global configuration mode.                    |

|        | Command or Action                                                                                                                                                  | Purpose                                               |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------|
| Step 5 | <b>ip tftp source-interface</b> <i>interface-type interface-number</i><br><br><b>Example:</b><br>Switch(config)# ip tftp source-interface<br>gigabitethernet 1/0/2 | Specifies the source IP address for TFTP connections. |
| Step 6 | <b>end</b><br><br><b>Example:</b><br>Switch(config)#end                                                                                                            | Returns to privileged EXEC mode.                      |

## Configuring Multicast VRFs

For complete syntax and usage information for the commands, see the switch command reference for this release and the *Cisco IOS Switching Services Command Reference, Release 12.4*.

For more information about configuring a multicast within a Multi-VRF CE, see the *Cisco IOS IP Multicast Configuration Guide, Release 12.4*.

### DETAILED STEPS

|        | Command or Action                                                                                        | Purpose                                                                                                                                                                 |
|--------|----------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                           | Enters global configuration mode.                                                                                                                                       |
| Step 2 | <b>ip routing</b><br><br><b>Example:</b><br>Switch(config)# ip routing                                   | Enables IP routing mode.                                                                                                                                                |
| Step 3 | <b>ip vrf</b> <i>vrf-name</i><br><br><b>Example:</b><br>Switch(config)# ip vrf vpn1                      | Names the VRF, and enter VRF configuration mode.                                                                                                                        |
| Step 4 | <b>rd</b> <i>route-distinguisher</i><br><br><b>Example:</b><br>Switch(config-vrf)# rd 100:2              | Creates a VRF table by specifying a route distinguisher. Enter either an AS number and an arbitrary number (xxx:y) or an IP address and an arbitrary number (A.B.C.D:y) |
| Step 5 | <b>route-target</b> { <b>export</b>   <b>import</b>   <b>both</b> }<br><i>route-target-ext-community</i> | Creates a list of import, export, or import and export route target communities for the specified VRF. Enter either an                                                  |

|                | Command or Action                                                                                                                                                         | Purpose                                                                                                                                                                                                              |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | <p><b>Example:</b></p> <pre>Switch(config-vrf)# route-target import 100:2</pre>                                                                                           | AS system number and an arbitrary number (xxx:y) or an IP address and an arbitrary number (A.B.C.D:y). The <i>route-target-ext-community</i> should be the same as the <i>route-distinguisher</i> entered in Step 4. |
| <b>Step 6</b>  | <p><b>import map</b> <i>route-map</i></p> <p><b>Example:</b></p> <pre>Switch(config-vrf)# import map importmap1</pre>                                                     | (Optional) Associates a route map with the VRF.                                                                                                                                                                      |
| <b>Step 7</b>  | <p><b>ip multicast-routing vrf</b> <i>vrf-name</i> <b>distributed</b></p> <p><b>Example:</b></p> <pre>Switch(config-vrf)# ip multicast-routing vrf vpnl distributed</pre> | (Optional) Enables global multicast routing for VRF table.                                                                                                                                                           |
| <b>Step 8</b>  | <p><b>interface</b> <i>interface-id</i></p> <p><b>Example:</b></p> <pre>Switch(config-vrf)# interface gigabitethernet 1/0/2</pre>                                         | Specifies the Layer 3 interface to be associated with the VRF, and enter interface configuration mode. The interface can be a routed port or an SVI.                                                                 |
| <b>Step 9</b>  | <p><b>ip vrf forwarding</b> <i>vrf-name</i></p> <p><b>Example:</b></p> <pre>Switch(config-if)# ip vrf forwarding vpl</pre>                                                | Associates the VRF with the Layer 3 interface.                                                                                                                                                                       |
| <b>Step 10</b> | <p><b>ip address</b> <i>ip-address mask</i></p> <p><b>Example:</b></p> <pre>Switch(config-if)# ip address 10.1.5.1 255.255.255.0</pre>                                    | Configures IP address for the Layer 3 interface.                                                                                                                                                                     |
| <b>Step 11</b> | <p><b>ip pim sparse-dense mode</b></p> <p><b>Example:</b></p> <pre>Switch(config-if)# ip pim sparse-dense mode</pre>                                                      | Enables PIM on the VRF-associated Layer 3 interface.                                                                                                                                                                 |
| <b>Step 12</b> | <p><b>end</b></p> <p><b>Example:</b></p> <pre>Switch(config-if)# end</pre>                                                                                                | Returns to privileged EXEC mode.                                                                                                                                                                                     |
| <b>Step 13</b> | <p><b>show ip vrf</b> [<b>brief</b>   <b>detail</b>   <b>interfaces</b>] [<i>vrf-name</i>]</p> <p><b>Example:</b></p> <pre>Switch# show ip vrf detail vpl</pre>           | Verifies the configuration. Displays information about the configured VRFs.                                                                                                                                          |

|                | Command or Action                                                                                              | Purpose                                                  |
|----------------|----------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| <b>Step 14</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

## Configuring a VPN Routing Session

Routing within the VPN can be configured with any supported routing protocol (RIP, OSPF, EIGRP, or BGP) or with static routing. The configuration shown here is for OSPF, but the process is the same for other protocols.

**Note** To configure an EIGRP routing process to run within a VRF instance, you must configure an autonomous-system number by entering the **autonomous-system** *autonomous-system-number* address-family configuration mode command.

### DETAILED STEPS

|               | Command or Action                                                                                                                     | Purpose                                                                                      |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                                        | Enters global configuration mode.                                                            |
| <b>Step 2</b> | <b>router ospf process-id vrf vrf-name</b><br><br><b>Example:</b><br>Switch(config)# router ospf 1 vrf vpn1                           | Enables OSPF routing, specifies a VPN forwarding table, and enter router configuration mode. |
| <b>Step 3</b> | <b>log-adjacency-changes</b><br><br><b>Example:</b><br>Switch(config-router)# log-adjacency-changes                                   | (Optional) Logs changes in the adjacency state. This is the default state.                   |
| <b>Step 4</b> | <b>redistribute bgp autonomous-system-number subnets</b><br><br><b>Example:</b><br>Switch(config-router)# redistribute bgp 10 subnets | Sets the switch to redistribute information from the BGP network to the OSPF network.        |

|               | Command or Action                                                                                                   | Purpose                                                                                         |
|---------------|---------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------|
| <b>Step 5</b> | <b>network</b> <i>network-number area area-id</i><br><br><b>Example:</b><br>Switch(config-router)# network 1 area 2 | Defines a network address and mask on which OSPF runs and the area ID for that network address. |
| <b>Step 6</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config-router)# end                                                     | Returns to privileged EXEC mode.                                                                |
| <b>Step 7</b> | <b>show ip ospf</b> <i>process-id</i><br><br><b>Example:</b><br>Switch# show ip ospf 1                              | Verifies the configuration of the OSPF network.                                                 |
| <b>Step 8</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config      | (Optional) Saves your entries in the configuration file.                                        |

## Configuring BGP PE to CE Routing Sessions

### DETAILED STEPS

|               | Command or Action                                                                                                                    | Purpose                                                                                                                 |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                                       | Enters global configuration mode.                                                                                       |
| <b>Step 2</b> | <b>router bgp</b> <i>autonomous-system-number</i><br><br><b>Example:</b><br>Switch(config)# router bgp 2                             | Configures the BGP routing process with the AS number passed to other BGP routers, and enter router configuration mode. |
| <b>Step 3</b> | <b>network</b> <i>network-number mask network-mask</i><br><br><b>Example:</b><br>Switch(config-router)# network 5 mask 255.255.255.0 | Specifies a network and mask to announce using BGP.                                                                     |

|                | Command or Action                                                                                                                                        | Purpose                                                                                         |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------|
| <b>Step 4</b>  | <b>redistribute ospf <i>process-id</i> match internal</b><br><br><b>Example:</b><br><pre>Switch(config-router)# redistribute ospf 1 match internal</pre> | Sets the switch to redistribute OSPF internal routes.                                           |
| <b>Step 5</b>  | <b>network <i>network-number</i> area <i>area-id</i></b><br><br><b>Example:</b><br><pre>Switch(config-router)# network 5 area 2</pre>                    | Defines a network address and mask on which OSPF runs and the area ID for that network address. |
| <b>Step 6</b>  | <b>address-family ipv4 vrf <i>vrf-name</i></b><br><br><b>Example:</b><br><pre>Switch(config-router)# address-family ipv4 vrf vpn1</pre>                  | Defines BGP parameters for PE to CE routing sessions, and enter VRF address-family mode.        |
| <b>Step 7</b>  | <b>neighbor <i>address</i> remote-as <i>as-number</i></b><br><br><b>Example:</b><br><pre>Switch(config-router)# neighbor 10.1.1.2 remote-as 2</pre>      | Defines a BGP session between PE and CE routers.                                                |
| <b>Step 8</b>  | <b>neighbor <i>address</i> activate</b><br><br><b>Example:</b><br><pre>Switch(config-router)# neighbor 10.2.1.1 activate</pre>                           | Activates the advertisement of the IPv4 address family.                                         |
| <b>Step 9</b>  | <b>end</b><br><br><b>Example:</b><br><pre>Switch(config-router)# end</pre>                                                                               | Returns to privileged EXEC mode.                                                                |
| <b>Step 10</b> | <b>show ip bgp [<i>ipv4</i>] [<i>neighbors</i>]</b><br><br><b>Example:</b><br><pre>Switch# show ip bgp ipv4 neighbors</pre>                              | Verifies BGP configuration.                                                                     |
| <b>Step 11</b> | <b>copy running-config startup-config</b><br><br><b>Example:</b><br><pre>Switch# copy running-config startup-config</pre>                                | (Optional) Saves your entries in the configuration file.                                        |

## Monitoring Multi-VRF CE

**Table 110: Commands for Displaying Multi-VRF CE Information**

|                                                                                                                                                                                                                                          |                                                              |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------|
| <b>show ip protocols vrf</b> <i>vrf-name</i>                                                                                                                                                                                             | Displays routing protocol information associated with a VRF. |
| <b>show ip route vrf</b> <i>vrf-name</i> [ <b>connected</b> ] [ <i>protocol</i> [ <i>as-number</i> ]] [ <b>list</b> ] [ <b>mobile</b> ] [ <b>odr</b> ] [ <b>profile</b> ] [ <b>static</b> ] [ <b>summary</b> ] [ <b>supernets-only</b> ] | Displays IP routing table information associated with a VRF. |
| <b>show ip vrf</b> [ <b>brief</b>   <b>detail</b>   <b>interfaces</b> ] [ <i>vrf-name</i> ]                                                                                                                                              | Displays information about the defined VRF instances.        |

For more information about the information in the displays, see the *Cisco IOS Switching Services Command Reference, Release 12.4*.

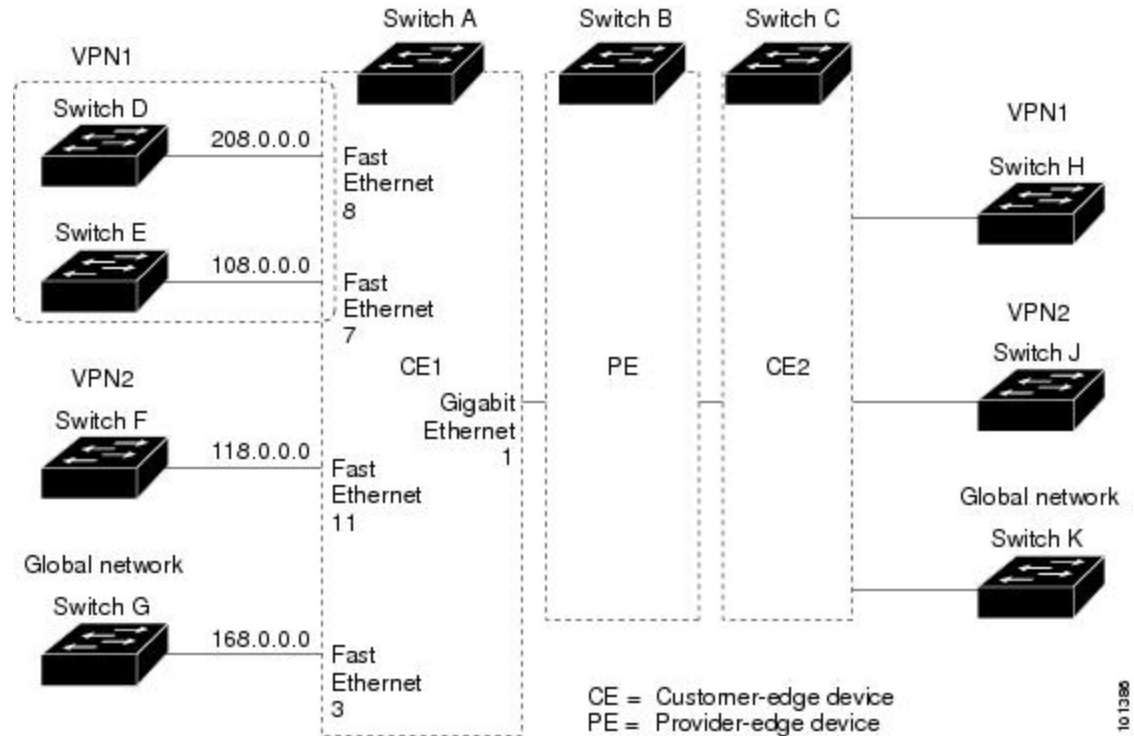

## Configuration Examples for Multi-VRF CE

### Multi-VRF CE Configuration Example

Figure 41-7 is a simplified example of the physical connections in a network similar to that in Figure 41-6. OSPF is the protocol used in VPN1, VPN2, and the global network. BGP is used in the CE to PE connections. The examples following the illustration show how to configure a switch as CE Switch A, and the VRF configuration for customer switches D and F. Commands for configuring CE Switch C and the other customer

switches are not included but would be similar. The example also includes commands for configuring traffic to Switch A for a Catalyst 6000 or Catalyst 6500 switch acting as a PE router.

**Figure 70: Multi-VRF CE Configuration Example**

On Switch A, enable routing and configure VRF.

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# ip routing
Switch(config)# ip vrf v11
Switch(config-vrf)# rd 800:1
Switch(config-vrf)# route-target export 800:1
Switch(config-vrf)# route-target import 800:1
Switch(config-vrf)# exit
Switch(config)# ip vrf v12
Switch(config-vrf)# rd 800:2
Switch(config-vrf)# route-target export 800:2
Switch(config-vrf)# route-target import 800:2
Switch(config-vrf)# exit
```

Configure the loopback and physical interfaces on Switch A. Gigabit Ethernet port 1 is a trunk connection to the PE. Gigabit Ethernet ports 8 and 11 connect to VPNs:

```
Switch(config)# interface loopback1
Switch(config-if)# ip vrf forwarding v11
Switch(config-if)# ip address 8.8.1.8 255.255.255.0
Switch(config-if)# exit

Switch(config)# interface loopback2
Switch(config-if)# ip vrf forwarding v12
Switch(config-if)# ip address 8.8.2.8 255.255.255.0
Switch(config-if)# exit

Switch(config)# interface gigabitethernet1/0/5
```

```

Switch(config-if)# switchport trunk encapsulation dot1q
Switch(config-if)# switchport mode trunk
Switch(config-if)# no ip address
Switch(config-if)# exit
Switch(config)# interface gigabitethernet1/0/8
Switch(config-if)# switchport access vlan 208
Switch(config-if)# no ip address
Switch(config-if)# exit
Switch(config)# interface gigabitethernet1/0/11
Switch(config-if)# switchport trunk encapsulation dot1q
Switch(config-if)# switchport mode trunk
Switch(config-if)# no ip address
Switch(config-if)# exit

```

Configure the VLANs used on Switch A. VLAN 10 is used by VRF 11 between the CE and the PE. VLAN 20 is used by VRF 12 between the CE and the PE. VLANs 118 and 208 are used for the VPNs that include Switch F and Switch D, respectively:

```

Switch(config)# interface vlan10
Switch(config-if)# ip vrf forwarding v11
Switch(config-if)# ip address 38.0.0.8 255.255.255.0
Switch(config-if)# exit
Switch(config)# interface vlan20
Switch(config-if)# ip vrf forwarding v12
Switch(config-if)# ip address 83.0.0.8 255.255.255.0
Switch(config-if)# exit
Switch(config)# interface vlan118
Switch(config-if)# ip vrf forwarding v12
Switch(config-if)# ip address 118.0.0.8 255.255.255.0
Switch(config-if)# exit
Switch(config)# interface vlan208
Switch(config-if)# ip vrf forwarding v11
Switch(config-if)# ip address 208.0.0.8 255.255.255.0
Switch(config-if)# exit

```

Configure OSPF routing in VPN1 and VPN2.

```

Switch(config)# router ospf 1 vrf v11
Switch(config-router)# redistribute bgp 800 subnets
Switch(config-router)# network 208.0.0.0 0.0.0.255 area 0
Switch(config-router)# exit
Switch(config)# router ospf 2 vrf v12
Switch(config-router)# redistribute bgp 800 subnets
Switch(config-router)# network 118.0.0.0 0.0.0.255 area 0
Switch(config-router)# exit

```

Configure BGP for CE to PE routing.

```

Switch(config)# router bgp 800
Switch(config-router)# address-family ipv4 vrf v12
Switch(config-router-af)# redistribute ospf 2 match internal
Switch(config-router-af)# neighbor 83.0.0.3 remote-as 100
Switch(config-router-af)# neighbor 83.0.0.3 activate
Switch(config-router-af)# network 8.8.2.0 mask 255.255.255.0
Switch(config-router-af)# exit
Switch(config-router)# address-family ipv4 vrf v11
Switch(config-router-af)# redistribute ospf 1 match internal
Switch(config-router-af)# neighbor 38.0.0.3 remote-as 100
Switch(config-router-af)# neighbor 38.0.0.3 activate
Switch(config-router-af)# network 8.8.1.0 mask 255.255.255.0
Switch(config-router-af)# end

```

Switch D belongs to VPN 1. Configure the connection to Switch A by using these commands.

```

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# ip routing
Switch(config)# interface gigabitethernet1/0/2
Switch(config-if)# no switchport
Switch(config-if)# ip address 208.0.0.20 255.255.255.0
Switch(config-if)# exit

```

```
Switch(config)# router ospf 101
Switch(config-router)# network 208.0.0.0 0.0.0.255 area 0
Switch(config-router)# end
```

Switch F belongs to VPN 2. Configure the connection to Switch A by using these commands.

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# ip routing
Switch(config)# interface gigabitethernet1/0/1
Switch(config-if)# switchport trunk encapsulation dot1q
Switch(config-if)# switchport mode trunk
Switch(config-if)# no ip address
Switch(config-if)# exit
```

```
Switch(config)# interface vlan118
Switch(config-if)# ip address 118.0.0.11 255.255.255.0
Switch(config-if)# exit
```

```
Switch(config)# router ospf 101
Switch(config-router)# network 118.0.0.0 0.0.0.255 area 0
Switch(config-router)# end
```

When used on switch B (the PE router), these commands configure only the connections to the CE device, Switch A.

```
Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# ip vrf v1
Router(config-vrf)# rd 100:1
Router(config-vrf)# route-target export 100:1
Router(config-vrf)# route-target import 100:1
Router(config-vrf)# exit
```

```
Router(config)# ip vrf v2
Router(config-vrf)# rd 100:2
Router(config-vrf)# route-target export 100:2
Router(config-vrf)# route-target import 100:2
Router(config-vrf)# exit
Router(config)# ip cef
Router(config)# interface Loopback1
Router(config-if)# ip vrf forwarding v1
Router(config-if)# ip address 3.3.1.3 255.255.255.0
Router(config-if)# exit
```

```
Router(config)# interface Loopback2
Router(config-if)# ip vrf forwarding v2
Router(config-if)# ip address 3.3.2.3 255.255.255.0
Router(config-if)# exit
```

```
Router(config)# interface gigabitethernet1/1/0.10
Router(config-if)# encapsulation dot1q 10
Router(config-if)# ip vrf forwarding v1
Router(config-if)# ip address 38.0.0.3 255.255.255.0
Router(config-if)# exit
```

```
Router(config)# interface gigabitethernet1/1/0.20
Router(config-if)# encapsulation dot1q 20
Router(config-if)# ip vrf forwarding v2
Router(config-if)# ip address 83.0.0.3 255.255.255.0
Router(config-if)# exit
```

```
Router(config)# router bgp 100
Router(config-router)# address-family ipv4 vrf v2
Router(config-router-af)# neighbor 83.0.0.8 remote-as 800
Router(config-router-af)# neighbor 83.0.0.8 activate
Router(config-router-af)# network 3.3.2.0 mask 255.255.255.0
Router(config-router-af)# exit
Router(config-router)# address-family ipv4 vrf v1
Router(config-router-af)# neighbor 38.0.0.8 remote-as 800
Router(config-router-af)# neighbor 38.0.0.8 activate
```

```
Router(config-router-af)# network 3.3.1.0 mask 255.255.255.0
Router(config-router-af)# end
```

## Configuring Unicast Reverse Path Forwarding

The unicast reverse path forwarding (unicast RPF) feature helps to mitigate problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network by discarding IP packets that lack a verifiable IP source address. For example, a number of common types of denial-of-service (DoS) attacks, including Smurf and Tribal Flood Network (TFN), can take advantage of forged or rapidly changing source IP addresses to allow attackers to thwart efforts to locate or filter the attacks. For Internet service providers (ISPs) that provide public access, Unicast RPF deflects such attacks by forwarding only packets that have source addresses that are valid and consistent with the IP routing table. This action protects the network of the ISP, its customer, and the rest of the Internet.

**Note**

- Unicast RPF is supported only in IP services.
- Do not configure unicast RPF if the switch is in a mixed hardware stack combining more than one switch type: Catalyst 3750-X, Catalyst 3750-E, and Catalyst 3750 switches.

---

For detailed IP unicast RPF configuration information, see the *Other Security Features* chapter in the *Cisco IOS Security Configuration Guide, Release 12.4*.

## Protocol-Independent Features

This section describes IP routing protocol-independent features that are available on switches running the IP base or the IP services feature set; except that with the IP base feature set, protocol-related features are available only for RIP. For a complete description of the IP routing protocol-independent commands in this chapter, see the “IP Routing Protocol-Independent Commands” chapter of the *Cisco IOS IP Command Reference, Volume 2 of 3: Routing Protocols, Release 12.4*.

## Distributed Cisco Express Forwarding

### Information About Cisco Express Forwarding

Cisco Express Forwarding (CEF) is a Layer 3 IP switching technology used to optimize network performance. CEF implements an advanced IP look-up and forwarding algorithm to deliver maximum Layer 3 switching performance. CEF is less CPU-intensive than fast switching route caching, allowing more CPU processing power to be dedicated to packet forwarding. In a switch stack, the hardware uses distributed CEF (dCEF) in the stack. In dynamic networks, fast switching cache entries are frequently invalidated because of routing changes, which can cause traffic to be process switched using the routing table, instead of fast switched using the route cache. CEF and dCEF use the Forwarding Information Base (FIB) lookup table to perform destination-based switching of IP packets.

The two main components in CEF and dCEF are the distributed FIB and the distributed adjacency tables.

- The FIB is similar to a routing table or information base and maintains a mirror image of the forwarding information in the IP routing table. When routing or topology changes occur in the network, the IP routing table is updated, and those changes are reflected in the FIB. The FIB maintains next-hop address information based on the information in the IP routing table. Because the FIB contains all known routes that exist in the routing table, CEF eliminates route cache maintenance, is more efficient for switching traffic, and is not affected by traffic patterns.
- Nodes in the network are said to be adjacent if they can reach each other with a single hop across a link layer. CEF uses adjacency tables to prepend Layer 2 addressing information. The adjacency table maintains Layer 2 next-hop addresses for all FIB entries.

Because the switch or switch stack uses Application Specific Integrated Circuits (ASICs) to achieve Gigabit-speed line rate IP traffic, CEF or dCEF forwarding applies only to the software-forwarding path, that is, traffic that is forwarded by the CPU.

### How to Configure Cisco Express Forwarding

CEF or distributed CEF is enabled globally by default. If for some reason it is disabled, you can re-enable it by using the **ip cef** or **ip cef distributed** global configuration command.

The default configuration is CEF or dCEF enabled on all Layer 3 interfaces. Entering the **no ip route-cache cef** interface configuration command disables CEF for traffic that is being forwarded by software. This command does not affect the hardware forwarding path. Disabling CEF and using the **debug ip packet detail** privileged EXEC command can be useful to debug software-forwarded traffic. To enable CEF on an interface for the software-forwarding path, use the **ip route-cache cef** interface configuration command.

#### Caution

Although the **no ip route-cache cef** interface configuration command to disable CEF on an interface is visible in the CLI, we strongly recommend that you do not disable CEF or dCEF on interfaces except for debugging purposes.

To enable CEF or dCEF globally and on an interface for software-forwarded traffic if it has been disabled:

#### 1 configure terminal

```
Switch# configure terminal
Enters global configuration mode.
```

**2 ip cef**

```
Switch(config)# ip cef
```

Enables CEF operation on a non-stacking switch.

Go to Step 4.

**3 ip cef distributed**

```
Switch(config)# ip cef distributed
```

Enables CEF operation on a active switch.

**4 interface *interface-id***

```
Switch(config)# interface gigabitethernet 1/0/1
```

Enters interface configuration mode, and specifies the Layer 3 interface to configure.

**5 ip route-cache cef**

```
Switch(config-if)# ip route-cache cef
```

Enables CEF on the interface for software-forwarded traffic.

**6 end**

```
Switch(config-if)# end
```

Returns to privileged EXEC mode.

**7 show ip cef**

```
Switch# show ip cef
```

Displays the CEF status on all interfaces.

**8 show cef linecard [detail]**

```
Switch# show cef linecard detail
```

(Optional) Displays CEF-related interface information on a non-stacking switch.

**9 show cef linecard [*slot-number*] [detail]**

```
Switch# show cef linecard 5 detail
```

(Optional) Displays CEF-related interface information on a switch by stack member for all switches in the stack or for the specified switch.

(Optional) For *slot-number*, enter the stack member switch number.

**10 show cef interface [*interface-id*]**

```
Switch# show cef interface gigabitethernet 1/0/1
```

Displays detailed CEF information for all interfaces or the specified interface.

**11 show adjacency**

```
Switch# show adjacency
```

Displays CEF adjacency table information.

**12 copy running-config startup-config**

```
Switch# copy running-config startup-config
```

(Optional) Saves your entries in the configuration file.

## Number of Equal-Cost Routing Paths

### Information About Equal-Cost Routing Paths

When a router has two or more routes to the same network with the same metrics, these routes can be thought of as having an equal cost. The term parallel path is another way to see occurrences of equal-cost routes in a routing table. If a router has two or more equal-cost paths to a network, it can use them concurrently. Parallel paths provide redundancy in case of a circuit failure and also enable a router to load balance packets over the available paths for more efficient use of available bandwidth. Equal-cost routes are supported across switches in a stack.

Even though the router automatically learns about and configures equal-cost routes, you can control the maximum number of parallel paths supported by an IP routing protocol in its routing table. Although the switch software allows a maximum of 32 equal-cost routes, the switch hardware will never use more than 16 paths per route.

### How to Configure Equal-Cost Routing Paths

#### DETAILED STEPS

|        | Command or Action                                                                                    | Purpose                                                                                                                                                                  |
|--------|------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                       | Enters global configuration mode.                                                                                                                                        |
| Step 2 | <b>router {bgp   rip   ospf   eigrp}</b><br><br><b>Example:</b><br>Switch(config)# router eigrp      | Enters router configuration mode.                                                                                                                                        |
| Step 3 | <b>maximum-paths <i>maximum</i></b><br><br><b>Example:</b><br>Switch(config-router)# maximum-paths 2 | Sets the maximum number of parallel paths for the protocol routing table. The range is from 1 to 16; the default is 4 for most IP routing protocols, but only 1 for BGP. |
| Step 4 | <b>end</b><br><br><b>Example:</b><br>Switch(config-router)# end                                      | Returns to privileged EXEC mode.                                                                                                                                         |
| Step 5 | <b>show ip protocols</b><br><br><b>Example:</b><br>Switch# show ip protocols                         | Verifies the setting in the <i>Maximum path</i> field.                                                                                                                   |

|        | Command or Action                                                                                              | Purpose                                                  |
|--------|----------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| Step 6 | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

## Static Unicast Routes

### Information About Static Unicast Routes

Static unicast routes are user-defined routes that cause packets moving between a source and a destination to take a specified path. Static routes can be important if the router cannot build a route to a particular destination and are useful for specifying a gateway of last resort to which all unroutable packets are sent.

The switch retains static routes until you remove them. However, you can override static routes with dynamic routing information by assigning administrative distance values. Each dynamic routing protocol has a default administrative distance, as listed in Table 41-16. If you want a static route to be overridden by information from a dynamic routing protocol, set the administrative distance of the static route higher than that of the dynamic protocol.

**Table 111: Dynamic Routing Protocol Default Administrative Distances**

| Route Source                | Default Distance |
|-----------------------------|------------------|
| Connected interface         | 0                |
| Static route                | 1                |
| Enhanced IRGP summary route | 5                |
| External BGP                | 20               |
| Internal Enhanced IGRP      | 90               |
| IGRP                        | 100              |
| OSPF                        | 110              |
| Internal BGP                | 200              |
| Unknown                     | 225              |

Static routes that point to an interface are advertised through RIP, IGRP, and other dynamic routing protocols, whether or not static **redistribute** router configuration commands were specified for those routing protocols. These static routes are advertised because static routes that point to an interface are considered in the routing

table to be connected and hence lose their static nature. However, if you define a static route to an interface that is not one of the networks defined in a network command, no dynamic routing protocols advertise the route unless a **redistribute** static command is specified for these protocols.

When an interface goes down, all static routes through that interface are removed from the IP routing table. When the software can no longer find a valid next hop for the address specified as the forwarding router's address in a static route, the static route is also removed from the IP routing table.

### Configuring Static Unicast Routes

Static unicast routes are user-defined routes that cause packets moving between a source and a destination to take a specified path. Static routes can be important if the router cannot build a route to a particular destination and are useful for specifying a gateway of last resort to which all unroutable packets are sent.

Beginning in privileged EXEC mode, follow these steps to configure a static route:

#### DETAILED STEPS

|        | Command or Action                                                                                                                                    | Purpose                                                                      |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------|
| Step 1 | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                                                       | Enters global configuration mode.                                            |
| Step 2 | <b>ip route prefix mask {address   interface} [distance]</b><br><br><b>Example:</b><br>Switch(config)# ip route prefix mask gigabitethernet<br>1/0/4 | Establish a static route.                                                    |
| Step 3 | <b>end</b><br><br><b>Example:</b><br>Switch(config)# end                                                                                             | Returns to privileged EXEC mode.                                             |
| Step 4 | <b>show ip route</b><br><br><b>Example:</b><br>Switch# show ip route                                                                                 | Displays the current state of the routing table to verify the configuration. |
| Step 5 | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config                                       | (Optional) Saves your entries in the configuration file.                     |

## Default Routes and Networks

### Information About Default Routes and Networks

A router might not be able to learn the routes to all other networks. To provide complete routing capability, you can use some routers as smart routers and give the remaining routers default routes to the smart router. (Smart routers have routing table information for the entire internetwork.) These default routes can be dynamically learned or can be configured in the individual routers. Most dynamic interior routing protocols include a mechanism for causing a smart router to generate dynamic default information that is then forwarded to other routers.

If a router has a directly connected interface to the specified default network, the dynamic routing protocols running on that device generate a default route. In RIP, it advertises the pseudonetwork 0.0.0.0.

A router that is generating the default for a network also might need a default of its own. One way a router can generate its own default is to specify a static route to the network 0.0.0.0 through the appropriate device.

When default information is passed through a dynamic routing protocol, no further configuration is required. The system periodically scans its routing table to choose the optimal default network as its default route. In IGRP networks, there might be several candidate networks for the system default. Cisco routers use administrative distance and metric information to set the default route or the gateway of last resort.

If dynamic default information is not being passed to the system, candidates for the default route are specified with the **ip default-network** global configuration command. If this network appears in the routing table from any source, it is flagged as a possible choice for the default route. If the router has no interface on the default network, but does have a path to it, the network is considered as a possible candidate, and the gateway to the best default path becomes the gateway of last resort.

### How to Configure Default Routes and Networks

#### DETAILED STEPS

|               | Command or Action                                                                                              | Purpose                           |
|---------------|----------------------------------------------------------------------------------------------------------------|-----------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                 | Enters global configuration mode. |
| <b>Step 2</b> | <b>ip default-network <i>network number</i></b><br><br><b>Example:</b><br>Switch(config)# ip default-network 1 | Specifies a default network.      |
| <b>Step 3</b> | <b>end</b><br><br><b>Example:</b><br>Switch(config)# end                                                       | Returns to privileged EXEC mode.  |

|        | Command or Action                                                                                              | Purpose                                                                    |
|--------|----------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| Step 4 | <b>show ip route</b><br><br><b>Example:</b><br>Switch# show ip route                                           | Displays the selected default route in the gateway of last resort display. |
| Step 5 | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>Switch# copy running-config startup-config | (Optional) Saves your entries in the configuration file.                   |

## Route Maps to Redistribute Routing Information

### Information About Route Maps

The switch can run multiple routing protocols simultaneously, and it can redistribute information from one routing protocol to another. Redistributing information from one routing protocol to another applies to all supported IP-based routing protocols.

You can also conditionally control the redistribution of routes between routing domains by defining enhanced packet filters or route maps between the two domains. The **match** and **set** route-map configuration commands define the condition portion of a route map. The **match** command specifies that a criterion must be matched. The **set** command specifies an action to be taken if the routing update meets the conditions defined by the match command. Although redistribution is a protocol-independent feature, some of the **match** and **set** route-map configuration commands are specific to a particular protocol.

One or more **match** commands and one or more **set** commands follow a **route-map** command. If there are no **match** commands, everything matches. If there are no **set** commands, nothing is done, other than the match. Therefore, you need at least one **match** or **set** command.

#### Note

A route map with no **set** route-map configuration commands is sent to the CPU, which causes high CPU utilization.

You can also identify route-map statements as **permit** or **deny**. If the statement is marked as a deny, the packets meeting the match criteria are sent back through the normal forwarding channels (destination-based routing). If the statement is marked as permit, set clauses are applied to packets meeting the match criteria. Packets that do not meet the match criteria are forwarded through the normal routing channel.

You can use the BGP route map **continue** clause to execute additional entries in a route map after an entry is executed with successful match and set clauses. You can use the **continue** clause to configure and organize more modular policy definitions so that specific policy configurations need not be repeated within the same route map. The switch supports the **continue** clause for outbound policies. For more information about using the route map **continue** clause, see the BGP Route-Map Continue Support for an Outbound Policy feature guide for Cisco IOS Release 12.4(4)T.

## How to Configure a Route Map

Although each of Steps 3 through 14 in the following section is optional, you must enter at least one **match** route-map configuration command and one **set** route-map configuration command.

**Note** The keywords are the same as defined in the procedure to control the route distribution.

### DETAILED STEPS

|               | Command or Action                                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>configure terminal</b><br><br><b>Example:</b><br>Switch# configure terminal                                                                         | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Step 2</b> | <b>route-map</b> map-tag [ <b>permit</b>   <b>deny</b> ] [sequence number]<br><br><b>Example:</b><br>Switch(config)# route-map rip-to-ospf permit 4    | Defines any route maps used to control redistribution and enter route-map configuration mode.<br><br><i>map-tag</i> —A meaningful name for the route map. The <b>redistribute</b> router configuration command uses this name to reference this route map. Multiple route maps might share the same map tag name.<br><br>(Optional) If <b>permit</b> is specified and the match criteria are met for this route map, the route is redistributed as controlled by the set actions. If <b>deny</b> is specified, the route is not redistributed.<br><br><i>sequence number</i> (Optional)— Number that indicates the position a new route map is to have in the list of route maps already configured with the same name. |
| <b>Step 3</b> | <b>match as-path</b> <i>path-list-number</i><br><br><b>Example:</b><br>Switch(config-route-map)#match as-path 10                                       | Matches a BGP AS path access list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Step 4</b> | <b>match community-list</b> <i>community-list-number</i> [ <b>exact</b> ]<br><br><b>Example:</b><br>Switch(config-route-map)# match community-list 150 | Matches a BGP community list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Step 5</b> | <b>match ip address</b> { <i>access-list-number</i>   <i>access-list-name</i> } [... <i>access-list-number</i>   ... <i>access-list-name</i> ]         | Matches a standard access list by specifying the name or number. It can be an integer from 1 to 199.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|                | Command or Action                                                                                                                                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                         |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | <p><b>Example:</b></p> <pre>Switch(config-route-map)# match ip address 5 80</pre>                                                                                                                                                             |                                                                                                                                                                                                                                                                                                                                 |
| <b>Step 6</b>  | <p><b>match metric</b> <i>metric-value</i></p> <p><b>Example:</b></p> <pre>Switch(config-route-map)# match metric 2000</pre>                                                                                                                  | Matches the specified route metric. The <i>metric-value</i> can be an EIGRP metric with a specified value from 0 to 4294967295.                                                                                                                                                                                                 |
| <b>Step 7</b>  | <p><b>match ip next-hop</b> {<i>access-list-number</i>   <i>access-list-name</i>} [...<i>access-list-number</i>   ...<i>access-list-name</i>]</p> <p><b>Example:</b></p> <pre>Switch(config-route-map)# match ip next-hop 8 45</pre>          | Matches a next-hop router address passed by one of the access lists specified (numbered from 1 to 199).                                                                                                                                                                                                                         |
| <b>Step 8</b>  | <p><b>match tag</b> <i>tag value</i> [...<i>tag-value</i>]</p> <p><b>Example:</b></p> <pre>Switch(config-route-map)# match tag 3500</pre>                                                                                                     | Matches the specified tag value in a list of one or more route tag values. Each can be an integer from 0 to 4294967295.                                                                                                                                                                                                         |
